It is significant that realization of some activities is continually traced to be sure that already done actions are acceptable. To be sure that realization is acceptable, it is necessary to prepare reports to the persons responsible for realization control. In that way there is a possibility, that immediately after the problem appearance, they can be discovered and resolved on time in a way not to endanger performing of all necessary activities, and to provide innovation realization according to the plan.

Innovations of some company elements have their specifics, and because of these problems can arise, which have to be seen and solved by specialists for specific business fields. It is very important to coordinate collaboration between some specialists.

In company A, special attention has been paid to these requirements, and because of it, a great number of innovations has plan realization. Problems can appear at some stages but thanks to the prompt reporting, corrective measurers can be applied and plan realization can be obtained.

After performance of all planned activities, it is necessary to define how far innovation plan has been realized and make conclusions how far planned innovation aim has been achieved. If the aim is not achieved sufficiently and if it is possible in the given situation to undertake new measures, they have to be planned again and then it is necessary to perform corrective action which affects the complete achievement of the specified innovation plan.

9. Conclusion

Innovations in a production company represent a special system which has to work harmoniously, since only in that case can good and long-term company operation be provided. System elements are individual innovations and they can be specially planned and traced according to the company elements, i.e. according to the personnel, production means, products and organization. Development degree of individual company elements has to be balanced as only in that case can the functioning be satisfied.

At the same time, the available innovation resources are limited and it is important to spend them very rationally and in that way create the great effects in the company.

It is important to define strategic aims, according to them tactical aims and finally operational ones. For each of them it is necessary to plan and perform certain innovations. After accomplishing them, the degree of the attained aim has to be estimated, and then the whole process has to be repeated: the definition of new aims, planning, performance and control.

In company A there is an aspiration for such work but it has to be concluded that substantiation of all innovation stages causes significant expenses and because of it only significant innovations have to be substantiated in details. By their analysis it can be established, that in company A, the innovation system is satisfied but in the future it has to be improved by methods which more efficiently and quickly provide the effects and which gravitate to reducing of realization expenses as well as expenses for tracking of innovation realization.

The scope of this paper does not allow in-depth and detailed analysis of the innovation system in company A, but with the global presentation of methodology with permanent review of the practice in company a, it intends to give global instructions for similar analyses in other companies.

Educational Data Mining by Means of a Power Instructor's Tool

Oktay Kir¹, Irina Zheliazkova², Georgi Teodorov Georgiev³

¹²³Faculty of Electrical Engineering, University of Rouse, Rouse, Bulgaria,

¹kir.oktay@gmail.com, ²irina@ecs.uni-ruse.bg, ³egorig@abv.bg

The current state in the *Educational Data Mining (EDM)* have been discussed in an exhaustive review [3], where the following research directions are identified: *data analysis and visualization, providing instructors with feedback, recommendations for students, predicting student's performance, detecting undesirable student behaviours, grouping students, student modelling, constructing courseware, planning and scheduling.*

A power and easy instructor's tool for post-processing the data gathered by task-oriented environments for e-teaching [6] is considered. Besides the well-known *EDM* techniques such as descriptive statistics, correlation, regression, and cluster analysis a parallel table, chart, and script visualization has been embedded in it. The instructor script language is open for more complex techniques as Analytic Hierarchy Process proposed by Saaty [4].

The paper presents Schulman's [5] and Jenny and Moon's [1] pedagogical models on which the tool is based. The tool's architecture, script language, files organization, and user interface is discussed. The technology of using the tool demonstrates some instructor's tasks on two environments data (test and exercise). Some methodological innovations and trends in *EDM*, such as discovery with models and the psychometric modelling is demonstrated too.

Keywords

Educational data mining, Instructor tool architecture, Pedagogical models, Script language, Technology of using

1. Introduction

During the last two decades the most substantial contribution in research of the process of teaching and its relationship with the process of learning has *Lee Shulman* [5] (cited about 5000 times). Its model "Pedagogy Reasoning and Action" is remained bellow as a sequence of subprocesses:

- *Comprehension of:* purpose, cognitive structures and ideas within and without the subject;
- *Transformation, e.g. the decisions made by the T, when created the pedagogical requirements.*
- *Instruction: organization and control of the teaching forms, presentation of clear explanations and descriptions, effective interaction with the learners by means of questions and attempts, answers and reactions, praises and critics, as well as forms for monitoring, testing and assessing the group work.*
- *Evaluation: testing for correct and wrong comprehension, that is used by the teacher during his/her interactive instruction, as well as more formal testing and evaluation, that ensure him/her with a feedback and points for decision making, evaluation of his/her own performing.*
- *Reflection: Activities, by means of which the teacher is taught taking into account his/her, accumulated experience.*
- *New comprehension: expectation, those trough reasonable actions the teacher reaches a new comprehension of the taught subject purpose, learners, and the pedagogic processes.*

It becomes clear from Schulman's model, that the traditional teaching process generates a lot of different datasets that could be processed additionally to extract useful information for making the right pedagogical decisions.

In their well-known survey *Leach & Moon, 1999* [1] (cited about 400 times) highlighted Schulman's statement that the key problem of teaching is in creation of the teacher's pedagogy knowledge base. The authors also studied the relationship between knowledge and pedagogy, as well as the purpose of the teaching and learning as its center. They presented graphically the teacher's knowledge as interaction among *subject*, *pedagogic* and *school* knowledge (figure 1).

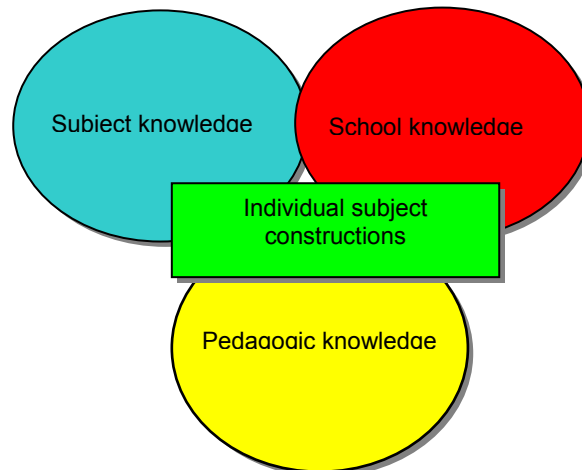

Figure 1 The teacher's types of knowledge

The educational data mining has emerged as a new research area, which current state has been exhaustively discussed by Romero & Ventura [3]. The purpose of this process is to convert the raw data coming from different educational systems (traditional, learning management, virtual laboratories, e-learning and so on) into useful information for the needs of the teaching theory and practice. The authors identified the following research tasks: a) *data analysis and visualization*; b) *providing instructors with feedback*; c) *recommendations for students*, d) *predicting student's performance*, e) *detecting undesirable student behaviours*, f) *grouping students*, g) *student modelling*, h) *constructing courseware*, and k) *planning and scheduling*. The main requirements for the corresponding tools design also are formulated in the same survey and concern: the user interface, visualization task, integration of the tool with an e-learning environment, standardization of data and models, as well as the algorithms for data mining.

When applied to teaching data the corresponding data mining techniques such as descriptive statistics, data visualization, correlation, regression, and cluster analysis must use semantic information, e.g. knowledge. This shows the need for more effective tools integrating domain knowledge into data mining algorithms. Specific techniques for mining in teaching can greatly improve instructional design and pedagogical decisions, and knowledge management in the e-teaching environments.

Data mining problems can be referred to the constructing problems requiring an active mental activity during their formulation and solving by the instructors. This paper presents an easy and power instructor's tool for post-processing the datasets gathered by the task-oriented environments for e-teaching developed and implemented by Zheliazkova's research group [6]. In this context this tool called postprocessor is developed for finding hidden knowledge helpful for the pedagogy knowledge base of the instructor. Different user-aspects of this tool are considered in the following sequence: use case diagram, script language, architecture, and technology of its using on which the paper focuses. The technology is demonstrated step-by-step on several tasks performance with two real datasets (test and exercise).

2. Use Case Diagram of the Tool

Nowadays the *UML* is accepted as a standard language for software description due to its platform-, technology-, and program-independence. The most commonly used of its 13 types of diagrams is the use case diagram. At an abstract level it presents the functional features of the tool from the user's view point (figure 2). In stand-alone mode of using the tool the instructor plays his/her own role, performing different use cases.

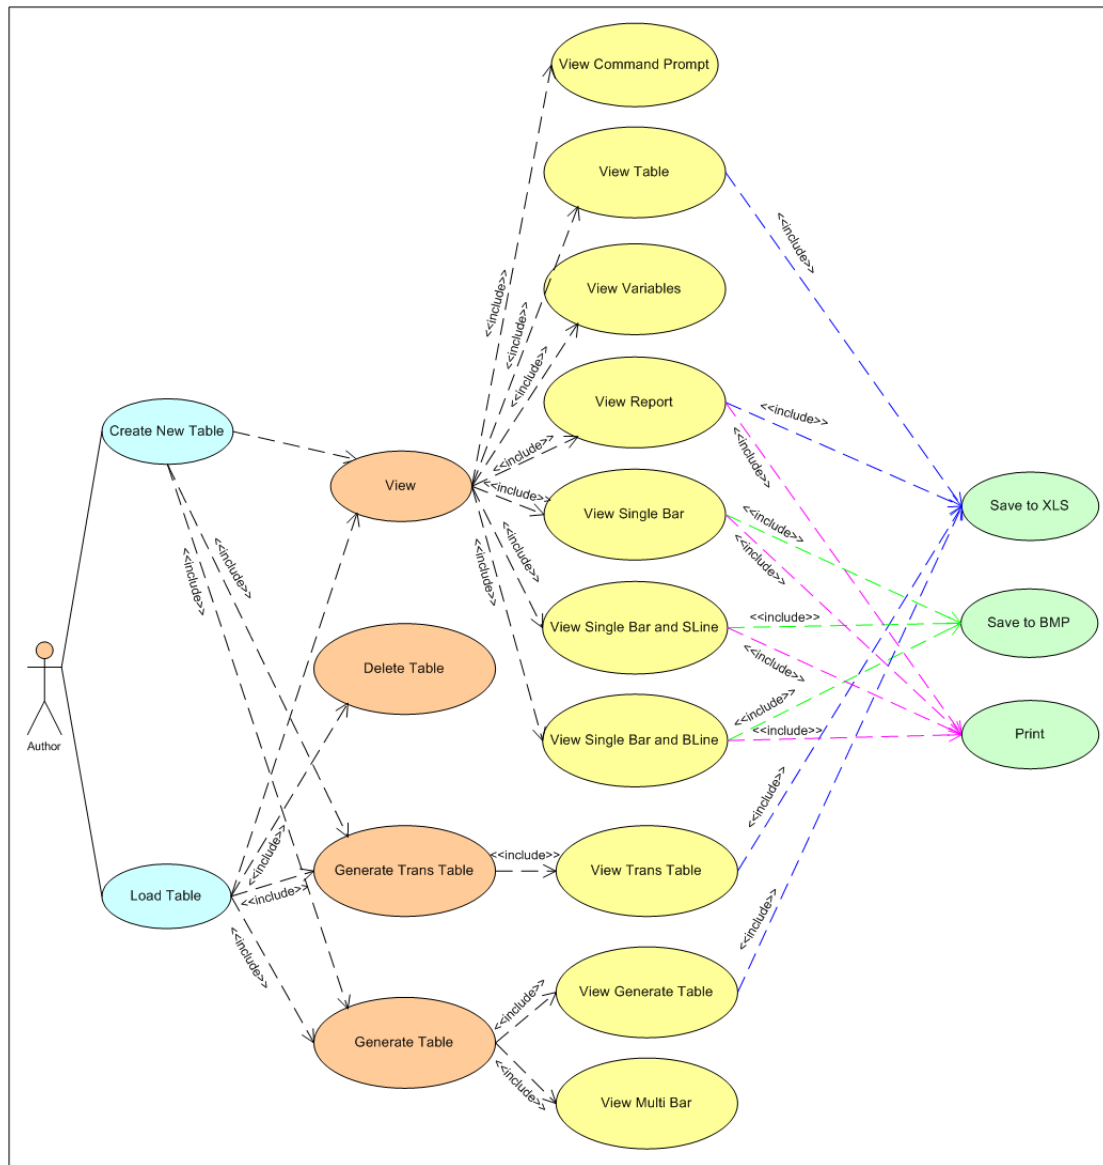

Figure 2 Use Case diagram of the tool

This diagram contains six paths (scenarios) from the actor, e.g. instructor, to the terminal use cases (ellipses). A solid line between the actor and an ellipse means that the instructor chooses the corresponding use case through the tool's interface. A dotted line between two cases means that they are performed by the tool. Such a step (instruction) is an element of the interaction between the user and tool. All lines are labelled only with one type of relationship <<include>>, e.g. when to extend its own functionality one case uses a part from the functionality of another. As can be seen on the figure when creates a new table with input dataset the instructor has opportunity to choose between the following alternatives, namely: to see the window with the program script and the window with the active table, to generate a new table, to see a single bar diagram with or without average line, and to see multiple bars diagram. The only difference between these two scenarios is that in the second case the table could be deleted, if the instructor wants.

Both subactivities (for table generation and processing results visualization) could be performed in parallel. The first subactivity consists of two actions respectively for table generation and multiple bars visualization. The second subactivity consists of four windows respectively for: active table, command editor, single bar diagrams with and without the average line (the last two chosen by the instructor). After returning to the main diagram two subactivities are merged in one common action – save the table in: .xls format, .bmp format and print the screen.

3. Tool's Script Language

The tool offers the instructor a power and expressive script language called SESSIONSCRIPT. Its open source code enhances the productivity, flexibility, and reusability of the data postprocessing. It can be classified as *visual very high-level mark-up* language. The language is "visual" because it describes graphics and tables as objects. "Very high-level" stresses on the fact that the keywords of the language are the terms of the domain knowledge blocks and atoms. The language is "mark-up" because it does not describe either algorithmic neither logical data processing.

In table 1 the common structure of programs in SESSIONSCRIPT is described in the meta-language of Bascus-Naur, using the following notation: ::= defines a syntactical construction; _ connects the words in a syntactical construction name; | separates alternative constructions; { } enclose a repeated construction; [] enclose an optional construction; < > enclose the title of a syntactical construction, which is still not defined. The operands of <expression> could be numerical constants (integer and real) or the identifications of the preliminary described parameters. In correspondence with the priority of the operations, acceptable in <expression>, are: +, -, *, /, ^, %. The change of their default priority is possible using brackets ("(", ")"). The embedded functions are three kinds: a) mathematical with an array as a parameter (SUM, AVG, MAX, MIN), b) mathematical with a variable as a parameter (ABS, LOG2, LOG10, and SQRT) and geometrical with an angle in radians as a parameter (SIN, COS, TAN, and COT).

Table 1 Common structure of programs in SESSIONSCRIPT

<pre> <common_program> ::= SESSION TABLE "<string>" DESCRIPTION "<string>" {<col_description>} {<row_description>} {<chart_description>} {< expression_description >} SET SCALE (<integer> {[,<integer>]} ; <real> {[<real>]}) GEN TABLE ("<string>",<string>{[,<string>]}) CORREL (<string>{[,<string>]}) TRANS ("<string>") DIGITS <integer> CTYPE <constant> <col_description> ::= ACOL "<string>" [=<string>] ACOLS ("<string>{[,<string>]}) ICOL "<string>" AFTER "<string>" DEL COL [<string>] "<string>" ALL SCOL "<string>",<string>" SORT "<string>" "<string>" ::= <string> < expression > <embedded_function> SCALE("<string>",<string>) <row_description> ::= AROW ("<string> <real>" {[,<string> <real>]}) </pre>	<pre> IROW AFTER [<integer>] [{"<string> <real>"} [, "<string> <real>" {[, "<string> <real>"}]]) DEL ROW [<integer>] ALL <chart_description> ::= YAXIS "<string>" ADD XAXIS "<string > <real>" ADD SLINE < string > ADD BLINE ("<string >" {[,< string >"]}) BARSTYLE <integer> DEL BLINE ALL DEL XAXIS ALL VIEW SINGLE BAR SINGLE BAR AND SLINE SINGLE BAR AND BLINE MULTI BAR <expression_description> ::= < string >=< expression > <string> ::= <letter>{[<letter> <digit>]} <integer> ::= <digit>{[<digit>]} <real> ::=<integer> <integer>.<integer>{[<integer>]} <constant> ::= BAR PIE AREA POINT < embedded_function > ::= SUM AVG MAX MIN SQRT ABS LOG2 LOG10 (<string> {[, .. <string>]}) SIN COS TAN COT (<string> < expression >) </pre>
--	--

4. Tool's Architecture

The architecture of the postprocessor is shown on figure 3 as connected program modules and their relationships with the data files. The purpose of the program modules is as follows: *Commands Editor* – the main program, supporting the window with the program in SESSIONSCRIPT and invoking the rest modules; *Commands Interpreter* – interprets the commands with arithmetic and other processing; *Table Processor* – supports the window with datasets in the table form; *Diagram Presenter* – interprets the commands for different types of diagrams, e.g. bar, pie, line, and point; *Report Builder* – creates the instructor's report with a set of indicators measured by the tool.

The specific data files contain respectively: *.tbl* - table and single bar diagram data; *.gtbl* - generated table and multi bars diagram data; *.abc* - program commands in SESSIONSCRIPT language.

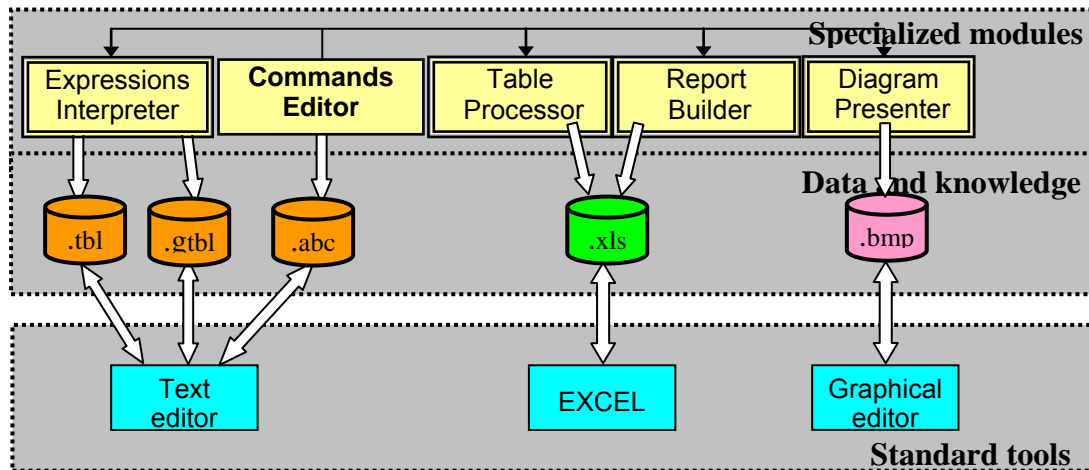

Figure 3 The postprocessor architecture

The tool is implemented in the *Borland C++ Builder 6* with the object-oriented style of programming and data files organization. Information about the embedded algorithms can be found in [2].

5. Technology of Using

The technological scheme of the instructor operating the presented tool is shown on figure 5. Although the pedagogic problem solving is presented as a sequence of steps in teaching practice some steps can be omitted others to be repeated or to present a subproblem solving. A new pedagogy free-text formulated task has to be clear, precise and compact (step 1). The instructor is also recommended to save it in a standard text file serving as a common catalogue of the problems already solved by the members of a course team. Each one of the task-oriented environments saves a standardized dataset in .xls format after each session, e.g. test, lecture or exercise (step 2).

In order to solve a new task a new user has to familiar with the tasks classification, data mining techniques, as well as the structure of the programs in SESSIONSCRIPT language. By means of a standard text editor he/she can review the script of the programs for related tasks (step 3).

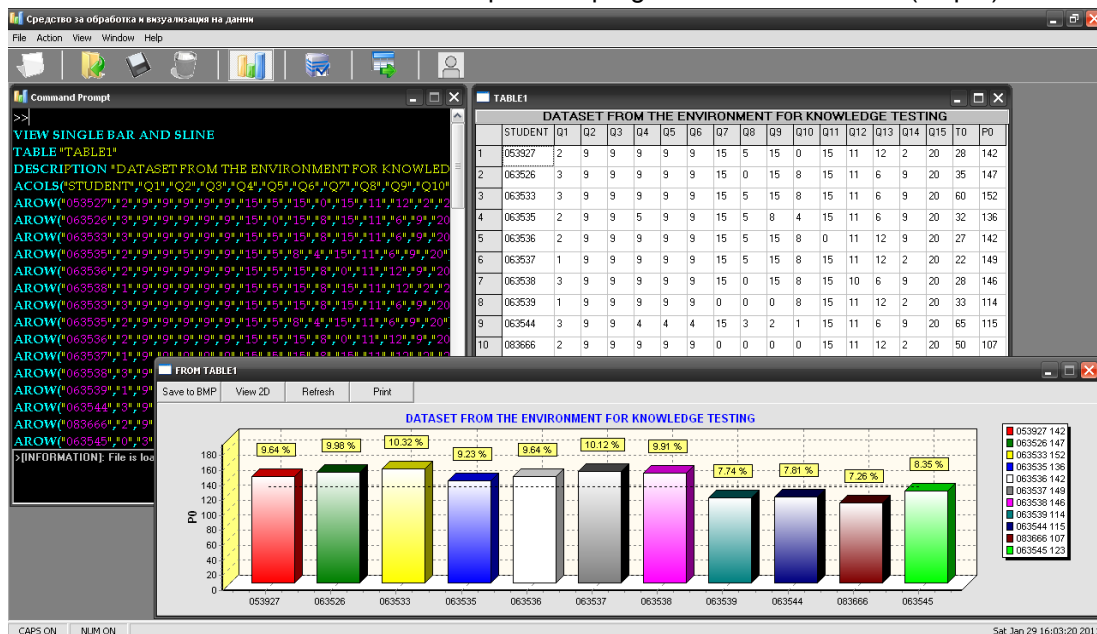

Figure 4 The windows for the command editor, table processor and diagram presenter

That's why the user is required to be familiar with the user interface as a whole and the groups of commands for the table description, including its metadata, e.g. the names of the rows and columns

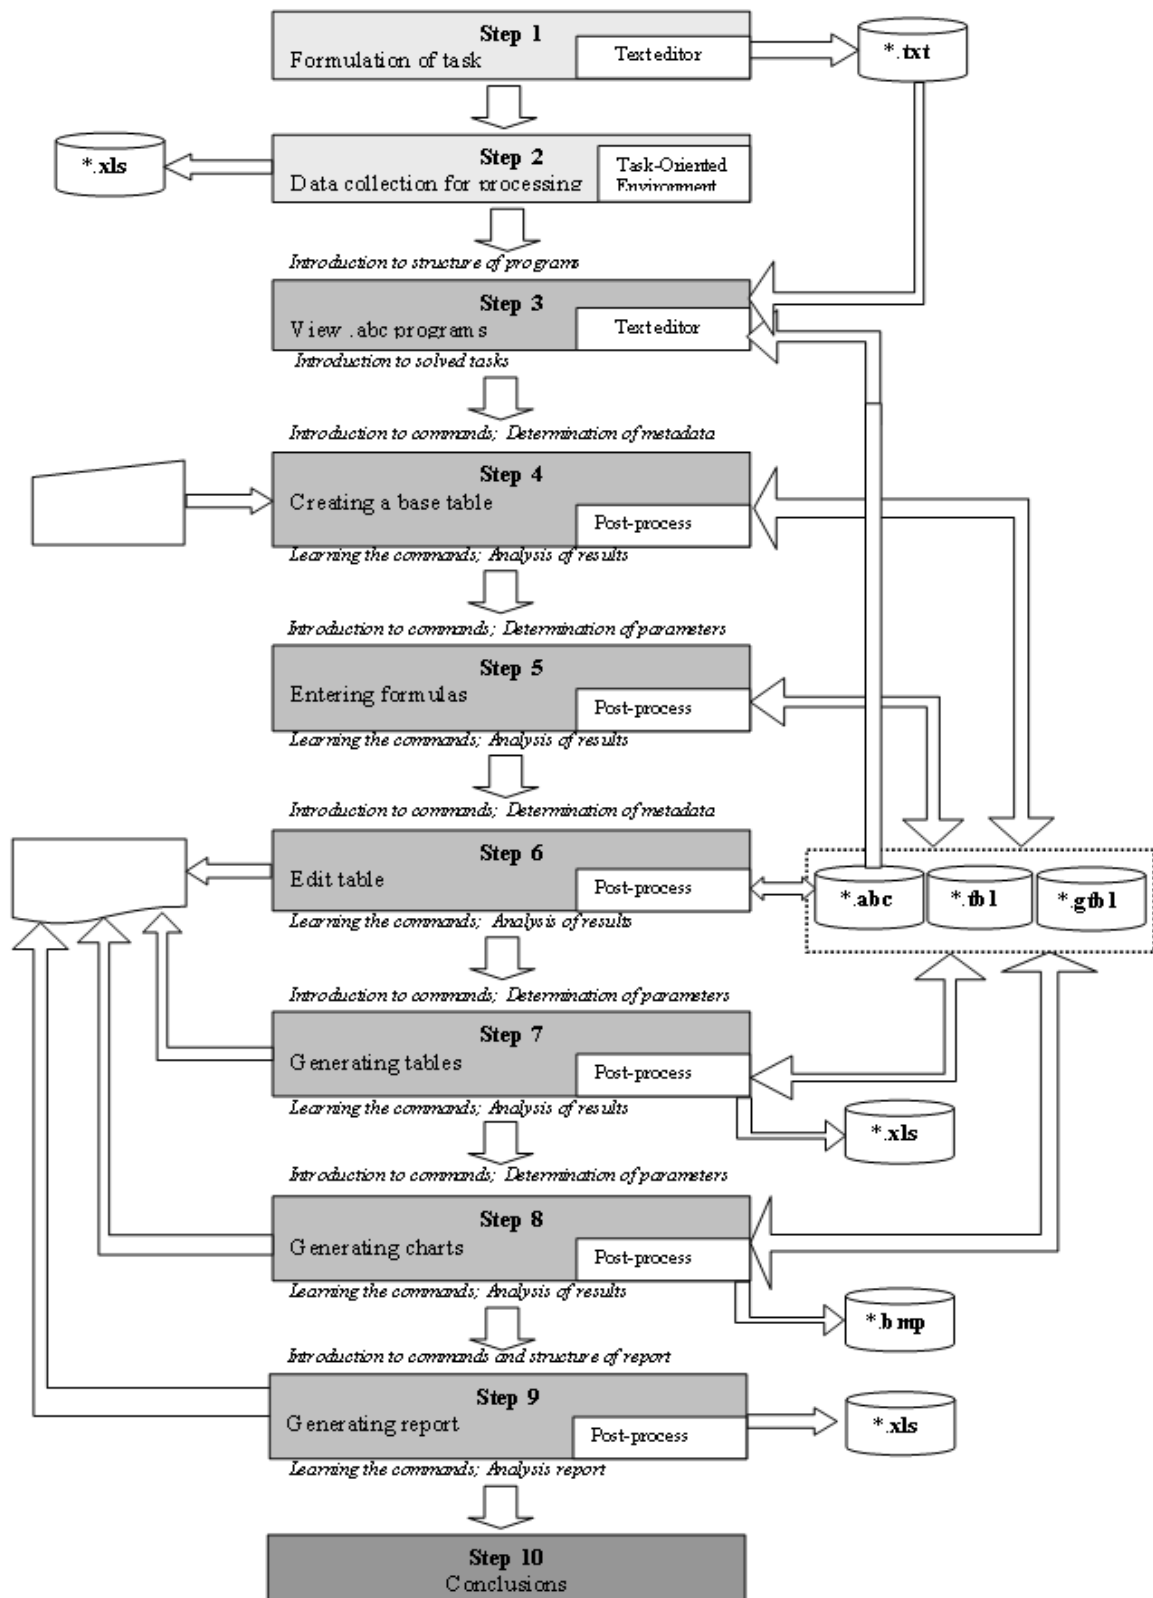

Figure 5 Technological scheme

and the input table name, e.g. with the input dataset. For example, the input table on figure 4 contains the following questions parameters: weight of a subanswer (L), degree of system prompt (C_p), degree of difficulty (D), coefficient of proximity ($PNORM$), time for test performance ($T0$), as well as the total test scores ($P0$). This table could be extended with additional rows and/or columns. Usually their values are received as a result of computation of some arithmetical expressions with some intermediate

program variables (step 4). Therefore, this activity requires the instructor to know the syntax and semantic of the corresponding group of commands.

In order to enhance the SESSIONSCRIPT language learning the following color coding scheme has been accepted: the correct commands names and symbols for operations are highlighted in *Agua* color; table, row and column names in *Yellow*; values in *Pink*; unknown keywords and current values of program variable in *Dark grey*; and messages in *Grey*. The current value of a program variable can be seen simply pressing <Enter> after the symbol “=” (figure 4). The instructor can choose also the menu-command *Window|Variables* to view the names and values of the system variables (figure 6) and the program variables (figure 7).

Variable	Value
NAME	TABLE1
DESCRIPTION	DATASET FROM THE ENVIRONMENT F
CTYPE	BAR
YAXIS	142
XAXIS	[053927, 063526, 063533, 063535, 06353]
SLINES	[SF1]
BLINES	NULL
DIGITS	3
SCALES	[2->0.44, 3->0.59, 4->0.75, 5->0.84, 6->1]

Figure 6 The list of the system variables

Variable	Value
PMAx	(158)
TMAx	(120)
X	(SUMA*6/158)
M0	(SUMA/158)
M1	[(2*SUMA-158)/158]
M2	(SUMA/158*120/T0)
M3	(SUMA/158*5)
MINIMUM	(107)
SF1	(133.909)
SF2	(107)
X_LOG	(LOG10((SUMA*6/158)))
Y	(ABS((LOG10((SUMA*6/158))))%SIN(23)) ³

Figure 7 The list of the program variables

The visualization allows choosing different kinds of diagrams, such as bar, pie, line, and point (step 6) viewed in separated windows. To perform this step the instructor again has to know the syntax and semantics of the corresponding group of commands. In order to view the corresponding diagram (for example, single and multi bars) the table name has to be chosen from the menu-item *View|Bars*.

For the needs of histogram visualization of the test questions and exercise tasks datasets five categories were chosen as in the Likert's psychometric scale and six-based assessment scale in Bulgaria: very easy (*VE*) from 0 to 0.29, easy (*E*) from 0.30 to 0.39, moderate from 0.40 to 0.59, difficult (*D*) from 0.60 to 0.69, and very difficult over 0.70. The histogram of the test questions difficulty is shown on figure 8 and that of the exercise tasks difficulty on the figure 9. The final step, e.g. the interpretation of the problem solution in the pedagogy terms, is obligatory for the instructor. For the example of histograms as it is expected an exercise task difficulty is higher than a test question difficulty. Also the distribution of the test questions difficulty and the exercise tasks difficulty is closer to linear as it is recommended in the pedagogy science.

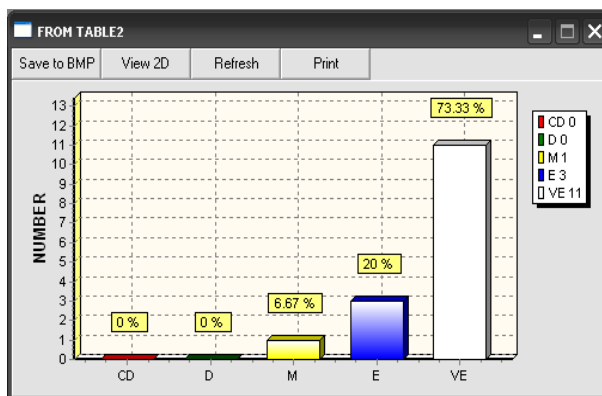

Figure 8 The histogram of the questions difficulty

Figure 9 The histogram of the tasks difficulty

To open a triple of files, e.g. script, table, and diagram, connected with a program, the menu command *File|Open* has to be chosen, and then to choose the *.tbl file name in the standard dialog window. Analogically, for saving a triple of files the menu command *File|Save* is chosen and then in the standard dialog window the name of the table has to be chosen.

The post-processor also allows the instructor to generate a new table, e.g. only with computed rows and columns (step 5). This possibility is illustrated on the power command CORREL for constructing

table with the correlation coefficients $r(i, j)$ between all couples of the above-listed questions parameters. In order to view an existing or generated table visualised in separated windows the corresponding table name has to be chosen from the menu-item *View|Tables*. Under the assumption $0 < |r(i, j)| < 0.4$ (weak); $0.4 \leq |r(i, j)| < 0.8$ (mediate), and $0.8 \leq |r(i, j)| \leq 1.0$ (strong correlation) the negative value of $r(L, Cp)$ means that the increase of the questions weight (L) is likely to decrease their system prompt (Cp), and the positive value of $r(L, PNORM)$ means that increases the L's assessment relatively to the instructor's one ($PNORM$). In both relations the coefficient values are interpreted as mediate that are reasonable conclusions.

	CP	L	D	PNORM	T0	P0
CP	1	-0.412	-0.12	-0.478	-0.216	0.248
L	-0.412	1	-0.597	0.537	0.023	0.083
D	-0.12	-0.597	1	-0.467	0.163	-0.755
PNORM	-0.478	0.537	-0.467	1	0.306	0.003
T0	-0.216	0.023	0.163	0.306	1	-0.412
P0	0.248	0.083	-0.755	0.003	-0.412	1

Figure 11 The instructor's report

During all steps of a task performance the tool checks the current command line and if it is incorrect a message (information or diagnostics) in the status line is displayed (figure 4). An information message (their number is 6) has the format: `[INFORMATION]: <text of the message><parameter><text> | [INFORMATION]: <text of the message>`. A diagnostics message (their number is 22) has the format: `[ERROR]: <text of the message> | [ERROR]: <parameter>`.

Before to exit the instructor can choose the menu-command *Window|Report* to see a detail report, print and/or save it in *.xls* format (figure 11). The extracted parameters: number of the program variables, rate of problem solving, invalid commands frequency, and so on can be used for comparison of one and the same task performance by different instructors.

6. Conclusions

A power instructor's tool for data mining is presented from the user's point of view. This tool is verified with two input datasets respectively by task-oriented environments respectively for knowledge testing and simulation tasks [6]. The main tool's difference is in its parallel script, table, and diagram processing and visualization. The tool offers the instructor a power, easy, and flexible script language demonstrated of the techniques of descriptive statistics, correlation analysis, and diagram visualization. It is not limited to implementation of other known data mining techniques as prediction, regression, and cluster analysis and even so complex as *Analytic Hierarchy Process technique* [4].

Organizational Change Management in Enterprises in Bosnia And Herzegovina

Zdenko Klepić¹, Mirela Mabić², Jelena Brkić.³

^{1,2,3}Faculty of Economics, University of Mostar, Mostar, Bosnia and Herzegovina,
zdenko.kleplic@sve-mo.ba, mirela.mabic@sve-mo.ba, jelena.brkic@sve-mo.ba

Modern company conducts business in the complex, heterogeneous and uncertain environment, and the change has become the essential part of organizational life and performance. Change has definitely become the condition for the company's development, but considering the dynamics and the complexity of the changes in the environment, it has also taken the status of the requirement for its survival.

Changes can be planned and scheduled, and their initiator or mover and the carrier is the company management, but they can also be unscheduled, happening as a reaction to an unexpected occurrence. A change that is planned is shaped and implemented in a manner so it anticipates future events, whilst the unplanned change is a response to occurrences that already took place. Change management has become one of the most significant manager skills and manager activity.

The aim of this research is to realize the extent to which the changes are conducted in a planned manner; how are the activities related to recognition of need for change and change management conducted; what are the targets of change; identification of change resistance and the ways to overcome them. Besides this, the aim is set to investigate if there is a difference in change management between enterprises in relation to their size.

The research was conducted in 2010, using the original questionnaire with the sample of 150 to 200 enterprises at the territory of the Federation of Bosnia and Herzegovina. The results are expected to demonstrate the significant difference in change management in relation to the size of the enterprise.

Keywords

Organizational change, small and medium enterprises

1. Introduction

Changes have always been a distinguishing feature and true meaning of existence of the human society and therefore have always been the centre of interest for individuals as well for the general public. The reason for this is found in the fact that, in a strong manner, changes influence the present and the future of the individual person, different organizations, companies, countries, entire nations and the society in whole.

Modern company conducts business in the complex, heterogeneous and uncertain environment, and the change has become the essential part of organizational life and performance. Change has definitely become the condition for the company's development, but considering the dynamics and the complexity of the changes in the environment, it has also taken the status of the requirement for its survival.

The company's general environment is the source of numerous changes throughout all of its components. Political changes are in perpetual motion and they have put an important stamp on the world's global level over the last 20 years to this day, causing various crises in the world. These changes affect the economies and business in whole as well as single companies having to deal with them in the business environment. Great changes are present in the technological environment and they have great impact on business possibilities of the company. Therefore the monitoring, application and proper deployment of the change is a necessity for the development and existence of the

company. Socio-cultural environment along with different demographic indicators are the source of numerous changes in the social trends, available human resources, general level of human education etc. Economic environment, with all of its segments, has always been a great source of all kind of major changes and the proof for that is evident in the present having a global crises influencing all of the world's economy and its companies including the ones in Bosnia and Herzegovina.

Business environment comprises many changes that have raised the level of the uncertainty and the great speed of these changes has amplified the dynamics of the business environment. Also, the number of present business subjects in this kind of environment is increasing which is making it more complex, and in addition activities of these subjects are even more diverse and more innovative which is giving the environment greater level of heterogeneity [1].

Internal business environment is also changing rapidly which is evident in all of the organizational structure shifts, organizational culture changes (which are happening in somewhat slower pace) and changes concerning organizational resources, material, human, financial and information ones.

Mankind is enriching the knowledge about itself and the surrounding world every day, it's trying to understand new work processes, it's applying more efficient techniques and technology and accordingly changing the comprehension of itself and its environment [2].

The speed and the significance of the changes that are happening in all of the environment segments are growing bigger and the ramifications are extremely high for the company in whole as well for the every individual within the company and the society in total.

Changes that are happening in one area of the environment may and often do cause and determine some other changes and the whole process is entrapped in the continuity with no evident ending.

Authors have different definitions of organizational change and according to R.L. Dafta [3] organizational change represents the acceptance of new ideas or behavior of individuals. The process of change is representing the fact that organization or some of its parts is transforming from current state to a new one.

Changes can be planned and scheduled, and their initiator or mover and the carrier is the company management, but they can also be unscheduled, happening as a reaction to an unexpected occurrence in the internal or external environment. A change that is planned is shaped and implemented in a manner so it anticipates future events, whilst the unplanned change is a response to occurrences that already took place. Considering the fact that this kind of situations demands a prompt respond, the lack of time, quality analysis of the problem and possible solutions, quality preparation and implementation of the change is often leading to a fact that, in the end, the change gets poorly understood and managed. Change management has become one of the most significant manager skills and manager activity.

Change is undoubtedly a key element of business and, if there is such possibility, it should be conducted before it becomes a necessity [4]. Managers are obligated to initiate and implement necessary activities concerning the adaptation of the organization for the change requirements which is implying the initiating and managing organizational change [2].

The goal of planned organizational changes is to enhance the organization by helping it cross from current state to some better, future, more quality state (which is more efficient and effective). The goal of unplanned changes, which are caused by the crisis within or outside the organization, is to reduce and diminish the caused damage and to help the organization to come out of the crisis with minimal harm.

Changes can occur in part of the organization or business process, but they can also take place in all of the organization, and the consequences of the changes are the source for different resistance.

2. Objectives of Research

The aim of this research is to realize the extent to which the changes are conducted in a planned manner; how are the activities, related to recognition of need for change and change management, conducted; what are the targets of change; identification of change resistance and the ways to overcome them. Besides this, the aim is set to investigate if there is a difference in change management between enterprises in relation to their size.

3. Methodology

The empirical research has been conducted in 2010 at the territory of the Federation of Bosnia and Herzegovina with the sample of 158 enterprises. The original questionnaire with 36 questions was

used as an instrument for conducting research. It contained questions related to characteristics of enterprise and questions related to organizational change management. Questions were formulated as closed-type questions and questions with offered answers in order of intensity (Likert scale type of five intensities where 1 indicates strongly disagree and 5 indicates strongly agree). Collected data were analyzed using the methods of descriptive statistics (absolute and relative frequencies, mean - M and standard deviation – s) and inference statistics (t test, χ^2 test, ANOVA). Level of significance was 0.050. SPSS 12.0 was used for data analyzing.

4. Research Results

4.1. Characteristic of surveyed enterprises

The analysis of research results of fundamental characteristics of observed enterprises has revealed the following:

- 46.8% enterprises were established between 1990 and 2000, 30.4% of them were established before 1990 and 22.8% after 2000,
- 24.1% enterprises have less than 10 employees, 27.8% of them have between 10 and 49 employees, 22.8% of them have between 50 and 249 employees and 25.3% of them have 250 and more employees,
- 71.5% enterprises are private owned, 15.8% enterprises are state owned, 12% enterprises are with mixed ownership and 0.6% enterprises are in cooperative ownership,
- 50.6% enterprises are organized as a limited liability company, 22.8% as stock companies and 26.6% have some other form of ownership (general partnership, sole trade, individual merchant companies etc.),
- Two types of characteristics (number of employees and revenue) have been combined to determine the size of the enterprise and following results have been obtained: 16.5% of the enterprises are micro enterprises, 31.6% of them are small, 27.8% are medium and 24.1% of them are large enterprises.

4.2. Management of organizational change

4.2.1 The recognition of need for change, diagnoses and planning of change

After every crisis, and also during its resolution, a change is present in company's processes as well as in people, and this change is necessary to prevent and avoid crises.

The dynamics at the enterprise and the extent to which it is open to different changes is rated by the respondents in the Bosnia and Herzegovina and has mean of 3.84. The rating for openness toward changes is different for different sizes of enterprises. Mean for dynamics of the enterprise and the extent to which it is open to different changes is the highest for micro enterprises (M=4.2, s=0.8), then for small enterprises (M=3.9, s=0.8). Middle and large enterprises which are bigger and thus slower and inert and have more complex organizational structure are somewhat less open to changes and less dynamic. Large enterprises have mean of 3.8 (s=1.1) and medium have mean of 3.7 (s=0.8). Although micro and small enterprises have bigger means comparing to medium and large ones, there is no significant statistical difference between them (F=1.981; p=0.119).

The changes in the organization can be planned and unplanned, and the number of unplanned or ad hoc changes should be reduced to minimum and these organizational changes [2] shouldn't be left to chance or arbitrariness, but they should be, in order to be successful, carefully planned and conducted.

How the surveyed enterprises approach implementation of changes is shown by Table 1. It is noticeable that ad hoc approach is not very present (10% and under) no matter what the size of the enterprise is. When it comes to micro enterprises there are a dominant number of enterprises (50%) that use mostly planned approach. Combined approach, that is partly ad hoc and partly planned, is preferred by small enterprises, 32% of them apply it, and middle enterprises where 43.2% of them apply it. Looking at large enterprises, 42.2% of them use planned and system approach which is understandable. There is no significant statistical difference when it comes to ways of implementing the changes in relation to the size of the enterprise ($\chi^2=19.542$; p=0.076)

Table 1 Distribution of enterprises according to ways of implementing the changes

Ways of implementing the changes	% of enterprises				
	micro	small	middle	large	total
Ad hoc approach	7.7	10.0	4.5	7.9	7.6
Mostly ad hoc approach	11.5	8.0	11.4	5.3	8.9
Partly ad hoc, partly planned approach	19.2	32.0	43.2	26.3	31.6
Mostly planned approach	50.0	26.0	25.0	18.4	27.8
Planned and system approach	11.5	24.0	15.9	42.1	24.1
Total	100	100	100	100	100

$\chi^2=19.542$; $p=0.076$

The need for change is always a consequence of the dissatisfaction with the current condition, and the greater the gap between the present and wanted state is, the bigger the need for change is. Sometimes, this need is evident, but most of the times, it isn't. This is exactly the reason for the management to keep track of the happenings in the external and internal environment in an organized and continuous manner so it could be able to anticipate and identify the changes that can affect their company [1].

In order to manage well organizational change in a quality manner before its implementation it is necessary to follow up and analyze elements of general (political and legal, economic, socio-cultural, technological) and business environment (customers, suppliers, creditors, trade unions, shareholders and so forth). General environment is least monitored and analyzed at micro enterprises (3.6 ± 1.0), middle enterprises follow (3.7 ± 0.9) and then large enterprises with mean of 3.8 ($s=1.0$). General environment is mostly monitored at small enterprises with mean of 3.9 ($s=1.0$) ($F=0.606$; $p=0.612$). Business environment, according to gained results, is also most monitored and analyzed at small enterprises (4.3 ± 0.9), followed by micro enterprises (4.2 ± 0.9), middle have the mean of 4.1 ($s=0.9$), while the lowest mean is for large enterprises and it is 3.8 ($s=1.1$) ($F=1.773$; $p=0.155$).

In addition to the analysis of environmental elements it is necessary to follow up and analyze the organizational culture, structure and resources that is the elements of internal environment of the enterprises.

The activities related to analysis of organizational culture, structure and resources is rated by mean of 3.7 ($s=1.0$), which is a relatively low and further research has shown that there is a significant statistical difference between enterprises in relation to their size. Micro enterprises have the lowest mean when it comes to analysis of internal environment elements ($M=3.6$, $s=0.8$), followed by middle enterprises (3.6 ± 0.9). The highest mean is calculated for small enterprises (3.9 ± 1.0) and for large enterprises it is 3.7 ($s=1.1$) ($F=1.004$; $p=0.393$).

The changes are not and should not be self purposed and prior to implementation of changes, objective/s that want to be achieved by those changes, should be clearly and realistically defined. When it comes to setting goals that want to be achieved by change, the mean is 4.2 ($s=1.0$) which is a good score, but it is surprisingly to find that the lowest mean was found at large enterprises: $M=4.0$ ($s=0.9$). Micro enterprises have mean of 4.3 ($s=0.8$), small enterprises of 4.4 ($s=0.9$) and these means are greater than those at middle and large enterprises ($F=1.966$; $p=0.121$).

Also, the identification of all the stakeholders which will be affected by the change (customers, suppliers, employees, managers, owners GOs and NGOs etc.) is needed before the change takes place so the planned change could be successfully conducted.

The research results indicate that the large enterprises have highest mean when it comes to identifying needs prior to change conduction (4.1 ± 0.9), followed by micro enterprises (4.0 ± 0.9). Small enterprises have mean of 3.8 ($s=1.0$), and middle have mean of 3.6 ($s=0.8$), which is the lowest score. There was no significant statistical difference between enterprises concerning their size ($F=2.020$; $p=0.113$). The mean for this group of activities at enterprises in Bosnia and Herzegovina is somewhat lower than previously mentioned activities (3.8 ± 0.9).

One of the significant activities in the process of need diagnosis and change planning is also the examination of positive and negative forces, and this research tried to answer the question how often do the companies, before implementing the change, try to identify individuals and groups that could have positive effect on one side, and on the other side, all of those that could have negative impact to the implementation of planned change.

According to obtained results, there is more effort invested in the process of identifying strengths (individual and groups) that should and could be moving force for the change implementation (3.9 ± 1.0)

than in the process of identifying forces that could be potential obstacles and setback to change implementation (3.7±1.0)

Small enterprises are most active in the process of identifying moving forces with mean of 3.9 (s=1.0), followed by middle enterprises with mean of 3.8 (s=1.0), than large with mean of 3.8 (s=1.1). The lowest mean is calculated for micro enterprises and it is 3.8 (s=0.8) (F=0.073; p=0.974).

When it comes to analysis of strengths that could be potential obstacles for change implementation, micro enterprises are most active (4.0±0.7), followed by small enterprises (3.8±1.1), then large enterprises (3.6±1.2) and middle enterprises (3.5±1.0) (F=1.672; p=0.175).

The research results also showed that, when it comes to the question of the extent in which the priorities and time and organizational capacities are taken into consideration in the process of change planning and implementation, mean is 3.9 (s=0.9). The highest mean is calculated for large enterprises (4.1±0.9), middle enterprises have mean of 4.0 (s=1.0), followed by small enterprises (3.9±0.8) and finally micro enterprises (3.8±1.0) (F=0.402; p=0.752).

4.2.2 Reasons for change resistance

Changes can be and often are the source of employee and manager, but also environmental resistance. Some of the resistances are easy to anticipate and recognize because they are explicitly manifested (strikes, intentional slower work or complaints), while others are not so visible and they are implicitly manifested (lack of motivation, errors, fallouts, absence etc.). The understanding about why some individuals and groups are fighting change is very important, because it allows the removal and reduction of resistance so the change process could be normally implemented.

The Table 2 is showing if individual resistance to changes in examined enterprises exist and in what measure.

Table 2 Distribution of enterprises according to reasons of resistance among individuals

Representation of certain reasons of resistance among individuals	Enterprises (M±SD)				F	p
	micro	small	middle	large		
They see things only personally not considering benefits for the whole enterprise	2.7±1.2	2.7±1.1	2.9±1.2	3.0±1.1	0.593	0.621
They are not disposing with sufficient information about changes	2.8±1.0	2.4±1.0	2.9±1.0	2.0±1.0	2.077	0.105
The fear that change will affect an individual personally	3.1±0.8	3.1±1.2	3.3±1.0	3.4±1.1	0.732	0.534
They do not wish to change existing habits	3.0±1.1	3.4±1.1	3.3±1.3	3.3±1.1	0.606	0.612
They do not like the initiator of the change	2.4±1.1	2.7±1.2	2.9±1.1	2.9±1.1	1.203	0.311
They want to maintain privileges, power and status	3.0±1.1	3.3±1.2	3.4±1.2	3.5±1.2	0.816	0.487

Destructive and irrational resistance is encouraging dysfunctional conflict which can endanger, not only change implementation, but also the prosperity and existence of the company, while in certain cases, change resistance [1] is a constructive and useful because it induces functional conflict and debates which can contribute to thorough analysis of the alternatives and their ramifications.

According to obtained results, the most common reason for change resistance in Bosnia and Herzegovina is desire to maintain privileges, power and status (3.3±1.2), followed by the desire not to change existing habits (3.3±1.2), then the fear that the change will affect an individual personally (3.2±1.0). The lower means are calculated for following potential reason for change resistance: not disposing with sufficient information about changes (2.9±1.0), they don't like the change initiator (2.7±1.1) and they see things only personally not considering benefits for the whole enterprise (2.8±1.1).

The resistance to change is greater in bigger enterprises comparing to smaller ones and this is the case at any given change resistance reason.

This is confirming the conclusion deducted within issue about openness and willingness of the enterprise for change where the significant difference regarding the size was indicated. Smaller enterprises are more opened to change and thus the resistance to change in bigger enterprises is larger which is partly the reason why they are less implemented.

4.2.3 Overcoming change resistance

Change resistance can be reduced or removed in a great deal if the necessary actions are conducted and employees and environment are prepared to the necessity and implementation of change. In order that resistance to changes would be less, employees should be informed about possible changes, draw their attention to the necessity of their implementation and ensure the participation of employees, especially those whom these changes concern directly, in their planning and implementation.

The results of the conducted research related to the ways that enterprises use to reduce change resistance are shown in Table 3. Enterprises mostly use "drawing attention to the necessity of changes" as a way to reduce change resistance (3.7±1.1) followed by "education of and communication with the employees" (3.6±1.1) and "willingness to help the employees in solving the problems caused by the changes" (3.6±1.0). The least used ways to reduce change resistance are the use of force by the superiors (1.9±1.1), manipulation of information in order to reduce the resistance of the employees (2.6±1.2) and offering different benefits to the employees (2.6±1.1).

The results indicate that smaller enterprises combine many ways (except the use of force) to reduce change resistance, which clearly demonstrates their willingness for change implementation and recognition that only changes can lead to survival and development of the enterprise.

There is significant statistical difference when it comes to "education of and communication with the employees" between micro and middle and also between small and middle enterprises. Statistical difference was discovered between small and middle enterprises in the area of "willingness to help the employees in solving the problems caused by the changes". There is significant statistical difference between micro and middle and also between micro and large when it comes to the way that superiors use force.

Table 3 Distribution of enterprises according to the ways of reducing change resistance

The ways to reduce change resistance	Enterprises (M±SD)				F	p
	micro	small	middle	large		
Education of and communication with the employees	3.9±0.8	3.8±1.1	3.2±1.0	3.3±1.2	3.416	0.019*
Drawing attention to the necessity of changes	4.0±0.9	3.8±1.0	3.6±1.1	3.4±1.2	2.444	0.066
Participation of subordinates	3.4±0.9	3.5±1.1	3.0±1.0	3.2±1.1	2.239	0.086
Willingness to help the employees in solving the problems caused by the changes	3.8±0.9	3.9±0.9	3.3±1.0	3.3±1.2	3.789	0.012**
Encouragement to employees to express their opinions and initiation of change	3.7±1.0	3.5±1.0	3.3±1.1	3.0±1.2	2.440	0.067
Manipulation of information in order to reduce the resistance of the employees is present	2.6±1.1	2.3±1.0	2.8±1.2	2.7±1.3	1.641	0.182
Different benefits are offered to the employees	3.2±1.0	2.8±1.2	2.5±0.9	2.2±1.1	4.859	0.003***
The superiors are using force	1.9±1.1	1.8±0.9	2.1±1.3	2.0±1.3	0.676	0.568

* micro-middle, small-middle; **small-middle; ***micro-middle, micro-large

4.2.4 The target of organizational changes

The targets of organizational change can be various, depending whether they are the result of the incurring crisis in the company, that is the organization or some part of it, depending on the source of the crisis, but also in the cases of planned changes about causes of organizational dysfunction.

According to the results of the conducted research, the most common target of organizational change is technology (23.4%) then products and services (20.3%), human resources (14.7%), organizational structure (14.2%), enterprise strategy (10.7%), organizational culture (5.6%) and management style (3%) as least targeted issue for organizational change. The results related to the targets of organizational change are shown in Table 4.

Table 4 Distribution of enterprises according to targets of organizational change

The targets of organizational change	% of enterprises				
	micro	small	middle	large	total
organizational structure	12.5	19.3	8.6	16.0	14.2
enterprise strategy	3.1	17.5	12.1	6.0	10.7
management style	0.0	3.5	1.7	6.0	3.0
organizational culture	0.0	8.8	6.9	4.0	5.6
human resource	6.3	12.3	20.7	16.0	14.7
technology	34.4	15.8	25.9	22.0	23.4
products and services	31.3	12.3	17.2	26.0	20.3
other	12.5	10.5	6.9	4.0	8.1
total	100	100	100	100	100

$\chi^2=27.448$; $p=0.157$

When it comes to micro enterprises, most common targets for organizational change are technology (34.4%) and products and services (31.3). Small enterprises aim their efforts to organizational structure (19.3%) and also technology (15.8%). Middle enterprises also target technology (25.9%) and human resources (20.7%). Large enterprises change their technology (22%) and products and services (26%). There is no significant statistical difference in relation to the size of the enterprise when it comes to possible targets of organizational change ($\chi^2=27.448$; $p=0.157$)

5. Conclusion

Introducing changes is necessary so that an enterprise would refocus, reposition, reorganize and conceive its business operation and development what would ultimately guarantee it the survival in increasingly turbulent environment. Also, the changes are also indicators of certain crises that enterprise falls into.

At the process of recognizing the need for change, diagnosing and planning the change, certain differences between enterprises have been perceived. Some of them are open to changes, they conducted and manage them in planned manner and some of them don't pay attention to changes in advance and don't know how to manage them. More than half of the surveyed enterprises use planned manner in conducting the changes. On the other hand, around 15% of them use ad hoc approach which is a noticeable number of enterprises.

The research revealed that the most common reason for change resistance in Bosnia and Herzegovina is desire to maintain privileges, power and status and the desire not to change existing habits.

Enterprises also use different activities to reduce the level of resistance to changes in order to have them efficiently implemented. Mostly used activities are drawing attention to the necessity of changes and educating of and communicating with the employees. For these activities there is also significant statistical difference among enterprises in relation to their size between micro and middle and also between small and middle enterprises when it comes to education of and communication with the employees. Also between small and middle enterprises in the area of willingness to help the employees in solving the problems caused by the changes and between micro and middle and also between micro and large when it comes to the way that superiors use force.

Changes in the enterprise usually target technology (23.4%) and then products and services (20.3%), rarely style of management (3.0%) and organization culture (5.6%).

It can be concluded that education about the importance and necessity of change is very important and should be brought to a higher level. Education is desirable not only for managers and leaders but also for all of those who will be involved in the process of change.

It is important to emphasize that the research involved employees who work at different workplaces and thus have different experiences related to changes and that can significantly affect the results of research.

For further research it would be advisable to identify general characteristics of enterprises like ownership, income, form of organization, number of employees etc. and the impact they have on identifying and overcoming problems. Also, whether changes come from internal or external

environment and whether they are the result of unplanned situations or on the other hand systematically designed by the superiors.

Performance analysis of the logistics processes within the supply chain management

Atanas Kocov¹, Ana Dzaleva²

¹Dean of the Faculty of Mechanical Engineering, Ss. Cyril and Methodius University, Skopje, Macedonia, nasko@mf.edu.mk

² Alkaloid AD Skopje, A Joint Stock Company Pharmaceutical Chemical Cosmetic Industry, Logistics and Procurement department, adzaleva@alkaloid.com.mk

As competition and complexity has increased, supply chain management has emerged as an increasingly important issue for the companies. The main challenge of the supply chain management is to identify and implement strategies that minimize costs and maximize flexibility, competitiveness and profit [1].

In the 21st century, changes in the business environment have contributed to the development of supply chain networks. First, as an outcome of globalization and the proliferation of multinational companies, joint ventures, strategic alliances and business partnerships, significant success factors were identified, complementing the earlier "Just-In-Time", "Lean Manufacturing" and "Agile Manufacturing" practices. Second, technological changes, particularly the dramatic fall in information communication costs, which are a significant component of transaction costs, have led to changes in coordination among the members of the supply chain network.

One of the biggest challenges today is to explore if there is the right way of supply chain management, if there is a possibility to create the optimal one, where is it positioned in the business strategy of the big companies, are there any risks, if yes, which ones, etc.

If we start our "journey" from the statistics promoted by the Institute for supply chain management, which says that, every 1% saved at the supply side is equal to 5% earned at the sales side, will realize the great importance of the supply chain management. In the last year-two, since we are facing the economy crises, even in the companies where the profit is reduced, or at least on a same level as the previous year, the top management will evaluate it as a successful year. This is all due to better organized supply chain management and cost cuttings.

Keywords

Supply chain management, Pharmacy, AlkaSAP, Organic tea, Acerola

1. Introduction

If we extract from the literature, there are few well known and accepted definitions of the supply chain management (SCM), that is considered as a management of a network of interconnected businesses involved in the ultimate provision of product and service packages required by end customers (Harland, 1996) [2]. Supply chain management spans all movement and storage of raw materials, work-in-process inventory, and finished goods from point of origin to point of consumption.

Supply chain management is the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole (Mentzer et al., 2001) [3].

A customer focused definition is given by Hines (2004:p76) "Supply chain strategies require a total systems view of the linkages in the chain that work together efficiently to create customer satisfaction

at the end point of delivery to the consumer. As a consequence costs must be lowered throughout the chain by driving out unnecessary costs and focusing attention on adding value. Throughput efficiency must be increased, bottlenecks removed and performance measurement must focus on total systems efficiency and equitable reward distribution to those in the supply chain adding value. The supply chain system must be responsive to customer requirements”[4].

Global supply chain forum - supply chain management is the integration of key business processes across the supply chain for the purpose of creating value for customers and stakeholders (Lambert, 2008) [5].

According to the Council of Supply Chain Management Professionals (CSCMP), supply chain management encompasses the planning and management of all activities involved in sourcing, procurement, conversion, and logistics management. It also includes the crucial components of coordination and collaboration with channel partners, which can be suppliers, intermediaries, third-party service providers, and customers. In essence, supply chain management integrates supply and demand management within and across companies. More recently, the loosely coupled, self-organizing network of businesses that cooperate to provide product and service offerings has been called the Extended Enterprise.

Not such a long time ago we were talking about supply chain management, which term is nowadays used always in plural, due to the globalization. Every supplier and every customer is a part of some supply chain, domestic or international. If the top management is observing the supply chain in this manner, it will definitely put the procurement department and the logistics as a pillar of the company.

According to the World's Bank study, logistics and the supply chain management are the key elements for development of a country. Countries with well developed logistics have better chances for economic growth. Thus the significance of this area globally, even more in local frames like Macedonian. According to the same study, these areas are neglected in our country due to the slow-going reforms, underdeveloped local market, low-grade human resources etc.

Macedonian companies everyday more and more understand the need of the quality supply chain management, even more when they realise that successfully organised supply chain could bring even 15% bigger profit for the company, lower prices and more quality services for the end user.

The accent of this article is to focus on the supply chain management in the field of pharmaceuticals in Republic of Macedonia, in order to compare it to the global trends, challenges and results. For this purpose one of the most successful companies in Republic of Macedonia, Alkaloid, joint stock company from Skopje is used. Supply chain management in the pharmaceutical industry has its own specifics, aiming towards the unique needs of the end users, to deliver the goods at the right time and place, in the cold chain system, by acceptable prices. The biggest challenges this industry is facing are shortening the delivery time and inventory.

Alkaloid's supply chain management is definitely one of the best organised in the country, from the supplier of the supplier, to the buyer of the buyer. It is supported with SAP [6] software package. The information system *my SAP ERP* (Enterprise Resource Planning), branded as AlkaSAP, is an integrated system performing complete data base management in Alkaloid, processing and monitoring data necessary for unimpeded and efficient functioning of the business processes.

2. Performance analysis of the logistics processes within the supply chain management in pharmaceuticals

Knowing the complexity of the pharmaceutical supply chain, given bellow as Figure 1, after many years using different software tools to organise the supply chain, and the logistics management in general, there was a clear need of finding improved solution.

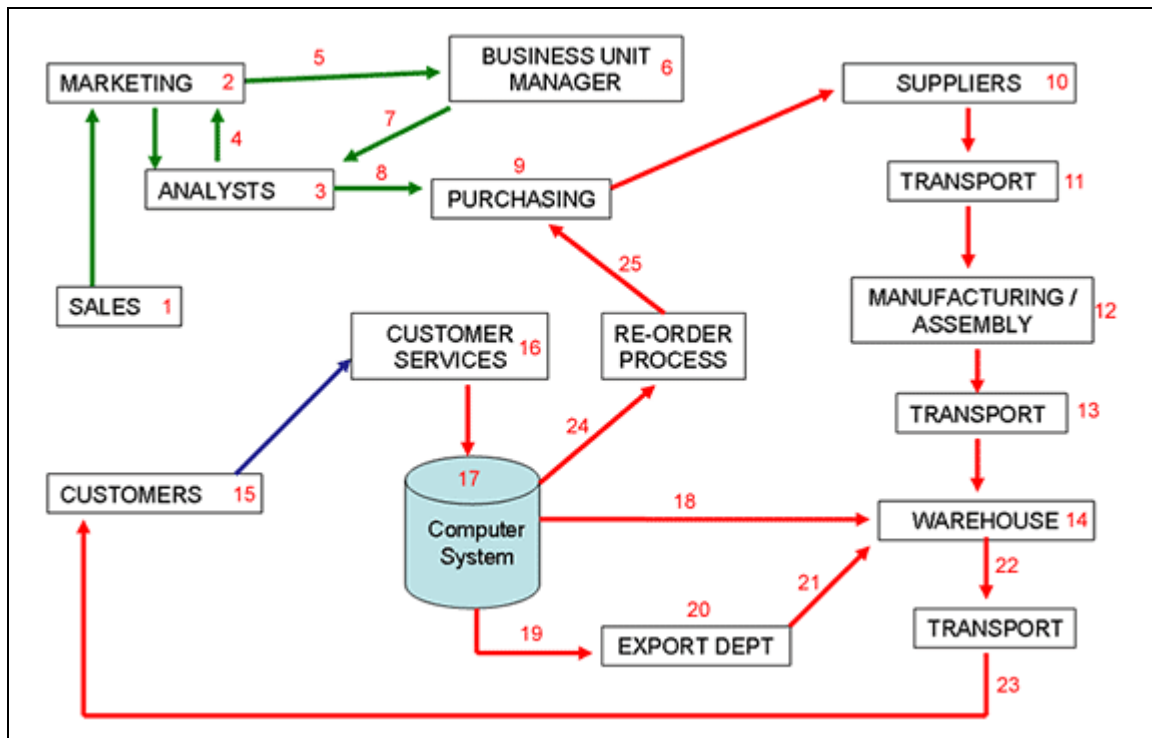

Figure 1. Pharmaceuticals supply chain with explanation of every phase

Source: DBC Logistics consultant UK

1. This flow chart shows a typical manufacturing supply chain work flow detailing which areas of the business are involved.
2. The sales department identifies a need for a product. The sales department tells the marketing department about their idea and provides any supporting information / data.
3. The marketing department use business analysts to support the project and to complete the research.
4. Data and supporting evidence is passed back to the marketing department for completion of a business plan.
5. A fully detailed business plan is forwarded to the Business Unit Manager / Directors.
6. This unit comprises of the senior business directors or managers who make a decision on the project.
7. After approval the plan is passed back to the analysts to prepare and implement the manufacturing process.
8. Details of raw materials and components passed to purchasing.
9. Purchasing work with logistics and transport to plan the purchase and delivery of the materials to the manufacturing plant.
10. Suppliers receive orders for product and then dispatch on agreed transport on agreed dates.
11. Carriers approved by the business transport the raw materials and components to the manufacturing site.
12. Products are received into the warehouse and then moved to manufacturing.

13. Finished products are moved from manufacturing to the finished goods warehouse which might be situated locally or in a remote location.
14. Finished goods are put into inventory awaiting orders. The company computer system is updated. Product is now available to sales.
15. Customers place orders through customer services.
16. Customer Services take orders and input them to the company computer system.
17. The central computer system maintains transaction records and provided visibility of product for sale.
18. An order is completed and a pick list sent to the warehouse.
19. A copy of the order is sent to the export department for completion of export documentation.
20. Export department manages the final dispatch of the product and produces any export documents.
21. Documents are sent to the warehouse to meet up with the finished order.
22. The order is dispatched by the warehouse.
23. The transport company collects the consignment and delivers it to the customer based upon the INCO terms of carriage.
24. As stock has now been used the computer system generates a request for new stock.
25. The re-order process generates a request to the purchasing department to place new orders with the suppliers.

Facing its 70th anniversary, Alkaloid started implementing SAP, a data transfer system worth over 2 million euro, a system that by its modules integrates completely all the business segments of the company. This also strengthens Alkaloid's position of a leader in one more field, as this is the first registered SAP that a company in our country installs.

The system has been functioning efficiently and continuously since its implementation and is consisted of six modules:

- FI (Finance) – Finances and Book-keeping
- CO (Controlling) – Business Planning and Controlling
- MM/WM (Material Management / Warehouse Management) – Material Management and Warehouse Management
- SD (Sales & Distribution) – Sale and Distribution
- PP (Planning Production) – Production Planning
- QM (Quality Management) – Quality Management

There are 197 users actively participating in the system's daily operations, having various level of authorization and scopes of work. The users continuously support not only the modules, but also the System Support, Program Support and Validation process [7].

While working on this study, main accent was put on SAP as a software solution: useful tool or huge extra cost? The result came even after comparing few figures since the first SAP was introduced in the company. It is definitely a solution for one fast growing competition market, as pharmaceutical is. It is clear that many factors contributed this growth, but AlkaSAP is definitely one of them.

Table1- 4 Growth figures in some areas since 2006

In *000 EUR	2006	2007	2008	2009	2010	Δ%

Registration of the new products	2006	2007	2008	2009	2010	Δ%
Macedonia	18	20	15	16	26	144%
Export	67	70	60	102	198	296%

Registration of the new products (tea dept.)	2006	2007	2008	2009	2010
Macedonian market and export	11	9	9	3	5

In order to show growing figures as a result of AlkaSAP use, two supply chains were monitored, one of the organic tea, that starts in Macedonia, and ends on the European markets, and the other of the food supplement, natural vitamin C, Acerola, that starts from international raw-materials supplier, and ends again on the European markets. The main points that were observed, parallel to SAP usage were:

- How the supply chain of a Macedonian pharmaceutical company works
- If the GMP norms and ISO standardizations are obeyed
- Is the material resource planning crucial for the process in general
- Is the procurement management used as a tool
- Is there warehouse management
- If AlkaSAP is good enough for the company of this size
- Is outsourcing of certain services as transport justified

After the study was performed and the figures compared it can be clearly seen that Alkaloid is a company where the logistics department and the supply chains are organized on a highly professional level, and both have a strategic role in the development of the company. Throughout the whole chain, GMP norms are fully followed. It was definitely shown through the figures presented by the company that AlkaSAP as a MRP tool is added value to the company which obliges using of the recourses in the most cost saving manner.

It is also proved that for the size of a company like Alkaloid, in this moment outsourcing of the transport services is economically most justified solution. From this, another conclusion is drawn, at this moment; the company is focused on its production and research and development, rather than transport department. In the years to come, maybe after five years, it will be useful to make new calculation, based on future year's figures.

3. Conclusions

As a result of the complete way of operating, Alkaloid definitely is a market leader, not only by market share, but also in building the supplier-customer from one side, and manufacturer-end user relationships, from the other. With AlkaSAP the company has obtained its optimum business potential, and is recognized as a superior company in the society. This was not done only by increasing the market share and the profit, but also building a sustainable manufacturing.

Probably, not very different from the global concept, the future definitely lays in the transformation of the supply chain management systems. It is certainly difficult to predict the future of the supply chains, but one is definitely a must: supply chains of a serious company should change, grow, expand and, again, change. It should be guided by the market and the customer, not by the marketing department, there should be development of the products that create demand and make profitable inventories, keeping in stock products that are constantly demanded.

This will definitely help any company in the world, even more in a country like Macedonia for better global positioning and bigger profit.

How micro lending practices affect entrepreneurial activity

Forcim Kola¹, Semiha Loca², Bajram Korsita³

²*Marin Barleti University, Tirana, Albania, semi.loca@gmail.com*

³*Faculty of Business, "Aleksander Moisiu" University, Durrës, Albania, bajramkorsita@yahoo.com*

Micro entrepreneurs are often considered as a risky client group for banks, because they lack collateral or the capacity to convince banks that they are able to get and repay a business loan. The most important barrier to new business formation is the inability of entrepreneurs to acquire the capital necessary to start a business. Micro entrepreneurs usually have no track record and lack financial reporting that the bank sector requires. The costs of processing small loans and the risks involved in lending to micro businesses make financial institutions hesitant to develop services for micro entrepreneurs.

Few entrepreneurs have or can rise from family and friends, the finance that they need to start in business. But even established businesses often need to raise more finance than can be provided by retained earnings.

This paper aims to bring facts and figures to analyze how and to what the process of micro lending practices in Albania has affected the entrepreneurial activity and how this category of small entrepreneurial firms can benefit by using it. In order to do so, we focus on different aspects of micro financial practices in Albania.

The methodology combined the application of both quantitative and qualitative tools including questionnaire on different indicators addressed to beneficiaries. Qualitative information was collected through Focus Group Interviews, Case Studies and Semi-structured interviews to understand the situations that people face, how they use and perceive micro finance, especially enterprises served by microfinance sector in Albania.

The paper will be organized in two parts, the first part will bring the data regarding the micro lending process in Albania, its challenges, the developments, the contribution on developing business skills, and the second part will analyze the perspective of increasing number of new small entrepreneurship practices as supposed to be supported by micro credit institutions in Albania.

Keywords

Micro lending, entrepreneurship, job creation, business skills

1. Introduction

In recent years, micro finance has gained growing recognition as an effective tool in improving the quality of life and living standards of very poor people. This recognition has given rise to a movement that now has a global outreach and has penetrated in the remote rural areas, besides slums and towns.

Micro Finance projects extend small loans to poor people for their varied needs such as consumption, shelter, income generation and self-employment, etc.

In some cases, micro finance programmes offer a combination of several services to their clients, in addition to credit. These include linkages with savings and insurance avenues, skill development training and marketing network.

Micro credit programmes, thus, assume significance since they facilitate poverty reduction through promotion of sustainable livelihoods and bring about women empowerment through social and collective action at the grassroots. In addition, micro finance interventions lead to increased social interaction for poor women within their households and in the community, besides, greater mobility that increases their self-worth and self-assertion in the social circle.

2. Methodology

This study has been done in 2011 in order to assess, on a national scale, the development impact of MFI programmes in relation to different product designs and delivery systems in various parts of the country aiming to measure the affect of micro credit in entrepreneurial activities. Keeping in view the anticipated socio-economic impact of its micro finance programme, the study has been focused on how the micro lending practices has affected entrepreneurial activities, to assess also the impact at the beneficiary level specifically the impact on enterprise level.

Research Questions. The primary objective of this study was to find out how micro lending practices affect entrepreneurial activity in Albania taking into consideration many business activities and measuring to them some attributes before and after taking the loan from any microfinance institution in Albania.

The key research questions addressed during the study include:

- Who is being served through micro finance?
- Does micro finance lead to poverty alleviation?
- Does micro finance contribute to enterprise growth and income?
- How does it affect rural women, particularly regarding empowerment?
- What effect does it have on other systems or sources of finance – both formal (*local banks*) and informal (*moneylenders*)?

These basic questions were translated into hypothesis linking input variables (MFI services) and moderating variables (enterprise client characteristics, programme characteristics and others) to ascertain the impact on entrepreneurial activity in Albania.

Sampling Design. The sample was composed of the *treatment group* and the *control group*. The target population for the treatment group was “two-year clients”, and included both *current and ex-clients*. The distribution of current to ex-clients in the treatment group was roughly proportional to the percentage of clients who dropped out of the program over the relevant time period. The control group consisted of pipeline clients, or new program clients, who either have not received their first loan or have received their first loan but have yet finished their first loan cycle.

Following best practice for conducting surveys, the selection of the survey sample was done by first geographically clustering the clients. It is revealed that geographical differentiation (rural, urban and peri-urban) was the most appropriate form of clustering for this survey. The final sampled numbers closely approximated the proportions of clients in terms of gender and percentage of borrowers and savers.

A total of 288 members of the Microfinance Institutions clients in Albania were interviewed for this survey which was conducted during January, 2011.

The small group interview sessions were conducted with clients who were stratified and segmented only along gender lines to identify any differences in outcome by gender.

Data Collection and Analysis. The study combined the application of both quantitative and qualitative tools including questionnaire on different indicators addressed to beneficiaries and other stakeholders. Qualitative information was collected through *Focus Group Interviews*, *Case Studies* and *Semi-structured interviews* to understand the situations that people face, how they use and perceive micro finance, especially enterprises served by microfinance sector in Albania.

The quantitative data of sample enterprises were analyzed to find out percentages, averages and frequencies for various indicators. The results were subjected to longitudinal analysis for two types the *treatment group* and the *control group*, and the same were tested for statistical significance. The results of comparisons were studied/super-imposed to find out whether the behavior of a particular indicator supports the micro finance intervention as the cause of change.

The quantitative results were supplemented by qualitative observations obtained from *Case Studies*, *Focus Group Interviews* and *Semi-structured interviews*.

3. Outreach

Hypothesis: Micro Finance is an effective solution for extending financial services to the poor and other disadvantaged groups not reached by formal sector finance.

MFI movement is predominantly taking place in better developed districts and in rural areas.

- MFIs generally serve poor clientele, but 'very poor' clients are still un-reached.
- Majority of clientele is from socially disadvantaged rural districts.
- Coverage of male clients is still predominant.

Table 1 Location of MFIs customers

	Total	Mature Clients	Ex-Clients	Treat. Group	Control Group
Location					
Rural	59 47.20	28 44.44	13 48.15	41 45.56	18 51.43
Peri-urban	39 31.20	18 28.57	8 29.63	26 28.89	13 37.14
Urban	27 21.60	17 26.98	6 22.22	23 25.56	4 11.43

MFIs in Albania generally serve rural clients (45.56 percent of clients). The proportion of urban clients is 25.56 percent and the peri-urban clients consist of 28.89% (Table 1). Female clients constituted 39.53 per cent of the total clientele and male clients were 60.47 per cent of the sample clientele.

Table 2 Gender of MFIs customers

	Total	Mature Clients	Ex-Clients	Treat. Group	Control Group
Gender					
Female	47 37.60	24 40.68	10 37.04	34 39.53	13 33.33
Male	78 62.40	35 59.32	17 62.96	52 60.47	26 66.67

4. Access to Micro Finance, Contribution and Use

Hypothesis: There is an overall improvement in access and use of MFI loans but not of other services. Access to micro credit has improved for clients

- Savings, under MFI programme has experienced a setback
- Micro Credit has been utilized for investment in productive activities and income generating business activities, besides other household requirements

Access to Micro Savings. Though after crediting, savings was the most popular micro finance service among the clients, the data show us that 71.74% of clients did not save before joining the microfinance programme, until only 28.26% of them save before (Chart 1).

Figure 1 Savings before joining MFIs

Provision of opening micro savings account in the group under the programme had proved to be a boon for the clients, especially for the vulnerable ones. The reasons for preference of the savings scheme were their ability to:

- *maintain savings account at their doorstep*
- *save small amounts on regular basis which was not possible in any formal financial institution*
- *create emergency fund to give them a kind of security against the odds*
- *contribute to their family or near and dear ones during distress*
- *pay monthly installments in case of paucity of funds*
- *exercise control over the expenditure decision*
- *create fellow feelings/bondage among the members of the group*

Members felt that savings was a solution as it helped in emergency situation including releasing of mortgaged land or house, medical purposes, children's education and social and religious functions.

Access to Micro Credit. Micro credit has made an appreciable impact on the lives of many client households through provision of small loans with easy repayment terms, which, in turn, has helped them in starting new enterprises or expanding their existing ones.

Taking of the loan from MFIs went up across all wealth rank categories but the increase was more visible for the 'very poor' category and all of them opted for it at the expense of the loan.

Micro credit has been utilized for various purposes by the client households. The future investment in business occupied the major share (35.37 per cent) in MFI loan-use pattern for all wealth ranks, both in the baseline and end line.

Figure 2 Crediting of MFIs clients

Use of Non-financial Services. While some MFIs were providing non-financial services like specialized training pertaining to the clients' occupation and/or enterprise development programme, a number of them had not taken adequate initiative in skill development of their clients in spite of the demand for such services.

There was unanimous demand from many members in all villages that skill development / training was required for undertaking any income generating activity and they felt that MFI loan alone would not help in improving the livelihood.

Most of the members felt that MFIs could have encouraged them in improving their skills. They also felt that had there been a proper venue for training, they could have extended their skills to others in the village. The non-clients had also shown interest in this regard.

5. Micro Finance and Enterprises

Hypothesis: Micro Finance increases enterprise activities

With micro credit support, clients have either started new or expanded existing enterprises which not only provided better employment opportunities but also increased enterprise income.

5.1 The average salary of employees

It is widely accepted that for an enterprise being microfinance client leads to higher employee salaries, job creation, increase enterprise assets, and many other improvements. Let's see the impact of lending practices of MFIs in average salary of employees using hypothesis testing for comparing two related samples;

Paired *t*-test is a way to test for comparing two related samples, involving small values of *n* that does not require the variances of the two populations to be equal, but the assumption that the two populations are normal must continue to apply.

For a paired *t*-test, it is necessary that the observations in the two samples be collected in the form of what is called matched pairs i.e., "each observation in the one sample must be paired with an observation in the other sample in such a manner that these observations are somehow "matched" or related, in an attempt to eliminate extraneous factors which are not of interest in test. Such a test is generally considered appropriate in a before-and-after-loan study.

Average salary of employees before and after the loan has been recorded for 10 enterprise activities as they are shown in the table below; Using the Paired *t*-test calculations made with STATA we can conclude if there is a difference between average salary of employees before and after the loan, or if the lending practice has been efficient or not in increasing employee salaries.

Table 3 Hypotheses testing for comparing two related samples of employee salary

Business activities	1	2	3	4	5	6	7	8	9	10
Before loan	25000	15000	21000	15000	25000	27500	30000	20000	23000	20000
After loan	27000	27000	32000	30000	30000	32000	32000	22000	28000	24000

Two-Sample Paired t Test

Paired T-Test of mean difference = 0 versus not = 0									
Alternative hypothesis: true mean of differences is not equal to 0									
N	Mean	StDev	SE Mean	Corr	95% Conf Interval	t	df	p-value	Alt Hypothesis
10	-6250	4685.9	1481.83	0.4235	[-9602.1; -2897.8]	-4.2177	9	0.0022	Accept

As shown in the table above, we have to reject the null hypotheses, concluding that there is a difference in average salary of employees before and after the loan or that the lending practice has been efficient for enterprises served leading to increase employee salaries.

5.2 The number of employees

It has been recorded the number of employees before and after the loan for 10 enterprise activities as they are shown in the table below; Using the Paired *t*-test calculations made with STATA we can confirm if there is a difference between number of employees before and after the loan, or if the lending practice has been efficient or not in job creation or increasing employment.

Table 4 Hypotheses testing for comparing two related samples of employee number

Business activities	1	2	3	4	5	6	7	8	9	10
Before loan	1	2	12	0	1	2	2	2	4	1
After loan	3	5	19	2	2	5	4	5	7	2

Two-Sample Paired t Test

Paired T-Test of mean difference = 0 versus not = 0									
Alternative hypothesis: true mean of differences is not equal to 0									
N	Mean	StDev	SE Mean	Corr	95% Conf Interval	t	df	p-value	Alt Hypothesis
10	-2.70	1.7029	0.5385	0.9926	[-3.91; -1.48]	-5.0138	9	0.007	Accept

As shown in the table above, we have to reject the null hypotheses, concluding that there is a difference in the number of employees before and after the loan or that the lending practice has been efficient for enterprises served in job creation leading to increased employment.

5.3 The profit margin and enterprise assets

For the purpose of this study It has been recorded also the profit margin before and after the loan for 10 business activities as they are shown in the table below; Using the Paired *t*-test calculations made with STATA we can test the hypotheses for comparing two related samples of profit margin before and after the loan, or if the lending practice has been efficient or not in increasing profit margin.

Table 5 Hypotheses testing for comparing two related samples of profit margin

Business activities	1	2	3	4	5	6	7	8	9	10
Before loan	14.8	14.5	10.3	9.7	20.1	15	28	37	18	21
After loan	15	18	16.4	12.5	25	21	35	41	20	27

Two-Sample Paired t Test

Paired T-Test of mean difference = 0 versus not = 0									
Alternative hypothesis: true mean of differences is not equal to 0									
N	Mean	StDev	SE Mean	Corr	95% Conf Interval	t	df	p-value	Alt Hypothesis
10	-4.25	2.1532	0.6809	0.9731	[-5.790; -2.709]	-6.2418	9	0.0002	Accept

As shown in the table above, we have to reject the null hypotheses, concluding that there is a difference in the profit margin before and after the loan or that the lending practice has been efficient in increasing profit margin of enterprises served.

Increasing profits of Enterprises. Many clients have used micro credit for developing their existing activities or diversifying into new activities with a view to increasing their sources of income. Between the treatment group and the control group, 48% of Treatment group reported an increase in enterprise profits compared to only 15% of the control group, and 42% of the enterprises from treatment group reported that their profits has increased greatly compared to only 3% of the control group as it is shown in the chart below;

Figure 3 Enterprise profits

A 35 years old female, found it difficult to make ends meet. She had studied up to the primary level. She and her family had no savings and stayed in a medium sized house. Her husband ran a small floriculture business, earning 2-3 Euro daily. Two of her sons were employed – one ran a barber shop,

which was on rental basis and the other a lotto-sport worker. She joined the microfinance program two years ago and availed of loan twice.

With the help of the loan received from the MFI, she was able to assist her eldest son in purchasing the barber shop. Her son's present income was 10 Euro daily, amounting to 300 Euro per month. Though the income did not increase much, this lady and her son were proud that they owned the shop and would be able to increase their business. The MFI credit had smoothed the income cycle of the family by way of ensuring regular income and helped the financially backward in developing their own enterprise and standing on their own feet, thus improving their standard of living to a large extent.

Change in Enterprise Assets. Clients reported increase in income from majority of business activities supported by microfinance institutions. The activities which accounted for higher investments in major tools were 23.24% of treatment group compared to 2.94% of control group. Also in means of transportation invested 16.2% of treatment group compared to only 2.94% from the control group as shown in table 6, proving the affect of micro credit on increasing enterprise assets;

Table 6 Investment in Enterprise Assets

Asset	Total	Mature Clients	Ex-Clients	Treat. Group	Control Group
Small accessories	33 18.75	18 19.15	9 18.75	27 19.01	6 17.65
Major tools	34 19.32	22 23.40	11 22.92	33 23.24	1 2.94
Means of transportation	24 13.64	16 17.02	7 14.58	23 16.20	1 2.94
Storage structure	22 12.50	11 11.70	9 18.75	20 14.08	2 5.88
Minor investment in marketing site	29 16.48	12 12.77	6 12.50	18 12.68	11 32.35
Structure for marketing site	34 19.32	15 15.96	6 12.50	21 14.79	13 38.24

6. Conclusions

Based on the survey and observation results we can conclude that lending practices have a positive affect on entrepreneurial activities in increasing employee salaries, in job creation or generating employment, in increasing profit margin of enterprises served as shown by the cases and models analyzed in the above text.

Besides credit, the poor need savings services to bridge income fluctuations and meet emergency needs. MFIs are not permitted to mobilize deposits, hence, are unable to offer savings services to their clients, so it is strongly recommended that MFIs may be permitted to mobilize savings at least from their own clients/members on the condition that they will follow prudential accounting norms. MFIs should offer interest on savings and savings be made withdraw able.

MFIs are often pressurized to bring down interest rates to unreasonable levels in the name of service to the poor without provision of any support. MFIs have to charge interest rates on loans to fully cover cost of funds, operational costs, loan loss provisions and reasonable margin of profit for servicing equity and building sustainability.

MFIs should follow a rational and transparent interest policy to avoid suspicions and encourage professionalism in the sector. MFIs may take steps like rationalizing the cost of funds by accessing various sources of funds, increasing operational efficiency, involving local small NGOs, etc.

Borrowers are often unaware of the effective cost of borrowing and complain about the high cost of loan and lack of transparency. MFIs should be transparent with respect to interest rate and other costs charged and effective cost of credit to the borrowers.

Regional competitiveness and development with the reference to the situation in Serbia

Suzana Kolar¹, Dejan Živkov²

¹PhD student at The Faculty of Economics, University of Novi Sad, Serbia, suzana.kolar@yahoo.com

²PhD student at The Faculty of Economics, University of Novi Sad, Higher business school, Novi Sad, Serbia, dejanzivkov@gmail.com

The main goal of the paper is to analyse methodical and practical aspects of region competitiveness and its impact on the development, with reference to the situation in Serbia. In this case the definition of competitiveness, as well as the definition of development requires adequate interpretation and quantitative assessment. Unfortunately, there is no single, all-encompassing economic theory that provides a generally accepted definition and explanation of regional competitiveness. As the same time, obvious is that for a successful integration of a country's economy into the global markets, its competitiveness is crucial. In this paper, we focused on Serbia's current competitiveness context and the challenges for its improving. Serbia, even though involved in the transition process as early as 1990, due to wars and economic sanctions, is very much in delay with its implementation. Indeed, a new competitive strategy is needed based on efficient macroeconomic management and micro-economic management, on fully privatised and transformed enterprises. In order to evaluate Serbia's strengths and weaknesses, this paper analyzes the most relevant studies dealing with international competitiveness. This paper also analysed the main tendencies in the industrial development of Serbia, and the key factors in the decision-making regarding allocation of foreign investments. Finally, we presented some recommendations for improving Serbia's competitiveness.

Keywords:

International Competitiveness of Serbia, Measurement of Regional Competitiveness, Regional Competitiveness

1. Introduction

In different economic encyclopedias, *competition* is described as a contention of producers and traders for better farming and goods' realisation conditions as well as for the entrench in the market, noting that competition stimulates culture development of economics and management. [1] International Institute for Management Development has defined competitiveness as a capability of national economy to create added value and increase national benefit, and has retained it till present. For countries, where resident business does not dispose higher technologies, or countries which do not have strategically important natural resources and which have just soaked up fundamentals of market economics, it is necessary to insure that every business unit, every decision of government, every feet of its territory would become competitive and completely responsible for their survival and value. [2]

Territorial economic policy aims to enhance *regional competitiveness* and attract new investments of various sizes in order to exploit more fully regional comparative advantages and generate significant growth in regional employment and income. Regional integration can be a powerful policy tool. [3] It can function as a dynamic catalytic interface that buffers local actors' exposure to global contexts. It can also provide a framework that helps to eliminate incentives for welfare-reducing fiscal wars among local districts that compete over foreign investment. Regional competitiveness is probably best seen

as an evolving complex self-reinforcing process, in which outputs themselves become inputs, and thus influence future outputs. [4] Outcomes feed back to influence drivers, fundamentals and externalities: all coevolved, in this instance in a virtuous circle.

2. Regional Competitiveness and Sustainability of Competitiveness

The competitiveness of a country depends upon its ability to make market participants efficiently use available resources, as well as upon its ability to introduce innovations and positively change environment to guarantee the development sustainability. [5] As the competition in the world is increasing, the role of country becomes more and more important. There are three *country's attributes*, that each of them and altogether constitutes the base of country's competitive advantages: (a) environment adequacy for training competitiveness; (b) technological and organisational perfection of the fields of activity; and (c) utility and efficiency of the international relations.

These factors along with the regional features most often guarantee regional resources, labor qualifications for the selected field of activity. The apex of each triangle illustrates the key point of competitive success achievement on the international scale: accessibility of resources and qualified labor force, information that forms good opportunities, and experienced pressure upon the company, making it introduce and realise innovations. In general, the presumption of competitiveness of a separate country and the whole of factors can be shown in Figure 1. [6]

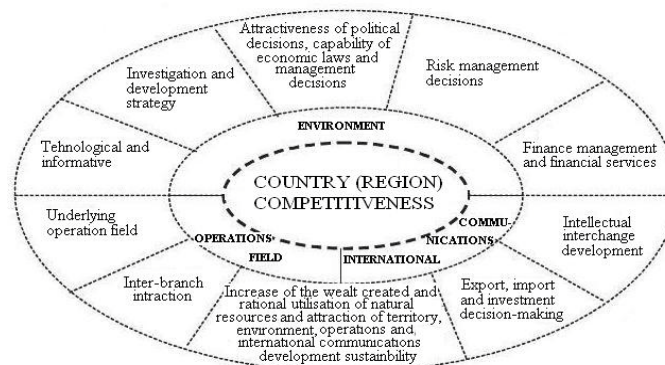

Figure 1 Presumptions of regional sustainable competitiveness

3. Measurement of Regional Competitiveness

The *World Economic Forum* has been measuring competitiveness of national economies. Each economic forum measures competitiveness by the *Growth Competitiveness Index (GCI)*, *Business Competitiveness Index (BCI)*, and *Global Competitiveness Index (GCI)*.

The *GCI* includes ratings of: the quality of macroeconomic environment; the state of public institutions and technological development. The global technology development phases as a base for building the national competitiveness strategy are: the factor based development; the investment based development and innovation based development.

The *BCI* is based on the assumption that macroeconomic and institutional stability are necessary, but not sufficient, because they provide the setting for the generation of wealth. According to *Porter's diamond of business clusters*, there are four interrelated factors of the business environment: strategic context; supply; consumption; and connected business. An inadequate level of entrepreneurial capacity is of special importance for developing countries and countries in transition because it continually leads to the cancellation of the positive effects of different stabilisation and monitoring programs, demanded by international financial institutions. [7]

The *Global Competitiveness Index*, which synthesises and expands the above-mentioned aspects of competitiveness, was introduced as the measurement of competitiveness. According to this approach, there are twelve pillars of competitiveness which is shown in Figure 2. Division to sub-components was performed based on the assumption that countries pass through three stages in their development. Economic growth at the first stage relies on the basic production factors. Economies at the second stage base their economic growth primarily on efficiency enhancement. Most relevant for the countries belonging to this group are the competitiveness pillars contained in the subgroup Efficiency Enhancers. Serbia is in the second stage of development. Finally, economic growth of the

countries at the last stage of development, depends to a large extent on innovation and sophistication of business processes.

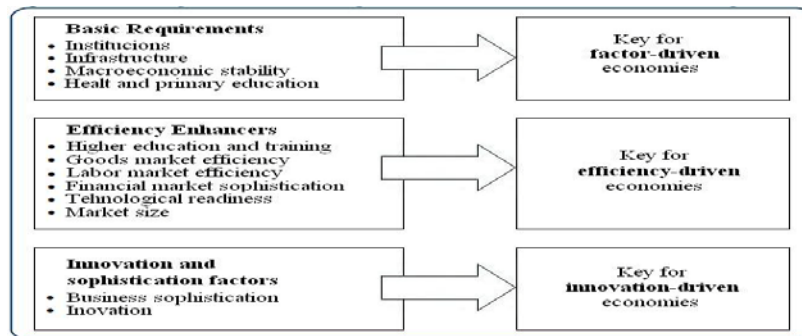

Figure 2 The 12 pillars of competitiveness

Generally speaking, productivity and the employment rate are measures of what might be termed *revealed competitiveness*, and both are central components of a region's economic performance and its prosperity. Figure 3. [8] suggests that productivity may differ between regions for a host of different reasons. But equally important is how such differences are predicted to evolve over time. Regional differences in productivity growth are explained by regional differences in the rate of technical progress and by regional differences in the growth of the capital labor ratio. [9] Martin adds two more measures of revealed competitiveness: wages and GDP per head.

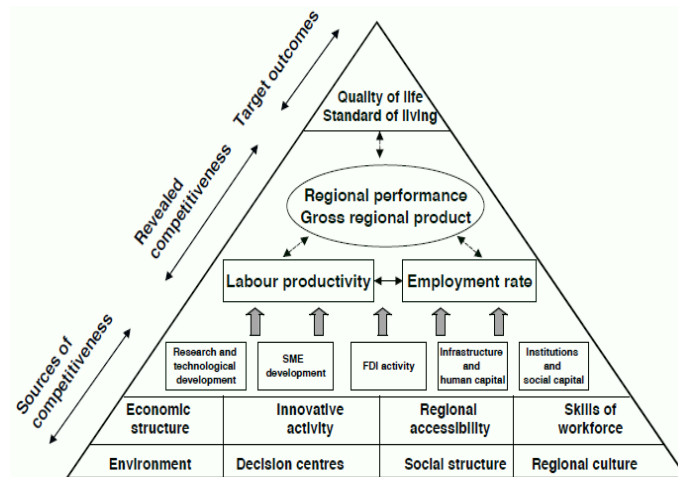

Figure 3 The Pyramid Model of Regional Competitiveness

Aiming to measure the regional competitiveness within the country by the *Regional Competitiveness Index*, Snieška and Bruneckienė have formed a Regional Diamond model. [10] The model was a means to evaluate the ability of regions to use factors of competitiveness for the formation of a competitive position and for its retention among other regions as well. It is presented in Figure 4.

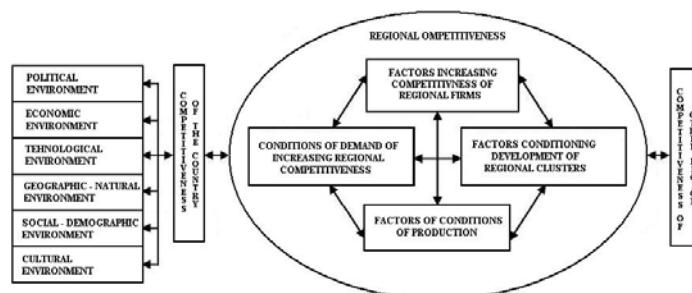

Figure 4 Regional Diamond model

With regard to the fact that a region is an open system, factors of competitiveness must be analysed in inner and outer aspects of a region. A reciprocal effect on regional competitiveness made by both external environments and general competitiveness within the country and other regions is also distinguished in the model of Regional Diamond. Despite the fact that these aspects are not included in the measurement of regional competitiveness by RCI, their influence is estimated indirectly via factors of regional competitiveness and its capability to use opportunities provided by these factors to strengthen its own competitiveness.

4. Analysis of Studies on International Competitiveness of Serbia

Serbia belongs to a category of small open economies, with an average level of national income. The long-term sustainable economic growth depends to a large extent on integration into international markets and increase in exports. [11] The adoption of appropriate measures in agreement with the IMF was key in re-establishing macroeconomic stability. [12] Serbia's external position improved. The pickup in economic activity led to a widening of the current account deficit which was limited on the back of strong export and subdued import growth. Foreign exchange reserves remained relatively high despite interventions by the central bank to buffer volatility of the exchange rate. Inflation was broadly maintained within the target.

In order to obtain objective insight into international competitiveness of Serbia, we have conducted analysis of the relevant studies dealing with comparative competitiveness analyses of a larger number of countries. Two studies we will focus are The Global Competitiveness Report of the World Economic Forum and the World Bank's Doing Business report, because they are widely accepted as reference studies and they take into account broad and complementary set of factors affecting international competitiveness of a country. The Doing Business report is focused on issues pertaining to the quality of business environment. On the other hand, The Global Competitiveness Report covers in more detail the factors directly influencing doing business and international competitiveness of a country.

4.1 The World Economic Forum Global Competitiveness Report

The Global Competitiveness Report of the World Economic Forum (WEF) is used in the same format in all 139 countries it covered. Executive managers provide answers to a wide set of questions about business environment. Most of the questions require scoring on a scale 1-7, with 1 being the worst, and 7 the best score. Apart from the survey questions, calculation of international competitiveness index includes quantitative data from secondary sources such as: gross domestic product, population size, inflation rate, tax rates, budget deficit, public debt, exports and imports, customs dues and tariffs, interest rates, data on mortality and morbidity, education costs, data on population education level, number of telephone connections, number of the Internet connections, etc. This approach enables precise identification of specific advantages and disadvantages of specific countries in a wider context. Since 2005, the WEF has based its competitiveness analysis on the Global Competitiveness Index. In 2010 Serbia is ranked 96th as regards competitiveness, out of 139 countries covered by the survey. [13] This represents a fall compared to the previous year, when Serbia was ranked 93rd of 133 countries. Serbia's ranks and scores considering overall index and sub-indexes are shown in Table 1.

Table 1: The Global Competitiveness Index 2010–2011

Serbia	Rank	Score
Overall index	96	3.84
Basic requirements	93	4.15
Efficiency enhancers	93	3.75
Innovation and sophistication factors	107	3.04

Figure 5 demonstrate the factors which have listed as the most problematic ones for doing business in the 2010 survey. The survey shows that corruption was identified as the biggest problem for the companies. Inefficiency of the public administration was listed second, followed by political instability. Obviously, the three problematic factors are closely interlinked and directly related to inefficiency of public administration agencies. The previous year's reports mentioned once again the same three factors as the most problematic ones, pointing out to the fact that significant progress has not been

made in improving business climate from the aspect of services provided to the companies by the state. Replies to this question clearly demonstrate that, despite certain progress achieved, there is still much left to be done by the public administration in terms of creating favorable business environment.

Figure 5 The most problematic factors for doing business

Figure 6 depicts value comparison of all 12 competitiveness pillars for Serbia and average of the countries at the second stage of development. What can be seen in the majority of indicators, Serbia is slightly below the average, that is, less favorable compared to the group of countries from the same group. Health care system and system of primary education in Serbia were ranked above the average of the group of countries being at the second stage of development. On the other hand, the area in which Serbia is most lagging behind this group is infrastructure. Additionally, it is noticeable that Serbia is also lagging in the goods market efficiency. Several items are included in computing of this competitiveness pillar ranking, in relation to which, low score of Serbia primarily represents a consequence of the poor ranking of competition in domestic market.

Figure 6 Serbia and average of countries at the second stage of development

Taking into account the overall rankings for this subgroup of factors, Serbia was rated somewhat better compared to the Western Balkans countries, but lower than the CEE countries. Business sophistication in Serbia was ranked in line with the regional average, but scored lower compared to the CEE countries. Innovations were scored above the average of the Western Balkans countries, but below the CEE countries. Extremely low rankings of Serbia in respect to availability of most modern technologies in general, specially in companies – are the result of particularly low import of technologies, serious crisis that hit metallurgy and machine industry of Serbia, and extremely bad condition of science in general, namely almost completely paralyzed research and development work in the Serbian companies. [14]

4.2 The World Bank's "Doing Business" Report

The basic assumption underlying this study is that the private sector is the leader of further economic growth. The World Bank used indicators or stages in development of the respective list covering the

ease of doing business. These indicators have been utilized for the analysis of business environment in context of administrative regulations which burden operation of businesses. Serbia is ranked 89 out of 183 economies, which is present in Table 2. [15] Countries of the Western Balkans have on average achieved the same results. The neighboring countries which have already joined the EU were ranked higher, which confirms positive impacts of the EU accession.

Table 2 Serbia's ranking in Doing Business 2011

Rank	Doing Business 2011.
Ease of doing business	89
Starting a business	83
Dealing with construction permits	176
Registering property	100
Getting credit	15
Protecting investors	74
Paying taxes	138
Trading across borders	74
Enforcing contract	94
Closing a business	86

We can see that only in relation to certain criteria Serbia is ranked in an acceptable position. Serbia was awarded good score as regards to the ease of getting credit for legal entities. This fact testifies about the high level reforms undertaken in domestic financial sector. Acceptable results were achieved in the category Trade across borders and in category Protecting investors. As per other categories such as: Paying taxes, Registering property, and especially the category Dealing with construction permits, Serbia is positioned at the bottom of the table, after all OECD countries. This should be a signal for the policy makers in Serbia that there is plenty left to be done in relation to further enabling of and incentives for the private sector development. It is also clear that exactly the category in which we are ranked lowest represents the administration bottlenecks and areas requiring urgent steps and measures oriented towards further reforms.

In the category *Starting a business* Serbia was ranked 83rd, given that in order to set up a business 7 procedures need to be completed, whereas the total period of starting a business takes 13 days. Certain progress has been made through establishment of the Business Registers Agency and reducing of the minimum paid-in capital requirement for the limited liability companies. The following figure illustrate the Starting a Business sub indicators in Serbia, which proved some improvement over the past 4 years, comparing to Eastern Europe and Central Asia.

Figure 7 Starting a Business sub-indicators 2007-2010.

The World Bank offers general reform-oriented recommendations, of which most relevant for Serbia would be introduction of *one-stop-shop* where all procedures underlying registration of a business, document standardization and abolishment of obsolete formalities, would be integrated.

According to the *Dealing with construction permits* criterion Serbia was ranked 176th, as regards the time and procedures required for issuing permits and licenses. This fact indeed speaks unfavorably about the quality of the Serbian public administration, whether at the state or local level. Inadequate municipal procedures were listed as a major problem for many of the investors. In comparison to the previous year, costs of procedures for issuing of approvals and permits have been reduced in Serbia, while the required duration has been extended. Significant changes did not occur in Serbia during the last two years. Moreover, it should be stressed that in terms of methodology, this analysis refers exclusively to the City of Belgrade. The World Bank recommendations refer to reducing the number of envisaged permits, availability of information on the required permits, introducing electronic filing of licensing applications, reducing the number of inspections and integration of procedures. The following

figure illustrate the above mentioned Dealing with Construction Permits sub indicators in Serbia over the past 4 years comparing to Eastern Europe and Central Asia.

Figure 8 Dealing with Construction Permits sub-indicators 2007-2010.

According to the *Registering Property* criterion, Serbia has made significant progress and was now ranked 100th, compared to 105th in the previous Doing Business analysis. This progress was realized primarily due to reduction of the property registration costs. On the other hand, this process is extremely slow in Serbia. In order to register a property, one needs to complete 6 procedures, but wait to realize them for 91 days. In the OECD countries, registering property is completed within 30 days. Such a low ranking demonstrates obsolescence and lack of reforms in state administration. The World Bank offers recommendations which takes strong reform-oriented political commitment in order for the reforms to be implemented given the ever present resistance. They imply simplification and reduction in dues and compensations, introduction of urgent procedures, establishing of electronic register, transfer of registration from judiciary to administrative domain and introduction of notary public.

Paying taxes is another category in which Serbia was extremely poorly ranked, even 138th. In Serbia it is necessary to execute payments 66 times annually, consuming thereby 279 working hours. Paying of various taxes in the regional countries is executed 47,2 times a year, whereas in the OECD countries, taxes are paid only 13,4 times at annual basis. Such rigid and demanding tax system in Serbia is rooted in extremely high tax evasion during the 90's, and necessity of the Tax Administration to fight such evasive trends. However, nowadays, when major part of economy is legal, and aiming at improving business climate and facilitating doing business, it is a must to continue efforts on simplification of tax procedures. On the other hand, the rest of the countries Eastern Europe and Central Asia also scored poorly in this category.

Procedures related to employment of workers significantly burden business activities of companies in Serbia. Besides poor ranking on the Doing Business list, initial results of survey conducted by *the National Alliance for Local Economic Development* show that procedures related to registration of workers represent a big problem for functioning of the economy. Along with the complicated registration procedures, labor legislation is likewise regarded as problem, since due to its rigidity it makes employment more difficult, thus leading to lower employment rate. Recommendations of the World Bank are as follows: flexible working hours, introducing special categories of wages for beginners, reducing costs of firing and increase age limits for retirement.

5. Conclusions and Recommendations

Serbia's economy is not highly competitive at the moment. All above stated reflects in very low level of production and export of highly sophisticated products and services, thus inopportune structure of export and therefore low level of comparative advantages of the country. Privatisation of the state-owned companies has been further delayed. The business environment continues to be constrained by red tape and weak legal predictability, in particular with respect to effective enforcement of property rights, which hamper market entry and exit. Furthermore, deficiencies in competition and infrastructure bottlenecks remain barriers to doing business. Besides extremely overvalued currency, other important reason for low Serbian economy competitiveness and sinking on the ranking list of countries in respect to their economy competitiveness results from growing social crisis.

Reforms aimed at creating a more favorable and predictable business environment have to be undertaken to boost the competitiveness of Serbian economy i.e. create conditions for the stronger growth of productivity of the real sector. Herewith recommendations on the possible directions these reforms could take: [16]

- Ensure a much more vigorous and effective implementation of the anti-monopoly policy.
- Simplify and ensure the greater transparency of numerous administrative procedures.
- Reform public administration and improve the efficiency of state administration.
- Establish medium-term macroeconomic stability.

The implementation of the above recommendations would help create a better business environment and improve the competitiveness of Serbia's economy in a relatively short period of time. There are two more recommendations on how to enhance economic competitiveness in the medium and longer term. The first regards the improvement of infrastructure, above all the road and rail networks, which are in relatively poor shape. The second recommendation concerns education reform. According to most economic growth theories, the education and technological progress levels of a country are the best predictors of its growth rate in the long term.

The new competitive strategy should be based on four pillars. [17] The first pillar must be efficient macroeconomic management, i.e. efficient strategy of the strong national currency, strategy of the prices of goods and services, strategy of trade, as well as development strategy. The second pillar must be efficient micro-economic management, i.e. building efficient business strategies, exercising good corporate governance, introducing new management practices, educating and training managers and the workforce, etc. The third pillar should cover legislation and institution efficiency. The fourth pillar has to be connected to the business ethics and the system of values. The main strategy in this area must be orienting Serbia to European ethics and values for business and eliminating corruption.

However, Serbia made some progress in meeting European standards in the area of *competition*. Implementing legislation of the competition law was adopted. Moreover Serbia should continue to work on its enforcement records. Knowledge of competition law and economics in the judiciary remains weak. Some progress has been made in the area of *state aid*. A State aid authority was established. The administrative capacity of the State aid Authority has to be strengthened. Effective implementation of the law needs to be ensured.

Microcredit as a source of future micro and small entrepreneurs' growth

*Olga Komarova*¹

¹*Faculty of Economics, State University - Higher School of Economics (HSE), Moscow, Russia, olga-spartak@yandex.ru*

The year 2005 was declared the International Year of Microcredit. Since this year microcredit development has accelerated to provide better access to credit, savings and other financial services to families with low incomes and small businesses all over the world.

Sector of micro and small entrepreneurs has a great social, economic and political significance as it covers virtually all types of activities in small towns. Small business contributes to the solution of such problems as: improvement of employment rate and increase in wealth of the population; enhancement of market economy competitiveness through the development of the consumer goods and services market; formation of the middle class which is the main guarantor of social and political stability in society; increasing investment attractiveness of the regions.

Limited access to external financing is one of the main reasons hampering the development of micro and small entrepreneurs. The ability to get financial resources is a fundamental need of every citizen. Moreover debt financing is crucial for originating and developing the business. Today, development of micro-entrepreneurship is the cutting-edge issue of the developing economies. Therefore, increasing financing of micro and small entrepreneurs is the basis for improving the efficiency and sustained economic growth. Moreover, the history, practice, economic theory suggests that small business is the most mobile and viable part of the economy in the crisis environment. Despite of the fact that small business is more vulnerable, it is able to restore quickly as its structure is quite flexible and responsive to macroeconomic changes.

International practice analysis has shown that microcredit program has a great opportunity for small business, individual entrepreneurs and so-called «poor active social group» to get access to financial resources. Microcredit has become increasingly widespread throughout the world. Historical facts and current situation justify the fact that small businesses and households (which have problems with settlement their debts) extremely need financial services segment supplementing the banking sector. Ability to quickly get financing would allow small businesses to smooth out the current problems and to be more confident about their business plans. This is also an opportunity for population to originate their own business.

Keywords

Informal financing, formal financing, microcredit, microcredit organization, micro and small entrepreneurs.

1. Introduction

The year 2005 was declared the International Year of Microcredit. Since this year microcredit development has accelerated to provide better access to credit, savings and other financial services to families with low incomes and small businesses all over the world.

Sector of micro and small entrepreneurs has a great social, economic and political significance as it covers virtually all types of activities in small towns. Small business contributes to the solution of such

problems as: improvement of employment rate and increase in wealth of the population; enhancement of market economy competitiveness through the development of the consumer goods and services market; formation of the middle class which is the main guarantor of social and political stability in society; increasing investment attractiveness of the regions.

Limited access to external financing is one of the main reasons hampering the development of micro and small entrepreneurs. The ability to get financial resources is a fundamental need of every citizen. Moreover debt financing is crucial for originating and developing the business. Today, development of micro-entrepreneurship is the cutting-edge issue of the developing economies. Therefore, increasing financing of micro and small entrepreneurs is the basis for improving the efficiency and sustained economic growth. Moreover, the history, practice, economic theory suggests that small business is the most mobile and viable part of the economy in the crisis environment. Despite of the fact that small business is more vulnerable, it is able to restore quickly as its structure is quite flexible and responsive to macroeconomic changes.

2. Literature background

Small entrepreneur' activity is the most relevant topic for today that is discussed in a lot of economic papers. In a growing stream of academic literature on the topic of small business activity and financial resources attraction the concern about entrepreneurial contribution to the growth and competitiveness is evident [1]. Small business development depends on its financing. The financial strategy of a starting entrepreneur leaves an imprint on the future business development and its impact on the overall development [2]. This statement is true not only for the starting entrepreneur, but also for the sector of micro and small entrepreneurs.

For an entrepreneur as for a single economic unit two ways of financing are available: own funds and a debt. As far as the equity financing (IPO or own funding) is concerned it does not cause negative effects in any case if we consider instability from the credit risk aspect (risk, initiated by the creditor-borrower relationships). The side of debt financing is rather multifaceted and includes a wide range of options which are not discussed in corporate finance theories: venture capital, business angels and informal capital [3].

The side of formal financial support is thoroughly investigated in the literature and taken into consideration by policy makers. Until recently it has been considered that the small business financing through banking facilities is the most convenient and effective source. Nevertheless, the study of Thorsten Beck reflected upon the contentious issue about the positive role of banking sector «in enhancing economic growth through more efficient resource allocation» [4]. Additionally, small firms are often out of the credit institutions' target customer base at their early stage of development because of the lack of credit and trading history, collateral [5]. Vice versa, credits are not attractive for entrepreneurs either: high rates and complicated conditions come as insuperable barriers [6].

Informal capital (as well as bootstrapping) investigations are in tune with the drive towards the growing demand for alternative financial sources due to the lack of available loan products [7]. The prevailing form of informal investments is venture capital which is the subject of an acute interest for both researchers and policy makers. Such an investment source fills in the financial gap during the growth of a new firm. Anyway, classic venture capital implies the allocation of financial funds among young entrepreneurial firms with a high growth potential [8], in other words, among technologically innovative small businesses.

In respect to business angels – private investors who provide capital to new and growing businesses in which they had no prior connection and excludes investments in their own firms or in family businesses [9] – it is also a formalized financial source in terms economic reasoning. Investors are seeking for the gain and returns whereas borrowers are interested in the essential resources based on rational risk assessment [10].

In this sense the informal financing (in the form of funds from family and friends) lacks such an inevitable economic grounding as rationality because of the biased perception.

Today, we can note the following trends in the financing of small entrepreneurs. Formal financing is of high demand in Europe: Greece, Netherlands, Belgium, Norway, Finland, Ireland, Italy and some others. The same pattern is observed in Canada and Russia with the exception of the dominant position of informal capital in the second country. Formal funds are not attracted and substituted by own capital and funds of close people in Brazil, Mexico, Peru, China, Jamaica and others. As far as US, UK, Australia are concerned the formal sources are suppressed by own financing. Business-angels' support is disseminated in Northern Europe: Denmark, Sweden, Norway, Iceland, and Finland [3].

Thus, there is a need for an alternative method of financing small entrepreneurs, which on the one hand is formalized, on the other hand is more available. Microcredit perspective is considered as an instrument for the risk mitigating along with preserving the cash flow intensity.

3. The content of microcredit phenomena

Microcredit is the extension of small loans (microloans) and other financial services (such as savings accounts) to those in poverty designed to entrepreneurship. These individuals have no sufficient collateral, steady employment and verifiable credit history and therefore cannot meet even the most minimal qualifications to gain access to traditional credit.

Microcredit is the system of economic relations between actors, who provide and receive microcredit. There is a whole infrastructure that serves the process of microcrediting. This infrastructure consists of a various microcredit organizations (MCO), whose main function is to mediate between consumers of microcredit services and their suppliers.

MCOs include nongovernment organizations, credit cooperatives, savings and loan associations, credit unions, various microcredit's funds, government and commercial banks, quasi-banks and others. The main activity of MCOs is the provision of microcredit services to target groups.

Microcredit is provided in the form of microcredit programs. Microcredit programs are the complex financial and consulting services provided by microcredit organizations to target groups of borrowers. Microcredit programs must satisfy the specific needs of selected groups (for example, increase women entrepreneurs' income, support for low-income families, creating new workplaces etc.).

The typical microcredit clients are low-income persons who do not have access to formal financial institutions. Microcrediting clients are typically self-employed, often household-based entrepreneurs. In rural areas, they are usually small farmers and others who are engaged in small income-generating activities such as food processing and petty trade. In urban areas, microcredit activities are more diverse and include shopkeepers, service providers, artisans, street vendors, etc. Microcredit clients are poor and vulnerable non-poor who have a relatively stable source of income.

The basic distinctive characteristics of microcredit organization:

- A database of clients. The target group of micro credit organizations: people with low income who have unofficial businesses or those who are on the lowest level of official businesses.
- A methodology of micro credits. Microcredit organizations use these methodologies which are based on information or reputation and also use systems of mutual protection of members from the same group.
- Administrative costs. Operational costs of micro credit organizations are higher than of commercial banks, therefore to defrayal such costs micro credit organizations have to use high rate which is higher than commercial banks usually use.
- Characteristics of a portfolio. Micro credit organizations can also give credits for a short period of time. The volume of such operations gives them an economy of scale.
- Management. Most of the microcredit organizations have similar organizational structures. Most of them have several small offices which directly interact with clients and back offices which ensure financial, managerial and technical support.

4. The motivation of a new mechanism for financing micro and small entrepreneurs' sector

As noted earlier, during the financial crisis access to finance for small enterprises was largely limited. The situation began to improve for the better by the end of 2009. So, according to the Russian public organization "Support of Russia" only 15% of entrepreneurs hadn't problems with financing (January 2009 - for 8%). Number of entrepreneurs, for which it was difficult or impossible to attract funds, decreased (56% in November and 75% in January, 2009). However this problem for small business is still very acute [11].

But the need for enterprises in debt financing has not disappeared. According to the NISIPP survey in May 2009 [12] 48,3% of the enterprises needed to attract financial resources. At the same time, the availability of these resources is still restricted: about 36,9% of respondents stated that they have some problems with access to debt financing, 16,1% - have significant problems, and only 9,4% of respondents characterized availability of credit funds as high or very high. Moreover, a significant

proportion of respondents evaluated the financial and economic situation of their enterprises as sustainable - 31,3% and as relatively stable- 53,7%.

The data of "TRUST Index SMEs" studies confirmed a significant necessity in financing to micro and small entrepreneurs. Results of survey conducted at the end of 2009 revealed that 24% of respondents were going to increase investments over the next year, whereas at the beginning of 2009 only 15% of respondents expressed the same opinion. About 13% of respondents said that at the end of 2009 they were going to attract loans for business development, but at the beginning of 2009 only 10% of respondents planned to attract loans for business development. Positive entrepreneurs' mood is a good indicator, of course. However, it should be mentioned that the willingness of micro and small entrepreneurs to get loans does not change the structure of demand for debt financing. According to various surveys, in recent years from 20% to 25% of micro and small entrepreneurs used credit and the most popular type of credit is a short-term lending program.

Thus, there is necessity of a new mechanism, which could formalize the informal cash flows. One should remember that it is an alternative source which has been "invented" by entrepreneurs themselves as the alternative to expensive banking credits, burdensome government procedures to get special grants and transfers, tough and demanding selection processes of venture capitalists and business angels. To replace it without provoking a negative response it is necessary to preserve main features which are attractive to micro and small entrepreneurs: easy access, quickness of getting finance, indifference to the internal characteristics of the business (industry, skills, experience, welfare, status, position and so on), low price, no binding obligations to return the debt (the terms of recovery and profit gain), no collateral [3].

The analysis of the main barriers to lending in according entrepreneurs' views showed that credit policy of banks is the greatest p of entrepreneurs. The main problem associated with credit process is the enormous number of documents which should be prepared and long consideration of applications. Since short-term lending is of highest demand among micro and small entrepreneurs, these factors are critical to the success of their business. The main factors which make bank services less attractive are shown in Figure 2 (according to entrepreneurs' views).

Figure 2 Reasons of dissatisfaction for the provision of credit services among small businesses, % of respondents [11]

However, if all the conditions are satisfied the problem of the downgrading quality will not be mitigated. The challenge is to find a balance between formal issues and marked informal advantages.

Keeping in mind, that the inability of entrepreneurs to access necessary financial services in an appropriate form is a key barrier for the business development, it is the first item that should be kept in mind when formalizing informal funds. 15% of the UK population does not have an opportunity to get banking credit, 15% - in Sweden, 11% - in Denmark, 13% - in Slovenia [13], 16% - in Russia [12].

The most plausible ways to resolve the problem is microcredit. The most crucial features of this institute have much in common with the attractive points of informal capital: alleviated accesses, lower prices, simplified procedures of getting finance and others.

Moreover one of the most fundamental missions of microcredit organizations is to curtail the share of informal credit markets (on a par with aiding the entrepreneurial activity, stimulating the savings among population and so on) [14].

Let's turn to the next part of our research to consider microcredit in detail.

5. The evidence of micro and small entrepreneurs' sector in Russia

According to official statistic data on the small entrepreneurs sector, the main indicators of this segment of the economy revealed positive dynamics in the years 2000-2009. During this period the small entrepreneurs sector was one of the most dynamic in the Russian economy.

Currently, in accordance with the data of the Federal State Statistics Service and the Federal Tax Service 1 602 521 small businesses of micro and small entrepreneurs operate in Russia, including:

- 1 374 777 microenterprises (in accordance with Federal law № 209-FL "On the development of small and medium enterprises" statistical survey of micro enterprises is carried out once a year) with the number of employees up to 15 people and an annual turnover of up to 60 million rubles,
- 227 744 small businesses with the number of employees from 16 to 100 employees and an annual turnover up to 400 million rubles.

It should be noted that the principles of statistical observation of small and medium entrepreneurs sector have changed since 2008. Until 2008, the criteria for small businesses (depending on the number of employees) were different for various industries. Since 2008, there is no such a differentiation; this led to improvement of all indicators of the sector (due to the inclusion of additional segments of the business). Figure 1 specifically highlights the point of changing the system of statistical observation [15].

Figure 1 Number of small enterprises (including micro-enterprises) in 1999-2009 [15]

Sector breakdown of small enterprises is characterized by a high proportion of whole- and retail sale. The number of such enterprises was 662.5 thousand in 2009 or 41% of all legal entities (in 2008 - 42%). These companies provide 29% of workplaces in small businesses (3,5 million people) – by data The Ministry of Economy and Development Russia. The second largest of the small business activity is the provision of services, in this sector 290 thousand companies (18% of the total number of SMEs) involved. This sector provided 16% of workplaces (about 2 million people). The third sector, which represents a significant number of small businesses, is a construction: 195 thousand enterprises (12%), which provide workplaces for 1.8 million people (15% of total employment in the SME sector). Such industry structure of small enterprises has remained largely unchanged over the past ten years. It should be noted that the number of sale's companies is gradually reduced (in 2005 whole- and retail sale enterprises were 46%) [15].

Dynamics of the turnover of small enterprises in 2006-2008 was positive. However, in 2008 due to financial crisis growth rate decreased and in 2009 the sales turnover of small businesses declined [15].

The dynamics of the small businesses' development in recent years reflected the growing contribution of small enterprises in key economic aggregates. Thus, the share of GDP produced by small enterprises in 2008 was 21%, and in 2009 – 22,5% (by data The Ministry of Economy and Development Russia). Share of small enterprises' turnover in total turnover in 2008 was 25,6%. At the same time, the contribution of small business in Russia's GDP remains at a considerably lower level than in the European Union, USA and Japan.

Small business sector suffered a lot in 2009. So, the number of employees in small enterprises decreased by 1,1% (compared to 2008), turnover of small businesses for the year declined by 17%.

Main problems of small enterprises in crisis environment were associated with the financing. The main characteristics of financial position were the next:

- the lack of working capital due to a significant reduction in small enterprises' turnover;
- the growth of the fail accounts payable to banks, leasing companies and counteragents;
- the lack of access to bank lending (in conjunction with stricter requirements for borrowers and rising interest rates on loans);
- the reduction in effective demand for products of small enterprises;
- the lack of free access to financial resources provided by the government.

Despite of the fact that the dependence of small enterprises from the banking sector and bank financing as opposed to large and medium-sized enterprises is not strongly pronounced, liquidity crunch in the banking sector reduced the banks' ability to allocate credit to small businesses. Small businesses use credit primarily for working capital, purchase of goods from large manufacturers, wholesalers. In other words, a small business has great demand for short and medium term loans. Banks were limited in their resources due to the crisis and could not satisfy the small businesses' demand. According to the Ministry of Economic Development and Trade in Russia during the first half of 2008 growth rate of lending to small businesses was about 31%, while in the second half of 2008 this figure dropped to 2,7%. Small businesses that work with small regional banks and which experienced considerable difficulties with liquidity, felt the impact of the banking crisis to a greater extent.

The financial crisis led to sharp deterioration of the typical problems that exist in small business. There was a significant reduction of access to additional financial resources.

In period from 2003 to 2007 microcredit market in Russia had positive dynamics. Number of microcredit organizations (including separate divisions) increased by 42% in 2007 compared with 2003 [16]. It should be noted that the number of structural units in 2003-2007 practically unchanged, while the number of separate divisions increased. This suggests that during 5 year new players hardly appeared, but existing players expanded their branch network. 2008 year and 2009 year were rather difficult for the microcredit' market in Russia due to the financial crisis and slowing economic growth. The highest peak of the crisis in the microcredit sector occurred at the end of 2008 and early of 2009, but the situation began to stabilize by the 2nd quarter of 2009.

Credit cooperatives occupy the leading positions in the microcredit market: their share increased from 69% in 2003 to 86% in 2008. The structure of cooperatives is as follows: credit consumer cooperatives (54%), credit cooperatives (17%) and agricultural credit consumer cooperatives (15%). The structure of microcredit organizations (according to 2008 year) is shown in Figure 3.

Figure 3 Structure of microcredit organization in 2008 [16], [17]

The main users of microcredit services in 2003 were sole traders (according to the structure of the client base of Russian microcredit organizations), but by 2008 the situation changed and the main users were individuals (see Figure 4). The same situation was observed in the banking sector - the active operations of credit institutions in 2008 were characterized primarily by credit growth (although growth rates of credit lending to non-financial organizations and the population was markedly lower than in 2007).

Figure 4 The structure of the client base of Russian microcredit organizations, % of respondents [16], [17]

The structure of the customer base is largely determined by the type of organization that provides microcredit services. This is due to legislative restrictions imposed on certain legal forms and goals of microcredit organizations themselves, their specialty, financing sources and the location.

Over the past 7 years the structure of the loan portfolio has changed significantly for all types of microcredit organizations. The share of loans for business purposes is reduced year by year and by 2008 amounted to only 28% (2003 - 62%). The share of loans to consumers, to the contrary, increased from 30% in 2003 to 61% in 2008 [16]. Aggregate demand for loans declined due to decrease in business activity and consumer demand in 2009, because during the crisis the population shifted from consumption to savings. Therefore the loan portfolio in microcredit organizations decreased.

6. Policy implications

Despite of slowdown in the microcredit sector's development, it is expected that in the condition of post-crisis growth micro-credit sector will play a key role, especially in regions where the underdevelopment of banking infrastructure is mostly noticeable. Moreover, it is expected that in favourable economic environment the loan portfolio and the number of borrowers will grow in microcredit organizations faster than in the banking sector.

Among different forms of the microcrediting (banks: cooperative, commercial, microfinance, savings; non-banks: financial cooperatives, non-profit companies, non-governmental organisations), credit cooperatives (both in the form of banking and non-banking organisations) can fulfill financial gap in the micro and small entrepreneurship. Such a form of financial institution has unique possibilities in the accumulating of non-operating savings of the population with the aim of the entrepreneurial activity crediting (as a particular case).

Financial cooperatives which are organized to serve small business support should meet minimum regulatory requirements in order to achieve a full-fledged displacement of informal cash flows. From the other point, it is essential to ensure that such a kind of transformed investments would not cause the same negative effect as in the case of informal capital. Due to the minimum regulatory control and taking into the account the findings that cooperative financial organisations are more stable than commercial banks micro-credit cooperatives ensure reasonable resources allocation. These institutions are more resilient to stress as their funds are not diversified in the open market and concentrated in the real sector.

In all European countries the long-term strategies concerning the microcredit stimulation are approved (for example Europe 2020). Moreover, in Russia the concept of the microcredit organization development is elaborated by the Russian Microfinance Centre. However, each policy should specialize in a concrete problem. In the scope of the research, informal capital sources should be formalized by means of financial cooperatives involving these investors to combine their resources and put them under control. And microcredit is alternative mechanism for financing micro and small entrepreneurs that allows doing it.

7. Conclusions

Informal capital in the small business financing can trigger off various effects. Firstly, it is an irreplaceable source for the early entrepreneurial activity at the addressed point of time. The lack of other sources due to the immature financial system, the absence of trust among investors and unstable environment encourage the choice in favour of this financial strategy in order to make good career or to enhance social status or to improve the well-being. Such an outcome is typical for the countries with low social and economic development.

Secondly, informal capital is a generator of potential instability in terms of the downgrading the quality of entrepreneurial activity. People are more likely to attract this source if they feel unconfident about their business activity, or they need moderate amount of money to start some typical activity: trading, transport and so on. This leaves an imprint on the profitability and solvency of such firms. They neither provide sufficient jobs nor enhance economic growth due to the low value added. The described course of event is appropriate to any nation: both with high and low values of macroeconomic indicators. It is especially dangerous for the developed countries because it can overwhelm the positive effect from the entrepreneurial activity substantially. However, it is worth considering in regard to less wealthier nations in order to ease the recovery process.

Thirdly, informal investments can exist as some additional and minor source, because it is an inevitable and uncontrolled element of any society: personal relationships. Notwithstanding this fact, other financial sources are affordable enough to be attracted by the most part of successful businesses. That is the balance which should be found to insure consistency in the economic growth.

To achieve this balance, micro-finance institutions should be spreaded around. More specifically, credit cooperatives are able to replace informal cash flows being the formalized analogue of them. The legal structure of such institutions preserves the most attractive features of informal capital: easy access, low prices and close relationships (an opportunity to resolve all the disputes inside the organisation).

This analysis shows that microcredit should be used as an alternative mechanism for financing micro and small entrepreneurs' sector. Therefore promotion of microcredit services is an important strategic objective for the development of any country; it is an important source of future growth of micro and small entrepreneurs which is the foundation of economic hierarchy. So it is an issue both economic and social importance.

Significance of quality and TQM in the process of local and regional development on the territory of Vojvodina

Biljana van Veghel Kondić¹, Hugo van Veghel²

Quality is a significant factor of success and prosperity and an important part of the overall management system. With fast and swift changes brought on by the process of EU accession, success is achieved only by those who are able to anticipate and adjust to it. The interest in establishing a quality system, improving quality and quality management, is shown not only by organizations dealing with production or service provision, but also by governmental agencies, local self-governments, educational and scientific institutions, economic, professional and expert associations, and even informal partnerships of the aforementioned entities which have local and regional development as their objectives.

Purpose of this work is to underline key aspects of Total Quality Management (TQM) implementation and its impact on the organization or organizational changes instigated by TQM with special emphasis on changes in TQM philosophy in organizations which are oriented to local and regional development.

In contrast to manufacturing, service organisations produce a product that is intangible, rather experienced and perceptions can be highly subjective. Implementation of TQM is therefore even more challenging in the service sector where local and regional levels organisations are striving for individual success rather than to develop and implement a coherent collaborative quality system that would have a positive effect on results and impact but also on the image of a region.

With fast and swift changes brought on by the process of EU accession, success is achieved only by those who are able to anticipate and adjust to it. This paper is a preliminary study for a deeper research on TQM in local and regional development in Vojvodina (Serbia), aiming to motivate and educate relevant development actors on the territory of Vojvodina and the broader region.

Human resource development, Local and regional development and Total quality management

1. Introduction

No man is a prophet in his own land, and this is particularly true of the work of Edward W. Deming. Deming's work and his original recommendations on quality were ignored in his homeland before Japanese business imported his ideas and made them work in Japan. Deming encouraged the Japanese to adopt a systematic approach to problem solving. He also encouraged senior managers to become actively involved in their company's quality improvement programs. His greatest contribution was the concept that the consumers are the most important part of a production line. Meeting and exceeding the customers' needs and requirements is the task that everyone within an organization has to accomplish. Quality means satisfying customers' requirements continually. In addition, the

management system has to enable everyone to be responsible for the quality of his output to his internal customers (Okada 2008)[1].

TQM functions on the premise that the quality of the products and processes is the responsibility of everyone who is involved with the creation or consumption of the products or services offered by the organization. In other words, TQM capitalizes on the involvement of management, workforce, suppliers, and even customers, in order to meet or exceed customer expectations. Considering the practices of TQM as discussed in six empirical studies, Cua, McKone, and Schroeder (2001) identified the nine common TQM practices as cross-functional product design, process management, supplier quality management, customer involvement, information and feedback, committed leadership, strategic planning, cross-functional training, and employee involvement. TQM is an integrative philosophy of management for continuously improving the quality of products and processes.[2]

The goal of TQM is for all operations to be of quality the first time; quality is built into any operation, which reduces the need for control and, consequently, expenses (Sthal, 1997). According to Costin (1999) and Dahlgaard (1998), TQM encompasses the following key principles: TQM management's commitment-leadership, a focus on the customer, employee involvement, training and empowerment; the design of quality management processes, continuing improvements – KEIZEN, suppliers quality management, international sensitivity to continue benchmarking, team problem-solving, stakeholders' common vision and an ever changing culture.

TQM as a management technique for improving a company's performance covers different quality systems. Of these, the most widely used is the ISO 9000 standard which is a useful first step on the journey to total quality (Porter, 1996), respectively it is also a component and complementary part of TQM. ISO 9000 standards can be an excellent starting point and are very appropriate for the standardisation of organisational systems and processes due to the documented procedures regarding a customer's requirements (Dahlgaard, 1998). [2]

In the past decade, much has been written about TQM in manufacturing; however, less attention has been paid to the service sector. The degree of TQM development in the service sector has certainly not kept pace with that of TQM in the manufacturing industries.

2. Local and regional development

The local development system is a term which we use here to describe the network of public, business and nongovernmental sector partners which work collaboratively within a defined area to create better conditions for economic growth, social cohesion and employment generation. Local development system might be tightly or loosely organized, precisely orchestrated to deliver a local development strategy, or rather imprecisely oriented (OECD 2009) [3].

A key feature of many reviews of local development is the prevalence of „co-ordination failures” where opportunities to better calibrate and integrative inputs to local economic performance are not taken for a variety of reasons and resulting in underperformance. Local and regional development agencies (as some of the actors in local and regional development) are a global phenomenon, and the experience of them is richly diverse. There is no 'blueprint' or 'template' for a development agency, choices has to be confronted and made locally. Most development agencies are now created to fulfil several rationales simultaneously. In the context of reviews of the contribution of development agencies (DA) to local economic performance we can observe that the chief issue are:

- Development agencies are part of the local development system and the relationship between the development agency and other parts of the system is of critical interest.
- DAs sometimes have explicit roles in co-ordinating or shaping local development systems
- DAs cannot succeed unless local development system are effective , unless they seek to internalise many of the aspects of the system itself
- Many of the challenges that DAs face can be seen as system failures, as much as agency failures.

Observe that sometimes there are multiple agencies competing for roles and resources in which we create duplicate, gaps, or waste. Occasionally, there is limited co-operation between the DA and other local bodies, especially if the DA is established by regional or national government. Equally, at certain times there is limited co-ordination between DAs and other parts of the local municipal government.

Local development systems tend to be relatively complex, as they require effective co-ordination between many different types of organisations or stakeholder groups. This potential constraint is also the local development system's most significant strength. It is often the task of local government to construct a system which holds together all its various component parts (public and private sector organizations; citizen and business; knowledge-based institutions and DAs) in a positive tension which makes maximum use of all available resources, expertise and experience. In a review of the literature

there is consensus around local development as the process of building the capacity of a local area to improve its economic future and the quality of the life for all. The local development system, therefore, involves both the structure within which development-oriented organisations are organized and the key relationships between them. At best, these systems involve high levels of vertical and horizontal co-ordination across a multitude of partners to address a number of key themes which support the holistic and sustainable development of local economy. Relations are pragmatic and constructive and the application of resources broad, deep, but notably efficient. At worst, key relationship break down through a lack of trust and because of competition for work and resources, personality clashes and other such frictions. Gaps may also exist for key work streams necessary to deliver effective local development. Conversely, some systems are so complex contested and convoluted it is not clear who does what and forward momentum dissipates. Despite their significance, there have been few attempts to describe what comprises a local development system. There remains progress to be made on the understanding of relationships between key stakeholders and the underlying principles for success.

Seven of the nine key messages of the Donor Committee for Enterprise Development (DCED 2008) are pointed at development agencies.[4]:

- Business environment reform is complex, operating on many levels and involving a very wide range of stakeholders. Development agencies should therefore ensure a thorough diagnostic analysis and maintain, as far as possible, a systemic approach and an understanding of the broader causal picture.
- Business environment reform is always political and development agencies should therefore take care to analyse the political context. They should have strategies to build coalitions of support and to engage with those who wish to protect the status quo.
- Development agencies should ensure that the inputs and participation of all stakeholders, including politicians, officials, the formal and informal private sector, and civil society, are reflected in the reform process. Reform interventions should be designed to enhance stakeholder capacity for ongoing and future reforms.
- Development agencies should ensure that systems are in place for donor coordination and take responsibility for the quality and consistency of the advice and assistance they provide.
- Development agencies should sequence reforms according to context. “Quick wins” and taking advantage of ad hoc opportunities such as changes of government, may build reform momentum. However, a long-term perspective is essential to ensure sustainability.
- Development agencies should understand and manage the implementation gap typically found between the adoption of regulation or principles, and changing practice and enforcing regulations on the ground.
- Development agencies should ensure the reform process has a strong communication programme so that all stakeholders are engaged and made aware of the benefits of reform.

In Serbia, in the process of defining the NUTS classifications, the bylaw stipulating the criteria for establishment of Development agencies for SMEs was replaced by a bylaw on Regional Development Agencies (RDAs). The former “SME agencies” had a transition period in which they could prepare for and request accreditation as Regional Development Agency. Whereas “old” formations failed to adapt adequately or timely, new RDAs were formed either based on existing municipal or district structures or on a “Greenfield” basis.

3. TQM and service quality

Total Quality Management is a process for creating organization-wide participation in planning and implementing continuous improvements in quality. TQM emphasizes the need for all members of a production unit or team to understand the needs and desires of clients or ultimate users of the service or product; use of data-related techniques to assess and improve the quality of the team’s output.

In contrast to manufacturing, service organizations produce a product that is intangible. Usually the complete product cannot be seen or touched. Rather it is experienced. The intangible nature of the product makes defining quality difficult. Also, since a service is experienced, perceptions can be highly subjective. In addition to tangible factors, quality of services is often defined by perceptual factors. These include the responsiveness to customer needs, courtesy and friendliness of staff, promptness in resolving complaints, and atmosphere. Other definitions of quality in service include time; the amount of time a customer has to wait for the service; and consistency, the degree to which the service is of the same quality each time. For these reasons, defining quality in services can be

especially challenging. Dimensions of quality for manufacturing versus service organizations are shown below in Table 1.[5]

Manufacturing organisations	Service organisations
Conformance to specification	Tangible factors
Performance	Consistency
Reliability	Responsiveness to customer needs
Features	Courtesy / friendliness
Durability	Timeliness / promptness
Serviceability	Atmosphere

Table 1 Dimensions of quality: Manufacturing versus Service Organisations

Managers in the service sector are under increasing pressure to demonstrate that their services are customer-focused and that continuous performance improvement is being delivered. Given the financial and resource constraints under which service organizations must manage it is essential that customer expectations are properly understood and measured and that, from the customers' perspective, any gaps in service quality are identified. This information then assists a manager in identifying cost-effective ways of closing service quality gaps and of prioritizing which gaps to focus on – a critical decision given scarce resources.[6]

Service quality is a concept that has aroused considerable interest and debate in the research literature because of the difficulties in both defining it and measuring it with no overall consensus emerging on either (Wisniewski, 2001). There are a number of different "definitions" as to what is meant by service quality. One that is commonly used defines service quality as the extent to which a service meets customers' needs or expectations (Lewis and Mitchell, 1990; Dotchin and Oakland, 1994a; Asubonteng et al., 1996; Wisniewski and Donnelly, 1996). Service quality can thus be defined as the difference between customer expectations of service and perceived service. If expectations are greater than performance, then perceived quality is less than satisfactory and hence customer dissatisfaction occurs (Parasuraman et al., 1985; Lewis and Mitchell, 1990). Always there exists an important question: why should service quality be measured? Measurement allows for comparison before and after changes, for the location of quality related problems and for the establishment of clear standards for service delivery. Edvardsen et al (1994) state that, in their experience, the starting point in developing quality in services is analysis and measurement.

The Servqual approach is the most common method for measuring service quality. Model of Service Quality Gaps There are seven major gaps in the service quality concept, which are shown in Figure 1. The model is an extension of Parasuraman et al. (1985).

According to the following explanation (ASI Quality Systems, 1992; Curry, 1999; Luk and Layton, 2002), the three important gaps, which are more associated with the external customers, are Gap1, Gap5 and Gap6; since they have a direct relationship with customers.[17]

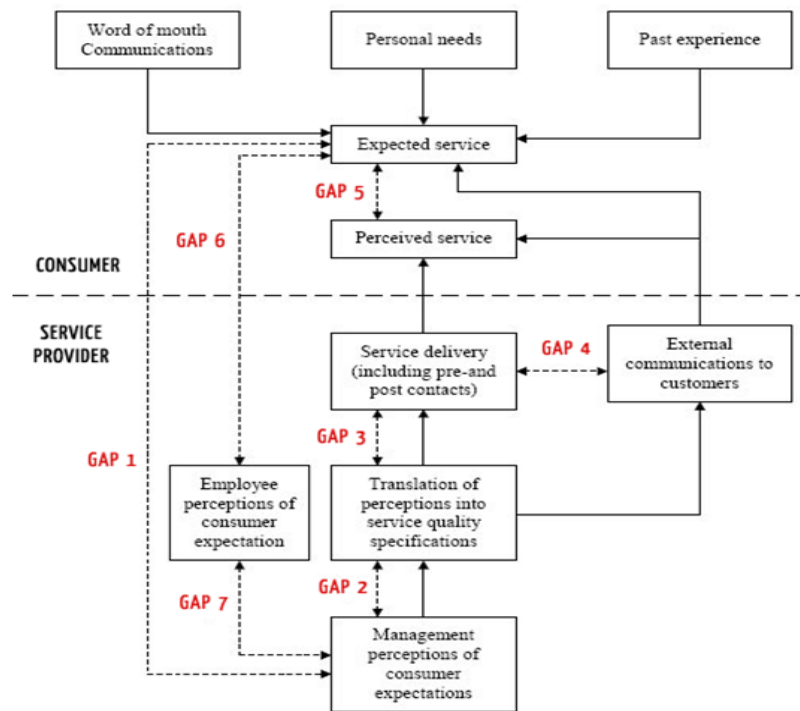

Figure 1: Service Quality Assessment (Servqual), Parasuraman, Zeithami & Berry, 1988 [6]

- **Gap1: Customers' expectations versus management perceptions:** As a result of the lack of a marketing research orientation, inadequate upward communication and too many layers of management.
- **Gap2: Management perceptions versus service specifications:** As a result of inadequate commitment to service quality, a perception of unfeasibility, inadequate task standardization and an absence of goal setting.
- **Gap3: Service specifications versus service delivery:** As a result of role ambiguity and conflict, poor employee job fit and poor technology-job fit, inappropriate supervisory control systems, lack of perceived control and lack of teamwork.
- **Gap4: Service delivery versus external communication:** As a result of inadequate horizontal communications and propensity to over-promise.
- **Gap5: The discrepancy between customer expectations and their perceptions of the service delivered:** As a result of the influences exerted from the customer side and the shortfalls (gaps) on the part of the service provider. In this case, customer expectations are influenced by the extent of personal needs, word of mouth recommendation and past service experiences.
- **Gap6: The discrepancy between customer expectations and employees' perceptions:** As a result of the differences in the understanding of customer expectations by front-line service providers.
- **Gap7: The discrepancy between employee's perceptions and management perceptions:** As a result of the differences in the understanding of customer expectations between managers and service providers.

While there have been efforts to study service quality, there has been no general agreement on the measurement of the concept. The majority of the work to date has attempted to use the Servqual (Parasuraman et al., 1985; 1988) methodology in an effort to measure service quality (e.g. Brooks et al., 1999; Chaston, 1994; Edvardsson et al., 1997; Lings and Brooks, 1998; Reynoso and Moore, 1995; Young and Varble, 1997; Sahney et al., 2004).

4. The impact of quality systems on organizations

From a Best Value perspective the measurement of service quality in the service sector should take into account customer expectations of service as well as perceptions of service. However, as Robinson (1999) concludes: "It is apparent that there is little consensus of opinion and much

disagreement about how to measure service quality". One service quality measurement model that has been extensively applied is the Servqual model developed by Parasuraman et al. (1985, 1986, 1988, 1991, 1993, 1994; Zeithaml et al., 1990). Servqual as the most often used approach for measuring service quality has been to compare customers' expectations before a service encounter and their perceptions of the actual service delivered (Gronroos, 1982; Lewis and Booms, 1983; Parasuraman et al., 1985). The Servqual instrument has been the predominant method used to measure consumers' perceptions of service quality. It has five generic dimensions or factors and are stated as follows (van Iwaarden et al., 2003):[7][8]

- Tangibles: Physical facilities, equipment and appearance of personnel.
- Reliability: Ability to perform the promised service dependably and accurately.
- Responsiveness: Willingness to help customers and provide prompt service.
- Assurance :(including competence, courtesy, credibility and security). Knowledge and courtesy of employees and their ability to inspire trust and confidence.
- Empathy :(including access, communication, understanding the customer). Caring and individualized attention that the firm provides to its customers.

Several international studies and papers indicate that TQM implementations have a strong and positive impact on organizational performance (Zakuan 2010); TQM has also a significant and positive effects on organizational learning, and TQM and organizational learning have both significant and positive effects on innovation performance (Richard y 2010)[9][10][13][15]

However, it is very common for organisations to find themselves focusing almost exclusively on the task of completing the quality assurance system, or getting the badge for a particular standard. Although the need for certification is an essential assumption of survival for any business or organization to prevail either from a manufacturing or services point of view this can mean they miss out on the most important benefit, which is embedding a permanent culture of ongoing improvement.

5. Sustainable Development of TQM

Evidence from the past has shown that TQM initiatives have failed because the Critical Success Factors (CSFs) were not in place. There have been nonetheless several case examples of successful TQM implementations and sustainability. Such examples show that TQM should not be reinvented at regular intervals but should become part of everyday working life. TQM should not be a fad or a flavor of the month but a durable culture that promotes business improvement over time (Curry *et al.*, 2002) [17]. TQM is only one of many possible means to attain quality. In other words quality is sacred; TQM is not (Harari, 1993).[16]. Sustainability is defined as 'the ability of an organization to adapt to change in the business environment to capture contemporary best practice methods and to achieve and maintain superior competitive performance' (Zairi & Liburd 2001). Quinn (2000) describes sustainability as the development that meets present needs without compromising the ability of future generations to meet their own needs. Without sustainability, there is little benefit to be gained from TQM (Curry *et al.*, 2002). [11]

5.1 PDSA cycle for sustainable development of TQM [11]

The Deming's PDSA cycle is a well-known model for continual process improvement. It teaches organizations to plan an action, do it, study to see how it conforms to the plan and act on what has been learned.[12]

5.1.1 Step 1: Plan for TQM

The adoption of TQM in an organization has to start from a strategy for implementation involving the planning and preparation of document detailing the way forward (Yusof & Aspinwall 2000a).

The preparation of such a document may constitute:

- Creation of a co-ordination body;
- Development of a vision, mission and policy statements;
- Education for the top management and coordinating body members on total quality principles and philosophy;
- Selection and trial run of the first improvement project; and

- Appraising the organisation's current level of quality management implementation.

5.1.2 Step 2: Implement TQM

Literature shows several researches on this issue and clearly indicates that every company or organization is implementing TQM based on different theories and models custom adapted to the specific environment of the organization and its constructs to be highly interrelated. In respect to local and regional development organizations and stakeholders we recommended an instrument, with

- Critical success factors,
- Proactive organizational orientation,
- Internal support,
- Competitive assessment and participatory orientation for effective implementation of TQM.

The most interesting point in a Romanian case study refer to the way in which sustainable development indicators become indicators of the quality management system (Seichea 2009) [14].

5.1.3 Step 3: Study and measure the level of TQM implementation

Regardless of which TQM model is adopted, the CSFs must be set in operation for effective TQM implementation. Manifestation of CSFs results in generation of Quality-related Action Programs (QAPs). The measurement of TQM involves selecting a list of QAPs to measure each CSF, providing a measurement scale for the QAPs, and then testing the instrument for reliability and validity. For each CSF the actual level of TQM practice is represented by the average of the QAPs ratings for that CSF.

5.1.4 Step 4: Take necessary actions to improve the less developed programmes of TQM

The evaluations and assessments keep organizations with alert on the gaps between, its internal satisfaction with existing system and the changing external demands in relation to externally defined systems (Van Der Wiele & Brown, 2002). Organizations should monitor the quality of their products and services in order to maintain their strategic and economic position. In addition, they should know with precision when, where, and how-much adjustments are needed in their existing total quality program activities in order to maintain, and possibly enhance, their strategic advantage. In turn, this means that organizations could use a methodology that not only provides reliable information pertaining to the existing state of quality, but also has the capability of identifying specific changes needed to maintain and improve their strategic position and profitability. Furthermore, because of the changing nature of environments and customer preferences, this information should be available quickly, that is, the methodology should be flexible enough to generate this information fast so that the necessary course corrections may be initiated in good time (Kumar *et al.*, 1999, 2004)[18][19].

6. Conclusion

TQM implementation in public service and service organizations is getting more attention in literature in recent years. Total quality management can be defined as a relation between management and the process that can permanently improve and secure the organisational development processes and achieve, enhance and consolidate customers' satisfaction. The basic value of the TQM is to watch over the whole organization as a network of different working processes and procedures where the quality has the most important role but always with satisfaction of the customers' needs on the end. In a TQM organization it is not important to find who is to blame for some mistakes, rather to develop and implement adequate and relevant mitigation measures, meaning that the quality system aims at self-improvement.

It is therefore important to identify all possible problems and sources of resistance inside of the organization and between human resources towards start up and implementation of a TQM philosophy. One has to know in the preparation phase what organizational changes will be caused by the implementation. Mitigation measures should be prepared to tackle sources of resistance among employees towards the new working methodology in order to prevent a hampering implementation process.

Sometimes even more important is that TQM implementation in public administrations, as in local and regional bodies established by them, has to face eventually the political and elitarian network with autocratic, passive and status quo bureaucracy, demonstrating resistance to change in most of the transition countries. The culture of quality, where customers (e.g. citizens) and their satisfaction are focal points is very difficult to be assimilated by the aforementioned stakeholders.

The management's selection of techniques should not be based on a random imitation of successful techniques from other environments, but on a profound knowledge of the techniques which include also strategic positioning along with the organisation's internal and external environments. However considered risky by some, TQM and service quality have proven to be beneficial to their implementing organizations in sustainability, competitiveness and economic success.

This paper is a preliminary study for a deeper research on TQM in local and regional development in Vojvodina (Serbia), aiming to motivate and educate relevant development actors on the territory of Vojvodina and the broader region.

Here in this paper is presented using of quality management at training implementation in a Training canter. Here are shortly presented EFQM (European Foundation for Quality Management) and self assessment as training quality ensuring tools and a short comparison between those tools. Also is written generally something about 4W (when, where, who, why) + H (how), and our efforts in order to ensure quality management of a training as a process and its phases. Explaining of all parts of 4W (when, where, who, why) + H (how) separately is done later on this paper. Than there are also presented author views about Quality ensuring and quality management. Describing of a Quality management achieved at our Training Centre, which has been done through self assessment also explaining the way it is done. Relationship between training centre (training) and customer (trainees) is also part of this paper.

Implementation, managing, process, quality, training, tools

1. Introduction

1.1 Quality

Each person has his or her own definition about the term "QUALITY", so we could say that by it self is a subjective term. So, it depends about what we are talking. It means that there are many explanations of "quality". Example if we are talking about a product, quality means ability of this product to fulfill customer requirements and needs at accepted level.

Quality has no specific meaning unless related to a specific function

Mostly, in technical usage, word quality could have two main meanings:

1. The characteristics of a product or service that meet or satisfy stated or implied needs or
2. A product or service without deficiencies.

By other words, nowadays, the word quality is oriented to the customer, so quality in a service or products means the level of product or service what customer is ready to pay for [1].

If we are talking about engineering or manufacturing, the word quality usually is linked with words control and engineering. In this concept the term quality (quality control and quality engineering) is used to ensure products and/or services are designed and all this must be linked with costumer requirements and needs.

So, term quality could be linked with producing parts, it could be linked also with different processes by it self.

Today this term is linked mostly with processes like teaching processes, training processes, producing process and so and so.

The approach to quality management can be applied to any business activity:

- Design work
- Banking
- Insurance
- Computer software
- Transportation etc.

In training area quality means an enough good training which fulfills requirements and needs of costumers. Training must be qualitative at training preparation, training development, training implementation and also at training evaluation. All those training phase must have its qualitative performances.

1.2 Management

One of the so called international words is also management. We say that it is an international word because it is understandable at all languages. There are many words used all around the world but mainly with different meaning, but word management has same meaning.

Humane been has capability to cooperate and ask for assistance about something what is impossible to do alone. So, if there are more than one people there is a need to lead some body. Nowadays most preferred word in this case is word managing. Word managing has a wider meaning [3].

Looking deeper, we have managing also if there is only one person. So, we can say that he is managing his selves. If somebody is managing his time, his job and his things he also is doing a kind of managing.

Mainly word managing we use when we have to do with a group. Groups can be managed in many ways but the best one is managing with group, using all resources contained by group. We could say that a group manager should be a person who is well informed about his group resources [3].

There are many types of managers, it depends on the way how we classify. It is also depending on what are we managing [3].

Training managing means the way on which we try to manage a training process and all phases of training [5]. While we are doing this we must carry out about quality [1].

1.3 Quality management

Earlier the quality was based mainly on product quality, but nowadays it is based on process quality. It means that we are carrying not only about the end of the process (product only) but we are carrying out about process completely (as a process).

The term ISO 9000 refers to training managing standards, where are included ISO 9000:2000, ISO 9001:2000 and ISO 9004:2000 [4].

Let we start with ISO 9001:2000. This is and international standard organization aspect. It means international standard due to quality management. This standard is revised and now it is ISO 9001:2008.

Another quality standard is *EFQM* (European Foundation for Quality Management). It is a framework for organizational management systems and it is designed for helping organizations in their drive towards being more competitive. The EFQM Excellence Model was introduced at the beginning of 1992 as the framework for assessing organizations for the European Quality Award.

The EFQM Excellence Model is a practical tool that can be used in a number of different ways:

- As a tool for Self-Assessment
- As a way to Benchmark with other organizations
- As a guide to identify areas for Improvement
- As the basis for a common Vocabulary and a way of thinking
- As a Structure for the organization's management system

At our training centre we are using the Self-Assessment tool, as a tool which helps us to ensure that we are about our job and its qualities. It means that at all steps we are assessing our training activities and its quality level.

So, we are using a kind of mixed tools to ensure our quality as step forward to other standards like EFQM or ISO standard.

2. Quality management at a training area

Under quality management methods are included ISO 9000, EFQM, Self assessment, TQM and Kaizen. Education and training institutions could use as well ISO 9000, EFQM and self assessment.

At our Training centre we are using self assessment as a management quality tool. Ensuring of quality management is done by clear algorithm where is everything defined.

In this algorithm we can clearly see that quality management is a systematic process approach in case to produce a product or offer a service.

In case to develop a quality management we have identified steps than we created a process which has 5 steps (what is same with ISO 9001:2000), those steps are [4]:

1. Process (training) development
2. Process (training) documentation
3. Process (training) Implementation
4. Process (training) Monitoring and
5. Process (training) improvement.

Each of steps can be called as a process. Each of those processes produces some results and those results are information to next process.

After we defined training process then we wrote procedures. Those procedures give us answer at many questions because those procedures are based exactly one those questions as a quality management tool.

Our procedures are derived by answering on 4W (when, what, who, where) and H (how). Sow by giving answer on:

- **What is happening?** It means what is happening in a process stage e.g. in implementation phase, it has to deal with what kind of training, it means it is an internal training or external training. What are we developing, what are we documenting. By answering on question what are we implementing also we answer on that what are we monitoring.
- **When is donning something?** It means time of donning something. So, when are we going to develop a training is there any limited time by customer or by other things, when will we document it during training process or at many phases or when is going to start implementation of training?
- **Who is doing?** This question has to do with who deals with training or saying better that who will implement the training, training centre or another person. By answering this question we get many information about that what kind of training is gone to be. Or, who is going to develop training. This answer we have if we know if training is a result of customer needs and requirements or it is a result of our training needs analyses.
- **Where is doing?** It means that training implementation will happen at training centre or somewhere else like on job training or training at another training institution. By answering on this question an who is going to implement training we differ trainings on internal training and external training.
- **How will be donning something?** If we are going to use again implementation, it means questions about the way of implementation. To explain 4W+H we used the training implementation phase, but we have to answer those questions for all steps or phases of procedures chart at our training centre. So, only after answering at all those questions we are sure that we are at the right way to realize quality management at our training centre.

Here we are presenting to you algorithm of our training procedures:

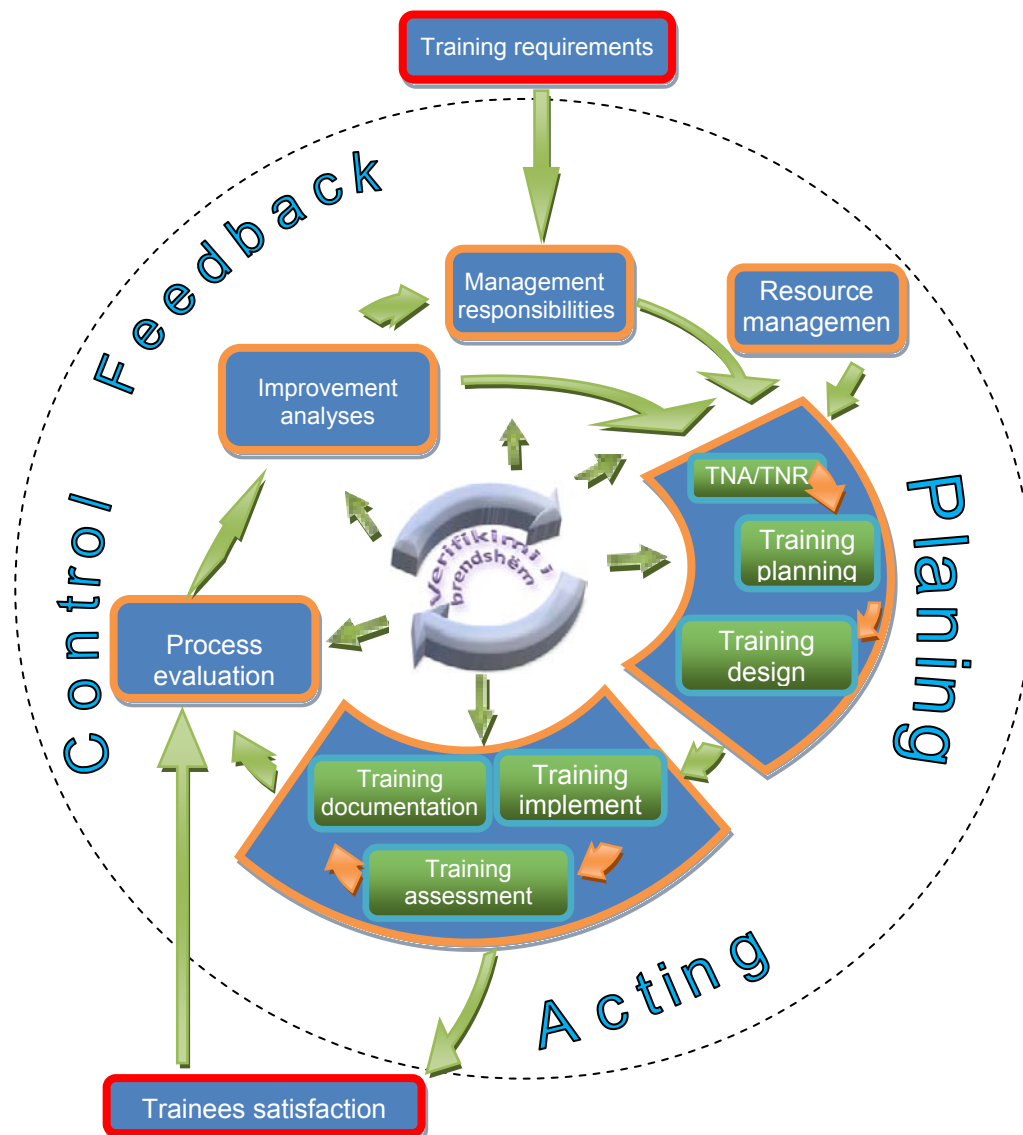

Figure 1 algorithm of training procedures

Ensuring those procedures is done by a well organizing of our training centre. All people are responsible to many steps, than there is a person carrying about that. He is our so called quality ensuring coordinator [4].

3. Ensuring quality management through training – costumer relationship

As it is said at the beginning of paper we are focused much more in improvement. The best way to improve our self is contacting our clients (costumers) at all steps of our trainings. So, we have contacts with our costumers at the developing of training. Costumers (mostly the costumers experienced with our trainings) give us information about what is important to their employees. Then we redesign and improve the training content, so we develop again our training.

In the second phase, we use documentation to prove what we have done through training. Than our costumers ask, if we could document them about a problem through training done earlier, and this has an impact in next our documentation.

Many times we consider costumers idea also at implementation of training. So, it happened that idea of our costumers was implementation of a training part at working area. We explained them that it is

very interesting and nowadays it is known as learning by doing. It means, we improved our training implementation.

Mostly, costumers don't have enough idea about training monitoring, so they have a small role on this part. This monitoring means training process monitoring as a whole process, including all phases of a training process.

Main part where are included costumers needs, requirements and demands is improvement of our training. In this phase we consider costumers remarks done through training evaluation and also remarks done through meetings with our clients.

4. Conclusions

Working together with customers it has its own benefits. We are there to feel customer's requirements, needs and justifications. We are there to fulfil our self by avoiding no needed things or possible boring things in training process.

Another thing which helps us on quality keeping is doing everything based on our training centre procedures, established by our self but based on those tools mentioned before.

Investigating Corporate Entrepreneurship within Banking Sector in Serbia

Ljiljana Kontic¹, Jovan Kontic²

¹Assistant Professor, Ph.D., Faculty of Legal and Business Studies, Novi Sad, Serbia, ljiljana.kontic@yahoo.com

²Regional manager, BSc in Strategic Management, Eurobank EFG, Belgrade, Serbia, jovan.kontic@eurobankefg.rs

Over the last decade, the banking sector in Serbia has witnessed substantial changes. It is evidenced a decrease in the number of banks, the dissolution of small, non-viable banks, and a take-over of the market by foreign banks. In this paper, authors presented main results of empirical study conducted in one regional bank about their activities in domain corporate entrepreneurship. The study had two independent aims. The first aim was to examine the level of centralization in the strategic issues concerning corporate entrepreneurship activities. The second aim of this study was to identify key factors that promote or inhibit corporate entrepreneurship. The research sample consisted of 150 managers and employees from all branches operated in Serbian market. The research findings revealed that corporate entrepreneurship exists in the Bank. The strategy for promote entrepreneurial behaviour has clearly stated. The level of engagement into entrepreneurial projects varied across the work experience in banking sector. The main areas for management improvement are suggested as well as directions for future researches.

Keywords

Corporate entrepreneurship, bank, strategy, entrepreneurial behaviour, Serbia

1. Introduction

Since 2001, till today banking and financial reforms have been conducted in Serbia. From 115 banks, today 33 banks operate at Serbian market. The banks currently operating have been successful in cleaning their balances and there are competent to perform serious change in order to meet all regulatory criteria. This is to significant extent contribution to the competition of foreign banks. They supplemented to the supply of banking services and rendered it more diversified, augmented the overall credit potential and contributed to enhancing the capital position of the banking system.

These changes make it necessary for banks to examine their strategies carefully and to devote great deal of attention to innovation and entrepreneurship. Little empirical research is available in the Serbian context that indicates the successes or failures of corporate entrepreneurship. This study addresses the management dilemma that exists as how to foster and implement corporate entrepreneurship to sustain this competitive advantage.

This empirical research study had two independent aims. The first aim was to examine the level of centralization in the strategic issues concerning corporate entrepreneurship activities. The second aim of this study was to identify key factors that promote or inhibit corporate entrepreneurship in the banking sector. The Corporate Entrepreneurship Assessment Instrument was used to measure corporate entrepreneurship in Eurobank EFG, Belgrade. Data were gathered from 137 participants in all bank's branches in Serbia.

This paper is organized as follows. The next section reviews the extant literature on corporate entrepreneurship. The third section discusses the research context. The section outlines the research methodology used in this study. The final sections discuss the main results and present the main conclusions and implications of this study.

2. Theoretical background

Within the literature in organizational theory and strategic management, the corporate entrepreneurship (CE) is a relatively new idea which can be track back to the mid-1970s [1, p306]. Corporate entrepreneurship became a separate research topic in the mid-1980s.

The relevant literature points that CE includes (1) the birth of new businesses within existing organizations, either (2) the transformation of organizations through strategic renewal. CE, like entrepreneurship, may be interpreted in many different ways and studied with many different variables to be measured. Summary of theoretical findings can be found in the studies of Belousova and Gailly [2] as well as Dess et al. [3].

There is no consensus on the definition of CE. Therefore, we present following statement that closely related to the purpose of our research. "CE includes situations where (1) an established organization enters a new business; (2) an individual or individuals champion new corporate ideas within a corporate context; and (3) an entrepreneurial philosophy permeates an entire organization's outlook and operations." [4, p50].

Corporate entrepreneurship refers to the development of new business idea within large and established companies [5, p17].

It is noted that CE can be used to improve competitive positioning and transform corporations [4]. The identification of strategy and structure introduces another wealth of literature that supports strategy for positioning of competitive advantage. The recognition of the importance of entrepreneurial dynamics in corporate context is increasingly acknowledged in both entrepreneurship and strategic management literature [6]. Three variables that underlie a firm's ability to behave in an entrepreneurial manner are opportunity recognition, organizational flexibility and a firm's ability to measure, encourage, and reward innovative and risk-taking behaviour [7].

Most early research focused narrowly on the parent-subsidiary relationship such as centralization, formalization, coordination and control. More recently, from the holistic point of view, the subsidiary is a semiautonomous entity within a differentiated system [8].

Centralization of authority refers to the amount of autonomy individuals have to make decisions regarding the use of organizational resources. Standardization of procedures refers to the extent to which behaviours are routinized within the company. The formalization of processes concerns the degree to which the company has prepared codified and written instructions about how procedures are to be followed.

Entrepreneurial capacity of company appears to be affected by multiple faces of organizational structure, but entrepreneurial capacity is negatively related to a company's level of structural centralization [9].

Other authors argued that centralized structure enables quickly decision making as well as deters potential conflict among separate departments - branches [10]. Although formalized routines constrain creativity, competitive advantages sourced by numerous capabilities rest on use of simple routines.

The five factors identified by Hornsby et al. [11] were rewards, management support, time availability, supportive organizational structure, and risk taken which represent internal organizational factors that influence entrepreneurial activity within established companies. The first dimension is the appropriate use of rewards. An effective reward must consider goals, feedback, emphasis on individual responsibility, and results-based incentives. Innovative organisations are characterised by providing rewards based on performance, offering challenges, increasing responsibilities and promoting the ideas of innovative people throughout the organisation [12].

A second important dimension is management support, which indicates the willingness of managers to facilitate and promote entrepreneurial activity in the company. This support can take many forms (e.g. championing innovative ideas, providing expertise). Managers play a key role in encouraging employees to believe that innovation is expected of all members of the organisation. The third dimension is resources (that includes time) and their availability for entrepreneurial activity. Organisations should be reasonable in assigning the workload of their employees and allow employees to work with others on solving long-term problems. In entrepreneurial work environments, employees are allowed to conduct creative, entrepreneurial experiments in a limited portion of their work time. The fourth dimension is the existence of a supportive organizational structure that provides the administrative mechanisms by which ideas are evaluated, chosen, and implemented. Organisations should avoid having standard operating procedures for all major parts of jobs and should reduce dependence on narrow job descriptions and rigid performance standards [11]. The fifth, and final, dimension is risk taking, which indicates the managers' willingness to take risks and show a tolerance for failure when it occurs. Based on the extensive field research, Hornsby et al. [11]

developed and refined the Corporate Entrepreneurship Assessment Instrument (CEAI) to measure the five internal factors of CE.

To summarise, the key factors of a supportive organisational climate nurturing CE are strategic leadership and support for CE, rewards for CE, empowered employees, resource and time availability for CE, a supportive organisational structure and limited boundaries between departments. There are eight empirical articles in total which study CE using the Corporate Entrepreneurship Assessment Instrument [11, 13, 14, 15, 16, 17, 18, 19]. The literature search was conducted using the following databases-Science Direct, Emerald Fulltext, EBSCO, and WileyInterScience.

There is no study regarding neither banks nor financial institution in which CEAI was used. We find one unpublished study which investigated 150 managers in one large European financial service company [20]. His results revealed that entrepreneurial behaviour has been stimulated by managers' socio-political support and access to resources. We did not find empirical article on CE in the context of Serbia. This was one of motivating factor for conducting this study.

3. Research context

Over the last decade, the banking sector in Serbia has witnessed substantial changes. It is evidenced a decrease in the number of banks, the dissolution of small, non-viable banks, and a take-over of the market by foreign banks. Banking sector has been chosen as the research context for the following key reasons. Banking sector in any economy is a vital service industry and when is competitive and efficient it is able to spur positive impact on other industries.

In 2009, the Serbian banking sector operated with considerable profit. Its nominal pre-tax profit came at RSD 20 billion. Of total 34 banks, 13 operated at a loss. Return on equity (ROE) worsened from 9.28% at the end-2008 to 4.6% in December 2009. Despite a high share of equity in balance sheet total, return on assets (ROA) dwindled as well to 1.0% y-o-y in December. A comparative analysis shows that local banks still report the highest efficiency ratio in managing their assets compared to countries in the region and that they rank exceptionally high in terms of ROE. This is highly important given the build-up of risks of consolidation of large international banking groups operating in the region of South Eastern Europe. Banking sector operational efficiency remains satisfactory as net earnings from interest (starting from March 2008) are sufficient to fully cover operational expenses – in Q4 2009, the efficiency ratio stood at 1.1x [21, pp30-31].

With the rapid spill-over of the crisis from developed European countries to South Eastern Europe and Serbia in September 2008, it became evident that the confidence in the stability of the Serbian banking sector largely depends on the reputation of parent banks of Serbian subsidiaries. Confidence in local banks was seriously dented by the bankruptcy of a number of world banks and uncertainties that surfaced with respect to Austrian banks (Hypo Alpe Adria in particular) that are systemically important for the Serbian banking sector. However, owing to the timely response of government institutions, confidence was restored and evidenced by visible signs of recovery already in 2009. Similarly, reputation of Greek banks may be dented by writings of economic analysts on fiscal problems in Greece [21, p29].

Focus bank: Two main criteria were used in selecting process: (1) access to the bank, (2) bank's competitive position. In Serbia, Eurobank EFG Group became operational in 2003 with a greenfield investment. Eurobank EFG Group has become the majority owner of the National Savings Bank in March 2006. Following the legal merger of National Savings Bank with Eurobank EFG, Eurobank EFG a.d. Beograd has been created as one of the top banking organizations based on market share, assets and size of its business network.

Despite the difficulties which the Serbian financial sector, Eurobank EFG improved its position in the local banking system. The bank's market share in terms of assets rose to 6.8%, bringing it to the fourth place, after just five years of actual presence in the country [22, p35]. It is worth noting that the bank is ranked third in terms of equity. Moreover, Eurobank EFG retained, with slight variations, the previous year's substantial market shares in most banking product categories. By the end of the year the bank's network comprised 119 branches and 10 business centres all over the country.

Eurobank EFG Serbia remains one of the best capitalized banks in the market and holds the third position in terms of total equity. As at 31 December 2009 Total Equity stood at RSD 38.4 billion while the Capital Adequacy Ratio was 18.3%. Pre-provision revenues increased by 3% reaching RSD 11.2 billion. Net Interest Income remained at RSD 8.5 billion, the same level as in 2008, despite of the increased cost of deposits and the lower returns on state and NBS securities. Net Commission Income increased by 38.7% and reached RSD 2.2 billion, while Net Interest Margin was at the level of 7.5%.

The vision statement is following [22, p3]:

"We want to become the first choice bank for our retail and corporate clients, operating with a sense of responsibility toward customers, employees, stakeholders and society".

The activities of the Eurobank EFG are governed by the Organization's values: creativity, innovation, efficiency, emphasis on quality and respect towards people and the environment comprise a web of values that permeates the philosophy and guides the actions of the Group's staff. The incessant effort to improve the economic environment, along with the cultivation of an open dialogue with its stakeholders and the Organization's active participation in, and contribution to society, comprise the corporate responsibility of Eurobank EFG [22, p16]. These principles and values not only create a spirit of cooperation and trust between employees, but also determine work within the local communities and how bank serves its clients and shareholders. These values are embedded in everyday practice and behavior and characterize the way that bank operates.

Applying its successful business model, Eurobank EFG offers wide spread of standard and innovative banking products to its clients, employing jointly with subsidiaries EFG Leasing, EFG Property Services, EFG Business Services over 1600 banking professionals. In 2009, the bank introduced many new products and services, such as the upgrading of e-banking services for corporate clients, the provision of text message notifications for credit card and current account transactions, the offer of bancassurance products through its branches etc. These initiatives helped the bank win the annual award of Serbia's Club of Economic Journalists, the "GOLD PLAQUE in the banking sector for 2009".

Eurobank EFG was actively involved in the field of Corporate Responsibility. The bank received the "VIRTUS" award of the Balkan Community Initiatives Fund for its contribution to the local community, and the "Best Regional Business Partner 2009" award of Mass Media International. Moreover, the bank upgraded its methods and programs for the efficient selection, training and development of human resources. One of the most important innovations in this field was the introduction and implementation of a mass e-learning program.

4. Research methodology

This study focused on the assessment of corporate entrepreneurship in the banking sector. Specifically, it attention was to determinate impact of centralization of CE, than to identify the factors that promoted or inhibited CE within Eurobank EFG, a.d. Belgrade. In pursuit of these aims, the following research questions are investigated:

Q1: Is centralization related to CE strategy?

Q2: To what extent is management support used to promote CE within Eurobank EFG?

Q3: Are rewards used to promote CE?

Q4: Do employees have time to think about innovations?

Q5: How employees assess bank's boundaries?

The empirical method is embedded in a case study design.

The assessment has been done by Corporate Entrepreneurship Assessment Instrument (CEAI) developed by Hornsby et al. [11]. The measuring instrument is constructed as a five-point Likert scale with options that ranged from strongly disagree to strongly agree. The desired outcome of the CEAI is to assessment a level of CE intensity and recognition of CE by management within an organization.

The questionnaire was consisted of two parts. The first part of questionnaire was consisted of following five sections:

- Management support (17 questions),
- Risk taking (10 questions),
- Rewards (6 questions),
- Time availability (6 questions), and
- Organizational boundaries (7 questions).

The second part of questionnaire was consisted of demographic characteristics of participants.

The research sample was 150 managers and employees in the Eurobank EFG. The parameters of the interest indicate that the participants must be full time employees from the top management level to account officers in all bank's branches in Serbia.

Over three-week period in October 2010, a total of 150 questionnaires were distributed to the managers and employees at aforementioned bank. The response rate was outstanding - 92%. The sample was distinguished by gender; education and age (see Table 1).

Table 1 Respondents' profiles

Description	Number of respondents	Percentage of total sample
Education		
High school	34	24.82%
College	41	29.92%
Faculty	58	42.34%
Master	3	2.19%
BSc	1	0.73%
Gender		
Female	73	53.28%
Male	64	46.72%
Age		
21-30	30	21.89%
31-40	60	43.80%
41-50	31	22.63%
51-60	16	11.68%
Total	137	100.00%

The validity and reliability of the questionnaire was tested. The validity of questionnaire was confirmed by factor analysis. Internal consistency was examined by Cronbach's alpha. Cronbach's alpha of five CE dimensions was in range from 0.72 to 0.90.

Data analysis was conducting using SPSS Statistics 19. Descriptive statistics, a principal factor analysis and correlation analysis were computed.

5. Main findings and contribution

Our results suggested that there is a strong relationship between centralization and CE in the Eurobank EFG. In order to assess their impact we identified factors that promote CE (for positive correlation) or to inhibit CE (in the case of negative correlation).

Table 2. Reports the results of an analysis of the relationships among the five factors of CE measured in this study.

There is relative strong positive correlation between all five factors ($p < 0.01$). As indicated in the correlation analysis, management support, risk taking, and rewards are significantly related to one another. This goes in line with the previous research that revealed that these factors are indicators of overall entrepreneurial activity in companies [15]. The strongest correlation is between risk taking and management support ($r = 0.641$). On the contrary to results of Seborá et al [15], our study revealed positive correlation between OB and other CE factors.

The weakest correlation is between time availability and organizational boundaries ($r = 0.254$).

Table 2 Correlation matrix

	MS	RT	R	TA	OB
Management support (MS)	1	0.641(**)	0.631(**)	0.367(**)	0.536(**)
Risk taking (RT)	0.641(**)	1	0.578(**)	0.400(**)	0.594(**)
Rewards (R)	0.631(**)	0.578(**)	1	0.531(**)	0.530(**)
Time availability (TA)	0.367(**)	0.400(**)	0.531(**)	1	0.254(**)
Organizational boundaries (OB)	0.536(**)	0.594(**)	0.530(**)	0.254(**)	1

Authors' calculations

Further analysis was conducted regarding the potential influence of gender, education level, and age of participants on all five CE factors.

5.1. Management support

Participants were asked to assess how the bank and management team supported the entrepreneurial behaviour.

The results indicated that there are not differences in the assessment of the factor between female and male participants. The 41-50 year old employees in Eurobank had the lowest management support rating. Faculty educated participants had the highest management support rating.

The results suggested that management support is high when it comes to promoting CE in the Eurobank EFG. The precondition for superior performance is combination of strategic management and entrepreneurship as the source of competitive advantage [10].

5.2. Risk taking

The participants were asked to indicate their agreement or disagreement with statements pertaining to their own decision-making authority and responsibility in their jobs; the attitude of the bank towards failure; and the extent of freedom that employees enjoy to use their own initiative. There are differences in evaluation of risk taking among older and younger employees as well as females and males. The employees between the ages of 41-50 rated risk taking lowly. Females rated risk taking lower than their male counterparts. Top managers rate this factor highly. It can be concluded that in Bank risk taking is commensurate with seniority.

Banking sector is highly regulated by procedures. Any mistake by employee can be costly to the bank. Therefore, tolerance of failure is relative low.

5.3. Rewards

Participants were asked to specify their agreement or disagreement with statements pertaining to increase in job responsibilities; recognition; removal of obstacles in the workplace by managers; and monetary rewards linked to performance.

The mean score indicates the level of recognition and reward associated with CE inside a bank. This goes in line with evidence of a correlation between the presences of the rewards which encourage CE. The results showed that faculty educated employees rated rewards higher than other employees. There was no significant difference according to gender or age. The management of Eurobank EFG has a CE strategy which is clearly understood by all employees. This strategy highlights rewards and bonuses in the transparent manner.

5.4. Time availability

Participants had to indicate their agreement or disagreement with statements regarding the time employees have to work on wider organisational problems other than simply their job responsibilities and workload.

Top managers and young employees (21-30 years) higher rated time availability than the other groups. Male rated time availability lower than their female counterparts. Based on our analysis it can be concluded that employees in the Bank thought that there is no time available to promote CE strategy. The mean score indicates that this factor inhibits CE in the bank. This can be solved by employing more people. Eurobank EFG operates in competitive market and under the pressure to manage cost. Salary costs are the biggest overhead for banks that operate in Serbian market. At the end of 2009 expenses in the Bank were reduced by 13%.

5.5. Organizational boundaries

Participants were asked to specify their agreement or disagreement with statements focusing on the certainty of employees with respect to job expectations and standard procedures, performance standards and outcomes of tasks.

Eurobank EFG has standard procedures for all parts of the job as result of the given the rigidity of the legislative environment banks in Serbia operates in. This result in relative lower assessment of the factor which implicates those employees must look at the bank from a broad perspective. Another explanation can be cultural difference, but in the proposed questionnaire there were no questions regarding national culture or divergences.

The following groups of participants assessed this factor different than others: 31-40 year old employees, males, and middle managers.

Eurobank EFG has the strategy for promoting CE. With the exception of organizational boundaries, the means for four factors are greater than four of maximum five on the Likert scale. The level of centralization had strong positive impact on the strategic issues concerning corporate entrepreneurship activities.

6. Conclusions

The main purpose of this study was to key factors that promote or inhibit corporate entrepreneurship. Strategic leadership, management support, and rewards are key factors of CE strategy in Eurobank EFG. The results of factor analysis showed that the Corporate Entrepreneurship Assessment Instrument (CEAI) is adequate for investigating phenomena of CE in banking sector. The answers to the proposed questionnaire can explain internal factors of CE.

This study makes at least two important contributions to the existing literature. Firstly, the findings contribute to our understanding of corporate entrepreneurial in banking sector in transition economy. Secondly, the study provides insights in the key influencing factors and barriers to CE in selected bank in Serbia. Because the study was limited on one bank it was possible to precisely identify the internal factors.

From a practical perspective, the results of this study have important implications for management in the bank. These implications are highlighted below:

- Strategic leadership and top management support play a critical role in creating entrepreneurial behaviour in the bank.
- Rewards for CE encourage entrepreneurial behaviour. Rewards need to be financial as well as non-financial.
- The strategies for promoting CE will be improved by provide employees the freedom to determinate appropriate method of problem solving.

Notwithstanding the results of this study, there are three main limitations. The study was conducted in a specific national (Serbia) and industry context (banking sector). Caution should be exercised in generalising the findings.

Future research should test these findings across other banks and financial institutions in Serbia. It is also suggested that future research should focus on identifying and measuring other organizational factors that may promote or inhibit the CE capability. Possible direction for future research can be identification of cultural differences between Western European banks and banks that operates in transition economies.

The prospects of economy growth and enlargement are set up years ago. Some of the key driving forces of the economic growth are economic and political alliances but on the other hand there are regional features like cultural and social behavior, that influence industrial dynamics. Our hypothesis is that there a lot of similarities among Balkan economies and the dynamic changes. According to the papers main idea, the industrial dynamics is naturally inherent to the national economies and is a key indicator for economic stability. The paper aims to present and to analyse similarities and differences in industrial dynamics. It includes comparative analysis of three different groups of countries – “old”, “new” and candidate EU member states, located in Balkan Peninsula, namely Bulgaria, Romania, Greece and Turkey, for the period 2000-2009. The authors claim that except national (macroeconomic) factors exist regional factors (i.e. political, historical, social, cultural) that have impact on the industrial development. The paper has following structure: section one is Introduction. Section 2 provides a brief explanation of the current economic situation in one “old” EU member state (Greece), two “new” EU member states – Bulgaria, and one candidate country – Turkey. The picture shows a close industry development even the different economy starting level. Analysis of the basic determinants of industrial growth in the last decade in four countries is given in Section 3. The conclusions of the study are presented in Section 4.

Keywords

Balkan countries, Industrial dynamics; Industrial growth; Innovation practices; Regional policies.

1. Introduction

Economies of Balkan countries perform different paths of development during the last fifty years. Bulgaria and Romania followed dramatic changes: through nationalization and centrally-planned economic development to market economy. They began the transition in 1989 with a largely obsolete industrial base and a pattern of output unsuited to the country's needs. Last twenty years both countries perform significant structural changes and economic stability. At the same time, Turkey has reduced state involvement in basic industry, banking, transport and communication, and an emerging cadre of middle-class entrepreneurs is adding dynamism to the economy. After Turkey experienced a severe financial crisis in 2001, Ankara adopted financial and fiscal reforms as part of an IMF program. The reforms strengthened the country's economic fundamentals and ushered in an era of strong growth - averaging more than 6% annually until 2009, when global economic conditions and tighter fiscal policy slowed growth to 4.7%. The economy, however, continues to be burdened by a high current account deficit and remains dependent on often volatile, short-term investment to finance its

trade deficit. After relatively smooth economic development, Greece faced severe economic and financial crisis in 2009 -2010, which negatively impact economic country performance.

Four Balkan countries, namely Bulgaria, Greece, Romania and Turkey, despite differences have similar and close competitiveness index 2010/2011. The best performed country is Turkey – rank 61, followed by Romania – rank 67, Bulgaria – rank 71 and Greece – rank 83. We can claim that the average competitiveness rank of all counties in the region is 70.5.

The studied countries participate in different alliances and unions. Bulgaria, Romania and Greece are members of the European Union, while Turkey is a candidate- member state. In the first group two sub-groups could be identified – “old” (Greece) and “new” (Bulgaria and Romania) member states. Some of the key driving forces of the economic growth are these economic and political alliances but on the other hand there are regional features like cultural and social behavior, that influence industrial dynamics. Our hypothesis is that there a lot of similarities among Balkan economies and the dynamic changes. According to the papers main idea, the industrial dynamics is naturally inherent to the national economies and is a key indicator for economic stability. The paper aims to present and to analyse similarities and differences in industrial dynamics. It includes comparative analysis of three different groups of countries – “old”, “new” and candidate EU member states, located in Balkan Peninsula, namely Bulgaria, Romania, Greece and Turkey, for the period 2000-2009. The authors claim that except national (macroeconomic) factors exist regional factors (i.e. political, historical, social, cultural) that have impact on the industrial development.

The paper has following structure: section one is Introduction. Section 2 provides a brief explanation of the current economic situation in one “old” EU member state (Greece), two “new” EU member states – Bulgaria, and one candidate country – Turkey. The picture shows a close industry development even the different economy starting level. Analysis of the basic determinants of industrial growth in the last decade in four countries is given in Section 3. The conclusions of the study are presented in Section 4.

2. Current economic situation

Industrial growth potential depends not only on current expenditures for innovations but on economic development of the country. According to this we find out first micro thesis of the paper: Participation in different economic and politic alliances gives a different development path.

Therefore we expect two find at least three different dynamic development trend of Balkans countries – EU old members (for example Greece); new members states (for example: Bulgaria and Romania) and EU candidate countries (for example: Turkey).

Confirmation of the micro-hypothesis above gives the overall indicators that depend on the economic alliances policy. Rejection of the micro-hypothesis above gives the Balkans regional indicator that brings similarity in Balkan countries industrial development.

Analysis of two different types of indicators gives enough reasons to confirm or to reject our hypothesis. These types are divided as follows: macroeconomic indicators (for example: GDP; CPI etc.) and industrial growth indicators (for example: new orders indices; production and turnover indices; price indices).

All of the analyses are based on available statistic data for a period (2000 – 2010).

2.1 Macro-economic indicators

Macroeconomic analysis gives the framework within which economic sectors perform. Data analysis confirms the severe impact of the recent economic and financial crisis. Observed stable annual growth of GDP - about 2 % to 3 %, between 2002 and 2007 in the EU, was interrupted by the crisis. All member-states and candidate countries encounter significant decline in economic growth (Figure 1). The breakdown of GDP growth by its main aggregates confirms that more than 70 % of EU total value added originates from service industries. The economies that we analysed are fairly heterogeneous in terms of size, income levels and economic structure, but they perform similar economic performance. Two of analysed countries – Greece and Romania, belong to the group of so called medium sized member states with a GDP share in EU27 between 1% and 5 %. Turkey also could be assigned to that group with its share from 2,4 % (2002) to 4 % (2008). Bulgaria is in the group of small sized member states which generate less than 1%. (Figure 2).

Figure 1 Real GDP Growth Rate (Eurostat,2010)

Figure 2 Share in EU27 GDP (:Eurostat,2010)

Divergences between GDP per inhabitant among the EU regions are still very high, but have been narrowing over recent years. Bulgaria, Romania and Turkey have similar level of GDP per capita in PPS, while this indicator in Greece is twice higher.

Figure 3 GDP per capita (Eurostat, 2010)

Figure 4 GVA in Industry (Eurostat, 2010)

The main effects of the recent crisis were a decline in manufacturing output, investments and profits, while government services, private consumption and 'compensation of employees' (i.e. pay) remained relatively resilient. The overall structure of the EU GVA was fairly stable over earlier years, some effects of the economic and financial crisis can be seen in the decline in GVA generated by total industry, which is dominated by manufacturing, and an expansion of other services, which includes public administration and defence, education and health GVA generated in industry in Bulgaria, Romania and Turkey are similar to the trend in EU27. Greece perform relatively lower level of GVA in industry than the other three countries. (Figure 4).

The annual average inflation rate in the euro area fell to a low of 0.3 % in 2009, after several years of relative stability at around 2.2 % and substantial increases in 2008 (EU trends followed a broadly similar pattern). Balkan countries and Hungary formed the group with the highest inflation from 2.8 to 8.6 %.

2.2 Industrial growth indicators

Industrial growth is measured by the production and sells change. These indicators could give a point of differentiation in growth potential of Balkans and Balkan countries. A growth potential could be measured by the new orders indices.

Looking onto statistic data [1], [4] as a static view (Figure 6) we can summarize that Balkans has a limited perspectives for industrial growth for the next few months. Bulgaria and Turkey show an average for European union (27 countries) industrial new orders dynamic. Romania is a Balkan favorite with almost over 50% increase of new orders. The Greece is an opposite side with new orders at almost double less then Romania level.

This result gives a primary alert for confirmation of the stated micro-hypothesis: we find evidences for differentiation in industrial development opportunities.

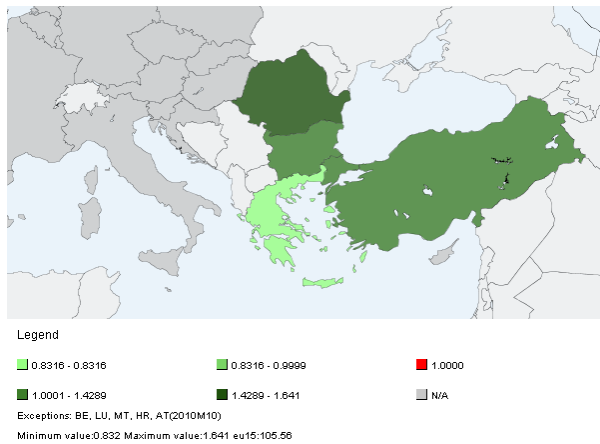

Figure 6 Industrial new orders (Nov 2010)

Figure 7 Dynamic indices of industrial new orders (Feb 2005 - Nov 2010)

To check our hypothesis we need to go deeply in dynamic of new order's indices change (Figure 7). The EUROSTAT database confirms the statement above. We can easily find that Balkan countries could be divided in three groups according to trend of the observed indicator:

- In first group we have Greece. Its dynamic change is very close to the European indices for the whole period (Feb 2005 – Nov 2010). This position shows that Greece has a different growth path despite the deep economic crises during the last two years;
- In second group we can see Romania. As a previous figure shows, Romanian industry development is opposite to the EU's (27) one. We find that at the period of EU countries new orders drop the Romanian ones are turning up, and vice-versa.
- In third group we put Bulgaria and Turkey. Although the observed indices in these two countries have a similar direction as a Greece and EU (27) ones, the dynamic of change is at different level. This statement could be evaluated positively to the beginning of 2007, but the roles have been changed in the last three years. Thus Bulgaria and Turkey show a slight less growth potential than the EU (27) does.

Results give an interesting picture: they confirm existence of three different country types of industrial growth potential, but Bulgaria is not in one group with Romania but with Turkey!

To find out some reasons for different industry development potential we need to see the change of two other industrial indices: production indices and turnover indices. The ratio between production and turnover indices gives a slight view of the industry development. It has to be close to one (1.00) if the industry and products are developing in a good market environment. The Bulgarian data shows that the observed ratio drops down continuously for the last five years (Figure 8). This trend is not the same with the ratio change in Romania and Greece as an addition. So, we can confirm the statement that Bulgarian industry is driven by a different set of management and marketing rules.

Figure 8 Production/turnover index in Bulgaria (BG), Romania (RO) and Greece (GR)

Figure 9 Production, turnover and price indices in Bulgaria (BG)

To find out more details we analyze the dynamic change in the three main industrial indices for Bulgaria (Figure 9). Main results are as follows:

- Production growth in Bulgaria has anticipated sales growth for the last three years. But it is more interesting that turnover indices have dramatically changed since the mid-2006. One reason for this state could be explanation that industrial plants produce more added value products or sell them at more expensive price. Otherwise the state could be as a result of lack of know-how for free market competition. In addition this state is pointed to the period immediately before Bulgarian membership in the EU. Therefore the common crisis of Bulgarian industry is defined as a medicine for curing EU membership's over-optimism in the industry [2], [3].
- Price indices trend does not follow the industry production's change. The industry prices have been raised slightly for last few years even a big drop of production and sell in the last two years. This state is directly pointed to lack of connection between product price and its added value. So, managers are more concerned on a total profit than on a market presentation. In addition, this state means that market competition in Bulgaria is more on paper than the real one.

Summarized we find out our hypothesis confirmed. Therefore industrial dynamic potential depends mainly on economic alliances integration. But there are some regional aspects. A closely collaboration between Bulgaria and Turkey supplemented with psychological and cultural aspects of this collaboration gives a different picture for Bulgarian industrial potential. In this term we find that EU over optimism and some bad trade practices gives a disadvantage of Bulgarian industry and limits its future industrial development!

3. Analysis of basic determinants of industrial growth

Industrial growth at the macro level is determined by the dynamics of growth of firms. Growth at the firm level is generated by many factors and driving forces, but particular attention among them deserve innovation and investment activity.

3.1 Innovation and innovation activities of firms as a factor in achieving industrial growth

In recent years, innovation has become a key factor in improving the competitiveness of national economies and has established itself as one of the key elements for achieving industrial dynamics with a positive growth rate. They proved a successful tool to overcome the negative effects of the global economic crisis. It could be argued that countries with high levels of innovation costs can generate growth. Comparing the costs of innovation per capita made in the countries of Balkan Peninsula (Figure 10) indicates that over the last decade all countries reported rising growth rate. This rate however is with varying intensity. There is a lagging rate of growth of spending on innovation in Bulgaria, despite identical starting points with Romania. There is a huge gap in this indicator between the old EU countries such as Greece and the new ones like Bulgaria and Romania (Figure 11). Under the influence of global economic crisis, our southern neighbor has experienced a number of economic shocks, but its expenditure for innovation activities are at times more than those of other countries in the Balkans. Turkey, which is currently not yet started negotiations for EU accession, in innovation is staying a lot better than Bulgaria and Romania. Based on this indicator can be concluded that the Turkish economy will be much lower brake on the European economy than the economies of Bulgaria and Romania.

F

Figure 10 Total R&D expenditure by all sectors of business performance in Euro per inhabitant

Figure 11 Total R&D expenditure by enterprise sectors in Euro pre inhabitant

High rate of spending on innovation in developed countries is a direct consequence of the sources used to finance these activities. World experience shows that in the countries with the most highly innovative economies, innovation costs are made by firms, not by the state (government). This is the result of conscious needs for businesses to produce and offer products, services and technologies with high added value. They thus generate growth and higher profitability levels. Comparison of costs incurred for innovation in the countries of Balkan region shows that they rely primarily on public funds for R & D (Figure 12, Figure 13). Only in Greece, the state and companies alike invest funds in developing new products, services and technologies. According to this indicator Bulgaria is lagging position again and is with the lowest percentage of GDP spending on innovation made by business. Given that the country has the lowest levels of GDP per capita can be argued that the underlying funds allocated to R & D by the state and the companies have not yet been realized and have not adopted the innovation as a necessity factor for growth.

Figure 12 RD funding by business sector in (%)

Figure 13 RD funding by government sector in (%)

In times of crisis, defense mechanism of the companies and the state is reducing the cost, including for innovation activities. To provide better conditions for economic development and overcoming the negative effects of economic crisis, the country (government) is less willing to cut those costs. Very strongly pronounced is this trend in Romania. There, in the last decade the natural rate of reduction in government spending and increased business is disrupted. At the end of 2008 and 2009, under the influence of global economic crisis are increased the government expenditure on R & D, compared with expense made by the companies. The situation in Bulgaria is similar, but with a much lower rate of change. Overall, the Bulgarian economy is characterized by the highest level of government expenditure on R & D and the lowest corporate R & D spending.

It can be concluded that the Bulgarian economy is characterized by the lowest cost to innovation per capita. Much of the funding is made by the state. If this trend continues, it will have limited impact on the industrial dynamics of the economy.

3.2. Business investment as a factor to generate industrial growth

The next most important factor, which directly affect on industrial dynamics of the countries, is the level of investment (general and foreign direct investment) in national economies. From the level of investment in the economy can judge the stability of the macroeconomic environment in the country, for the degree of risk, and for the attractiveness of the economy and ultimately for the pace of industrial growth. According to the Global Competitiveness Index of the World Economic Forum, Bulgaria is placed at 115th spot, which means that in comparison with the countries of Europe and rest of world, the foreign direct investment in Bulgaria rarely transferred technology in the national economy. The indicator "investment in R & D" puts 101-ranked country, suggesting that foreign companies do not use local human resources to its research activities. Cooperation between universities and industry is very low (92th place in Bulgaria). By indicator Presence of scientists and engineers, Bulgaria is located at 93th place. Despite this unenviable position of the country, compared with investment activity in the Balkan region, Bulgaria has significantly higher levels of investment. This trend is very strong in the years before the onset of the global economic crisis (Figure 14). In the last two crisis years, investments in the country sharply reduced. This shows the deep recession in which the Bulgarian economy fell. For industrial growth not allowed speaking. The aim of the Bulgarian economy in the short term should be restoring the levels of investment before the crisis. The serious

decline in total investment in the economy of Bulgaria is inversely proportional dependence with relatively stable levels of investment in training of staff of firms (Figure 15). This results from the traditions of the Bulgarians to bet on investments in education and the availability of funding for various operating programs of the EU for continuing education.

Figure 14 Direct investment flows - Million EUR

Figure 15 Expenditure on education from private sources as % of GDP

Classification of the country on different criteria for degree of competitiveness in the methodology of the World Economic Forum and the analysis of this base did conclude that investment in the economy rarely carry some kind of innovation in the country. Foreign companies investing in R & D does not use the human potential of research institutions and universities in Bulgaria. In confirmation of this is the structure of investment activity of firms in Bulgaria. The high level of investment is the result of investment in tangible assets (Figure 16). The "investment boom" in DMA indicates appreciable retardation in technical and technological development of the production of Bulgarian enterprises. This is an indicator of low value-added investment, although investment in fixed assets can be a certain extent the bearer of innovative knowledge in the form of technical documentation and know-how.

Figure 16 Investments in fixed tangible or intangible assets, machinery and equipment, vehicles and buildings as a % of GDP.

From analyzed data on innovation and investment, can be summarized:

- Globally, they are a factor to generate industrial growth;
- Innovation activity of the new member States (Bulgaria and Romania) significantly lags behind that of the old members (Greece) and to a lesser degree in Turkey;
- The funding of innovation (as far as available) in these countries are mainly from public funds. Much less reliance on corporate R & D investment. This shows that many companies haven't separate departments for R & D. They have not cooperation with universities and other research units;
- The high rate of investment in the years before the crisis are resulting from the competitive level of wages in the two new EU countries (Bulgaria and Romania);
- Investments were mainly in fixed assets and low value-added and technology transfer;

All this gives us grounds to conclude that are confirmed the initial hypotheses formulated, for different levels of influence factors of industrial dynamics in the three categories of countries it is the Balkans - new and old EU members and countries outside the EU.

4. Conclusions

The prospects of economy growth and enlargement are set up years ago. Some of the key driving forces of the economic growth are economic and political alliances, but on the other hand there are regional features like cultural and social behaviour, that influence industrial dynamics. The analysis prove our hypothesis confirming existence of three different country types of industrial growth potential. Usual believe that Bulgaria and Romania have similar and very close path of development was not proved. The analysis shows that Bulgaria is in one group with Turkey.

The analysis highlights the role and the importance of different types of cooperation and integration. Industrial dynamic potential depends mainly on economic alliances integration. But there are some regional aspects. A closely collaboration between Bulgaria and Turkey supplemented with psychological and cultural aspects of this collaboration gives a different picture for Bulgarian industrial potential.

Innovation activity of the new member States (Bulgaria and Romania) significantly lags behind that of the old members (Greece) and to a lesser degree in Turkey. This conclusion is proved by the ranking of the four countries according to the Innovation sub index [2].

The perspective for future development for analysed countries is in direction of deepen and enlarged economic alliances and business networks in industry subsectors, which will have positive impact on industrial growth of each country in the region.

The impact of trade unions on entrepreneurship

Tanja Kosi¹, Bojan Nastav²

¹Faculty of Management Koper, University of Primorska, Slovenia, tanja.kosi@fm-kp.si

²Faculty of Management Koper, University of Primorska, Slovenia, bojan.nastav@fm-kp.si

The paper separately investigates how labour unions and other institutions affect the small business ownership rate (best reflecting risk-bearing and managing) and the business entry rate (relatively well reflecting innovativity). Different variants of the general regression model explaining the investigated dimensions of entrepreneurship are estimated on time-series cross-section data for nine EU member states and the United States for the period 1995-2007. The estimation follows the Parks (1967) feasible generalized least squares approach. The results show that trade unions have small and somewhat differential impact on the two dimensions of entrepreneurship. It also provides interesting results about the impact of control variables on the two entrepreneurship indicators.

Keywords

business entry, business ownership, FGLS, trade unions, OECD countries

1. Introduction

Entrepreneurship is recognized as an important source of economic growth, which has been confirmed by several empirical studies (e.g. Braunerhjelm et al. 2010, Thurik et al. 2008, Carree et al. 2007, van Stel and Carree 2004, Blanchflower 2000, van Stel et al. 2005). Formation of strategies for stimulating entrepreneurship ranks high on supranational (see e.g. European Commission's (2003) Green Paper on Entrepreneurship), national and local government agendas. Strategies for boosting entrepreneurial innovations include measures related to labour and product markets. Labour market and product market regulations are often viewed as being hostile to innovative entrepreneurship. High wages, high taxes, high entry cost, and strict technical standards raise costs, distort incentives, and therefore present barriers to entrepreneurship.

The paper empirically investigates the impact of trade unions and other chosen (mainly labour market) institutions on entrepreneurship in selected OECD countries. Due to multidimensional nature of entrepreneurship (see Iversen, Jørgensen and Malchow-Møller 2008), we measure entrepreneurship by two alternative indicators: the business ownership rate and the business entry rate from the. While the business ownership rate better reflects Knightian entrepreneurship (related to the Knight's (1921) concept of entrepreneurship), whose distinctive dimensions are managing and uncertainty bearing, the business entry rate relatively good highlights innovative or Schumpeterian dimension of entrepreneurship (the dimension related to Schumpeter's (1911 [2002]) early concept of entrepreneurship). We try to disclose whether institutions (in particular trade union power) affect dimensions of entrepreneurship highlighted by the two indicators in the same way.

While few studies investigate the effect of trade union power on entrepreneurship as measured by self-employment or business ownership rate (e.g. Ilmakunnas and Kannianen 2001, Kannianen and Vesala 2005), we encountered no empirical study directly relating trade union power to business creation/entry.

The impact of trade unions and other institutions on entrepreneurship is estimated on time-series cross-section data for nine EU countries (These nine EU countries are: Belgium, Denmark, Finland, France, German, Ireland, Italy, Netherlands and United Kingdom) and the United States for the period 1995-2007. The models including different sets of regressors are estimated by the feasible generalized least squares (FGLS) approach as proposed by Parks (1967). Beside trade union density and dummies for the existence of extension procedures, the set of explanatory variables includes other labour market institutions, variables that proxy shocks in terms of trade, industry structure and

openness, etc. The analysis is especially relevant for continental European economies with traditionally strong trade unions.

The paper consists of five sections. Following the introduction, Section 2 presents a framework for econometric analysis and describes the estimation approach. Section 3 describes a set of variables that are, in line with previous theoretical and empirical literature, important for the investigated dimensions of entrepreneurship. Results for different variants of the general model are presented in section 4. Section 5 concludes.

2. Econometric framework and methods of estimation

Our econometric analysis focuses on the impact of labour unions and other chosen (labour market) institutions on entrepreneurship measured by two alternative indicators: the (small) business ownership rate, which is a static measure, and the business entry rate, which is a dynamic measure. By estimating the empirical model, we are eager to find out if there are significant differences in how unions and other labour market institutions affect each of the two entrepreneurship indicators (highlighting different dimensions of entrepreneurship). The general form of the empirical model reads:

$$ent_{it} = \alpha + LMI_{it} \beta + MV_{it} \gamma + a_i + \varepsilon_{it} \quad (1)$$

where the subscript i denotes a country, and t stands for a time period; ε_{it} is the white noise error term, while a_i present country-specific effects (included only if necessary and appropriate as discussed in the follow-up).

The variable used in the regression equation are defined as follows. The dependent or explained variable, ent , is the business ownership rate (bor) or the business entry rate ($entryr$), respectively. LMI is a vector of labour market institutions that includes: the trade union density (tud), the gross unemployment benefit replacement rate ($grossbrr$), and the tax wedge on labour income (tw). MV is a vector of relevant macroeconomic control variables, which includes logarithm of real GDP per capita ($lnGDPpc$), the lagged unemployment rate ($lagunempl$), the share of ICT manufactures in total economy's employment ($eictman$), the logarithm of the size of population ($lnpop$), total trade as a percentage of GDP ($open$), the indicators of obstacles to starting a business ($dbstartb$) and obstacles to getting a credit ($dbgetc$), the level of educational attainment (edu), and government spending share of real GDP (gov). A more detailed description of variable is provided in the next section.

The regression model (1) is the most general variant of the model. We start by estimating the most specific version of the model (including only most relevant labour market institutions) and then gradually add other variables as suggested by economic theory and related empirical studies. If the signs and the significance of the regression coefficients of labour market variables are not substantially different between the variants of the model, we can speak in favour of their robustness.

The random effects model and the fixed effect model may be very useful for panel data but they do not deal with the important issues of heterogeneity in TSSC data (Beck 2006, 8). We expect data series to follow a particular (potentially cross-section specific) autocorrelation process, i.e. correlation of errors within cross-sectional units. What is also of crucial importance when choosing the estimation approach (or data transformation) is the stationarity of variables. To lower the risk of spurious regressions, it is very important to check whether the (dependent) variables follow stationary processes. For this purpose, we employ Fisher's test for the presence of a panel unit root that is based on an augmented Dickey-Fuller test (the test is proposed by Maddala and Wu 1999; for explanation see also Barbieri 2006, 10). Furthermore, our data might also suffer from typical problems with cross-sectional data such as cross-sectional or groupwise heteroskedasticity (i.e. the errors for different cross-sectional units have differing variances) and cross-sectional correlation (i.e. contemporaneous correlation of errors across cross-section units). For chosen model specifications, we check for these common problems with TSCS data by following the next diagnostic procedure:

- Firstly, we run Wooldridge's (2002) test for first-order autocorrelation in panel data..
- Secondly, the presence of heteroskedasticity in the error term is checked by running two regressions: i) iterated FGLS regression on the selected variables by imposing heteroskedastic error structure across cross-sections and ii) FGLS without any correction (therefore, OLS). Then we perform a likelihood ratio (LR) test, where we need to correct for the degrees of freedom (Wiggins and Poi 2003) and conclude which of the models is superior. If the LR test appears significant, we reject the null hypothesis of homoskedastic error term (Greene 2003, 327). To detect groupwise heteroskedasticity in the residuals we use the modified Wald statistic (Greene 2003, 324).

- Thirdly, we use the LM test of independence developed by Breusch and Pagan (1980) to check if data series violate the assumption of independence between cross-sectional units.

If the diagnostic checks show that our data do not significantly violate above mentioned assumptions, we estimate the regression equation by the fixed or the random effect approach. If the diagnostic checks confirm that our data violate some of the above assumptions, we estimate the regression equation by FGLS as proposed by Parks (1967).

3. Data and descriptive statistics

The paper employs two alternative measure of entrepreneurship: the business ownership rate and the business entry rate. *The business ownership rate* is calculated as a share of business owners in the total labour force. Business owners are unincorporated self-employed (sole proprietors and partners) as well as incorporated self-employed with less than 50 employees (owners-managers of incorporated businesses) in the non-agricultural sector, where contributing family members are excluded (van Stel 2005, 7). The data is taken from (EIM 2010a) from the harmonized dataset called COMPENDIA (COMParative ENTrepreneurship Data for International Analysis).

Schumpeterian aspect of entrepreneurship is measured by the business entry rate. The data is taken from the International Benchmark of Entrepreneurs (IBE) database compiled by EIM (2010b). The IBE entry rate is calculated as the number of enterprise entries divided by the total number of active enterprises in a certain period. Where an *entry* is defined as establishment of a new enterprise by a new entrepreneur (start-up) or by an existing entrepreneur, for which one person works at least one hour a week. The database includes all (incorporated and unincorporated) businesses and does not provide size-class and sector distributions. The agricultural sector is excluded from the dataset.

Beside selected labour market institutions (trade union density, the availability of legal procedures(In certain countries we observe a substantial gap between the union density rate and the union coverage rate *i.e.* the share of employees covered by collective agreements. For this reason we also use two interactive elements *tud*ext1* and *tud*ext2*) that extend the bargaining outcome to non union members, gross unemployment benefit replacement rate, tax wedge), the set of regressors in (1) includes control variables that in line with theoretical and/or empirical literature affect investigated dimensions of entrepreneurship (see Table 1).

Table 1 Description and basic statistics for relevant variables for nine EU countries and the United States for the period 1995-2007

Variable	Name and description	Mean	Std. Dev.	Data source
<i>entryr</i> (in %)	Business entry rate (see the main text).	9.8785	2.3315	EIM (2010b)
<i>bor</i> (in %)	Business ownership rate (see the main text).	10.7085	3.7344	EIM (2010a)
<i>tud</i> (in %)	Trade union density (the union membership rate among active workers).	37.2754	22.3178	OECD (2010c).
<i>ext1 / ext2</i> (0 or 1)	<i>ext1</i> : dummy that takes the value of one when legal provision for mandatory extension is available but affects less than 10 percent of the workforce and zero otherwise. <i>ext2</i> : dummy that takes the value of one when legal provision for extension is regularly applied and affect at least 10 percent of the workforce.			Visser (2009)
<i>grossbr</i> (in %)	Unemployment benefit replacement rate, <i>i.e.</i> the level of gross unemployment benefit relative to the average gross wage. (A summary measure of benefit entitlements employed).	33.1692	13.1657	OECD (2010a)
<i>tw</i> (in %)	Tax wedge for single persons without children at average earnings, <i>i.e.</i> the share of the sum of personal income taxes, employee plus employer social security contributions together with any payroll tax, minus benefits in labour costs (OECD 2007, 12).	42.8331	9.3577	OECD (2007, 2008)
<i>open</i> (in %)	Openness of a country to international trade (the share of total real value of trade (<i>i.e.</i> the imports plus exports) in real GDP in constant prices).	80.7	42.5558	Heston, Summers in Aten (2009)
<i>pop</i> (in mio)	Population expressed in millions of inhabitants.	58.6275	8.0626	Heston, Summers in Aten (2009)

Variable	Name and description	Mean	Std. Dev.	Data source
<i>eictman</i> (in %)	The share of ICT manufactures in total economy's employment.	1.0632	0.5396	OECD (2009b)
<i>dbstartb</i> [0,1]	Summary <i>starting a business</i> indicator (calculated as the arithmetic average of different components). It is rescaled such that it can take the values between 0 and 1; the closer it gets to 1, the heavier are the barriers to starting a business.	0.2117	0.0863	World Bank Group (2010). We use 2004 data for all years in the period 1995–2004.
<i>dbgetc</i> [0,1]	Summary <i>getting credit</i> indicator (calculated as the arithmetic average of the four components). It is rescaled such that it can take the values between 0 and 1; the closer it gets to 1, the harder it becomes for a business to get a credit.	0.1966	0.1313	
<i>TOTvol</i>	The volatility in the terms of trade calculated as the absolute value of the annual change in the logarithm of terms of trade multiplied by the indicator of trade openness: $TOTvol = \Delta \ln(PX/PM) * open$, with <i>PX</i> denoting export price index and <i>PM</i> standing for the import price index (Gillitzer and Jonathan 2005).	-0.1489	1.703	OECD (2010d)
<i>lngdppc</i>	The (logarithm of) real GDP per capita (<i>lnGDPpc</i>) as one of the regressors. For this purpose, we use GDP per capita in 2009 United States dollars.	10.4703	0.1411	TEDI (2010).
<i>unempl</i> (in %)	Unemployment rate.	7.59	2.8356	OECD (2010b)
<i>edu</i> (in %)	Educational attainment (the share of population aged between 25 and 64 years with completed tertiary education.	26.0571	7.1592	OECD (2006, 2010e)
<i>gov</i> (in %)	Government's share of real GDP (the percentage share of government expenditures in real GDP per capita at constant prices).	13.9282	2.9625	Heston, Summers in Aten (2009)

4. Description and interpretation of the results

For estimating different variants of model (1), we use TSCS data for nine EU countries (see footnote 1) and the United States over the period 1995–2007. In the first part of the section, we present and interpret the results for regression models explaining variation in the business entry rate with different combinations of included control variables. Specific combinations of control variables satisfy the assumption of low multicollinearity (i.e. variance inflation factors, VIFs, are considerably below 10). In the second part, we present and interpret the results for regression models explaining the business ownership rate. Also these models differ with respect to a combination of included control variables that satisfy the condition of low multicollinearity.

4.1 Explaining the business entry rate

In this section, we present the results of estimation of different variants of the regression equation (1) with the business entry rate serving as the dependent variable. Fisher's test for the presence of a panel unit root for the business entry rate rejects the null hypothesis of the presence of a unit root for all considered cases: driftless random walk, random walk with drift, and trend (The results of the tests are available from the authors on request). We may therefore conclude that the business entry rate follows a stationary process. Since many of the control variables are also stationary, we estimate (1) on original (rather than transformed) data series.

We have decided to estimate five variants of the general regression equation (1). All five models regress the business entry rate on the trade union density rate, the gross benefit replacement rate, and the tax wedge. All models but the first also include two interactive elements ($tud * ext2$, $tud * ext1$) that enable us to estimate a differential impact of union density in the presence of mandatory provision for extension of union bargaining outcomes to non-unionized sectors. Control variables included in the last four models are: *dbstartb*, *dbgetc*, *eictman*, *open*, *pop*, and *TOTvol*. Different models differ with respect to a combination of chosen control variables as shown in Table 1.

In the first stage of estimation, we *preliminarily estimate* all five variants of (1) presented in Table 1 by the OLS and calculate VIFs, which for all variables (in all models) take the values significantly lower than 10. We also perform the *diagnostic tests* and confirm the presence of AR(1), cross-sectional dependence and groupwise heteroskedasticity in all five models. This implies that we should *correct the preliminary estimates* by estimating the models by Parks (1967) FGLS approach. Table 1 depicts the FGLS estimates with common AR(1) and with panel-specific AR(1) for all five models.

The results in Table 1, somewhat surprisingly, suggest that in countries with no legal or mandatory provision for extension of bargaining outcome the union density positively affects the business entry rate. The respective regression coefficient has positive signs in all models and appears significant in the first three models and, when correcting the standard errors for common AR(1), also in the fifth model. The results, however, provide evidence on the reverse (therefore negative) impact of union density on the business entry rate in countries where the union bargaining outcomes are extended by law or other rule to at least 10 percent of the workforce that is not directly covered by the negotiations. The regression coefficient of gross benefit replacement rate, *grossbrr*, is negative (but small) in all five models; in all models but the fifth it also (weakly) significant. The regression coefficient of the tax wedge is negative in all models but appears highly insignificant when controlling for the size of population or the share of IT sector in economy's employment. Moreover, the size of the regression coefficient implies that quantitative effects of the gross benefit replacement rate and the tax wage on business entry is very small.

The first among the control variables that is found to significantly affect the business entry rates is World Bank Group's (2010) indicator of obstacles to getting a credit, *dbgetc*. Its impact is negative, quantitatively important and highly significant in both models that include *dbgetc*. The regression coefficient for the World Bank Group's (2010) indicator that measures obstacles encountered when starting a business, *dbstartb*, is negative in all cases but statistically insignificant. Population (in logs), which is present only in the fourth model, is found to have a significantly positive and quantitatively non-negligible impact on the business entry rate. Bigger countries therefore exhibit higher business entry rate, which is expected (see Eurostat – OECD 2008, 10 – 11). Country's openness, *open*, significantly positively influences the business entry rate in two out of three models, in which it is included.

Note:

* Correlation coefficient is significant at the 5% (2-tailed), ** Correlation coefficient is significant at the 1% (2-tailed), *** Correlation coefficient is significant at the 0.1% (2-tailed).

N stands for the number of observations. Figures provided in brackets are the significance levels of respective regression coefficients. The equation is estimated by feasible generalized least squares (FGLS) approach. Standard errors are adjusted to take into account heteroskedasticity (H) and common autocorrelation (AR(1)) or panel-specific autocorrelation (psAR(1)).

Source: own estimation.

4.2 Explaining the business ownership rate

Let us now present the results of estimation of different variants of the regression equation (1) with the business ownership rate serving as the dependent variable. Fisher's test for the presence of a panel unit root for the business ownership rate cannot reject the null hypothesis of the presence of a unit root (for driftless random walk and random walk with trend). Further analysis confirms that the variable is first-difference stationary. Since estimation of the regression equation on original data series yields a non-stationary error term (The results of the tests are available from the authors on request), we estimate the model in first differences. This removes all time constant effects (omitted and observed, including country-specific effects) from the analysis and limits our analysis to within-country movements, which sweeps away lots of interesting information about explanatory variables. We accept this as the price of lowering the risk of getting a spurious regression.

We have decided to estimate four variants of the general regression equation (1) on first-differenced data series. All five models regress the first difference in business ownership rate on first differences in the trade union density rate, the gross benefit replacement rate and the tax wedge. Control variables included (in first differences, as indicated by the prefix D. In Table 2) in the last three models are: *lngdppc*, *lagunempl* (i.e. once lagged unemployment rate), *open*, *gov*, *edu*, and *TOTvol*. Since *dbstartb* and *dbgetc* are nearly time invariant, we exclude them from the analysis. The models differ with respect to a combination of chosen control variables as shown in Table 2.

Note: *bor* – business ownership rate, *lnGDPpc* – logarithm of real GDP per capita, *lagunempl* – once lagged unemployment rate. Variables are added to the prefix *D.*, since they are expressed in first differences (i.e. annual changes). For other denotations, see the note to Table 1.

Source: own estimation.

In the first stage of estimation, we *preliminarily estimate* all four variants of (1) presented in Table 2 by OLS and calculate VIFs, which for all variables (in all models) take the values significantly lower than 10. Diagnostic tests detect some problem with the AR(1) processes, cross-sectional dependence and groupwise heteroskedasticity. For this reason we estimate the model using the Parks (1967) FGLS approach with common AR(1) and, alternatively, with panel-specific AR(1).

The results in Table 2 suggest the union density negatively (and in most cases statistically significantly) affects the business ownership rate. The quantitative effect expressed by the size of the regression coefficient is, however, very small (a decrease in *tud* for 10 percent increases *bor* by only 0.5 percent). The regression coefficient of gross benefit replacement rate, *grossbrr*, is positive but statistically insignificant in all models. Similar holds for the tax wedge on labour income.

T-tests (and the corresponding p-values, *i.e.* the exact levels of significance) for the regression coefficients of control variables show that countries' openness to international trade positively affects the business ownership rate, which is in line with our expectations. Negative shocks to terms of trade significantly negatively affect the business ownership rate, which is intuitive. The negative sign of the regression coefficient of (first-differenced) lagged unemployment rate (which is statistically significant) confirms that unemployment acts a push factor for self-employment. In other words, self-employment serves as a solution to a job loss. Educational attainment and the share of government expenditure in GDP do not show statistically significant impact on the business ownership rate in the nine EU countries and the United States in the period 1995-2007.

5. Conclusions

The paper empirically investigates how labour unions and other institutions affect the business ownership rate and the business entry rate. Different variants of the regression model explaining the investigated dimensions of entrepreneurship are estimated on time-series cross-section data for nine EU member states and the United States for the period 1995-2007. We adopted the Parks (1987) feasible generalized least squares approach to estimation.

The results show that trade unions have small and somewhat different impact on the two dimensions of entrepreneurship. In countries with no legal or mandatory provision for extension of bargaining outcomes, the union density positively affects the business entry rate. The impact of labour union density on the business entry appears to be reversed (therefore negative but very small) in countries where the union bargaining outcomes are extended by law or other rule to at least 10 percent of the workforce that is not directly covered by the negotiations. The impact of union density on the business ownership rate is negative (even in countries without legal provisions for extensions of the bargaining outcome to non-union members). The quantitative effect expressed by the size of the regression coefficient is, however, very small (a decrease in unions density for 10 percent increases the business ownership by 0.5 percent). According to our estimation results, unemployment benefits do not significantly affect the business ownership rate, while they show negative (but weak) influence on the business entry rate. The impact of the tax wedge (*i.e.* the overall tax rate on labour income) on entrepreneurship is insignificant whatever the measure of entrepreneurship (at least when controlling for other important factors).

Model for Effective “Science – Business” Collaboration in Bulgarian Economy

K. Kostadinov^{1,2}, G. Raichevski¹, Tsv. Yorgova¹,

¹*GIS Transfer center Foundation; Sofia, Bulgaria, e-mail: office@gis-tc.org*

²*VUZF, kostadinov@vuzf.bg*

The aim of this paper is to develop a model for effective science-business collaboration based on the project competitiveness concept oriented to the practical applications and innovations. The model is verified on the basis of 4 projects generated by practical problems defined by companies from the chemical industry branch. The research teams from scientific institutions or universities are those who deliver research results for the practical problems. This science – business collaboration based on the common issue – project with clear defined aim, results and indicators are the tool allowing the science and research team and business or company team to build fruitful collaboration on the common practical problem and interact effectively to find a research decision.

Keywords

Innovation, project competitiveness model, science-business

1. Introduction

In this paper we consider science – business cooperation as the main driver in the National innovation system [1] to increase innovations in Bulgarian economy. In this system at least, three different social systems - ‘business’, ‘science’, and ‘policy’ - with different modes of interpretation, decision rules, objectives, and specific communicative standards are interacting.

The innovation as the overarching policy objective of the EU and its Member States [2] is to adopt a much more strategic approach to innovation. An approach whereby, all policy instruments, measures and funding are designed to contribute to innovation, where EU and national/regional policies are closely aligned and mutually reinforcing.

The business system is profit-oriented and communicates via the market mechanism. The science system aims at the production of knowledge and communicates via publications. In fact, the specific advantage of the innovation system is not being a system in the meaning of a separate and autonomus entity, but the process of collaboration between actors who often belong to different systems. It is the exchange of formerly unrelated information that reinforces innovativeness. Crossing the border between different systems stimulates changes in the systems in general [3]. In the particular case of industry-science interaction this might, among other things, result in product innovation. There was held in Bulgaria 12 academy-industry meetings for 2-years period for different industry branches with participants from research organizations and universities and industrial companies. As an initial process of the science-business communication the results were quite encouraged – 12 innovative projects have been initiated and realized, while the participants were more than 1000 in total. Even the effectiveness of such bridges is not so satisfied they were essentially necessary to establish this communication. Most important was that they put the question how to increase the effectiveness of science – business communication in order to make their collaboration more profitable and leading to more innovative products, processes and services.

In the National innovation system as in the knowledge triangle [4] another important element is the education.

So, the aim of this paper is to develop a model for effective collaboration between science and business in Bulgaria including the education, too. Another aim is find indicators which can evaluate the effectiveness of this science-business collaboration.

2. Problem Statement

GIS Transfer center foundation is developing this model in the framework of a project supported by the National Science Fund using its active network of companies that offers its members vital contacts with customers as well as peer and stakeholder groups. Networks are of great importance in general, particularly in the current situation when we considered the knowledge-based economy. For companies this means a sound innovation based and easy access the necessary knowledge and to qualified labor in order to be competitive with innovative products, processes or services. Close and effective cooperation between the science and business actors is of particular importance now that the word economy is recovering from the turmoil of the financial crises and global recession. The proposed model is based on the concept of project competitiveness [5] as it is shown on Figure.1.

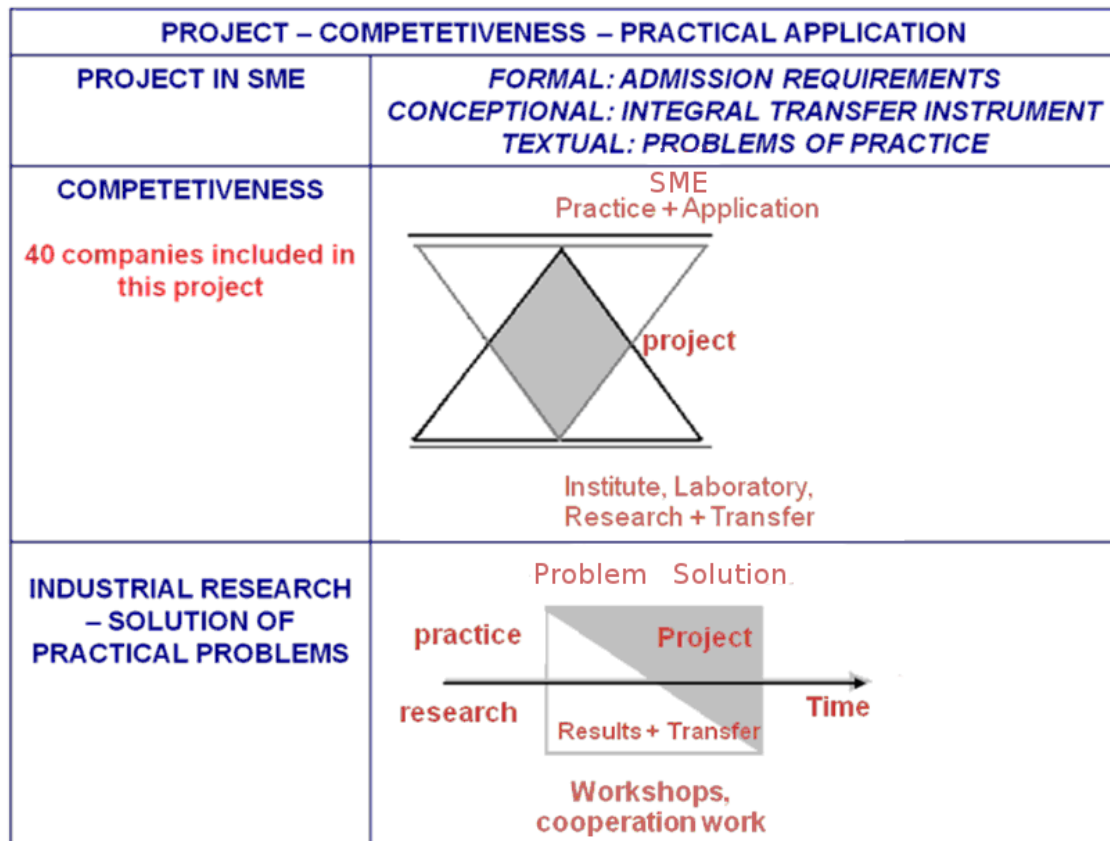

Figure1 Project competitiveness concept.

2.1 Methods and instruments for effective interaction science – business

For having a successful interaction between the science and the business is necessary to create in the scientific researches in addition of their creative ability a spirit of an enterprise, what will be achieved by:

- Creation of innovations for the production practice.
- Obtaining the specific professional qualification for a technological activity /work.
- Determination
- Adaptability
- Communication skills.
- Learning new subjects such as business – plan, market – surveys etc.

The successful and getting more effective interaction between the science and the business during the project establishment is realized by various methods and instruments, namely:

- Common work meeting with company representatives to prepare work plans of scientific research in order to obtain the project results and to exploit them.

2.2 Methodology

The methodology applied in the proposed model for project competitiveness comprises different actions, which can be classified in the following groups :

- Scientific research tasks with fundamental character.
- Scientific applicable tasks for creation of innovative technologies and products.
- Development works in the companies, trial samples, prototypes development.
- Financial operations, purchasing new apparatus and equipment and putting them in action, registration and protection of intellectual properties.
- Public activities (conference ,web site of the project , posters , showing in the medias)
- Dissemination plan of results.
- Management of project accomplishment, stage and final report.

Methodology to obtain the aim of this paper is based on the following steps and actions:

- Right selection of proper science subjects-scientific tasks which contain recourse of obtaining scientific applicable results. Most of them have to be finished to laboratory technological innovations and products.
- Selection of requested partners- scientific and research teams with qualified researchers with successful experience in technological development and in practice.
- Selection of manufacturing companies as partners and co-partners among our successful partners from the GIS-TC network.
- Establishment of good coordination among the companies performing all projects defined, including building a Project Council for better exploitation of project results.
- Systematic work on the project implementation and management.
- Realistic action plan for consecutively realization of the tasks and their upgrading for creation of:
 - new scientific knowledge with a fundamental character;
 - Scientific applicable results;
 - Laboratory innovation technologies and products (new materials) ;
 - Experimental development (development work for testing and optimization) in manufacturing companies;
 - Trial samples obtained in industrial conditions;
 - Preparing of common applications for patents and useful models to protect the intellectual property created in the framework of the common projects;

Preliminary marketing surveys and prognoses.

- Training of partners teams aiming increasing of their qualification and enterprising skills
- Consolidation of this common base in inters institutional integration among manifold groups. Continuing of combined actions through new common projects for participation in national and European competition procedures.
- Preparation of multiplication plan for exploitation of the most successful technological and product innovations, which will have the highest market potential;
- Public relation activities for informing our society and national institution about successful results as well the difficulties in implementation of this new kind of projects.

2.3 Quantity measurable indicators of the model implementation.

The progress in the implementation of the model verification plan is done through the following indicators measured as a number and as a quality:

- Working meeting between representatives of scientific organizations and companies.
- Working programs of joint scientific – applicable investigations and laboratory testing.
- Scientific publications in international and Bulgarian journals.
- Lectures at national and international forums, published in
- Test laboratory processes – technological innovations.

- Test samples of obtained new materials, including nanomaterials.
- Functional indicators for qualifying the test samples in accordance with internationally recognized standards.
- Development activities realized in the companies – tests and optimization of the **experimental** technologies and the equipments as well.
- Analysis's and Testing carried out in the scientific project teams.
- Combined technical and economic appraisals of the test processes and samples.
- Applications for patent and useful design requests jointly made by partners.
- Technological audits of the companies.
- Offers for participation of firms in SMEs EF.
- Common seminars.
- Participations in fairs and expositions.
- Prepared common projects for participation in competition procedures.
- Surveys of the possibilities for an innovative cluster creation.

2.4 Common research projects.

To verify the proposed model for science-business collaboration several common research projects have been initiated in cooperation with companies from the chemical industry branch. The companies have been used to specify the specific requirements to the research results as an output of the following projects:

1. "Electrochemical obtaining of Ni nanocomposite layers for application in protective-decorative and functional coatings"

Nowadays the electrolytic obtained nanocomposite layers/coatings are not very investigated for potential industry applications. Another case is the nanocomposite zinc coatings.

The scientific-fundamental aspect aims the mechanism determination of the incorporating in the Ni matrix of carbon nanotubes, the changes in the microstructure and morphology of the layers. The scientific-applied aspect is targeted on important functional properties of these coatings – protective ability against corrosion as well as the main physical-mechanical parameters: brilliance, hardness and wear resistance. The technology for electrolytic obtaining of the layers has been investigated non-sensitive against contamination with iron ions by Institute of physic-chemistry from Bulgarian Academy of Sciences (IPC-BAS) and Chemical Faculty at Sofia University "St. Kl. Ohridski" (CF-SU). The developed nanotechnology [6] for the obtaining such protective-decorative and functional coatings is proved and optimized by the company "Gabex" Ltd, Sofia.

2. "Electrolytic obtaining of functional silver alloy coatings"

The obtaining and investigation of the properties of some series of silver alloys is an accelerated tendency in the last decade. The fundamental results obtained for self-organized creating of symmetric structures in the layers, as well as the results with applied character for technology for high-speed electro deposition of silver coatings for the company FEM, Schwäbisch Gmünd, Germany take a significant place in this area.

The project task is the optimization of the obtaining of different coatings: Ag – Bi, Ag – Sb, Ag – In and Ag – Sn accompanied by studying of the kinetics and mechanism of the electrodeposition [7, 8]. Additionally, the main functional properties of these coatings like hardness, wear resistance, electrical conductivity, lubrication (very low friction against other surfaces), appearance etc are investigated [9].

The laboratory technologies are oriented for application in some industrial branches – electronic and electronic engineering, mechanical engineering, jewellery. Part of these investigations [10] is realized by IPC-BAS in cooperation with the Institute for noble metals (FEM), Schwäbisch Gmünd, Germany.

3. "Rust converters on water-organic basis including compositions with passivating effect".

Scientific-applied investigations upon new generation of rust converters on organic-water basis including compositions with stable passivating effect against iron and steel wares after the rust conversion process have been carried out by the common team from IPC-BAS and CF-SU. The development activity is consisted of producing of experimental samples and their testing at real conditions. These results are compared with laboratory results and from the accelerated standard tests (ISO standard), realized in wares. These products ensure fully and fast conversion of the rust in a dense protective oxide-phosphate film with high corrosion resistance and act as a hopeful basis for laying on polymeric protective-decorative coatings [11,12]. Additionally, this product can be also used in the building industry, transport, ore output, metallurgy, mechanical engineering etc.

The development activity for several products is carried out in the company "Chemical products" Ltd, city of Yambol and "Podeminvest-technology" Ltd, Sofia including the obtaining and testing of experimental samples.

4. "Chemical compositions without six valence Cr and technology for passivation of galvanic Zn and Zn alloy coatings".

The scientific-investigating aspect in this project includes obtaining of results by IPC-BAS and CF-US for the element and phase composition of the passive films (XPS – analysis), as well as for the changes in the composition and their structure as a result of the corrosion treatment in model aggressive media. The implementation of different practical orders will lead to obtaining of compositions for surface films with several colors like transparent, black, gray and green, iridescent yellow [13]. These films increase 3-4 times the corrosion resistance of the system "base metal – zinc coating - passive film" [14,15]. The main innovation is the realizing of these results in the technological processes and branches in the absence of Cr6+, which is forbidden in EU from 2007.

The development activity is carried out in "Chemical products" Ltd, Yambol, "Artchim" Ltd and "Gabex" Ltd, Sofia including also the obtaining and testing of the experimental samples.

5. "Chemical and electrochemical obtaining of protective conversion layers without six valence chromium (Cr6+) on aluminum and Al alloys".

The processes and peculiarities (catalysts) during the formation of protective-decorative films on Al and its alloys widely used in the practice, mainly for components in the electrical engineering, mechanical engineering, transport and building industry, which is the aim of this project study.

The innovation takes place in the fact that the electrolytes do not contain the harmful Cr6+, but other effective substitute [16]. At present, some compositions for chemical and electrochemical finishing are offered on the market, but they do not ensure sufficient corrosion resistance. In our product some newly developed by IPC-BAS compositions will lead to higher protective ability compared to the other products and technologies of the leading foreign firms.

The development activity is carried out in cooperation with company "Samel", city of Samokov. The compositions and technologies for the different colored films – transparent, black, yellow, iridescent yellow etc. are optimized including preparing and testing of experimental samples.

6. "Obtaining and properties of multi-component Ni and Co based alloys for electrodes in fuel cells for hydrogen energetic".

The investigation and functional properties of multi-component Ni and Co based alloys (additionally components can be B, Mn, W, Mo, V, P etc.) is realized by IPC-BAS team in the framework of this project #6. The aim is to receive new materials with appropriate properties to be used as electrodes in electrochemical current sources - fuel cells, as well as for anodes in electrochemical manufacturing and hydrogen storage containers including obtaining and testing of experimental samples [17].

Here with this project an appropriated Bulgarian company wishing to carry out the development activity will be looked for, since for this case such company has been not provided in advance.

7. "Obtaining and specifying the properties of oxidized alloyed Titanium anodes".

In scientific-fundamental aspect the main functional characteristics of oxidized and alloyed Ti anodes in the composition of the films also other oxides – of Ru, In, Sn etc. incorporated together with the Ti oxides is investigated by CF-SU. Special attention is paid on to following characteristics: film composition, structure, morphology and their influence on the kinetics and overvoltage during the electrolytic oxygen evolution.

The scientific-applied aspect includes the optimizing of the following parameters: corrosion resistance in model media and wear resistance of the films during the intensive oxygen evolution since these properties play an important role by using of such anodes in the cathodic protection against corrosion as well as in electrochemical reactors including units for purification of polluted water.

"Aquaproducts" Ltd, Yambol is carried out the technological testing in semi-industrial electrochemical reactor aimed to characterize the anodes and to optimize the experimental technology for purification of polluted industrial water.

3. Sustainability activity plan for model implementation.

Sustainable implementation of the activities validated and optimized in the framework of this project is important criterion for its successful implementation. Such activities to get sustainability of the project are foreseen in the framework of two groups of organizations considering the science-business interaction:

1. First group are partners and subcontractors of this project, for which continuation of the common activities is consisted of:

- Delivering consultancy services for initiation, preparation and implementation of common project with research teams from IPC-BAS and Sofia University “St. Kliment Ohridski” mainly from Chemical and Physical Faculties;
- Widening the collaboration between GIS-TransferCenter and Technology Transfer Office of Sofia University for common work with the technology oriented company from the South-West region of Bulgaria, selection of attaché consultants, initiation of contract research services, assessment of new technological projects, technology consultancy, expertise’s, etc.
- Continuation of implementation activities in the industry as follow up of the stage of prototyping and preparation of the research results in the form more acceptable for the industry;
- Initiation and preparation of common projects between Institute of Physical Chemistry – BAS and some research teams from Sofia University with industrial partners for application in the operative program “Competitiveness of Bulgarian Economy”, National innovation fund, European competitiveness and innovation program (CIP), FP7, etc.
- In the framework of the follow-up activities of the project ROSIO Sofia initially funded by PHARE (2006-2007) GIS-TransferCenter Sofia and Kostinbrod municipalities will continue to attract the investments in the high-technology enterprises, especially in the fields of new materials and ecology, i.e. the priorities of the National Science Fund of Bulgaria.
- Specialization and mobility of staff members of those companies into the research organizations in preparation and implementation of research and high technology projects, as well as in GIS-TransferCenter in preparation, monitoring and management of projects.
- Common feasibility studies and forecasts for innovative processes as well as marketing studies, too.
- Preparation of common applications for patents, trademarks etc.

2. The second group of activities planned after the end of the project aim to initiate similar activities in other NGO, research institutes, universities and industry, not taking part in the project yet, but having good contacts with the project participants and with companies wishing to increase their competitiveness based on the proposed in this paper model for project competitiveness.

4. Discussion and Conclusion remarks

The developed model for effective collaboration between science and industry will be used for widening of above described activities as well as those described in the dissemination plan of the results for the second group wider in structure and research teams.

This group will be in size of about 100 research institutes and universities, NGO and companies, mostly SMEs, but and large sized enterprises, too. For example companies like NPS“Kozloduy”, Toplofikacija-Sofia S.A., Toplofikacija – Pernik S.A. etc.

Synergy between science and innovation is always bilateral. Sometimes precedes innovation and science explained her subsequently (steam motor - the principles of thermodynamics), but always the science-business interaction takes play the important role in the competitiveness of the Bulgarian economy.

People in industry may build relationships with academics and vice versa using the proposed model based on the project competitiveness. Actually, the question how to manage the interaction and how to ensure both that science is useful for the benefit of society to innovate and ensure the reproduction of science- updated the scientific staff and research infrastructure is very important when the society has to decide how to harness the science for society purposes[18].

We think that there is enough evidence that the benefit in terms of increased innovativeness on the side of business as well as stimulated research activities on the side of science makes it worth while for science and technology policy to target these difficulties and to stimulate collaborative relations between industry and science more intensively and effectively.

Acknowledgements

This work is partially supported by the Project OMINS-BG Optimization and application of a model and tools for intensification of the interaction “science – business” at a support of strong and competitive Bulgarian industry” funded by National Science Fund under contract DTK02-31/2009 and the project SEE IFA Network/2009 funded by European Union.

metka.kostanjevec@prva-gimnazija.org*

The innovative approach has become an important aspect in the design and implementation of the organizational strategy. The multi-criteria (MC) model allows the systematic planning of successful investments. Through this methodology, both the strategic as well as operational aspects of the integrated innovation management system are addressed.

A prime advantage of this methodology is the systematic approach, something that leads to complete continuity throughout the whole investment cycle, even though it is already a primary tool in the early phases of the cycle.

In order to arrive at a practical tool that facilitates the whole process of arriving at a successful investment, the different process phases are coupled to existing and new methods of planning. This not only describes the steps required (what should be done) but also shows how to do it practically with the aid of methodological support.

In the following article the most important requirements for a methodology to plan technological investment will be described. On the one hand, these requirements have been deduced from the characteristics of the planning object "Investment as Innovation" and the planning process "Innovation Process as Route".

On the other hand, they have been deduced and changed based on practical experience as well as by analyzing available studies looking at innovation and the requirements of a planning methodology. As such, they are a reflection of the requirements of public organizations.

The planning process and the specific methods used during idea generation for technological investment are unique for each specific planning object of working organisation.

In Slovenia, each public organisation must prepare, according to legislation, an investment project in the correct and transparent way. The document "Decree amending Decree on the uniform methodology for the preparation and treatment of investment documentation in the field of public finance" lays on organisation that has to use a word of MC approach for evaluating different investment project and its possibilities.

Investment projects are evaluated from different points of view – including economical, political, health, and time aspect. Public money should be used as transparently as possible and in accordance with certain methodology.

In our article we present a unique approach to an investment project in the area of idea recognition and of investment idea evaluation in the early phase. This model has already been proven on different products and it has already been used for the development of potential ideas.

Keywords

product development, investment, innovation, public institutions.

1. Introduction

Investment decisions are at the core of any development strategy. Economic growth and welfare depends on productive capital, infrastructure, human capital, knowledge, total factor productivity and the quality of institutions. All of these development ingredients imply - to some extent - taking the hard decision to sink economic resources now, in the hope of future benefits, betting on the distant and uncertain future horizon.[1]

Every time an investment decision has to be made, one form or another of weighting costs against benefits is involved, and some form of calculation over time is needed to compare the former with the latter when they accrue in different years. Private companies and the public sector at national, regional or local levels make these calculations every day.

“Decree amending Decree on the uniform methodology for the preparation and treatment of investment documentation in the field of public finance” (Decree) [2] accepted by the Slovenian government in 2010 is the basic legislation for the field of preparing investment documentation of projects which are financed through public finance or the national budget. The Decree is part of a greater field of financial legislation of the Public Finance Act in the Official Gazette of the Republic of Slovenia Nr. 79/1999 and its changes. All Slovenian legislation in the field of investment is in accordance with the European legislation and its principles. The Decree has been written with the ambition to be helpful to managing authorities, public administrators and their advisors in Slovenia and Member States of the European Union (EU), when they examine project ideas or pre-feasibility studies at an early stage of the project cycle.

In fact, a timely and simplified financial and economic analysis can do a lot to unveil weaknesses in project design. These weak points would probably become apparent at a later stage, when a lot of time and effort has been already wasted on an option that in the end has to be abandoned or thoroughly restructured. Using the tools presented in the Decree, or included in national guidelines, to check projects before preparing the application for EU assistance and build a national or regional selection process, will be beneficial to all actors involved, as their attention will focus only on the really good projects to enhance their probability of success.

The preparation of investment documentation is composed of three main fields divided by the cost of the project. The so called Document of identification of investment project – its prefeasibility study of the new project and its cost should be half a million Euros. The second degree is the Pre-investment plan which must be written for projects over two and a half million Euros. The third and most important document is the Investment program which presents the complete program for projects over half a million Euros and also includes the realization study. The Investment program describes the complete investment for only the most appropriate variant and this article discusses the way, in which the most promising idea comes to realisation.

The product development (PD) has a long history in engineering including research in global industrial experience [3, 4], design and analysis product design [5, 6] and creativity in product innovation [5].

On the other hand, it includes research in marketing on customer preferences [7], product positioning and segmentation [3, 8, 9], product forecasting [10, 11, 12] and test marketing [13, 14].

The applications have been many and varied and have led to a deeper understanding of how to gather and use information about the customer and engineering in the design, testing, launch, and management of new products. Many integrative texts on product development have been published to review the issues, the methods, and the applications [15].

2. Structural approaches to new project investment

A project can be defined as an operation comprising a series of works, activities or services intended to accomplish an indivisible task of a precise economic or technical nature; one which has well defined goals. The appraisal needs to focus on the whole project as a self-sufficient unit of analysis and not on fragments or sections of it. Partitions of projects for purely administrative reasons are not appropriate objects of appraisal.

Cost-Benefit Analysis (CBA) is an applied social science and it is not an exact discipline. It is largely based on approximations, working hypotheses and shortcuts due to the lack of data or because of constraints on the resources of evaluators. It needs intuition and not just data crunching and should be based on the right incentives for the evaluators to do their job in the most independent and honest environment. [1]

Practical tools for product development are presented in different literature. [12, 15]. The main requirements for a methodology used to plan investment can be summarized in nine points [16]. Those nine steps are written hereon to show how the idea was developed.

2.1 Nine steps to investment in public institutions

Practical tools for product development are presented in different literature. [17] The main requirements for a methodology used to plan investments can be summarized in nine points – similar to product development. Those nine steps are written hereon to show how the idea was developed [16, 18]:

1. Set clear goals

Setting *clear goals* and following these systematically ensures that both the goals of the institution as well as those of the decision maker (Ministry of Health) are known and are being followed. Only when innovation goals and the innovation strategy - based on the enterprise strategy - have been identified, defined, and communicated within strategic and operational planning can relevant solutions be sought or found.

2. Quality of ideas more important than quantity

Innovation studies and project experience show that successful product innovation is more often than not the result of ideas from individual, motivated employees, and as such basically happens by chance. The methodology for investment planning must support the systematic generation of *qualitatively highly valuable ideas*.

3. Create for the future

The fulfilment of future and latent patient requirements through future-oriented or at least leading-edge technology creates uniqueness. An important prerequisite for not only the continued success of an institution but also the improvement thereof through the continuous and precise fulfilment of patient wishes and demands will be the ability to continually recognize or even create new or developing trends, and then to develop relevant investment through a network of the most competent, creative and innovative institutions. Part of a strategy-driven investment planning therefore has to be *the identification or recognition of these latent and future customer (patient) requirements* and from these the deduction of the innovation potential.

4. Use existing strengths

Good ideas lead to success only if they are implemented. This can be achieved only if the institution succeeds in leaning on or using its own particular strengths. In rating or choosing certain investment ideas, besides the competitive potential, the "institutional fit" of the ideas also needs to be evaluated.

5. Create transparent and standardized processes

Successful control of complex problems requires two distinct levels. On the one hand, the theoretical struggle with such a complex problem has to be simplified and done systematically, while on the other hand, the holistic overview needs to be kept in the detailed analysis. To be efficient, particular attention has to be given to rationalization potentials.

6. Objective, retraceable idea selection

The easier it is to physically imagine something, the more available specific information regarding a certain alternative is, the higher the chance that that idea will be regarded in a positive light. In practice, this can lead to the fact that existing, well-known solutions are rated higher than new, lesser known technologies. This results in ideas being further refined that seem to have a higher information availability, instead of exploring or searching for further information on possibly better alternatives. It is therefore vital for an objective idea selection not to focus on the institutional specific history and even on well-known approaches, but to make sure that totally different but functionally equivalent opportunities are included in the analysis.

In judging or rating different ideas, vague and qualitative factors need to be taken into account. Should the decision maker insist on using well-defined, quantified information, the implementation risk might be reduced, but in order to obtain this information.

7. Accepting uncertainties

In the early phase of the investment process one will always be confronted with the uncertainty of the eventual realization of envisaged developments. In this environment of uncertainty and time pressure relevant methods are required.

8. Synchronize national health problems, technology requirements and institution possibilities

In technology-intensive environments such as medicine it is especially important to obtain a high technological competence. To be on the forefront in new technology requires that the necessary resources for the development and refinement of these are made available. In the development of medical equipment there is, however, an inherent risk. Technologies developed too late result in the

non-satisfaction of a hospital demand. On the other hand, too early developments of technologies put undue pressure on financial and human resources that could have been used more effectively. It is therefore required that market and technology developments are synchronized through a methodical, systematic support system that makes the realization of necessary technologies on a just-in-time basis possible.

9. Keep an open mind and stimulate creativity

The planning process and specific methods used during idea generation and the implementation of technological product innovations are unique for each specific planning object. There is no generic or "ideal" way; there is only the "best" approach for successful investment.

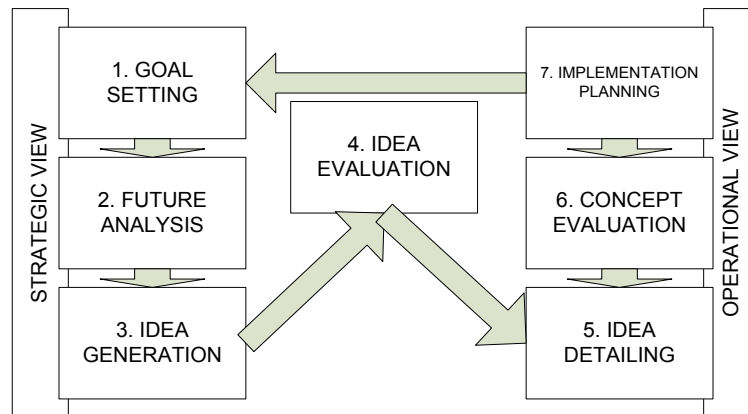

Figure 1 The W model [16]

This standardized approach has the advantage that, though providing for the specific requirements for creativity and intuition, the co-ordination of all participants is made easier and the underlying structure of the approach does not need to be re-developed for each separate planning process.

2.2 Simultaneous development with MC approach

The idea about MC analysis of investment acceptability in the health system was developed from observing two-dimensional graphs showing the dependence of the dependent variable from the independent one. The independent variable represents time, the dependent one is derived from the observed and most representative parameters [15, 19].

Besides the strategic goals, an analysis of the technological potentials is required for innovation planning. Here the potentials refer to the totality of all institution capabilities in answering requests for problem solutions and reacting quickly to public health requirements as well as to develop and apply new products and commercial success.

The analysis and collection of trends is a continual process used in the early clarification. A trend can be described as the basic direction of either a development or a development bias. The "trend scanning" takes place in different observation areas, which together form the observation field. It represents the global environment of the formation field. In the ideal case, detailed information on developments in single observation areas already exists in the business so that these can be analyzed formation field-specifically. If the trend-scanning in a business is established, a list of trends from the various observation areas exists, that is reviewed, updated permanently and/or analyzed regarding its relevance. In addition to the available trends, the observation areas can be examined formation field-specific. Obviously, a complete analysis of the collection of trends is required.

In the trend test, the examination of the resemblance of the trend identified in the individual observation areas is important. During the resemblance analysis, the goal has to be to objectively rate the weighting of the trend while avoiding an overrating of a trend direction by the consideration of several similar trends. If similar trends are taken up in the matrix such as Table 1, this could lead to an overrating of future projections.

2.3 Empirical study of renovation of Paediatric clinic of University clinical centre of Maribor

Data which are represented in the following text is part of the larger investment documentation prepared for the Rebuilding of the Paediatric clinic of the University clinical centre of Maribor in 2011. Due to the complexity of the health care infrastructure, there is a need to clearly describe the objectives and characteristics of the project proposed. The main typologies of features to be considered are the following [1]:

1. Functional features:

- the group of pathologies involved,
- the scope of the target population,
- the diagnostic functions,
- the short or long term treatment.

2. Basic data:

- the average and maximum numbers of users per day, month, year,
- a list of the departments for assistance and prevention, treatment and diagnosis.

3. Physical data:

- the surface area and covered area,
- number of treatment rooms, wards, prevention and/or diagnostic consulting rooms,
- existence and size of outpatients departments.

4. Technical and engineering features:

- arrangement of internal/external areas (lay-out),
- description of the principal equipment and machinery for diagnosis and/or treatment (e.g. X-ray, scans, nuclear medicine, endoscopes etc.),
- construction, and layout of buildings or parts,
- viability and access systems (plus possible car parks) and links with the local communication routes.

The feasibility of the projects should be verified according to patient flows and trends and by taking into consideration the epidemiological data available. For the alternative options, the critical issues to establish are: different medical-technological solutions, the construction of a new infrastructure, or the enlargement of the old one, different treatment systems.

Financial inflows are fees for hospital admission, fees for diagnosis, fees for treatment, additional services, single rooms, and transfer from the government budget.

Financial outflows (the time horizon is usually around 20 years)

1. Investment costs:

- works,
- general expenses,
- expenses for special equipment;

2. Operating costs:

- raw materials for operation,
- maintenance,
- medicines,
- medical and administrative personnel costs - out-sourced medical services.

Table 1 shows the matrix of different opportunities for the complex University clinical hospital located in Maribor, Slovenia. Variant 1 represents the option without investment and is not acceptable. Also, physical conditions such as that of the clinic cannot meet the statutory obligations relating to the coexistence of the child and parents. Given the increased workload, overcrowding and the conditions for coexistence of the child and parents, years ago a very large number of complaints was received by the clinic from patients, visitors, parents, and others.

Variant 2 meant to adapt non-medical facilities on the ground floor and on the 4th floor, and at their location to reconstruct the facilities necessary for carrying out medical activities. On the roof the appropriate remediation is planned. Facilities for children in the 4th surgical floor are removed to the Central hospital tower, which does not guarantee the quality of treatment for children in child surgery at the same time.

Variant 3 is a complex address space, functional and organizational problems of the two organizational units, and therefore the complete variant does not have better alternative. Senior Staff from the Clinical centre surgeries notes that the professional growth of children with any kind of surgery. Lack of individual space for children with parents is crucial. In this context it is obvious that the ideal solution in the hospitalization of paediatric patients and parents is to remain in the same

building as the paediatric intensive care unit and operating rooms. Simultaneously the location and the entire children's department of surgery in this building should be connected to the maternity hospital with a passage.

Table 1 Analysed parameters of investment opportunities

Time (year)	Variant parameters estimated in %			Σ
	VARIANT 1	VARIANT 2	VARIANT 3	
2006	40	50	10	100
2007	35	45	20	100
2008	35	40	25	100
2009	20	30	50	100
2010	10	20	70	100
2011	5	15	80	100

Limitations of different combinations of variants were eliminated in the beginning due to the demand for fast and effective reconstruction of the building and its still running activities.

Figure 2 Demonstration of moving the centre of gravity in multi-dimensional space

Figure 2 shows the »skeleton« multidimensional graph of product development. Limits to the system are set uniformly with boundary lines of observed parameters.

Figure 3 Demonstration of quadratic dependant trend

Figure 3 gives us the opportunity to observe a multidimensional curve, which is defined by the absolute value of the angle of aggregate indicator of the trend of the centre. These curves show a quadratic trend which, in the upcoming years, moves the centre of the observed investment towards

the importance of choosing the appropriate one. The importance of Variant 3 is shown as the most appropriate one.

3. Conclusion

Hospital and other healthcare infrastructure investment projects are correlated with the prevention and/or treatment of pathologies and refer to different categories of the population. The overarching goals are the increasing life expectancy and life quality.

Establishing the rational environment is largely a matter of institutional building, local culture and transparency of the decision-making process, including the political environment. No technical document can address these important issues which are beyond the scope of the Decree. In fact, the content of the Decree is no more than a structured set of suggestions, a check list, but good project analysis needs adaptation to local circumstances and it should be based on professional skills and personal ability.

Life cycles of technologies, products and processes are becoming ever shorter, so technological foresight is a very important aspect of their planning. In a time when foretelling the development of products is difficult and the price of error as steep as it is, the article offers a solution for the development of products through multidimensional analysis.

The developed model of product design through MC analysis can be used in the development of virtually any mass produced product. Model has a lot of potential and a lot of space for further investigations and real case study modifications.

The benefits of the investments in healthcare infrastructures can be derived primarily from morbidity and mortality changes, added quality of services or efficiency gains. Assigning a monetary value to health benefits is complex. The most prominent techniques are to refer to the market prices of the service or to use standard methods, such as the indices for increased life expectancy suitably adjusted by the quality which can be valorised according to the principle of lost income or to similar actuarial criteria. In accordance with this the most appropriate variant for the University clinical centre of Maribor is Variant 3.

Our methods try to forecast and analyse carefully the patient flows and trends in the area involved in the project. Special attention should be paid to the choice of the epidemiological data sources. Both presented methodologies try to forecast the trend in operating costs, specifically with reference to personnel, maintenance, and the replacement of equipment.

Considering the fact that the main economic benefits of health infrastructure investments are related to the human life value, analysts should focus on the value of statistical life evaluation approaches.

Testing the Possibility for Reducing the Papadopoulos/Heslop's PCI Research Variables by Combined Use of Factor and Regression Analyses

Igor Kostovski,

The primary purpose of this paper is to test the possibility for reducing the 36 variables for conducting PCI research that were suggested by Papadopoulos and Helsop [1]. In addition, respecting the specifics of the region of South-East Europe, the paper argues in favour of adding two additional variables to this list and tests their significance.

Related to the above stated, a series of factor regression analyses were conducted in order to reduce the number of variables. The factor analysis as well as the regression analyses were enabled by the data collected from a survey previously conducted in nine geographical regions in Macedonia.

The idea behind the paper is the attempt to reduce the PCI research variables in order to open the door for cheaper, faster and more extensive PCI research in Macedonia and the region of South-East Europe. Besides the aforementioned, the side focus of this paper is to introduce Country-of-Origin (COO) surveying in Macedonia.

Keywords

Country of Origin, Factor Analysis, Multiple Regression Technique, Product Country Image, Salient Variables.

1. Introduction

The phenomenon of *Country of Origin* (COO) has emerged in mid-sixties of the last century, and become widely understood as an important factor in the decision-making process in marketing thought along with other factors such as brand, price, warranty and colour. It was launched as a product of the increased trade between the nations and its significance continues to grow with each additional product traded between the nations. It is in human nature to evaluate each product purchased and compare it with other products. This single attribute has resulted in defining the core characteristics and traits of some country's products. For example, the German products are usually perceived as reliable, precise and of good quality, Japanese as hi-tech and modern, English as solid and traditional, etc. One can think of some of the dozens of products marketed by linking the product to their place of origin: Russian vodka, Scottish whiskey, French perfume, etc.

Among the many factors which are believed to influence consumer perceptions of products in an age of global competition, COO effects have attracted the biggest attention [2]. The studies conducted in the field of COO and *Product-Country Image* (PCI), tend to examine these consumer's perceptions. According to Papadopoulos and Heslop "a country's particular image influences purchase decisions significantly, quite often more so than a brand name" [3]. Another excellent example of the importance of COO and PCI is presented by the work of Tan and Farley who claim that such effects "are the most researched issue in international buyer behaviour" [4].

The world today is strongly following a path of globalisation. National market boundaries are blurring, opening the door to a single international market. The barriers of entry for non-domestic products are vanishing and the importance of PCI effects is being recognized even more. South-Eastern Europe is also experiencing a transformation of this type. It would be more correctly to say that it is experiencing a process of regionalisation, rather than globalisation, however the effects would remain the same. In the dawn of this new, large and open market, the marketers increasingly justify their actions with the results of the conducted PCI surveys. Thus, it can be easily concluded that as the regional market becomes more and more visible, the demand for understanding the PCI effects progressively rises.

2. Country of Origin (COO) and Product Country Image (PCI)

2.1 Introduction to the Issues of Country of Origin and Product Country Image

A valuable definition of COO was provided by Roth and Romeo claiming that “country image is the overall perception that consumers form of products from a particular country, based on their prior perceptions on country’s production and marketing strengths and weaknesses” [5]. Papadopoulos and Helsop moved this issue to a qualitatively higher stage by introducing the term Product-Country Image (PCI), defining it as “an image of a country and thoughts such image creates in the minds of the consumers” [6]. Another, more up to date, but also broader perception of PCI is suggested by Laroche et al. who claim that “PCI effects refer to the extent to which the origin of a particular product influences its evaluation” [7].

As Shapiro noted “Uncertainty about quality is a widespread and important feature of markets for most firms’ goods and services. Virtually all goods and services are impossible to be evaluated until they are used”. [8]

In order to overcome this unpleasant situation of being uncertain of a product’s quality, a customer may refer to the Country-of-Origin effect along with other attributes, before she/he makes the purchasing decision [9]. One may detect the similarity between this and the case when the price serves as surrogate for other (not available) information of a product’s quality.

As Papadopoulos and Helsop argue, the whole idea “was inspired by an apparently simple hypothesis that customers regard products made in more developed countries as being of higher quality than those made in less developed ones” [10]; however, the research results presented a more complicated picture than the expected one.

2.2 Different Dimensions of the Country of Origin Phenomenon

In the early years of studying the Country-of-Origin phenomenon, the issue was perceived and treated in its most general form, as a single-dimension concept (i.e., as “Made in” issue). Accordingly, Nagashima defined the COO as “the picture, the reputation, and the stereotype that businessmen and consumers attach to products of a specific country” [11]. The widely proved influence and importance of the “Made in” label effects were present until recently. Namely, in the mid 1990s, a considerable number of Bulgarian producers labelled their products as “Made in Europe” or “Made in EU”, rather than as “Made in Bulgaria”. The Bulgarian authorities have tolerated these actions due to their belief that this strategy might result in better selling of domestic products, both at home and abroad. Commenting on the issue Thakor and Kohli noted that when a manufacturer is concerned over a consumer reaction on a product’s country of origin, it may attempt to mask the actual origin [12]. They consider that this is usually a case in the less developed countries.

In the beginning of 1980s, Bilkey and Nes narrowed the scope of COO to the “country of manufacture” [13]. In many cases, however, the rising process of globalisation has allowed international companies to some extent to choose the COO of their product. This became possible due to the different parts that were produced in different countries and then assembled in the final product, or when a product is produced in one country and marketed as having the quality of products of another country. Acknowledging this fact, Chao suggests that such cases, when products are designed in one country and manufactured in another, do not support the one-dimensional concept of the COO [14].

The types of products (when designed in one country and manufactured in another) are referred as hybrids, and have considerably influenced the issue of Country-of-Origin. Namely, they have forced academics to start recognising two separate aspects or dimensions of the issue: design (conception, engineering) and assembly [15]. In light of this, Chao calls for abandoning the one-dimensional concept of “Made in” and adopt a bi-dimensional concept of COO, consisting of Country-of-Design (COD) and Country-of-Assembly (COA) [16]. He supports this action with the continually increased presence of hybrid products in the global marketplace. Five years later, the same author summarising the findings of several international marketing studies, concludes that the consumers have used their knowledge on a country in order to assume the quality and the purchase value of the product in question [17]. Commenting on this matter, Ho stated that “the idea of one single country of origin is becoming increasingly out of date and out of touch with reality” [18].

Recently, some other authors like Lin and Kao have even further decomposed the issue of COO, claiming that it actually consists of not two, but four dimensions [19]. Namely, they argue that Country-of-Parts (COP), Country-of-Assembly (COA), Country-of-Design (COD) and Country-of-

Manufacture (COM) are the four key cues in the process of buyers' purchasing decisions. Identifying this trend, Papadopoulos and Helsop stated that "made-in can mean manufactured-in, but also assembled-, designed- or invented-in, made by a producer whose domicile is in, and, often wanting to look like it was made in" [20]. On the other hand, besides this claim of Lin and Kao [19], some other authors, like Lim and O'Casey, consider that the need for extracting multiple country information, such as manufacture, design, assembly, etc.), further complicates such studies and reduces the relevance of overall COO information [21].

Product related variables Prime Group P	Country related variables Prime Group P	People related variables Prime Group P
P1 - Workmanship	C1 - Knowledge on the country	N1 - People's trustworthiness
P2 - Reliability	C2 - Political stability of the country	N2 - Rich/Poor people
P3 - Innovativeness	C3 - Admirable role in world politics	N3 - The people have refined taste for beautiful things in life
P4 - Quality	C4 - Admirable role in regional politics	N4 - Highly educated people
P5 - After sales service	C5 - Technologically advanced country	N5 - Hardworking people
P6 - Hard to find	C6 - Aligned with the domicile country of the research	N6 - Likeableness of the people
P7 - Attractiveness of appearance	C7 - More investments from the country are welcomed	N7 - Knowledge on the people
P8 - Knowledge on country products	C8 - More imports from the country are welcomed	
P9 - Value for the money	C9 - Likeness to visit the country	
P10 - Have what customer likes to buy	C10 - Willingness to have closer ties with the country	
P11 - Technically advanced	C11 - Ideal country	
P12 - Recognisable brand names		
P13 - Wide variety		
P14 - Normally buy a lot of country's product		
P15 - Expensive		
P16 - Willingness to buy country's products		
P17 - Proud to own country's products		
P18 - Country's products are not for people like me		
P19 - Good overall products		
P20 - Satisfaction with country's products		

Table 1 List of the 38 PCI variables used in the survey and analysis process organized in prime groups

In 2002, Papadopoulos and Heslop together with their international research group have established a comprehensive and extensive PCI research database integrating more than 750 publications by more than 780 authors [1]. Using the findings of three other authors, Kotler et al. [22], Jaffe and Nebenzahl [23] and Gold and Ward [24], and analysing the findings from the established database, the two authors have drawn number of conclusions, among the following one seems to be of great importance for future PCI researches: PCIs appear to consist of seven key constructs – three country constructs (comprising 16 variables) and four product constructs (comprising 20 variables). The general focus of the study was to test the significance of the three constructs for evaluation of buyer's willingness for purchasing a certain country products, and to test the significance of the variables proposed by Papadopoulos and Heslop [1].

With regard to these three categories of questions, for the purpose of the research, the question on the level of knowledge of the country and the people was divided into two separate questions – the level of knowledge of the country (coded as C1), the level of knowledge of the people (coded as N7), thus the number of questions increased by one. In addition this, acknowledging the regional aspect of the survey, additional – 38th question on the perception (positive or negative) of the regional politics of the country was added (coded as C4). A complete list of the 38 variables is presented in the Table 1.

3. Research

3.1 Factor Analysis of Coherent-Group System (Combined Pair of Prime Groups)

The overall survey has incorporated the following three steps:

- Research conducted by using a single-entity questionnaire,
- Factor analysis that should reveal the different factors influencing the buyers in Macedonia, and
- Regression analysis of the variables included in the survey in order to point-out the salient ones and reduce the total number of PCI variables needed for conducting a PCI survey.

As part of the step one of the process, a structured monolingual (Macedonian) questionnaire was used. Slovenia was chosen as a country to be researched in the survey. This was due to the following reasons:

- The admirable presence of Slovenian products on the Macedonian market,
- The significant quantity of Slovenian investments in Macedonia,
- The perceived stronger knowledge of the Macedonian buyers on Slovenia and its people.

The questionnaire contained 5 sections: Letter to the respondent, Instructions, Background Information, Evaluation of the country, its people and products, and Comments. A total of 8 questions related to gender, nationality, age, level of education, level of monthly incomes, etc., are incorporated in the Background information section. The main part of the questionnaire (i.e., the section for evaluation of products, country and people) incorporated the 38 aforementioned questions, which for analytical purposes were divided into three categories, i.e. prime groups: Product group of variables – 20 variables coded as Group P, Country group of variables – 11 variables coded as Group C, and People group of variables – 7 variables coded as Group N (see Table 1). The rating system of all questions was based on a seven-point Likert scale anchored at poor and good.

Thus, the survey was conducted on a sample of 460 respondents. A total of 343 subjects (74,6%) responded to the survey; however, in 31 cases the returned questionnaires were incomplete and therefore eliminated from the analysis process. The response rate of the fully completed questionnaires was 67,8%.

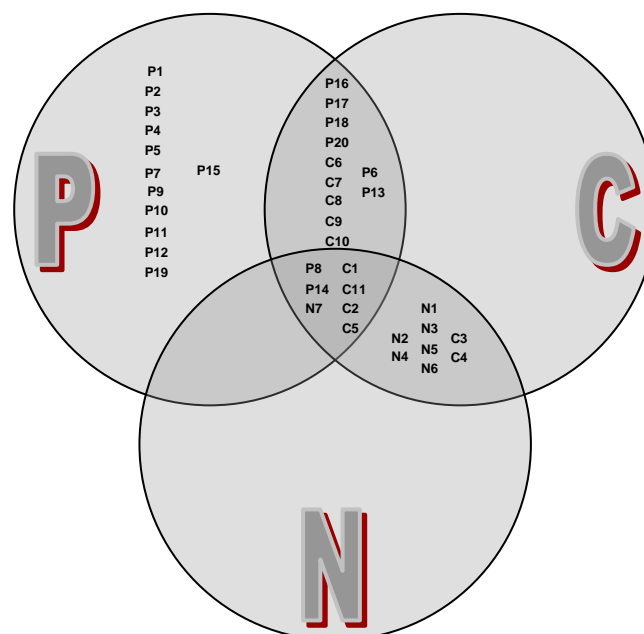

Figure 1: Graphical presentation of the prime group pairs factor analyses summary results

A logical starting point for conducting the factor analysis should be considering all 38 variables as single group (the PCN group of variables). However, keeping in mind that the pre-survey has obtained 312 valid responses, the N/K ratio (i.e., proportion between number of records - N and

number of variables - K) in this case equals 8.2 which is unsatisfactory and indicates an unstable system [26]. Thus, the results that will be provided by analysing the PCN group of variables will lack validity.

Consequently, in order to ensure a stable system (i.e., S/N ratio higher than 10), additional grouping of the variables was required. Therefore, the most reasonable action was to combine the already existing prime groups of variables, into a coherent-group system comprised of number of groups of coherent variables (for the purpose of this paper, each group (prime or factor group) that consists of variables that are strongly inter-related will be considered a coherent group of variables).

A combination of three factor analyses for investigating each of the three joined pairs of prime groups was conducted. The first pair consists of variables originating from P and C prime groups, the second one is formed by the P and N prime group variables, and the third one is created by merging C and N prime groups. In the first two analyses, the N/K ratio equals 10.1 and 11.6, respectively, which indicate limited system stability. The N/K ratio in the case of CN group analysis is 17.3, and therefore no signs of instability of that system were noticed.

A summarized graphical presentation of the three factor analyses results is offered in Figure 1. The figure clearly presents the affiliations of some variables to other prime groups. It appears that P1, P2, P3, P4, P5, P7, P9, P10, P11, P12 and P15 have strong affiliation to their “mother” prime group. The remaining 27 variables “demonstrate” doubtful group affiliation. For that reason, additional factor analysis was conducted in order to discover the precise affiliation of these variables. In light of this, one factor analysis was conducted for all variables included in the P segment (the p Group – P circle on the Figure 1 – 30 variables), and the second one included only the variables that are covered by the C segment (the c Group – C circle on Figure 1 – 26 variables). The summary results of these factor analyses are graphically presented in Figure 2. The N/K ratio for the p Group is 10.4, while for the c Group is 12, both presenting slightly stable systems.

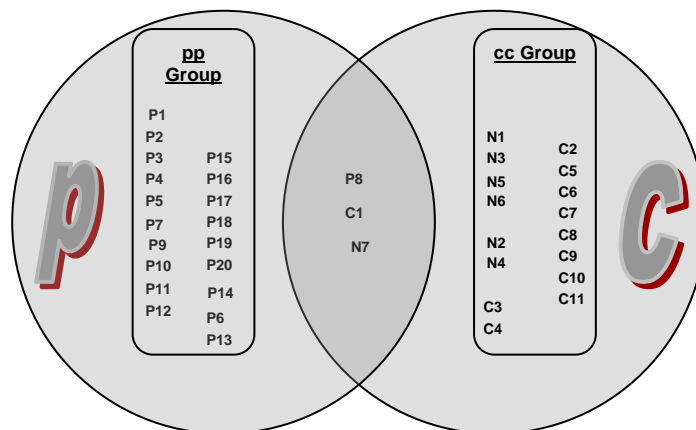

Figure 2: Graphical presentation of the summary results of *p* and *c* segments

The analysis of Figure 2 reveals that P8 (Knowledge of the products), C1 (Knowledge of the country) and N7 (Knowledge of the people) continue to present doubts over their group affiliation. During all factor analysis performed in this case, these three variables have also presented a very strong interrelationship among each other, and therefore might be considered as a separate factor. Therefore, the first group (the *pp* Group) will integrate all variables within the *p* segment (excluding P8, C1 and N7), while the second group (the *cc* Group) will incorporate the variables within the *c* segment (excluding P8, C1 and N7). The *pp* segment consists of 19 variables and its N/K ratio equals 16.4. On the other hand, the *cc* segment is composed of 16 variables, resulting in an N/K ratio of 19.5. Both group ratios are very satisfactory, ensuring significant stability of the two systems.

As result of the two latter factor analyses, four factors have been extracted from the *pp* segment (factors *pp*#1, *pp*#2, *pp*#3 and *pp*#4), and three factors were generated by the *cc* segment (factors *cc*#1, *cc*#2 and *cc*#3). Adding the previously identified (P8, C1, N7) factor provides the summarized table of variables organized by factors:

Factor *pc*#1 (P1, P2, P3, P4, P5, P7, P9, P10, P11)
Factor *pc*#2 (P14, P16, P17, P18, P19, P20)
Factor *pc*#3 (P6, P12, P13)
Factor *pc*#4 (P15)

Factor *pc*#5 (P8, C1, N7)
Factor *pc*#6 (C8, C11, N1, N3, N5, N6)
Factor *pc*#7 (C6, C7, C9, C10)
Factor *pc*#8 (C2, C3, C4, C5, N2, N4)

3.2 Multiple Regression Analysis

The idea behind the regression analysis of all factor elements was to test whether some of the 38 variables are more significant than others and thus, to reduce the overall number of the needed PCI variables. In light of this, regression analysis was conducted for each of the eight factors separately. The analyses have pointed to the results, presented in Table 2.

	Factor #1	Factor #2	Factor #3	Factor #4	Factor #5	Factor #6	Factor #7	Factor #8
P1	X		X		X	X		
P2	X		X					X
P3	X					X		X
P4	X	X				X		
P5	X							X
P6	X		X		X			
P7	X		X	X				
P8		X			X			
P9	X	X		X			X	
P10	X							
P11	X		X					
P12	X		X					X
P13	X	X	X					
P14	X	X	X	X	X			X
P15	X	X				X		
P16	X	X				X		
P17		X				X	X	
P18	X	X				X	X	
P19	X	X						X
P20		X						
C1	X	X			X			X
C2	X	X	X			X		X
C3	X						X	X
C4	X				X	X		X
C5	X	X	X			X	X	X
C6						X	X	
C7							X	X
C8	X	X				X		X
C9							X	
C10		X				X	X	X
C11	X	X				X		X
N1		X		X		X		X
N2			X		X	X		X
N3	X	X		X	X	X		X
N4	X					X		X
N5	X				X	X	X	X
N6					X	X		X
N7			X		X			X

Table 2 Significant variables identified for each of the eight factors

The key for evaluating the usefulness of the regression technique to the COO research lies in the value of the equations' adjusted R squares. The values of the highest and the lowest adjusted R squares equal 0.706 and 0.154, respectively, while in all remaining cases it mostly ranges between 0.400 and 0.600. This means that in majority of the cases, the dependent variables can be 40 to 60% explained by their significant variables, which indicates that they cannot provide a solid accuracy of the results all variables of the system. However, some high values of the adjusted R squares of certain variables can ensure legitimate use of those variables' regression equations. Accordingly, instead of being generally applicable on all variables, the approach can be used only on those variables with substantially high values of the adjusted R squares

A closer inspection of the adjusted R squares for each factor separately, reveals that this particular approach can be used on the variables consisting Factor #2, which probably is one of the most important factors of all. The factor incorporates six extremely significant variables from the P prime

group: Buying a lot of products, Willingness to buy, Owning the products, Not for the people like me, Overall good products, Satisfaction of the products – which may be considered as core COO effects. The regression equations related to this factor point to a total of 19 variables that are significant to the six COO factor variables. However, this paper will focus only on the variables with the highest adjusted R squares (i.e., P16-Willingness to buy, P17-Owning the products, P19-Overall good products and P20-Satisfaction of the products), which for the purpose of this paper will be referred as the four COO variables.

The regression equations of the four COO variables identified a total of 16 variables (P4, P8, P14, P15, P16, P17, P18, P19, P20, C1, C2, C5, C8, C10, C11, N3) which are significant to them. Nine of them belong to the P prime group, six to the C prime group, and one to the N prime group. The system of equations has also shown that the four COO variables are significant to the remaining COO variables. The values of the adjusted R squares are very favourable, ranging from 0.649 to 0.706.

In conclusion, this particular approach of including the multiple regression analysis technique in the COO research has presented useful results. Namely, the number of COO-related research variables was reduced from 38 to only 16 (a 58% reduction), which may show as very beneficial for rapid expansion of the PCI research in Macedonia and the region of South-East Europe.

In addition, the regression analysis provided the answer to another important question – the validity of adding two additional variables (C4 and N7) to the original list of 36 variables. Namely, by analysing the variables which consist the factors pc#5 and pc#8, one may conclude that their “twin” variables C3 (Admirable role of a country in world politics) and C1 (Knowledge on the country), belong to the same factor, and therefore may question their contribution and usefulness to the system. However, the regression equations identified the significant variables for each variable separately, and offer additional arguments for deciding on the relevance of the two variables. Probably the most important finding, emerging from these results, is that all system variables are significant to at least one other system variable. For the case of the two aforementioned variables, C4 is significant to four other variables, while N7 to three variables. Therefore, it may be concluded that both variables are part of system’s significant variables, and thus, their importance to the system is widely confirmed. Consequently, this paper argues in favour of including these two variables in all future COO researches in Macedonia and the region, as well as examining their relevance in studies to be conducted in the other countries in the region.

3.3 Limitations of the Study

This particular study has a number of limitations which may partially influence the results and findings of the research. Several limitations should be kept in mind when interpreting the results of this study. Namely, the initial constrain is due to the number of respondents planned which is far lower than a representative sample size in the case of Macedonia. This study has been further constrained by the inadequate representation of the Macedonian population within the sample in terms of ethnic affiliation, gender, educational background, etc., besides the efforts made towards decreasing the demographic bias. This implies that the survey results cannot be used for official purposes and cannot provide the adequate accuracy and should be perceived only as an attempt to introduce and foster the foundations of the COO research in Macedonia.

4. Conclusions

The 36 variables identified by Papadopoulos and Heslop [1] were the actual starting point for this research. Additional two variables, that latter confirmed to be significant for the system, were also joined to this list, resulting in a total of 38 variables. The factor analysis has revealed that the 38 initial system variables that were used in the survey can be reduced to only eight. Naturally, these eight factors can not completely substitute the information that can be collected from the answers of all 38 variables, but they are offering a possibility for fast collection of data related to several tens of countries.

The factor analysis results have confirmed and supported the findings of number of authors on the large number of different factors influencing the process of purchasing decision-making. This survey, as many before it, has also confirmed that COO effects, price, and brand (three strong marketing elements) were clearly distinguished by the respondents. In addition, these initial results related to the Macedonian PCI factors can be also used as a base point in the process of identifying the importance (i.e., the influence) that each factor has on the purchasing decision.

One may question the relationship of the country and people related variables (i.e., questions) with consumer evaluations and attitudes towards products. However, the results of the regression analysis presented in Appendix G strongly oppose to this assumption by presenting a clear influence of the majority of C and N group variables (excluding C6, C7 and C9 variables) to the P group variables. Thus, it can be concluded that each researcher that aims to investigate purchasing patterns should research variables originating from all three prime groups (i.e., P, C and N prime group).

The results of the regression analyses resulted in the following conclusions:

- Each system variable is significant to at least one other system variable meaning that all 38 variables are salient; thus, the number of research variables cannot be reduced, and therefore, to study all the different dimensions of the issue, no reduction of the variables should be considered.
- The two new variables added to the list of the 36 original Papadopoulos/Heslop's variables, prove to be significant and thus should be included in the research process.
- The results unveiled the relationships among all system variables (i.e., which variables influence a particular variable).
- The most salient system variables (salient to more than 5 other system variables) are the following: P14-Buying a lot of country's products, C2-Political stability of the country, C5-Technological advancement of the country, N3-Country's people level of refined taste for beautiful things, and N5-Hardworking people.
- Product related variables are influenced by a total of 35 system variables, while the most salient to products (salient to at least 5 product variables) are the following variables: P1-Product workmanship, P9-Product value for the money, P14-Buying a lot of country's products, P15-Level of product pricing, and N3-Country's people level of refined taste for beautiful things,
- The low values of the regression equations' adjusted R squares cannot guarantee a solid accuracy of results for all variables of the system and this approach cannot be used for the system as a whole. However, some high values of the adjusted R squares of certain variables can ensure legitimate use of those variables' regression equations. Accordingly, instead of being generally applicable on all variables, the approach can be used only on those variables with substantially high values of the adjusted R squares,
- A total of 19 variables influence the six variables consisting the COO factor (i.e., Factor pc#2), while 16 variables influence the four COO variables.

THE TOURISM AND ITS IMPROVEMENT – KEY FACTORS FOR COUNTRY DEVELOPMENT: CASE STUDY OF THE REPUBLIC OF MACEDONIA

*Kosta Koteski*¹

¹*Institute for Sociological and Political Juridical Research, Skopje, Macedonia,
k_koteski@hotmail.com*

The aim of this paper is to present the tourism sector and its precondition for international country development with the case study of the Republic of Macedonia. Also, the purpose of this study is to identify the tourism potential, examine the significance of tourism to the national economy and evaluate the marketing of the Republic of Macedonia as a potential tourist destination. The concepts of tourism development include government strategy, planning and promotion activities for tourism. Policy recommendations are created to design a strategy framework to improve the performance of the tourism sector in Republic of Macedonia.

This study provides some perspectives for understanding tourism planning and the importance of marketing promotion in creating the image for awareness and acknowledgement of the country's tourist product among international tourists markets. It provides useful empirical data and information that help tourism policy makers in Macedonia to develop their plans and strategies for the tourism sector, mitigate its problems and overcome its obstacles, which overall lead to sustainable tourism development.

The primary objective of this paper is to use the service sector setting of the Macedonian hotel industry to help the country to explore the strategy for planning the expansion of the tourism sector over the next years.

This study concludes that, without government contribution and commitment, together with an appropriate strategy and adequate budget for promotion, the potential for tourism will not be achieved. Creating strategies and policies for tourism must be carefully considered with high quality expertise which will lead to well-organized and sufficient plans to achieve sustainable tourism development that can make a significant input to sustaining the national economy.

Keywords

Country development, Government strategy, Quality service, Tourism development.

1. Introduction

Macedonia is a country which is recognised by its culture and art, also by the many of historical monuments which can be found all over the country. Very often recognised as a 'Balcan pearl', the beauty of the country can be a significant factor in developing the tourism sector. Also, the friendliness and the kindness of the people symbolize Macedonians as welcomed and warmed people. However, in order to attract more foreign tourists, the country needs a good promotion which will increase the international awarness and this will lead to a positive perception and economic development of the Republic of Macedonia. The government has to use all natural resources and the culture program in order to attract more foreign tourists to visit Republic of Macedonia.

This paper will focus on the development of the tourism sector and the hotel industry in the Republic of Macedonia. Tourism promotion is an important aspect in promoting and selling the tourist products. The countries like Macedonia usually suffers from a number of problems, the most important of which is the difficulty in promoting the tourism potential in the country as well as the level of the quality of service offered to the travelers. This may be due to the lack of expertise and funds allocated for the

purpose of marketing or the low level of employee's interest to make a career in this industry in the Republic of Macedonia.

2. Development of the hotel industry

The development of the hotel industry is in a close relation with the development of the tourism sector. The hotels have a very important role in many countries through their ability to provide hotel guests with different services: accommodation, meetings, conferences, seminars, recreation and entertainment. According to Medlik [1], the importance of the hotels is through the following: the hotels provide their guests with different services such as meetings, conferences, recreation and entertainment, the hotels are essential part for the economy as they allow continuous movements of passengers, communication and distribution of goods and services. In many areas, hotels are very important attractions for their guests who are able to spend more money during their stay at hotels instead of staying at home. And, at the end, the hotels are very important for the national economy as they employ many people in different departments.

As the changes in the business environment continuously increasing, the hotel industry continuously meets the challenges in different areas such as finance, development, marketing and operations [2]. The internet continues to create new opportunities for the industry and change the market in many different innovative ways. On the profit side, the easier access to information for travelling and making bookings on line will possibly increase the number of travelers and the users of those services. The hotels became aware of the marketing potential of internet and they installed a very fast internet connection in their rooms. Also, every hotel aims to offer a perfect service to its guests which will lead to entire guest's satisfaction.

3. Macedonian hotel industry

Macedonia tourist industry in the past ten years has been showing some growth as well as some falling. The number of tourists has been going down for up to 100 000 tourists and in 2002 the number of tourists including business tourists was about 125 000. This was far below the 1980s when Macedonia had over 600 000 tourists who visit the country. Since 2003 until 2007, the number of tourists in the Republic of Macedonia has increased and from 157 000 tourists in 2003, this number has reached 230 000 tourists[3].

In the period between 2006 and 2008, the biggest contribution to the GDP for about 44 % was through the services including trade, hotels and restaurants, transport, financial consultancy, activities related with real estate and public institutions, health, education and other services. On the other side, the industry, including energy and constructions, had about 25 % contribution to the GDP. And, at the end, the agriculture had about 10 % contribution to the GDP [3].

3.1 Tourist traffic in the Republic of Macedonia

The tourists traffic in the Republic of Macedonia in the period between 2003 and 2007 is shown on figure 1:

Figure 1. Tourist traffic in the Republic of Macedonia.

Source: Ministry of economy of the Republic of Macedonia, 2010

The figures have shown that the number of foreign tourists continuously increased in the period between 2003 and 2007 which is a good sign that the awareness of our country is growing and this trend needs to continue in the future. However, we can see that there is no continuous increase or decrease of the total tourists in the Republic of Macedonia in the past years. This is why it is difficult to announce that the government strategy for attracting more foreign tourists over the past years gives significant results. We need to see continuous increase of the total tourists to be able to agree with the government strategy for attracting more foreign tourists.

According to the National Institut for Statistics in the Republic of Macedonia in 2011 [3], most of the foreign tourists in Republic of Macedonia have stayed in a four star hotels comparing with home tourists who mostly stayed in a two star hotels. The reason for their stay in different star hotels is probably the budget, but also new visitors would prefer to stay in a better hotel, so they will feel more secure and they will expect to get a better service.

4. Key factors that affect hotel guest's decision

There are four major factors that affect hotel guest's opinion for the atmosphere at the hotel: employee's personalities, their greetings, leisure condition and employee's behaviors [4]. According to other authors, key factors that have an effect on the hotel industry are: the price, the location and the quality service [5]. The price is the main reason why the customers choose the selected hotel. After the price, the safety is the major factor for choosing the hotel, and the third factor is the hotel location [6]. Pricing is one of the most important elements in the tourism marketing mix. It signals to the customer the nature of service on offer. The right price should both satisfy tourist and meet the objectives of the tourist organisations. It is in this sense that the individual makes a judgement as to whether the price is in an acceptable range. Hence, pricing decisions are fundamental for the profitability of the tourist organisation, as it has immense impact on demand and sales volume.

Apparently, there are six major factors for the success of the hotel: the quality service, business environment, the price, the rooms and the reception, the food, the ability for leisure activities and the safety of the hotel [7]. Any of those factors has to be on a high level to make customer happy and leave the hotel fully satisfied. Sheldon [8], talks for innovation as a major factor for the hotel's success. Some authors look at the information technology as a crucial factor for the success in the hotel industry [9]. Creating an excellent web site became a good advantage to attract hotel guests.

4.1 The importance of the quality of the service for the hotel industry

The hotels that put priority on better quality service are aware of the importance of the 'word of mouth' and they will do anything to satisfy hotel guests. Some of the hotels believe that through their survey for hotel guests and their comments, they will have a clear picture about the level of the quality service within the hotel. Also, some hotels perceive that the occupancy in their hotel compared with other hotels can be a good indicator for the level of customer satisfaction. Unfortunately, many of those models which are made through survey of hotel guests are not credible measure for the satisfaction of hotel guests which statistically is valid [10].

However, in any case the quality of the service is a crucial factor for customer satisfaction and the researchers need to be focused on new areas such as training for the employees, performance orientation which will all lead to real customer satisfaction.

4.1.1 The role of hotel managers

Hotel managers has the most important role In the process of managing the performance in the hotel industry and they should be the one who needs to adapt its strategy in order to increase the number of its guests through introducing a very high quality of service. David [11] implements five main managers activities: Planning, organising, motivation, employment and controle.

Planning is the process that is nessecarly to connect the past with the future and increases the chances of achiving its goals. This process needs to have manager's involments, but also involments and support from all other employees. The process of plannning can easily affect all other activities (organising, motivation, employment and controle). Different level of management plans activities for different time, low level of management normally plan activities between two weeks and six months, middle management plans activities between six months and two years, and the top management plans activities for a period between two and five years.

If the monthly salary is one of the crucial factors for motivating the employees in the hotel industry in the Republic of Macedonia, then this industry is facing a big problem. One charateristic of the hotel industry in the Republic of Macedonia is the lowest salaries to its employees. This probably decreases the motivation for working in this industry and the students loose the interest to continue with education in this field. According to the National Institut for Statistics in the Republic of Macedonia in 2011 [3], the average salaries in the hotel industry are amongst the lowest paid in the country. The average net salary in Macedonia in month April 2010 was 20 449 MKD and the average monthly salary (for the same period) in the hotel industry in Republic of Macedonia was 14 209 MKD, which is about 30 % lower than the average net salary in the country. The low salary can affect the quality of the service which is one of the key factors to make hotel guests loyal to the hotel.

Another problem within this industry is that our country is not seen as an attractive destination comparing with other neighboring countries (who has access to sea), which means the requirements for new employees is not very high. At the hotels around the lake of Ohrid, the hotels are looking for new employees only during the summer period. The employees come to work for a very short time (approximately one or two months) and their priority is to receive only a salary for that period. They do not see opportunities for longer stay at the hotel and that is why their motivation is on a very low level. Their employment contract is generally for a few months and this does not give them an opportunity to look at those positions in a long term. This creates a problem for the hotel managers to have a better selection when they choose new employees. The solution for this is if they can possibly give a guaranty to the new employees that they will keep them for long term (or call them when there are available positions), but, of course, hotel managers need to be satisfied with their work commitments and professionalism. This will increase the competition for giving better performance at work, so the quality service can be especially improved.

The process of employment is very important for the hotel industry and the employment of the right candidates is the key for the success of every hotel [12]. If the company makes the right choice and employs the right candidates, then this will save time and money, which in another case will be spent on training for the employees. Every employee, especially the one who is in a direct communication with hotel guests needs to have the essential knowledge and skills to be able to offer a first class of service quality [13]. The question is how the organization should identify which candidate is the right choice for the company.

4.1.2 The importance of the training for the employees

It is very important for every hotel to be able to give enough education to its employees so they can professionally do their job. This can be done through additional education including attendance of seminars, trainings etc. The continuous investment in training and education are very important part for organization's success which enables employees to improve their performance and increases their motivation to a high level. In our country, hotel managers still look at those costs as wasted amount of money which is spent and does not give the wanted results. They need to understand that the continuous training and an additional education are among the factors that increase employee's motivation and this will lead to professionalism and perfect quality service offered to the hotel guests. The hotel manager's role should be to define, plan and forecast the return of investment in training and education and they should give a direction how to maximize the profit. It is necessary to give training to all employees, but especially to the employees that have a direct communication with hotel guests. The expenses for this kind of training and education will result with good handling of unexpected situation and flexibility in adaptation to hotel guest's requirements and this need to be aim of every hotel. The high level of quality service will give an opportunity for recommendation from the perspectives of hotel guests, and they should pass the message that Macedonia is the place that everyone needs to visit.

4.2 Government strategy to attract more foreign tourists to the Republic of Macedonia

The subvention that are given to the foreign tourists are definitely in a direction to increase the number of incoming tourists, but this model has to be more deeply analyzed and promoted in the best possible ways. The idea is to inform as more foreign tour operators as possible and get them excited about tourism potential in the Republic of Macedonia.

If we look at the SERVQUAL instrument for measuring the quality service, there are five basic factors: exterior design of the hotel, its safety, the willingness of the employees to offer a fast and prompt service, their knowledge and their friendliness and the opinion that hotel guests have for the hotel management and its organization [14]. If we take those factors as basic factors, 85 % of the all respondents in the Republic of Macedonia have stated positively to those factors. It is very important to notify that those results are based on the 4 and 5 star hotels in the Republic of Macedonia. The percentage of satisfied customers in the hotels with 3 or 2 stars will probably be much lower. Those results should be additional motivation for the government in creating the strategy for attracting more tourists to the Republic of Macedonia.

There are many institutions in Macedonia that have a priority to promote the country as a potential tourist destination. Those institutions are: the Hotel Association of Macedonia (HOTAM), the Agency for promotion of the tourism, the department for tourism at the Ministry of Economy, the department for tourism at the Chamber of Commerce, Association for touristic agency and others. It must be a good coordination among those institutions and also, well organization.

Both, international tourists and Macedonian tour operating companies viewed Macedonia as a small and beautiful country nestled in the South East of Europe who offers a unique blend of natural wonders, traditions and cultures as well as long tradition of first class hospitality and excellent quality service. The majority of Macedonian tour operating companies, who sells Macedonia as a holiday destination, have an average degree of familiarity with Macedonia as a holiday destination. There are many tour operators that offer Macedonians to go on holiday abroad, but not many tour operators see the potential in promoting Macedonia to the home and foreign tourists.

The majority of foreign tourists are not satisfied with the price of the tickets to visit Macedonia and also with the problem of not having a direct flight to most of the biggest European cities including London, Paris, Madrid and Moscow. The transfers are normally not convenient for the tourists, especially for the business tourists. Also, some foreign visitors are facing some difficulties with visa entrance procedure. Awareness, knowledge of the country, and safety were major reasons over the past years for foreign travelers eliminating Macedonia as a tourist destination among other tourist destination. However, it has been some improvements over the past few years regarding the promotion campaign of the country and this trend needs to continue.

5. Conclusion

The tourism in the Republic of Macedonia is a growing sector, but not enough developed touristic infrastructure, the budget constraints, and the promotion strategies that requires immediate consideration are the major barriers that affect tourism industry in the Republic of Macedonia and this will lead to a slow development of this sector. The tourism will not be developed on the satisfactory level if there is not a high contribution and maximum commitment from the government and if there is not a sufficient strategy and adequate budget for marketing promotion. There is an urgent need for creating of a strategy for tourism promotion which will be carefully consider by the high quality experts within this industry which will lead to very well organized and effective plans and ideas which aim is to achieve sustainable development of the tourism from one side, and also this will have a positive influence to the national economy.

Developing a model which will increase the number of foreign tourists is mainly dependent on overseas tour operators. Large tour operators have incredible control on directing a considerable influx of tourists to a particular destination, by organising package tours aimed at cutting the cost of travel and making holidays easier to be undertaken for travellers from different demographic backgrounds. Marketing promotion is essentially a process of communicating with selected target markets. Most promotional activities require an investment of time and money with careful planning in order to achieve excellent results. The promotional tools selected will essentially be determined by target markets and marketing budget. In the tourism industry, the satisfaction of people to travel and see new places, depends, not on the efficiency of one producer but rather on the performance of numerous organisations of different kinds, with not always similar objectives, operating in different places and at different times. To be successful in marketing a tourist destination, co-operation between public and private sectors became essential. Foremost, the right promotion mix must be developed where each of these is used as needed. In fact, the tourism marketer has most control over advertising and sales promotion. Both of them are created, implemented, and paid for by the marketer, while personal selling and public relation are the opposite. The first one is done indirectly through travel agents and the second is produced through the media. It is, therefore, meaningful for the tourism marketer to sustain good relations with both the travel trade and the media.

At the end, it is very important to have a clear picture about priorities in the tourism and what is the target group for the Republic of Macedonia, whether the tourists will be targeted by the culture offer, their budget, archeological wealth or the entertainment life. However, not matter of what group of people will be targeted, all hotels need to have intention for offering a perfect quality service, because every guest, not matter of his/her intention for the visit, will be expecting a high quality service from the all employees at the hotels in the Republic of Macedonia.

Emphasizing the role of creating successful entrepreneurial marketing strategies, this paper aims to point-out the key factors in consumer behavior analyses, as a cause for creating customer satisfaction. The total effectiveness of every marketing strategy is basically depending on how well a company recognizes, classifies and manages different consumer demands and actions.

Through the analyses of consumer behavior, emotional and cognitive aspects, and consumer surroundings, entrepreneurs can use this data to develop effective-based marketing designs. These concepts of common consumer actions as a result of their intrapersonal emotional reactions and their attitudes can be explained in correlation with the natural individual characteristics and their common social development.

Although long-term and constantly continuous work, consumer behavior analyses surely helps in better understand and clarifying the customer demands, which at the end, is the ultimate goal of every entrepreneur.

Keywords

Consumer behaviour, Consumer analysis, Entrepreneurship, Marketing, Marketing strategies

1. Introduction

In the dynamical surroundings of today's familiar characteristics of this global economic world, and particularly in the free market economies, the entrepreneurial marketing, as one of the basic tools of entrepreneurial existence, has the key role in creating innovative and growth-based concepts of the marketing itself. Basically, in every free-market national economy, entrepreneurship activities are involved in more than 85% of all enterprises. On a local and regional level, entrepreneurial marketing strategies are the main force of the trade and services economy. Therefore, satisfying customers' needs becomes natural right and a business obligation for every entrepreneur. On the other hand, the concept of marketing-oriented company is a choice, which allows more detailed understanding of the consumer needs, and finally – developing ways to satisfy those needs. The basic model of analyzing the consumer's behavior is dynamic but very broad field of marketing research and it has huge potential for effectively analyzing the thinking processes, behaviors and actions of different individuals or groups, and contributes to delivering the required marketing results. In this particular part, the entrepreneurship itself carries the straight of the direct involvement with the clients, understanding their feedback and desired needs, as well as the aspect of creating fast, flexible and adequate marketing approach.

2. Entrepreneurs Marketing – dynamics and effects

What makes the marketing driven by entrepreneur's principles so effective? If we analyze the entrepreneurial marketing researches, we can see that they are fundamentally made-up from several basic economic principles:

- client-orientation;
- implementing in relatively short period of time;

- fast feedback info;
- change-oriented flexibility

These kinds of starting positions in collecting, classifying and analyzing the feedback information and putting them into the mechanics of the future strategies of marketing-planning, as well as in development of the business plan and business model in particular, can significantly contribute to the success rate of satisfying consumer's needs. Therefore, the aspect of consumer behavior can be freely accepted as "moves vivendi" of the process of creating satisfied clients. Using the consumer behavior analyses, this powerful "scientific tool", the existing entrepreneurs can be brought even closer to the so-demanded competitive advantage to their businesses in front of other competitors on the market.

Also, the fact that this consumer behavior analyzing tool is very dynamical category which seeks permanent monitoring of the available resources, and even adding new ones, makes good entrepreneurs not taking them for granted, and as a result, the gained effects are far more clear and more precise. The fact is, every company should (and must) have this determination as their prime goal – the satisfied clients.

2. Analysing the consumers behaviour

According to the American Marketing Association, Consumers' Behavior is "a dynamical mutual action of all emotional and cognitive elements, surroundings and the behavior in which a certain person implements the trading aspect in his life" [1]. This particular definition is maybe the most clarifying definition that incorporates the key parameters in understanding the full concept of consumer behavior.

The behavior of the average consumers is always dynamic. It includes constant interaction between the businesses, their products, the marketing mix, consumers' needs and business current and future clients.

The fact is that consumer's behavior is "mutual action of all emotional and cognitive elements". In an open reaction, consumers often use the system of emotions and cognitions, which are mutually mixed in order to bring them into a conclusion of making a decision of taking or not taking an adequate action of the decision-making process.

"The surroundings and the person behavior" are the two key factors that can stimulate/dissimulate certain desired or undesired behavior or action in the decision-making process.

"The trading aspect" is a process that formulates certain individual actions which that particular individual is willing to trade for some other good or service.

According to this, the elements of the necessity of cognition and analyzing process can be put into 3 basic elements of consumers' behavior [2] and their strong connections, which can be a subject of broader scope of view by the decision-makers in the entrepreneur marketing segment.

Picture 1: The three elements of consumers' behavior analyses

2.1 Consumers' behavior

Consumers' behavior is a process which recognizes reviews and analyses the actions of the individuals, through defining their physical procedures in buying or procuring the goods and services that they need. But, this way of behavior doesn't include, or specifically excludes the mental activity of the individual. This particular type of behavior is especially important for the entrepreneurs, because only this kind of behavior can result in actual buying the goods and services that one company can offer on the market. Although the behavior itself cannot be perceived as safe-sustained process, which in fact can be also said in the context of consumers' surroundings and the emotional and cognitive effects, it represents the first and very significant element in successfully understanding the basic causes and motives of the specific actions undertaken by the specific consumers. The physical behavior of the consumers can be observed from several stand-points:

2.1.1. The Consumer-product Connection

The Consumer-product Connection is a pretty underestimated subject of matter considering the big companies. They spend significant sum of money each year on understanding these values. On the other hand, entrepreneurs can relatively easy evaluate and estimate this type of connection relaying just on the fact that they are actually and physically closer to their clients and are in direct communication with them, which gives them the unique opportunity of gaining fast feedback and a chance to make competitive advantage. Every salesperson should know, understand and use the cognitive and emotional aspects of the consumer-product relation [3]. Successful entrepreneurs which are familiar with these opportunities, use this advantage like the consumer-product connection with bikes, cars, clothes lovers and people who enjoy new technologies, books, extreme sports... They should always have in minded the fact that consumer on the one hand, and salesman or manufacturer on the other, have often different or sometimes totally opposite views on the product characteristics, whether they may be technical or emotional.

This Consumer-product Connection may also refer to brand-loyalty. Many research projects which deal with the brand-loyalty confirm that these types of connections between the clients and the company trade-marks are pretty strong. That's why it's very hard to pursue certain clients to give-up a certain brand. The next picture gives a clear view of the existence of strong connections of the consumers with some types of brands [4].

Picture 2: Consumers connection with certain brands

Personal relevance among people has also significant role in consumer-product connection. If salespersons can effectively understand this connection, it can become useful marketing segmentation tool having in mind the personal relevance of the consumer [5].

2.1.2. Decision Making

Making a decision on buying or no-buying a product/service from consumers' point of view is treated as solving a certain problem. If we elaborate the needs and goals of the buyer in relation with his/her desired values, we'll get a system of values-decisions whose primary objective is to satisfy some of that needs and goals. Although it seems rather complicated, these issue of problem solving which the average consumer is facing, actually includes simultaneously delivering a set of decisions, and then solving a few smaller problems. These kind of real processes of solving given issues consist of multiple continuous interaction between cognitive processes of the customer, his/hers behavior and the aspects of social and physical surroundings [6]. The problem-solving model consists of the following components: 1) recognizing the problem; 2) searching of alternative/s; 3) evaluating the alternative/s; 4) buying/no-buying decision [7].

2.1.3. Time as a decision –making factor

The “time” factor has a significant impact on decision making issues, and with that, it has a significant impact of the whole process of making decisions. Time as such, affects:

- consumers' intentions; and
- consumers' behaviors

Consumers' intentions are those desired actions which are characterized with buying goods and services. According to the marketing criteria, the time spent from the moment of exposure on the marketing tools of the companies and perception of those messages, until the time spent in buying the product/service, can significantly change the original intentions of the consumers. For example, one survey shows that around 60% of the people which have intended to buy a car have actually bought a car during a one year period [8]. In broader sense, the time itself is that key factor that lowers the precise forecasts on buying actions in relevance to consumers' intentions to the concrete actions. Unexpected events on the other hand, can change consumers' intentions in a relative short amount of time. One electrical appliances manufacturer once asked his customers which were entering his shop which brand they intend to buy. From those who have responded, only 20% had actually bought that same brand [8]. Obviously, the events or the situation that occurred inside the shop had successfully changed the intentions and behavior of the consumers.

2.1.4. The Internet – useful shopping decision-making tool

Lately, the Internet becomes more dominant media not just in the field of unlimited source of information, but also in the field of specialized data-base browsing, which gives customers relevant info on products, services and the companies any given time. The power of the Internet is excellent chance for entrepreneurs of better and easier understanding of their customers, as well as directly introducing their products, services and business operations, and even getting a fast feedback directly from their clients. Although the e-commerce sector is rapidly increasing, still, most of the customers refuse buying all kinds of stuff on the Internet. The comfort of “shopping” in comparison with, it seems – still difficult and complicated ways of “on-line shopping” and replacement of senses, smells, the touch, sounds and stimulations of all senses in good-old shops, cannot be easily replaced with the advanced technology of the Internet shopping. Still, relevant info-browsing, as well as testimonials and recommendations of other clients about using certain goods or services cannot be totally ignored [9].

2.2 Emotional and Cognitive aspect of the consumer

As especially important part of the consumers' behavior analyses, both emotional and cognitive processes are presenting powerful tool in entrepreneurs marketing chain. Although, knowing the emotions and thinking processes often seek a continuous and deep analysis, which sometimes even

exceeds the frames of the business management or the company itself, it's very important that every good manager recognizes his clients' behavioral elements.

The emotional and cognitive aspects can be easily interpreted as feelings and thoughts. As opposite as it seem, the human brain functions in that way that, they cannot be studied separately because of their compatibility. The system of human feelings and thoughts is one unit, it has mutual interaction, and it compliments on many different levels. Both emotional and cognitive parts are products of the emotional and cognitive systems, and even separate, they are very connected in influencing each other [10]. Individually, every person has a unique interweavement of those two systems.

The emotional system is consisted of four main types of emotional reactions: 1) emotions; 2) concrete feelings; 3) moods; 4) values [11]. Any type of reaction may cause positive or negative reactions among consumers. It is important to mention that, the emotional system behaves reactive and impulsive. Reactive because it cannot plan, forecast or make decisions on meeting targets on its own, and impulsive because it reacts automatically on surroundings or on different concepts, like colors for example. Also, the emotional system is difficult to control. It's an impulse reaction, although the attitude reflecting on that specific reaction can be easily controlled. From physical standpoint, emotional reactions are easily noticed and you can physically feel them on your body.

The cognitive aspect on the other hand is an evolutionary process which performs highly sophisticated mental processes of understanding, evaluating, planning, making decisions and thinking [12]. This cognitive aspect has particular functions of interpreting, creating and understanding the personal experiences of the consumer. As its secondary objective, cognitive aspect can identify individual goals, ways of fulfilling them, and setting alternative ways of reaching them.

In today's world, the experts opinion on which of those two aspects – the emotional or the cognitive is more dominant are also divided. Some of the experts claim that the emotional part is more dominant simply because it is based on instinctive reactions. Others claim that the cognitive part should be more dominant because of man's highly refined characteristics of the evolutionary and rational process of thinking. Anyway, from marketing point of view, the most common approach is the one that recognizes both systems as one mixed system that, apart from other relevant occurrences shouldn't be overlooked in the role of consumer behavior analyzes, and at least should be positively used.

The attitude is also called "the necessary concept in modern American social psychology" [13]. Today there are more than 100 possible definitions of attitude, but the most accepted and, as it seems, the simplest is the one of Fishbaine and Turston that says: "the attitude is the level of feelings that a certain person has towards a certain object" [14]. The attitude actually is emotional valuation created by the cognitive system. In general, it presents a positive or a negative reaction to a certain product, trade mark, idea or a concept, through witch an individual defines its standpoints on certain issue. The personal view of the authors of this text is that the attitude refers more to the process or the benefit of the usage of some form or idea from the consumer side, then to the object or the intention that it's referred to. In short terms, if the subject is a product or concept of smaller significance to someone, then the attitude to that product or concept will be insignificant and vice-versa. In practice, even neutrality is an attitude, although in marketing it is considered that neutrality can't produce strong reaction from customers – at least not the one that is expected. But surely, attitudes can be changed. Many government agencies and public enterprises often use the tactics of changing the attitudes of the general population on subjects like: ecology, smoking diseases, consuming alcohol etc.

2.2 Consumers' surroundings

Today, when every customer is bombarded with all kinds of marketing strategies on every possible step, entrepreneurs should carefully choose their adequate marketing approach. The modern characteristics of the surroundings cover all physical and social aspects of the consumers' outer-world, including physical objects, spaces, relations and social behavior of other individuals [15]. Micro-surroundings which consist of the direct things surrounding a person are in the focus of attention by many entrepreneurs. This includes the design of the store, retail saloons, the staff and their looks, social interactions, the lighting, the colors, rooms, sounds even the climate conditions and everything else that can impact consumers' behavior in that particular moments while they're buying or purchasing.

As integrated part of the consumers' behavior are *the culture and sub-culture*. We understand the culture as "meanings which are shared from most of representatives of one social group" [16]. Often the culture is analyzed by entrepreneurs on a macro-level, as cumulative values of one social group of people. That is generally wrong. Modern entrepreneurs must consider the sub-cultured values of minor groups, and referent groups as primary marketing values, even the so-called behavioristic

groups as: students or bikers. Multiculturalism is also an interesting part of studying the societies with multi-leveled cultural influences.

On a basic marketing level, besides the direct surroundings and cultural specifics along with the referent groups and their characteristics, *the products* themselves and their *prices* are playing the role of key factors on direct customers' surroundings. If we agree that the products are the main media of the consumers' actions, then each business strategy should be focused on planning the products [17]. Customers' satisfaction from buying the product or the brand, in marketing sense is the target concept. Therefore, the conclusion is that the main goal of the entrepreneurs' and every other kind of marketing is to increase the probability and frequency of customers that are coming in contact with the product and by doing so, to increase the desired action of actually buying the product. This includes the stimulations of the products and their attributes like: packaging, colors of the packaging, size, brand recognition etc. that also influences on consumers behavior.

The price as a factor, not by the relevance of pricing strategy from entrepreneurs' side of view but rather as part of the marketing mix of a product and as part of the consumers' direct surroundings remains relatively abstract concept, which can but not necessarily have, some heavy impact on consumers actions. From the consumers' perspective, the price is usually defined as something that must be traded in order to have possession on some product or service [18]. Not discussing the details of the classical value of money in these sorts of trades, and the perception of other non-financial factors, entrepreneurs must use the so-called "customers' value" which often does not correspondent with the actual price of the product/service. Here are some examples of that: every individual doesn't see the money as strict value. The money that is received as a gift, interest or lottery income in the sub-conches doesn't have the same value as the earned one. The same example can also be applied to the credit cards. Second example: the additional time, or the additional mental or physical effort that should be made while buying or purchasing a product/service sometimes is a motive plus, when deciding of buying certain good with higher price. Therefore, the price is mainly divided in three consumers' perceptions [19]:

- Comparison with the individual reference price – the individual referent price is the price that the consumers think that's fair and are ready to pay for;
- Encouraging consumers' interest – if the consumer is interested in buying the product, then the price has relatively lower influence on the decision of buying, of course, if the price itself is within the range of consumers' fair pricing;
- Controlling the alternatives – for large amount of products, consumers' must bring a decision between buying the product or cancel the purchasing. If they decide buying, the price is something that can be controlled by the consumer.

3. Conclusion

Entrepreneurs' marketing strategies today, more than ever, are being exposed to a fast, simple and efficient way of satisfying consumers' needs. For creation of successful marketing strategies among entrepreneurial companies, entrepreneurs must incorporate the concept of customers' satisfaction on continuous level. Reaching the targets, in that context, depends on the basis of collecting, analyzing and evaluating the consumers' behavior in every step of the way.

The core essence of consumers' behavior aims on explaining the thinking processes, influences and consumers actions when they come in direct contact, or when they are subject of a marketing campaign, whose main goal is to activate the consumers' interest and finally result in selling the product or service. Therefore, creating entrepreneurial marketing strategies based on the consumers' behavior presents a starting point of every business.

Entrepreneurship, LLL (3L) and labor market in Montenegro

*Dragan Lajovic*¹

¹*Chairman of the Board of Directors of IDF and professor at the University of Montenegro, dragan.lajovic@irfcg.me*

Focus of this work "Entrepreneurship and labor market in Montenegro." Key issues of work are covered by the current employment situation and entrepreneurship in Montenegro.

Empirical researches show that expressed interest during hiring is worrying. If entering more deeply into this issue, one will find the problems and challenges facing the Montenegrin labor market.

Implementation of entrepreneurship is increasingly present in the world, and in our country. Nature of such a work is determined by management, which is undoubtedly needed to any business successfully managed. Entrepreneurial management reflects the situation of an organization in order to create change and exploit opportunities. Accordingly, organizations should strive for the Strategy of lifelong entrepreneurial learning, based on the three "L" (LLL).

When talking about the labor market in Montenegro, we should not leave out the regional development as the foundation for boosting employment and reducing regional disparities. Accordingly, it is necessary at all costs to attract green field investments in Montenegro, not so much for the money, as much for a change in the value systems of the environment in which to potentially invest.

Keywords

Labor market, regional development, lifelong learning entrepreneurial.

1. Introduction

Human resources and human resources management in modern environment are important key factor for the success of every organization. In this sense, the concept of "human resources management" means a paradigm shift in content and method of organizing the personnel function in the modern enterprise.

Human resources management has become not only the most important business function, but also a specific philosophy and approach to management (Management) that people considered the most important potential and a key strategic and competitive advantage. This philosophy is focused on some elements of organizational performance in which people have a central place.

2. Employee engagement: Issues and Challenges

Studies have shown a positive correlation between increased engagement and higher performance (operating result), which is reflected in the factors of employee satisfaction and customer loyalty, improved efficiency and productivity, greater profits and higher incomes, lower fluctuation, less absenteeism (absence from work) and presentism (due to the presence of the risk of loss of employment), a small number of accidents at work, better quality of work performed.

On the other hand, data on non-engagement of employees are quite disturbing since the index of non-engaged employees is very high compared to other countries. Despite the general belief, dissatisfaction with salary and rewards is not the main reason for non-engagement of employees. For most of the more important to how they evaluate the top leaders - whether they treat it as the greatest wealth the company or they are considered a necessary evil. Maintain and increase the level of engagement of employees depends primarily on how well management and leadership, meets their needs and expectations.

Engaged employees want an appropriate balance between work and lifestyle, flexible work, excellent leadership that shows respect and trust, they want to participate in decision-making, to work with top managers in the industry (clients, suppliers) and with people who inspire them. Want to work on important projects, seek opportunities for managing others, seeking recognition of ideas, open communication, supportive work environment, international opportunities, positive feedback and individual development sponsored by the employer, flexible financial benefits, opportunities for advancement and the like. If the company wants to improve engagement and business results, it is essential that the concept of employee satisfaction (also a customer satisfaction or customer) is directly and effectively linked with the overall performance management and relationship management factors with customers, since that time, and executives to gain interest in the implementation of various programs encouraging satisfaction and commitment of employees. Connection between employee satisfaction and performance, or a combination of higher employee satisfaction and high performance can be subsumed under the term of engagement of employees. It is, in fact, the environment and individuals who are willing to engage in order to achieve maximum notable and measurable business results (with assumption necessary confidence in the management of employees, associates and the entire organization). The main objective of today's organizations is clear: how to better manage human resources in order to maximize those involved, or at least reduce the number of so-called non-engaged contributors? The solution lies in encouraging the innovative abilities of employees in the different treatment of employees.

3. From entrepreneurial to management company

What we can say with certainty is that the entrepreneur is the manager. An entrepreneur is someone who manages the entrepreneurial way. They are often operated by entrepreneurial work / business, or a new organization in an effort to revive an existing business. The entrepreneurial business is the management challenge. The nature of entrepreneurial business management determines that it needed to work successfully managed. Therefore we can say that entrepreneurial management is characterized by three items, namely:

- Changes
- Chance and
- Management of the overall organization.

3.1 Change

Entrepreneurs are managers of change. They connect people, money, ideas and resources to establish new organizations and to not change existing ones. Entrepreneurs are not so important because the results of its activities, but because of the changes they bring.

Unlike the entrepreneurs, managers in order to maintain the existing situation in the existing organization, and protection of its market position. Managers do not lead to change.

3.2 Chance

Entrepreneurs are constantly looking for the possibility of performing a particular job in a different and better way. They innovate business to create new value. Entrepreneurs are more interested in acceptance than likely to save resources.

This does not mean that entrepreneurs are not interested in the resources. On the contrary, they are aware of the fact that available resources are limited. Entrepreneurs can use their own resources, but

if you use return on investment will be under the control of the same. But entrepreneurs viewed resources as something that must be spent to create value, not to be kept as such. Entrepreneurs resources exposing risk, but the maximum use to achieve recovery. This distinguishes them from the foundation of business managers, because managers are saving more rare resources, than they used to accept the offered opportunities.

3.3 Overall management of the organization

Entrepreneurial management approach implies taking into account the entire organization, not just its specific parts. This does not mean that some functions, such as marketing, finance, operations management, and the like. irrelevant. However, entrepreneurs look at this function as segments that have a role in the overall business, not as isolated activities.

3.4 Entrepreneurial managers as businessmen

An entrepreneur is a manager who is ready for business: to create change and accept the odds, rather than maintaining the status quo and preserve resources. Of course, the contractor performs all these tasks at the right time. In certain circumstances it is necessary to maintain the status quo, and sometimes not wise to waste resources. One of the skills of successful entrepreneurs knows when to not take risks. However, at the right time, the entrepreneurial manager is ready to go on. There is no strictly defined the difference between entrepreneurs and other types of managers, which does not diminish the specificity of the entrepreneur, nor the importance of their work. Since entrepreneurship is a style of management, it is something that can be taught. Managers can be selected to be entrepreneurs. Very clear definition of entrepreneurship gave Czarniawska-Joerges and Wolff (1991), who are into theatrical language, but to emphasize the economic difference between management and entrepreneurship leadership:

"Management is the activity of introducing order by coordinating flows of things and people toward collective action."

"Leadership is a symbolic performance that expresses hope for the control of destiny."
"Entrepreneurship is the creation of whole new worlds."

In conclusion, it can be argued that entrepreneurial management is characterized by its scope the entire organization, its goal is to create change and exploit opportunities to focus.

4. Regional Development

Regional development strategy should define the objectives and instruments for the construction of the overall development potential, contribute to reducing inequalities in regional development and enhance the potential of those parts of the country which are lagging behind in the direction of the greater competitiveness.

The relevant objectives of the Regional Development Strategy are:

- Customization and development needs for better links between the local and regional level with development priorities at the state level;
- Adjusting the need to develop local and regional level with the available national and EU funds intended for development;
- Providing support to less developed regions / municipalities that is focused on identifying, enhancing and most of their development potential, through the elimination of the causes that prevent their development.

Regional Development Strategy of Montenegro should be based on three of foundation:

1. Determination of the level of development - classification and typology of the area;
2. Definition of development policies used to encourage regional development and
3. Strategy development institutions.

Moreover, there are significant differences in the degree of development of three regions: Southern, Middle (Central) and the North, as well as the income gap within the region. In this division using the geographic approach, while at the same term used by the European Union, the region includes the so-called. economic region, or division of territory into regions by development under certain socio-economic indicators.

The fundamental objectives of regional development strategy can be summarized as:

1. Sustainable development;
2. The growth of regional competitiveness;
3. Reduction of regional unevenness and poverty;
4. Stop the negative demographic trends;
5. Continuation of the decentralization process.

4.1 Development strategies of the institutional framework for regional development

Large differences in the level of regional development in Montenegro, among others, are due to lack of necessary institutional framework for balanced regional development, which would allow flexibility in the formulation of goals, mechanisms and instruments of regional policy.

Montenegro still has no law on regional development, and has not built any institutional network. Therefore, this important issue as soon as possible should be treated. Legislation to regulate the field of regional development of Montenegro should be regulated by the following questions:

1. The basic principles of regional development;
2. Definition and application of basic strategic planning documents of regional development, both at national and at other levels;
3. Institutional framework and mechanisms for managing regional development;
4. The new model of categorization of all local and regional authorities towards real development indicators;
5. The basis for the operational application development tools provided for the Strategy;
6. Sources of financing the implementation of regional development policies and
7. Lay the foundation for the development of methodology for monitoring and evaluating regional development policies CG.

Montenegro as a small and very open economic system has the potential to be flexible in the global trends in foreign direct investment, and in that sense it primarily has to devote its attention to the overall economic environment. Actions to attract foreign investment, except for changes that go in the direction of liberalization of FDI regimes (protection of property tax relief law, labor law), requires the simultaneous promotion of positive change and educating the local population.

4.2 What you need to let the local government was an attractive investment?

Successful and attractive to investors, local government is characterized by good infrastructure, and that means having good roads, water supply and sewage system, electrification and gasification. In addition, it implies the existence of good business infrastructure, i.e. landscaped GUP, the DUP and location studies, simple administrative procedures, and attractive conditions which the municipality provides for new investors. We should not ignore the fact that the required trained and friendly human resources, employees of local public administration, and qualified local residents that the municipality can offer investors for employment. Successful local government must actively promote their capabilities and diversity of potential investors. Therefore, to a local government was interesting to investors must have all the prerequisites for it and work on active animating them.

Last but not least, the proposal of fiscal measures that involve different treatment of economic operators that invest in manufacturing and services in the undeveloped area whether it be at the level of the entire local government or one of its segments. In particular, special treatment in fiscal terms, investment in office buildings and equipment intended for production. Does this violate the principles of the market and whether this intervention. Probably yes! But such measures exist everywhere in the world I have no other treatment than the treatment of state aid. Simulate the market makes sense only

if the bit causing demand and consumption for some time, the balanced level and the specific, in spatial terms, a market segment.

In order to stop the negative trends it is necessary at all costs to provide foreign investors (green field) and not just because of money investing as much due to changes in the system of values and thinking environment in which it invests.

Thus, the introduction of entrepreneurial culture that encourages entry into new businesses, a break with the value system in which success is vital to be employed in local or national government, and the crown of success make a transfer in Podgorica. And therefore, Montenegro will be in the area of balanced regional development is minimal and efficient public administration at the state and local levels that will place the institutions to dispose of high-quality and adaptable instruments. And with similar attributes to be a strategy and a law on regional development which would be eliminated barriers to business in the North of...

5. Strategies for lifelong learning Entrepreneurial LLL

Building a knowledge society based on human capital, education, research and innovation (creativity) enhances the potential for growth and allows to be prepared for the challenge that bears further development. Developing and fostering a culture of lifelong learning, starting from an early age, a key condition for building a knowledge society and to gather and organize all the partners in the country - ranging from support of the Government and all interested partners at national level, to local communities, institutions and individuals directly involved in educational and training processes.

Everyday technological change, increasing competition and globalization, resulting need for constant development and improvement. Once acquired knowledge and skills are not and may not be sufficient for personal and professional development. Estimates are that each individual in the course of his professional life to change the occupation of five to ten times. The question is how to adjust educational - educational system that meets the needs of contemporary society? The answer to this challenge is to build core competences - multi-functional, portable packages of knowledge, skills and attitudes that are necessary for every individual to personal fulfillment and development, inclusion and employment.

Entrepreneurship is a key driver of innovation, competitiveness and growth and one of eight key competences. Entrepreneurial learning offers people the opportunity to develop and exercise their creativity in a variety of economic and social contexts. Of entrepreneurial-minded people come ideas for creating wealth, necessary for economic growth, and they can be implemented in practice. They also can contribute significantly to the development of first-class public services and creating a successful social services sector, which responds to the needs of society.

Strategies for lifelong entrepreneurial learning will help the development of human capital that will make a significant contribution in creating a competitive and dynamic economy capable of sustainable economic growth with more and better jobs and greater social cohesion in Montenegro. The purpose of this strategy is to specify a set of goals for Entrepreneurial Learning, which will cover its development in a number of sectors over the next five years. They will include the role of entrepreneurial learning in all institutions involved in the stimulation and promotion of entrepreneurial activities.

Target groups of this strategy are in the framework of the education sector and outside it. The strategy is aimed at those involved in education and training. Overall responsibility for entrepreneurship in the education sector in the ministries and related institutions at the national and local levels. Target groups outside the education sector are those that provide help for self-employment or starting their own businesses, and those who provide assistance to businesses that are developing. This strategy also should be of interest to large employers, aimed at their organizations encourage a culture in which employees at all levels, encouraging the entrepreneurial activity.

The strategy of lifelong entrepreneurial learning is created in cooperation working group, composed of representatives of all relevant partners at national level: Ministry of Health, Labor and Social Welfare, the Ministry of Education, the Directorate for Small and Medium Sized Enterprises, Employment Service, Department of Education, Center for Vocational Education, Union of Employers and the Centre for Development of NGOs. Prepared in accordance with the new National Strategy for Employment and Human Resources Development for the period 2007-2011 and document the discussion 'Human resource development - Montenegro 2017th The'.

Entrepreneurship as a business activity has effects on the economy, and indirectly on the society. In this way it contributes to the economic and social growth and development of all countries regardless of the level of their economic development.

Although the prevailing view is that the entrepreneurial business is reserved for the male world, in modern times, almost a third of the world's entrepreneurial activities belong to women. In Serbia, "female" Entrepreneurship has been present over the last few years. At present, "female" Entrepreneurship is not developed sufficiently, and Serbia has done a little about it. Still, women are not treated equally as men due to external environment, that is, economic, political, technical, technological and social factors and certain elements of culture (national and business culture of a society and personal characteristics of women).

The analysis of the impact of cultural environments of American and European regions, regions of the Far East, Middle East and North Africa, and cultural environment in Serbian displayed that certain elements of culture determine the position and role of women in entrepreneurship. These elements are social structure of the national cultural environment, social norms and customs, values and attitudes, religion, education, business culture of a society and personal characteristics of women. The position and role of women in entrepreneurship are under the great influence of social norms that are the results of the values of prevailing religions and ideologies of a society. The aforementioned has been proved in preliminary studies that researched "female" Entrepreneurship in Serbia compared to "feminine" entrepreneurship in other countries. The research indicates that cultural environment has a significant impact on entrepreneurial ideas and ventures by women, taking into account political, economic, technical and technological factors.

Keywords

Business Culture, Culture, Entrepreneurship, Religion, Women in Business

1. Introduction

This paper will analyze the impact of culture on the position and role of women in entrepreneurship. It examines the cultural environment of the American region, European region, then the cultural environment of countries of the Far East, the Middle East and North Africa. Cultural environment of Serbia will be individually analyzed.

It is indicative that many countries with very heterogeneous religious structure (USA, Canada, Switzerland, Australia) have a high level of GDP per capita, while, on the other hand, countries that are also religiously heterogeneous (Nigeria, Kenya, Ghana) with very low social product. Countries like Norway, Ireland, Finland have a high level of prosperity and great confessional homogeneity,

while other states where there is only one practical, mostly state religion (Egypt, Senegal, Colombia) have very low levels of GDP. But at first glance it appears that the possible influence of culture on economic development and growth is very complex. Such analysis requires a broader analysis of economic and political environment that sets the framework for the development of entrepreneurship and the position and role of women in it. Justified, because entrepreneurship is a multidimensional phenomenon that can be viewed through different aspects of human behavior, but is still largely recognized as a modern economic categories.

2. Analysis of the impact of culture on women - entrepreneurs

The result of analysis of the impact of cultural influences surrounding the American and European regions, regions of the Far East, Middle East and North Africa, and cultural environment Serbian indicate the certain elements of culture that determine the position and role of women in entrepreneurship. These are the social structure of the national cultural environment, social norms and customs, values and attitudes, religion, education, business culture and personal characteristics of society women. The position and role of women in entrepreneurship depends of the great influence the social norms that are the result of the values on which the predominant religions and ideologies of society.

2.1 The influence of culture on women entrepreneurs in the U.S.

Analysis of the impact of American cultural environment on women in business will be conducted through an analysis of U.S. cultural environment for women - entrepreneurs. Although the U.S. representative of the country with the highest proportion of female entrepreneurship, there is still room to increase that participation. Justified, because the developed sector of services (creating almost 80 percent of GDP) and manufacturing sectors that are attractive for entrepreneurial business (products, chemicals, electronics, food, consumer goods, wood production). [12]

The dominant religion in the U.S. are Protestant (52 percent) and Catholic (24 percent), and English language (over 80 per cent). We stress this fact because the cultural shaping of social and private and business life U.S. is under considerable influence of the values that cultivated Protestant and Catholic religions. [5]

In terms of differences in position between women and men, the American Society is far away from all developed countries. Although the 80-ies of XX century in American society prevailing "rule of men", from the '80s to accept "feminist" version that mothers need to develop their career as well as fathers, but we still have such a position difficult to apply in practice . It suffices to mention the fact that the previous hypothesis is confirmed, it is only 1/5 Jobs of men and women entirely balanced in the American economy, and that women are still paid less. Therefore, companies in the U.S., employ women because they think they will agree to work for less money.

To change attitudes in American society comes the following shows. According to new statistics, as soon as men start in a large number to deal with traditional women's interest, it becomes more appreciated and more is paid.

2.2 The influence of culture on women entrepreneurs in the EU

European business practices are more difficult to determine in relation to the U.S. and Japan. Europeans have a sense of reality and patience. Greatly appreciated tradition. European management style consists of: cynical realism, the belief that the individual is the center of social and business structure, social responsibility, doubts about the formal authority, the desire for certainty, the belief that maximum profit is not the main objective of the business. Those characteristics are common to a number of European countries, but among them there are significant differences that are due primarily historical heritage. Each country has developed a composition of values and customs that are partly different in other countries.

Women - entrepreneurs in Europe face the same difficulties as well as male entrepreneurs. The problem of finance for starting entrepreneurial business for European women is more difficult to readily. Women in Europe often lack the confidence and skills to successfully started and run a business. Business and family life, women tend to balance the European than American, especially women who are in high places.

- *Great Britain*: The ethnic structure of the population of Great Britain dominated the English (more than 80 percent). The dominant religion in Britain is a Christian - Anglicans, Catholics, Presbyterians, Methodists (70 percent). Combined effect of variations of Christianity is reflected in the position and role of women in society and business. Open possibilities of employment and self employment of women in the attractive sectors for entrepreneurial business, as evidenced by the fact that women in the UK, despite a number of adverse working conditions, are in high positions in business service industries.

Women in the UK are lower levels of education than men. The British believe that education is not crucial for advancement in business, or that substantial training on the job. This fact can have negative consequences in terms of motivation for people to raise the level of education and training as important conditions for the acquisition of knowledge that are required for starting entrepreneurial ventures. [4]

- *German*: The significant participation of the private sector and service sector in the German economy confirms the fact of the importance of SMEs and entrepreneurship in this country. It contributes to the investment that is substantially in the following forms: establishing a company in its own domain or with domestic and foreign partners, buying an existing company, gaining share in the company, establishing joint venture (Joint Venture), equipment companies and funds for workshops or giving money help and approval of loans. www.ino.komora.net developed entrepreneurial culture encourage the development of female entrepreneurship in Germany, which is still low.

Causes of adverse position of women in the German economy and society should be sought in the traditional understanding of women is rooted in the values of the Catholic faith which exists. In Germany the government view that women should be with the children in the kitchen in the church. Mica and Ana Women who do not accept such a box set of universally accepted values have not been well accepted in the region.

- *France*: The ethnic composition of France dominated the French Celtic and Roman origin, with minorities of German, Slavic, North African, Indo-China and the Basque origin. [12] The dominant religion is Catholicism. More than 80 percent of the population declare themselves as Catholics, but it is only traditional religion, because most of the population is not considered to Catholic traditions. It should be noted that Islam in the last fifty years would greatly expanded because of the French Muslim immigrants from former colonies in North Africa.

The service sector in France could be a source of employment, especially self-employment of women. Since the French government takes care of maintenance of relative social justice and equality, which cause the reduction of disparities in income of most citizens, we can say that the situation of women as socially vulnerable groups in France, favorable. But not yet reached the optimum gender equality in the labor market and society.

Although exceptional attention to education, level of education of women is lower than in men. In France, women are most prevalent in intellectual circles as writers and teachers. Also present in the field of cosmetics, advertising, fashion and art. Mica and Ana Unlike the intellectual world, in the business world is a small number of women that can be found at the top levels. Mostly work as secretaries or dealing with administrative tasks low. France strictly distinguish between work and private life. They believe that family life is solely a private matter, and in this context, the role of women in society and business.

- *Sweden*: Sweden is ethnically homogeneous, because the Swedes do 93 percent of the total population. The dominant religion is Roman Catholic - Protestant. High living standard is due to the large industrial discipline and culture. Privately owned enterprises make up about 90 percent of Sweden's industrial production, which means that entrepreneurial activity was determined in the manufacturing sector. [12]

In Sweden, most women are employed and have higher birth rates than women in other countries who are not employed. Sweden is a country with the smallest differences between the sexes.

Most of the population are Finns. Religious, most evangelicals - Lutherans (84.2 percent). Finland's social life is focused on home and family. [5]

- *Finland*: Finland has a highly industrialized country and in managerial positions in Finland, both can be found both sexes. Women are represented at all levels in the organizational structure of enterprises, including top management or top management ladder. It is interesting that the educational qualifications of women at a higher level of qualifications of men. Relations between the sexes are equal and all kinds of discrimination against women are unacceptable.

- *Norway*: Most people are Norwegians, Religious evangelists. Norway has a successful economy. Norwegian women are present everywhere in the company, occupy high positions in government agencies and other organizations. A number of women top executives is also present in marine and

rail transport and banking. It is expected that women be treated with respect in the business. Norway is a country on the second place after Sweden with the smallest differences between the sexes

2.3 The influence of culture on women entrepreneurs Far East

Japanese society is "corporate" society with a high degree of vertical integration. Relationships within families, between families, and society are strictly hierarchical. As in China and Korea, a lasting impetus to political and social modernization of the high valuation of education, strong family connections and high work ethic. [5].

Citizens of Japan traditionally shown a willingness subordination of authoritarian leadership and increasingly accepted hierarchical status differences. Primarily in rural areas can be found deeply rooted commitment to the individual, who wishes his community assumes its own interests. The Japanese define their social position with loyalty to their social group that has similarities with *lojalnošu* within the family. Therefore, more distinct than in other countries, as opposed to political institutions, there are specific social norms.

The position of women in Japan was not at all favorable. A woman's place was in the house - a family with children. Male dominance in Japanese society is weak in recent years, especially among the younger generation. Although one of the relations that characterize Confucian culture relationship a husband, women require their husbands to stay home after work and dedication to family life. High standard of living has created many opportunities for travel, the women of Japan closer to the European lifestyle.

The essence of Japan's industrial power is reflected in the educational system, Encouraging the competitive spirit necessary to undertake ventures in business. Revitalization of SMEs is one of the main directions of development of the Japanese economy in the future, and a source of social restructuring and changes the position of women in business and entrepreneurship.

Chinese culture based on Confucianism. In Chinese and Korean traditional role of the family, her father's authority, his son's love and unconditional respect, much more pronounced in a Japanese tradition. In China it is difficult to do anything if you do not know the ancient customs that have a major impact on business and the corporate culture, and thus the position and role of women in the business world. Therefore, the "female" Entrepreneurship less developed in this country. However, in the Asian countries, China ranks first in the level of gender equality (after it was Japan, and the back area of South Korea).

What has particularly raised the Korean economy and business is a great willingness of small entrepreneurs to educate their children and so prepare to be successful managers, modern entrepreneurs and owners.

2.4 The influence of culture on women entrepreneurs, the Middle East and North Africa

In the countries of the Middle East and North Africa, women make up half of 325 million people in some countries as much as 63 percent of students. The causes of unemployment among women in the Middle East and North Africa and the unequal position in politics, economy and society are, in addition to laws on labor market regulations that favor men, conservative social norms. Accordingly, women's place in the house with her husband and children. The World Bank has urged policy makers to work on securing the same rights for men and women in the Middle East and North Africa, and to pay attention to women education and reform of regulations in the labor market. [13]

Arab business and private world, then, is linked exclusively to men. The position and role of women in entrepreneurship in the Arab World is committed traditions, local customs and norms that are rooted in religion.

By "the will of God," men and women are the same. Both have the same duties in religion and they will be on the Day of the same measure was tried. According to the Prophet's will, the daughter should have the same opportunities for education and a son. However, the position of women in society makes it difficult motherhood. Islam emphasizes the important role that women play in raising their children, believing that the future of mankind and societies depends on the mothers. It is a society in which the institution of marriage plays an important role. Critics say that Islam teaches that women are less valuable, and the Muslims to defend themselves by saying that the inequality between men and women of the consequences of natural and cultural differences, rather than Islamic law. The key to the advancement of women in the Muslim world is their economic and social independence.

Education is another area where Muslim women are lagging behind. According to numerous polls, more than 75 million women in the Middle East and North Africa were illiterate. Women in the Muslim world moving at a different pace, especially in Saudi Arabia, the cradle of Islam, the flow of change is very slow, and women are not entitled to vote or to have a driver's license

3. Analysis of the impact of cultural factors on women - entrepreneurs in Serbia

Research on women's entrepreneurship has shown that women decide to work independently at different ages, and the earliest start to those who come from families where there was a tradition of the basic patterns of entrepreneurial culture adopted through socialization. Women to start their own business usually decide when they have no other alternative, when they enter the discharge list in the transition period, and because of "middle age" in which they are located, have the opportunity to re-employment. Those who start a business and continue a successful business, usually have the full support of their families, mostly engaged in trade and crafts or business for which were prepared in previous careers. Family and friends are critical to strengthening the confidence of women.

One of the problems of women in entrepreneurship is the distance of the business environment where women appear as the owner, director or manager of a company. Therefore, they require much more effort than men in order to be respected in what they do. [7]

Entrepreneurs in Serbia are well educated, belong to different professional groups, with previous relevant work experience. Their social origin extends along the ladder of social stratification, fairly equally divided into married and divorced, usually with children. Have developed their own business within a typical female areas - retail and traditional services, with the tendency of penetration in the area of certain types of intellectual services. There are specific problems and constraints for entrepreneurial endeavors of women in unstable economic conditions and still quite patriarchal regulated environment. Perceptions of personal characteristics related to success in business quite realistically reflects the requirements and principles of market economy, but also sheds new light on the differences in the understanding of these characteristics between men and women. Comparisons with the owners of private businesses in transition countries and developed countries point to the similarities and differences in personal characteristics of entrepreneurs, the motivation and requirements for private businesses

4. Conclusions

Entrepreneurship is seen as a new sector of modern economy, and entrepreneurs as creators of new jobs. Inclusion of women in entrepreneurial business is encouraged self-employment, which is especially important because the rate of women is greater than the rate for men.

Unequal position of men and women throughout history is interpreted as a consequence of biological differences between them. [7] In modern societies, regardless of their economic and cultural development is considered to be the woman 's place in the house, the family, with her husband and children. Even in countries like the Nordic countries which are perceived as a country with the highest level achieved gender equality status of women in society, business and entrepreneurial businesses still can not be assessed as satisfactory. The limiting factors to improve the position and role of women in these areas are in the area of cultural elements such as social norms, values and attitudes that are the result of traditions based on patriarchy and ideology based on the traditional understanding of the nature of men. In this regard, religion and ideology almost as determine the status of women in society, business and entrepreneurial business, where Buddhism, Shinto, Taoism and Islam have a more limited action in relation to Christianity.

Under the influence of globalization of culture is changed life style of women in an economically and culturally less developed regions or regions where the traditional and conservative social norms determine the place of women in the house (the region of the Far East, Middle East and North Africa). Education level of women in the world is growing, which is a prerequisite for their advancement in society, business and entrepreneurship. Education is key to economic and social independence of women especially in the Middle East and North Africa.

In cultures that are characterized by traditional and conservative social norms can be seen a slight increase trend of employment and self employment of women in the service industry. In Japan, women require their husbands to stay home after work and dedication to family life and to have more opportunity for their business life.

Serbian women in entrepreneurial businesses faced with fact that the business world is reserved for man. One of solutions in addition to increasing education and work is to institutionalize gender equality, however practice shows that have not yet created optimal conditions for the development of entrepreneurial businesses by women who would be characterized as satisfactory. This is favored by slow implementation of legislative norms, weak financial and credit support, slow process of breaking up the phenomenon of "glass ceiling", poor networking and women's and PhD. Often, the rule of rules and social norms is more important than democracy and the law.

Challenges of the audit system's innovation according to the development of the public accountability

² Technological and Economical Faculty, Institute of Business Sciences, Eötvös József College, Baja, Hungary, simon.jozsef@ejf.hu

In a democratic state citizens expect that those currently in power should give a detailed account on spending and utilising the public funds trusted to them. The enforcement of accountability has several preconditions, out of which this study focuses on the characteristics arising from the accounting system, since accounting requirements significantly influence the audit system's room for manouvering.

At the same time the accounting system is one part of the public sector's information system. Studying the information system in a systemic manner is important because the quality of the audit system is influenced not only by public accountability, but also by the other elements of the information system. It must be emphasised that the information system must meet differentiated needs. The paper would like to show these requirements.

Public accountability systems show a quite colourful picture in international comparison. The thinking of countries is different about in which area and how can be used the cash-flow approach and accrual based accounting. In consequence of these factors these two methods appear in public accountability nearly in all countries.

The application of public accounting methods can be examined according to various criterions. On the one hand there are some differences which accounting method are being used vertically and horizontally at different levels in public administration by budgetary accounting and accounting system. On the other hand we can obtain for further interdependencies from the horizontally point of view if we compare to the applied techniques of the two areas of public accountability. Third part we make comparison between the public accounting methods on certain levels of public administration.

The target of this paper is to verify that the usage of accrual based accounting how influence the public accounting methods the functions of public accountability.

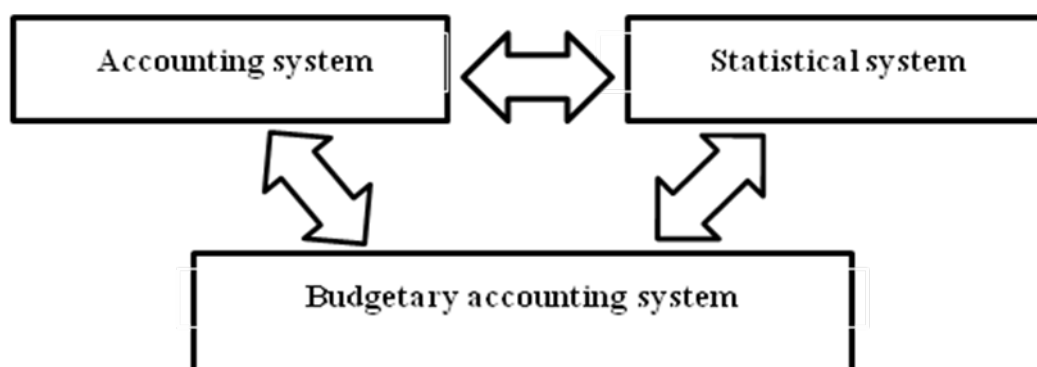

Keywords:

Accrual based accounting, cash-based accounting, finance of local governments, information system, public accountability.

1. Introduction – the information system of public finances

The information system of the public sector plays a significant role in the solution of the above written. Studying the information system in a systemic manner is important because the quality of the audit system is influenced not only by public accountability, but also by the other two elements of the information system. This article presents the structure of the information system, and locates the accounting system within that.

Table 1 Structure of the financial information system.

It must be emphasised that the information system must meet differentiated needs. The interested parties require different information on certain fields of the public finances, and look at the information system from different perspectives. Decision-makers typically want to know in which fields public funds have been used, but at the same time cost-efficiency is shifted to the background. In contrast with this, the operative implementers of tasks are driven by the aim to make the effectiveness of utilisation of public funds measurable. The society requires comprehensive information about the utilisation of public funds. In this respect the structure, understandability and information content of the report are of crucial importance.

The quality of the audit system cannot be separated from the system in which the audit activity forms only a portion. The information system of the public sector consists of three main parts: the budgetary accounting system, the statistical system and the accounting system. The systemic overview of the information system requires the presentation of the subsystems.

1.1 The budgetary accounting system

The budgetary accounting system registers appropriations and the fulfilment thereof by matching them to voting units. [1] The goal of the control system (which appears in the "Final accounts" at the local governments) is to check whether the executive power utilises public funds and public assets in a transparent manner within the framework specified by law. Furthermore, it is responsible to restrict excessive influence by the executive power to ensure that political decision-makers retain their competence in relation to the utilisation of public funds and to prevent that a few elements of this power be returned to the scope of the government.

The basic element of the budgetary accounting system is the "voting unit", a group of tasks and budgetary frameworks that are approved by the National Assembly, and the fulfilment of which is mandatory upon authorization by the Budget Act. The basic principle is that the tasks must be implemented within the budgets specified by the National Assembly. Apart from this, the National Assembly has an exclusive right to modify the voting units, and the executive power has no say in this. When defining the voting units too broad or too narrow definitions should be avoided. In order to achieve the goals set in the budget it is necessary to create possible transfers between the voting units and the governmental functions. Practically this means that it is advisable to collect budget data according to supply functions, too, since the fact and extent of the achievement of the set social objectives can be determined on this basis. The main tool for the preparation of these data is the so called COFOG, which stands for the Classification of the Functions of Government in Britain. The Ministry of Finance is making efforts to introduce this method, but comprehensive application is still to come.

1.2 The statistical system

The goal of statistical methodologies is to measure the financial transactions of public finances, and to process them in a unified structure. According to the statistical concepts, the basic feature of public finances is that the state supplies services to the society, and covers the costs of such tasks from taxes and other revenues, while it also redistributes income and assets.

Due to their significance, the SNA, the GFS and the ESA95 methodologies stand out of all the other statistical methodologies. The methodologies can be distinguished according to the following characteristics:

- temporal relationship between income and consumption – according to which either the cash flow or the accrual based approach is used,
- the conceptual interpretation of public finances,
- assumptions related to the income owners' behaviour – whether they are characterised by short or long-term thinking.

In the period of preparation for the EU budget supervision procedure Hungary was required to prepare its fiscal policy report in accordance with the ESA95 requirements within the Pre-Accession Economic Programme, already from 2001. According to the 2002 amendment of the Public Finance Act, the ESA95 rules need to be taken into account in the annual budget acts. The GFS type data of the budget had to be supplemented, corrected and re-classified so that the public finance deficit and debt data could be determined according to the ESA95 methodology.

1.3 The accounting system

The accounting system must reliably and accurately reflect changes (growth and reduction) in public funds and public assets. The accounting system of the public sector must be in line with the fact that the primary goal of the public sector is the provision of a public task, the profit motive is generally not typical, a significant portion of resources for most institutions come from subsidies, and the effectiveness of financial management cannot be assessed simply on the basis of changes in assets in the given period. It is more difficult to establish relationship between the input and output units, and last but not least differences in the principal's and the consumer's entities also reinforce the specific features.

The accounting system of the public sector must not only provide information on the sources and value of public funds, but must also be able to present the costs of the provision of public goods, as well as the costs spent on individual goods and services.

Tasks of the accounting system of the public sector [1]:

- recording data derived from the monitoring, measurement and evaluation of the events occurring in relation to the economic systems, and of the resulting situations,
- processing and comparison of the information in a closed system,
- mediation of the reproduction process in organisations that economically separate the sub-processes of production, distribution, replacement,
- satisfying the need for information of the interested parties,
- and enforcement of the interests of the affected parties.

From among the elements of the public accountancy system two areas deserve utmost attention, the book-keeping and the reporting systems. The characteristic features of these two subsystems determine to which extent the public accountancy system is able to fulfil the tasks specified above.

Public finance institutions keep modified performance approach records about events affecting their assets and financial situation of their activities in the system of double bookkeeping, and in fact they apply the principle of the cash flow based approach. Hence, the expense and cost categories cannot be differentiated in the accounting system, and the revenues and revenue appropriations are not differentiated either.

2. Characteristic features of the public accountancy system

The biggest problem of the budgetary accounting system is the lack of definition of the voting units. In the budget approved by the National Assembly titles and appropriations play a crucial role. Under the term voting unit the budget typically means budget titles, which appear in different forms. In certain places the budget title means an institution, while in other places a task or a type of transaction. Yet, the system of titles changes from year to year, and the accounting system is unable to follow. For the time being there is no methodology that could ensure the comprehensiveness and accuracy of the performance data. On a "small scale" this holds for the budget of the local governments, too. Here it would also be necessary to define voting units and build the budget accordingly. The individual local governmental tasks could be interpreted as voting units, or in the case of larger local governments the breakdown of the individual tasks would also be possible. The situation that has emerged is further complicated by the fact that the chapters and titles change year after year, and that the National Assembly renounces a significant portion of its budgetary right and transfers it to the executive power

branch. Therefore the National Assembly makes only apparent decisions about the distribution and utilisation of public funds, the real decision making power is vested to the Government.

In the financial and statistical system of the government serious methodological, and information system development tasks must be completed so that EUROSTAT conform data could be supplied by the Ministry of Finance. [2] During the development of the statistical system it cannot be ignored that more and more countries tend to apply the ESA95 methodology, and in relation with that, a version of the accrual based approach.

It can be asked to which extent the current accounting technique complies with the needs of modern financial management. It can be stated that the cash-flow approach does not meet the requirements set against efficient financial management.

Arising from the basic principle of the cash flow approach, liabilities and claims do not appear explicitly in book-keeping, since they do not imply actual money movements. [3] Consequently, one of the most important accounting principles, the principle of entirety is not enforced. Although the institutions may decide to keep separate analytical records about their liabilities and claims, but this cannot be regarded as a good practice for two reasons. On the one hand, the utilisation of information from this source is not ensured, since as long as no actual money movement is made, claims and liabilities are factors outside the system, and on the other hand keeping any additional records imply costs. What is more, these costs accumulate as time goes by. However, in reality, claims and liabilities carry important information, since the actual financial situation can be determined only with the joint consideration thereof.

Book-keeping fails to show the economic content of depreciation, too. Although it is specified for the institutions what depreciation rate they can use for the different assets, however the real value of depreciation is a factor outside the accounting system. On the other hand, if depreciation is not shown at the real value in accounting, in reality there is a big discrepancy between the market and book values of the assets. Consequently, asset management also gets into a hopeless situation.

Arising from the cash-flow approach the institutions are not able to determine the actual costs of the tasks they supply, since only those economic events are recorded that imply immediate money movements. However, this technique causes problems during budgeting, too, because several events of the accounted transactions burden a year other than the budget year, and vica versa, several items are not included in the budget for the subject year despite the fact that they should form integral parts thereof. However, without knowing the entire costs no decision can be made about the optimum organisational framework of the completion of the given task, about its implementation in an entrepreneurial or another organisational form. Effective financial management is impossible without knowing the entire costs.

The cash-flow approach makes it possible to cover financial management problems experienced in the public sector, the bad economic situation can be presented as favourable. The objective assessment of the financial management of the public sector is further hindered by the deficiencies of the reporting system. Due to the inaccuracy and incompleteness of the basic data on financial management the reports prepared on the financial management of the institutions do not give a real picture about financial management. The balance sheet is unsuitable for laying the foundation for any asset related decision. The asset balance sheet contains a lot of misleading information. The principle of evaluation is not only intransparent and incomprehensible, but it is explicitly suitable for misleading the decision-makers. The supplied information can be evaluated according to the objectives, and can be taken both as favourable and unfavourable values.

Ratings related to misunderstandings could be further listed. Such misunderstandings can result from the fact that the valid legal regulation does not include the mandatory separation of the operational and the development budgets. As a result it often happens that development funds are channelled to the other budget to cover operational expenses. This makes the evaluation of the financial management of the processes more confusing, less transparent and inaccurate.

Measuring the effectiveness of financial management is almost impossible. The calculation of the economic indicators used in the business sector is hindered, and the yielded results must also be taken with reservations. This problem is encountered by, for instance, the economic partners of the local governments, who must assess the financial situation of the local government in order to reduce their risks, but this is not possible in the absence of relevant information. The financial evaluation of the public sector is an especially important and topical issue for Hungarian financial service suppliers, since the local governments are becoming increasingly indebted. The strategy formerly used by credit institutions, according to which it is worth lending to local governments, since in case of non-payment the state will support local governments in need of help, is beginning to change. Credit institutions are more prudent about lending to local governments, since it has become clear for them, too, that most of the Hungarian local governments have insufficient resources, and two thirds of the nearly 3,200 local

governments are unable to fulfil even their mandatory tasks, i.e. the overwhelming majority of the local governments lack adequate financial capacities to secure or repay loans.

For political decision-makers application of the cash-flow approach may seem advantageous, since it can be easily seen from the budget which institutions and in what amounts receive public funds, and after the closure of the subject year the reports reflect spending the given resources. In other words, the desired objectives may seem to have been achieved for the decision-makers.

The institution-centred cash flow financing technique does not allow for tracking the spending of public funds, and only shows the amounts spent by the individual institutions during the given year. Therefore, the actual performance of the institution performing the task cannot be measured, and on top of that, the adequate quality of task performance cannot be guaranteed either. However, political arguments for the cash-flow approach represent only half of the truth. In the short run, within a year, the above political interests can prevail, however, in the long run, over more than a year, not only the path of financial resources, but the cost-efficient utilisation thereof would matter equally for politicians committed to public affairs. In the case of limited resources efficient utilisation is a key question.

Information on revenues yielded and costs spent in a given budget year is provided by the final accounts in order to make the executive power and the assembly of the local governmental give account of the utilisation of public funds trusted to them, as well as of changes in the value of public assets. [4] However, for the time being the content of final accounts is not defined exactly, requirements exist only for the structure thereof. Presentation of the statements and balance sheets required to be attached to the final accounts represents a rather sizeable problem at the level of public finance institutions and local governments alike. The major elements of the established table system are defined; however the concrete content thereof is not clear. These deficiencies are highlighted by the audits conducted by the State Audit Office (SAO) every year. It would be extremely necessary to provide clear regulations for the table system, and tables showing non-relevant information should be deleted from this set of tables.

The accuracy of data contained in the final accounts can be questioned. This comes from the fact that on one hand almost all revenue items are presented without compliance with centrally regulated financial reporting rules, while on the other hand the basic financial reports contain only hardly over 50 percent of the expenditures. It poses a further problem that hardly more than 30 percent of the basic reports are subjected to financial audits. Another problem related to the reports is that they are prepared according to the institutional approach, i.e. data are specified at the level of the institutions. The other problem is that the accounting system includes the appropriations, too. Hence, the accounting records become even more detailed, which considerably hinders the interpretation of voting units. It can be noted that the local governments could calculate other data, too, from the mandatory registration and accounting systems, from which information relevant to them could also be generated.

The greatest problem of the current regulation is that cash flow based book-keeping and the related reporting practice do not serve the interests of public finance management, the pieces of information are often inaccurate, and therefore they too generate the possibility of squandering.

3. Expectations of the audit system towards public accountability

For the time being public accountability cannot produce the appropriate information for the affected parties, including the audit system. To prove this statement we must first of all interpret the type of information required by the audit system, and then we must explore the causes due to which the public accountability system is unable to generate the required information. The inspection of all connection points between the audit and the public accountability systems would be beyond the scope of this study, wherefore in this article the subjects of analysis are SAO audits within the audit system, and the accounting systems of the local governments of settlements with the public accountability system.

Pursuant to the law in effect, the SAO is responsible for the audit of the financial management of the local governments, however the concrete content of this task is not specified. The SAO is free to decide on the method of task performance, as well as on the subject and method of such audits. Due to its limited capacity the SAO is unable to audit the financial management of all local governments each year. Therefore, the SAO focuses its so called comprehensive audits on the local governments of the capital, the counties, towns with county rank, and of the districts of Budapest, which have more significant assets at their disposal. Comprehensive audits affect around 300 local governments a year, and on top of that a few hundred other local governments can be audited within a given year using other audit types. [5] Consequently, in a given year the financial management of more than 2,000 of

the 3,200 local governments is not subjected to an external audit. Typically small local governments are left out of the audits. This requirement is a typical example of legal underregulation.

The information needed for SAO audits in the local governmental sector can basically be derived from the characteristic features of comprehensive audits. The main objective of comprehensive audits is to provide a systemic evaluation for a given period of whether the development and operation of the internal control systems in the public sector provide sufficient security for the adequate, lawful, cost-effective, efficient and/or effective completion of state and/or local governmental financial management tasks, for the protection of resources, and for ensuring reliable financial and non-financial information supply and reporting systems.

During comprehensive audits the internal management system becomes assessable through the evaluation of the control system. The most important areas of the analysis of the control systems are the following [6]:

- the budgeting and the final accounts preparation processes,
- the level of regulation of the financial and accounting activities of the mayor's office,
- whether or not the IT system used during financial and accounting tasks is regulated.

SAO audits must collect information on these areas. However, practical experience shows that the accounting system is not suitable for the generation of the required information.

4. Conclusions - Why does the accounting system used by the local governments fail to meet the audit needs?

The problem is caused by the inadequacy of the public accountancy system. Not only has Hungary got no public accountancy act, consistency among the elements of regulations is not ensured either. Under- and overregulation are present at the same time. The applied bookkeeping technique, i.e. the cash-flow approach is not able to meet the needs of the affected parties. The features arising from the cash-flow approach hinder the efficient performance of SAO audits, too.

Certain part of the generated information is unnecessary, these pieces of information can be used neither during the decision-making process, nor during the audits. The accounting principles are not fully enforced in the accounting and the registration systems, and consequently the public accountancy system cannot be expected to be efficient. Another feature of the system is that the data can be generated only at significant costs. Due to the cash-flow approach local governmental decision-makers cannot determine the exact actual costs of the individual tasks, without which rational financial management is inconceivable.

Transparency is also hampered by the fact that the local governments do not separate their operational and development budgets, although this can be regarded as a golden rule in public finances. In many cases separation is not effected due to the financial problems of the local governments, since in this manner the balance of the budget can be seemingly ensured. However, the risks that will appear in the budget later on may jeopardise task performance by the local governments. Even if separation is carried out formally, it often happens that the operational and the development budgets include "rows" that belong to the other budget type contentwise, and where operational and development expenditures are mixed. The basic principles of budgeting are not enforced during the compilation of the budget or the final accounts, wherefore accountability is almost impossible to maintain. Another problem is institution-centredness in financial management, which does not serve efficient task performance. Institution-level financial management itself hinders task-level financial management, and the definition of expenditures at task level.

The cash-flow approach and institution-level financial management do not allow for financial management on the basis of the cost-benefit principle, not even where it would directly be possible. Institution-centred financial management further aggravates the situation arising from the application of the cash-flow approach, since most of the available information can be interpreted at institutional level, and due to the cash-flow approach the reality content must also be taken with some reservations. The books of the institutions, similarly to those of the local governments, do not clearly show the actual expenditures, wherefore breakdown by tasks is not possible either, which would be of utmost importance. It causes further problems in the system that due to the established financial system the players are not interested in maintaining transparency. In most cases the financing local government obviously knows that the resources provided are not sufficient for the quality operation of the institution, but has no adequate funding ability.

The rules of local governmental reporting are not well thought after; the data tables required to be attached to the reports contain little information. Due to the basic principle of the accounting system

the reality content of the basic institutional reports can be questioned, what is more, the external, independent audit thereof is not ensured either. External audits cannot rely on internal audits either. The asset management of the local governments is not efficient, the asset balance sheet contains unreliable data, mostly due to the improper handling of depreciation. The accounting and the registration systems are unable to functionally classify book-keeping data, which would be the starting point for external audits. Changes in and non-compliance with the rules result in the fact that it is impossible to create multiannual data series, and audits are unable to do comparisons.

The situation is further complicated by the fact that public finance institutions can also establish economic organisations. These organisations have significant public funds at their disposal. According to some estimates, in the local governmental system such funds account for around 15–20 percent of local governmental expenditures [7], whereby they significantly influence economic processes. In fact, these organisations form a quasi-sector where the public sector (community policy aspects) and the private sector (market economy aspects) are present at the same time, and separation of the public area is ensured neither theoretically, nor empirically. The applied accounting logic is of utmost importance from this point of view, too, since the book-keeping and reporting obligations of institutions belonging to the quasi-sector are stipulated by the Accounting Act, while other public finance institutions are governed by Government Decree 249 of 2000. This means that in the system of double-entry book-keeping organisations belonging to the first group apply the rules pertaining to business organisations, while public finance organisations apply the cash flow based approach. Consequently, aggregation of the data is hindered, and not only the methodology is unavailable, but unfortunately, the desire for transparency is also often missing. Audits by the owners must evidently be reinforced.

Apart from the lack of information audits are also hindered by the lack of definition of audit tasks. As an example one can cite the budget proposal, the content of which is not specified in the Act on the SAO. The SAO gets into a difficult situation at the local governments, too, since the law appoints the SAO to audit the financial management of the local governments, however it is not clear whether other organisations may also perform checks, and if yes, with what content. The relationship between SAO audits and book-keeping at the local governments is an especially topical issue.

In today's Hungary public accountancy does not provide an appropriate registration and accounting basis for audits to follow the movements and utilisation of public funds in a comprehensive and continuous manner. Therefore, audits are primarily able to examine the validity and lawfulness of the utilisation of public funds.

The accounting system used in the public sector needs to be transformed. The most important step is that a shift must be made from cash flow to accrual based accounting. This improves the conditions for financial and SAO audits to have an adequate manoeuvring room, and to be able to assess the legality, economic rationality and efficiency of the utilisation of public funds.

The Impact of Economic Internationalization on Economic Growth

Ina Lejko¹, Štefan Bojnec²

²Faculty of Management, University of Primorska, Koper, Slovenia, stefan.bojnec@fm-kp.si, stefan.bojnec@siol.net

The paper analyses the economic growth of ten new member states (NMS-10) of the European Union (EU) in relation to internationalization of economies. The degree of internationalization is measured by foreign direct investment (FDI) and international trade. The widespread opinion of research literature is that there is an existing association between internationalization of economies through international trade and FDI on one hand and economic growth on the other.

Our research focus is on NMS-10 before and after their accession to the EU. We expect that EU economic integration has contributed essentially to the increase of trade and FDI flows. We investigate both the impact of inward FDI and outward FDI on host country's economic growth. In addition, we test the association between international trade and economic growth. The research uses panel datasets for the NMS-10 during the period 2000-2008. We employ panel data regression analyses using fixed effects model. We find that trade and investment liberalization have provided an important incentive for exports and FDI flows in NMS-10 countries, which have had a positive impact on their economic growth. The findings would be useful for possible scenarios and thus for predicting the change in trade and FDI flows for the candidate countries as future members of EU with implications, which are expected by accession in EU.

Keywords

Economic growth, Europe, foreign direct investment, foreign trade.

1. Introduction

Globalization is the word, which has several different meanings. However globalization is first and mainly thought of as an economic globalization, which means a high level of internationalization of the world economy at different levels of regions and countries. The level of their economic globalization is most suitably expressed as a level of internationalization of their economies. The magnitude and intensity of globalization can be measured by several indicators, such as capital movements and foreign direct investment (FDI) flows, international trade flows, the economic activity of multinational firms and the internationalization of technology. [1]

FDI can be defined as an internationalization strategy in which the firm establishes a physical presence abroad through acquisition of productive assets. [2] Similarly Organisation for Economic Co-operation and Development (OECD) [3] defines FDI as an objective of establishing a lasting interest by a resident enterprise in one economy (direct investor) in an enterprise (direct investment enterprise) that is resident in an economy other than that of the direct investor.

FDI is considered a key component of national development strategies for developed and developing countries. Although FDI inflow is expected to have a positive correlation with economic growth, empirical evidence gives mixed results, and the role of FDI as a driver of economic growth is not a unanimously supported fact in economic literature. Typically some new studies give support to a positive contribution of FDI inflows on economic growth. [4] OECD points out the positive influence of FDI on total factor productivity raise and increase in resource efficiency. The FDI is also considered as a major catalyst to development especially in developing countries, emerging economies and

countries in transition. FDI is expected to trigger technology spill-overs, assist human capital formation, contribute to international trade integration, help to create a competitive business environment and enhance firms' development. [5] Summing up the previous theoretical literature, it argues that the FDI has an impact on economic growth in two basic ways. Firstly it affects capital accumulation and secondly it stimulates technology diffusion. In relation to domestic investments, the presence of FDI can crowd in domestic upstream and/or downstream investments, but can also overtake or displace domestic investments and thus crowd them out. [6]

Possible influences of FDI on economic growth are biased to the host economy's characteristics hence transition economies are expected to experience similar effects. The transition-induced liberalization of international trade attracted large capital inflows, including FDI, to transition economies, although FDI inflows to the Central and Eastern European (CEE) transition economies in the 1990's started as relatively low. [7] The conditions in transition countries enabled potential gains from the FDI in the presence of adequate human capital.[8] The association between transition process and FDI is endogenous, since the transition process enables the basis for effective FDI, whilst the FDI accelerates the transition process. [9]

In addition to the transition process, trade liberalization and investment risk diminution in form of global and regional European integration also played an important role in creating an environment that enables countries to benefit from FDI. Several researches established a positive correlation between EU accession and FDI inflows to acceding countries. [10], [11], [12], [13] Strong FDI inflows, following the EU accession, largely contributed to the new EU members economic performance. [14] The announcements about EU accession prospects or accession negotiation positively affected the attraction of FDI to candidate countries. On the other hand, FDI inflows can largely contribute to the fulfilment of the economic conditions for EU accession. [9] As seen from Figure 1, the growth rate of inward FDI of ten new member states (NMS-10) was constantly surpassing the rate of the EU-15 countries until the downfall, experienced in the year 2005, which could be the consequence of the adverse impact of EU accession on FDI, as suggested by Iwasaki and Suganuma. [13]

Figure 1 Growth rate of inward FDI (in percentages)
(Source: UNCTAD, 2010 [15])

The importance of establishing the direction of the impact of FDI on economic growth lies in the fact that it represents a base for policy decisions of countries, which will consecutively either encourage or restrict FDI. Most of authors, which are strong supporters of the positive effects of FDI on economic growth in transition process, highly recommend transition countries to take every possible measure to enhance the investment climate. At the same time attention is given to the fact, that FDI incentives should promote activities that create a potential for spill-over effects, linkages between foreign and local firms, education, training, and research and development (R&D). [16], [17] Especially authors, focusing on the non-EU emerging market economies, point out the importance of higher FDI inflows for the progress in transition process. [9]

Previous and ongoing research on the impact of FDI on economic growth in NMS-10 is primarily affected by the relative small number of countries, which experience advanced FDI inflows in the transition process and during adjustment to the EU integration. There have been also considerable

differentials between NMS-10 in the initial starting point conditions and different pace in reform progress. The main limitation for empirical analysis is the availability of data for longer observation period. Considering these facts and limitations, the empirical analysis of this research consists of the NMS-10 that joined EU in its largest single expansion on 1st May 2004, observed during the period 2000-2008, which enables the comparison of periods before and after the EU accession in the limits of available data.

2. Literature Review

The impacts and channels of FDI on economic growth have been investigated by several studies. There has been a shift in literature from a highly negative connotation of the impact of FDI on economic growth during the 1960's and 1970's towards more positive connotation during the 1980's and 1990's.

The neo-classical economists include technological progress into the production function as a production factor, [18] although their models handle technological progress as exogenous and focus on the capital accumulation as the main active factor of economic growth. FDI therefore contributes to the capital accumulation and subsequently affects the economic growth in the short-run, while the long-run impact is constrained due to hypothesis of diminishing returns.

On the other hand, endogenous growth theory developed a model, which handles economic growth as a result of endogenous factors. [19], [20] Latter model also includes knowledge and technology, which enable increase in rates of economic growth on a long-run. In endogenous growth models, FDI has a role of a diffuser, which facilitates the transfer of knowledge and technology as drivers of economic growth. They identified two-channels for the impact of FDI on economic growth: transfer of tangible and intangible assets. [21] The transfer of technological and business know-how through FDI helps to bridge the "ideal gap" between nations and can have spill-over effects on entire national economy. [22] The impact of FDI on economic growth has been tested by several empirical studies. They are largely based on either neo-classical or endogenous growth theoretical approaches. Microeconomic studies provide mixed results on the association between FDI and economic growth. Typically they find that the association can be attributed to certain specific factors and therefore cannot be generalized. On the other hand, macroeconomic studies mostly suggest a positive impact of FDI on economic growth, especially if some additional requirements about absorptive capacities are met. Among additional important factors are technology diffusion and stock of human capital available in the host country, which enables the exploitation of the spill-over effects of FDI. [23], [24] There are also mixed findings about the effect of FDI on domestic investment.

The positive impact of FDI on economic growth can also be explained through adequate level of development of financial markets conditions in the host country that allow the exploitation of FDI spill-over effects. [25], [26], [27], [28] Some other studies promote the importance of absorptive capacities with market structures and human capital. [29], [30], [31] In addition, economic freedom in the host country can be an important determinant for a positive impact of FDI on economic growth. [32]

There might be some statistical weaknesses of previous research and consequently their results on the association between FDI and economic growth. [33] Similarly some studies that have been conducted for transition economies also did not find evidence of causality effects between FDI and economic growth, [34], [35], [36] while some other studies confirm findings on the importance of absorptive capacities for the interaction between trade and FDI to be decisive for the impact on economic growth. [8], [23], [7]

To sum up, most of the studies on the impact of FDI on economic growth are of microeconomic nature, dealing with the benefits of firms from FDI, or locally limited on certain regions, whilst studies, focused on a specific group of countries in a certain period are rare. Some studies on transition economies exist, but they focus either on strictly Eastern-European and Balkan countries or they miscellaneously study Eastern-European with other Eastern, former Soviet Union countries. This research therefore contributes to the empirical analysis of the NMS-10 for the studied period.

3. Methodology and Data

The research uses balanced panel data for the NMS-10 for the period 2000-2008. The data used was acquired from UNCTAD (UNCTADstat) [15] and World Bank (World Development Indicators database) [37]. Table 1 presents basic summary statistics of variables that are used in the empirical analysis,

which values vary from negative minimum to largely positive maximum values, the exception being the variable for investment (I) to gross domestic product (GDP) ratio (I/Y).

Panel data was chosen for the research, as it provides advantages over cross-sectional and time series data, enabling the observation of heterogeneous cross-section units in a specified time period, and thus providing more informative, variable and efficient data. With panel data it is possible to study the dynamics of adjustment as well as to construct and test complicated behavioural models.

The data was analyzed using a fixed effects regression model, which summarizes theoretically grounded important determinants of economic growth. The model was adopted from the literature, [7], [4] and adjusted in accordance with the subject and period of study, as well as the availability of data. The model can in its simplest form be written as:

$$Y_{it} = \alpha_i + \beta' X_{it} + \varepsilon_{it}$$

where Y_{it} is the annual growth rate of real GDP, α_i is the fixed effect of country-specific factors, that do not change in time, is a vector of independent variables and ε_{it} is a random error, which is individually and equally distributed in time and units (with a mean 0 and variance σ_ε^2). The main characteristic of panel data regression model is a double index on its variables, which denotes the cross-section component i and time component t. Vector of independent variables consists of the growth rate of employment L_{it} , computed as the first log difference of annual aggregate

employment, investment to GDP ratio ($\frac{I_{it}}{Y_{it}}$), computed as gross capital formation as a percentage of GDP, the growth rate of inward $[(IFDI)_{it}]$ and outward $[(OFDI)_{it}]$ FDI, both calculated as the first log difference of FDI stock, acquired in US Dollars at current prices and current exchange rates in millions and converted into constant prices using GDP deflator, the trade openness ($OPEN_{it}$), computed as the sum of aggregate exports and imports to GDP, and the gross domestic expenditure in R&D $[(GERD)_{it}]$, computed as the R&D percentage of GDP. The final equation to be empirically estimated can consequently be written as:

$$Y_{it} = \alpha_i + \beta_1 (L_{it}) + \beta_2 \left(\frac{I_{it}}{Y_{it}}\right) + \beta_3 [(IFDI)_{it}] + \beta_4 [(OFDI)_{it}] + \beta_5 OPEN_{it} + \beta_6 GERD_{it} + \varepsilon_{it}$$

The decision for using fixed effects model mainly follows from the previous literature, especially due to the fact that the NMS-10 are at the similar level of economic development and are experiencing similar initial conditions, which are not in the primer interest of the research, and are therefore traded for country-specific factors. Furthermore, fixed effects model is chosen as a way of eliminating omitted variable bias. [4], [7] Finally, the decision for the use of the fixed effects model is supported by the results of the Hausman test, which pointed out statistically significant differences between random and fixed model and therefore justified the use of the latter.

Table 1 Summary statistics

	Mean	Std. Dev.	Min.	Max.
DGDP	0,047256	0,028409	-0,046904	0,115409

4. Econometric Results

Regression results are presented in Table 2, which includes coefficient estimates and p-values. The results indicate a statistically significant positive effect of employment rate, investments to GDP ratio and inward FDI stock growth on GDP growth, with especially high value of the coefficient of employment rate. The coefficient of FDI growth with the acceptable level of significance indicates, that

one percentage point increase in the growth of inward FDI causes approximately 0,04 percentage point growth of GDP. The indicated effect of trade openness on GDP growth is statistically insignificant regardless to the exclusion of FDI component from the regression model. The fact that the coefficient of gross domestic expenditure in R&D indicates a statistically significant negative effect, can with the respect of previous research be attributed to the fact, that the NMC-10 have already reached a threshold level of human capital stock. [4]

In addition to the regression analysis using fixed effects model, we also run regressions using ordinary least square method, random effects model, AR(1) disturbances, cluster and robust estimation procedures, which have shown similar results. Even with the use of heteroscedasticity and autocorrelation robust estimators, growth of inward FDI still expresses a statistically significant positive effect on GDP growth. Correlation analysis was also performed showing a mild correlation between gross domestic expenditure in R&D and investments to GDP ratio, which can be attributed to the fact that both variables are computed as a part of GDP. Regression model also passed the Jarque-Bera normality test at 5% significance level.

Results of empirical analysis partially confirm the results of previously cited researches, with the respect differences due to sampling and observation period.

GERD	-0,051*** (0,002)

Note: Coefficients marked with **(*) are statistically significant.

5. Conclusions

The paper analyses the economic growth of NMS-10 countries in relation to internationalization of their economies. The degree of internationalization of economies is measured by inward and outward FDI and international trade. The paper also analyzes the effect of investment risk diminution, caused by adjunction to the EU regional integration.

The research model is based on an extended traditional growth theory and includes the growth rate of employment, investment to GDP ratio, growth rate of inward and outward FDI, trade openness, and gross domestic expenditure in R&D as determinants of economic growth, measured as annual growth rate of real GDP. Explanatory variables are summed in a fixed effect regression model, previously used in literature and adapted to the specific characteristics of NMS-10 and analyzed years.

The regression results indicate a statistically significant positive effect of inward FDI stock growth on GDP growth, with a statistically insignificant effect of trade openness, which persists regardless to the exclusion of FDI explanatory variable from the model. The negative effect of gross domestic expenditure in R&D on the GDP growth, which does not interfere with the effects of FDI and therefore rejects the findings of some previous studies, can be interpreted as a consequence of the fact that the NMS-10 already achieved a threshold level of human capital stock.

Linking Factual and Normative Cross-National Cultural Values with Entrepreneurship

Miri Lerner¹, Amir Shoham², Ilan Alon³

²The College of Management, Rishon Lezion, Israel, amir1s@colman.ac.il

³Rollins College, Winter Park, Florida, U.S., ialon@rollins.edu

It has been assumed that certain cultural beliefs encourage entrepreneurial activity; however the results of many studies are mixed. This article investigates the links between cultural values and entrepreneurial activity in different countries, which are disputed in the current literature. Given the inconsistent results regarding the culture-entrepreneurship link, we argue that previous studies have ignored an important distinction of cultural values: the duality of normative values and factual practices. By introducing the double nature of values into the research on the link between culture and entrepreneurship, we aim to fill the existing gap and contribute to clarifying the link. The current study firstly differentiates between normative values and factual practices of culture, and tests hypothesis on the relationship between them and entrepreneurship in 20 countries represented in the Global Entrepreneurship Monitor (GEM) and Global Leadership and Organizational Behavior Effectiveness (GLOBE) databases. The current study demonstrates that introduction of these two different aspects of culture, may help resolve the inconsistency in previous results.

Our findings clearly demonstrate that normative values (should be items in the GLOBE study) exhibit significant relationships with each of the entrepreneurial variables that were explored: uncertainty avoidance, individualistic values, assertiveness, performance-orientation and future-orientation. In contrast, the factual attitudes (as is items of the GLOBE study) do not exhibit significant relationships with the entrepreneurial variables in the regression after controlling for GDP per capita and Gini. We found that normative culture is more important than factual culture for determining entrepreneurship, and the significant dimensions of normative culture are future-orientation, collectivism and assertiveness. Overall the findings may suggest that entrepreneurs tend to refer to future order rather to the current one.

Keywords

Cultural orientations, entrepreneurship

1.Introduction and hypotheses

The potential for and frequency of entrepreneurship has been shown to be associated to some extent with the occurrence of certain culture specific variables [1]. Studies linking culture to entrepreneurship exist, but show no consistent pattern. Moreover, current knowledge is relatively eclectic and not gathered in a comprehensive, concise form [2]. Most of the studies that have been skewed towards cultural values and entrepreneurial behavior stemmed from Hofstede's research [3]. Particularly, previous studies that used Hofstede's dimensions of cultural differences failed to consistently demonstrate correlation between various cultural dimensions and measures of entrepreneurial activities [4],[5].

Given the inconsistent results regarding the culture-entrepreneurship link, we argue that previous studies have ignored an important distinction of cultural values: the duality of normative values and

factual practices. By introducing the double nature of values into the research on the link between culture and entrepreneurship, we aim to fill the existing gap and contribute to clarifying the link. The theoretical foundation for our distinction between factual and normative values of culture dates back to the seminal works of sociologists Talcott Parsons [6] and David Lockwood [7] who both suggested that every social situation consists of a normative order, an factual order, or some substratum of the former. Normative and factual values are part of the exterior constraining the social world. Parsons' sociological theory was concerned with the "should be" as this normative stance affects social and psychological processes, social structure, and the conditions of human motivation and actions [7].

This study aims to investigate the links between cultural values and forms of entrepreneurial activity in different countries. It uses two multinational databases, one of cultural variables, the Global Leadership and Organizational Behavior Effectiveness (GLOBE) database and the other relating to entrepreneurship, the Global Entrepreneurship Monitor (GEM).

Perceptions of factual practices vs. normative values are available in the GLOBE database for individualism/collectivism, future orientation, assertiveness, performance orientation and uncertainty avoidance. Our study examines whether each of these various cultural values, in both their factual and normative forms, correlates significantly to different patterns of entrepreneurial behavior. This study first distinguishes between factual practices and normative values, and then explores to what extent factual and normative aspects of culture interact with various manifestations of entrepreneurial activity across 20 countries.

Based on theoretical consideration, which we will describe below, we would expect factual practices ("as is") and normative values ("should be") to be associated with entrepreneurial behaviors. We claim that the reason past research did not find consistent results on the impact of national culture on entrepreneurship is due to a persistent focus on the factual elements of culture, rather than the normative aspects that influence intentions.

For Parsons [6], the social system as a system of action was made up of the interactions between individuals that are not random but rather mediated by common standards of evaluation. Most important among these are moral standards, which may be called norms. The regularity, or patterning, of interaction is made possible through the existence of norms that control the behavior of actors. According to Parsons, the dynamic processes with which the sociologist is concerned are those which function to maintain social structures, or, in other words, the processes by which individuals are motivated to act in conformity with normative standards.

In criticizing Parsons' book *The Structure of Social Action*, Lockwood emphasized the non-normative elements of social action that were ignored by Parsons, because he concentrated on the normative elements of social structure and process [7].

1.1 Hypotheses

Based on the literature reviewed our *general hypothesis* expects that

Hypothesis 1. Cultural values on both the factual and normative levels are expected to be related to entrepreneurial activities.

From this general hypothesis, we develop several specific hypotheses, looking at subsets of cultural values.

- Hypothesis 2a: Future-orientation (FO) values are expected to be related with entrepreneurial activities; e.g. individuals who express the value of planning for the future tend to be more entrepreneurial.
- Hypothesis 2b: Individualistic values are expected to be more related to entrepreneurial activities than collectivistic values.
- Hypothesis 2c: Assertiveness values are expected to be related to entrepreneurial activities.
- Hypothesis 2d: Performance-orientation (PO) values are expected to be related to entrepreneurial activities.
- Hypothesis 2e: Uncertainty avoidance (UA) societal values are expected to be negatively associated with entrepreneurial activities.

2. Method

To examine our hypotheses we used two major data sources: 1) the Global Leadership and Organizational Behavior Effectiveness (GLOBE) Survey, and 2) the Global Entrepreneurship Monitor

(GEM). The GLOBE research program is a long-term, multiphase, multi-method research program consisting of three phases of three related empirical studies that were conducted between 1994-1996 (House et al., 2004). The GLOBE study has nine cultural dimensions, each with separate versions for "as is" (or factual, practice) and "should be" (reflecting ideals, values, normative). The GLOBE sample included countries from North and South America, Asia, Europe, the Middle East, and the Pacific Rim. A total of 17,370 middle managers from 951 domestic organizations (excluding multinationals) in three industries completed the culture and leadership questionnaires.

The 2007 cycle of the GEM database that was used for this study collected data of respondents from 39 countries. Using population samples, the GEM project estimates the prevalence rates of nascent and new businesses in different countries. In each country, a standardized survey was administered to a representative sample of adults (18-64 years old) [8]. To test our hypotheses, we used data from 20 countries that were included in both the GLOBE and GEM surveys.

Using the two separate databases to examine our hypotheses enabled us to avoid the common method bias that frequently characterizes studies where the same respondents provide data both for the independent and the dependent variables. In contrast, our research design can strengthen the validity of the findings.

2.1 Variables

2.1.1 Dependent Variables

GEM identifies three different stages of the process of creating and sustaining a business. *Nascent* entrepreneurs are individuals who are in the process of trying to start a firm and have done something tangible towards this end during the 12 months preceding the interview. Individual in this category plan to become an active owner-manager of a start-up but have not paid salaries to anyone for more than three months. *New (or early-stage) entrepreneurs* are owner-managers of entrepreneurial start-ups, as defined above but have been in existence for more than three months but fewer than 42 months. *Established entrepreneurs* are owner-managers of entrepreneurial firms that have been in existence for at least 42 months. Finally, *Total Entrepreneurial Activity (TEA)* includes both nascent and new entrepreneurial activities. It indicates the percentage of the adult working-age population (18 to 64 years old) in a country who are classified as either nascent or new entrepreneurs, (including self-employment attempts), as defined above.

2.1.2 Independent variables

The six cultural dimensions in GLOBE have their origins in the dimensions of culture identified by Hofstede [9]. The GLOBE measure of collectivism vs. individualism is derived from a factor analysis intended that resulted in two dimensions: Institutional Collectivism and In-group Collectivism reflects the degree to which people have pride and loyalty in their families and organizations [10]. Future-orientation was derived from [11] past, present and future-orientation dimension, which focuses on the temporal orientation of most people in the society and is similar to Hofstede's Long-Term Orientation [9], [12]. Assertiveness is a measure developed by GLOBE that is similar to Hofstede's Masculinity dimension. Performance-orientation was derived from McClelland's work on need for achievement [13], however the GLOBE measure was measured on a seven-point Likert scale. One score was calculated for each value/attitude variable and each GEM entrepreneurial variable for each of the 20 countries included in our sample.

2.1.3 Control variables

Gross domestic product per capita (GDPPC). The relevance of the GDP per Capita to entrepreneurship was displayed by GEM examinations [14] and in particular to control for economic effects in studies of entrepreneurship and culture [15]. *Gini Index* (Distribution of family income): GEM data have shown that there are pervasive differences in entrepreneurial behavior in different global regions and countries according to the different income distribution.

3. Results

To test the hypotheses, we ran a series of OLS regressions of which the dependent variables were the 4 entrepreneurial activity variables (TEA, nascent, and young & established firms). We introduced the GLOBE scores in their factual form as independent variables in each of the 4 regressions. To avoid the multi-colinearity bias, we did not include the factual and the normative indices in the same regression. GDP per capita and Gini of the countries were added to each of the regressions as control variables.

The results of the four regressions show that none of the GLOBE scores in their factual form exhibits a significant relationship with the entrepreneurial activity variables after controlling for GDP per capita and Gini, thus refuting Hypothesis 1 regarding the factual variables. In contrast to the factual variables, normative values (“should be” items in the GLOBE study) exhibit significant relationships with each of the entrepreneurial variables with relatively high Adjusted R squares. (See Table 1).

Specifically, in the first regression with the Total Entrepreneurship Activity (TEA) as dependent variable, four values out of the six that were entered to the regression were significant, except performance-orientation and uncertainty avoidance. Together with the two control variables, the Adj Rsquare was 0.38. Of the four significant normative values future-orientation had the highest marginal impact on TEA and was the only normative value that had significant negative marginal impact on TEA.

In the second regression, using nascent entrepreneurship, four values out of the six were significant, (assertiveness and performance-orientation were significant at $P < 0.1$). In this regression, institutional collectiveness had the strongest marginal impact, followed by future-orientation.

In the third regression that related to young firms only three out of six values were significant. (Group collectivism was significant at $P < 0.1$) and future-orientation had the strongest marginal negative impact. Finally, in the fourth regression for established firms, only one out of the six normative values showed significant impact, group collectivism.

In all four regressions there was a consistency between the directions of each the coefficients. For example, all the future-orientation coefficients had a negative significant impact. The exception was institutional collectivism that had positive impact in three out of the four regressions. Its only negative impact was on regression for established firms.

The regression of the established firms was found to have only collectivism in group as significant independent variable. This finding may suggest that normative values are more related to early-stage entrepreneurial firms rather than to established firms. Furthermore, this finding corroborates our conceptual framework that values are related to entrepreneurs as change agents.

3.1 Specific Hypotheses

Hypothesis 2a that expected future-orientation (FO) values to be related with entrepreneurial activities is refuted (see Table 1), meaning that future-orientated values are negatively related to entrepreneurial activities. Contrary to our expectation (2b) our results showed that the collectivistic rather than individualistic values were related to entrepreneurial activities. The expectation that assertiveness would be related to entrepreneurial activities, as expressed in 2c is clearly supported by our findings.

Hypothesis 2d that performance-orientation (PO) values will be related to entrepreneurial activities was not confirmed uniformly, other than marginally for nascent enterprises. Finally, 2e that predicted uncertainty avoidance (UA) values would be negatively associated with entrepreneurial activities was not confirmed.

Table 1 Cultural variables and entrepreneurship (OLS regressions)

Dependent variables	TEA	Nascent	Young firm	Established firm
C	-40.81*	-41.78**	-3.62	8.53
FO (SB) Future Orientation	-7.32**	-3.77*	-4.10*	-2.86
CI (SB) Collectivism	3.47*	1.69	1.95+	4.31**

Dependent variables	TEA	Nascent	Young firm	Established firm
in-group				
CII (SB)	5.54*	4.66*	1.52	-1.68
Collectivism institutional				
AS (SB)	2.26*	1.26+	1.04*	0.40
Assertiveness				
PO (SB)	3.88	3.81+	0.50	0.17
Performance Orientation				
UA (SB)	2.5	3.1	2.3	2.1
Uncertainty Avoidance				
GDPPC	-9.16+	-3.69	-6.11+	1.68
GINI	0.31**	0.17*	0.16**	-0.02

*P-value<0.01 ** P-value<0.05+-value<0.1

4. Conclusions

Our findings clearly demonstrate that normative values exhibit significant relationships with each of the entrepreneurial variables. In contrast, the factual attitudes do not exhibit significant relationships with the entrepreneurial variables. Overall, the findings suggest that entrepreneurs tend to refer to the future order rather to the current one.

Furthermore, out of the four significant normative values, future-orientation was found to have the highest marginal impact on total entrepreneurial activity (TEA) and was the only normative value that had significant negative marginal impact on TEA. This may suggest the presence of a paradox. On the one hand, our results show that normative values (“should be”) rather than factual attitudes (“as is”) are consistently correlated with the entrepreneurial activity variables. On the other hand, the negative coefficients of the future-orientation with all the entrepreneurial activity variables seem to contradict the former findings.

These contradictory results may be interpreted by the tendency of entrepreneurs to emphasize the “here and now” especially in their early entrepreneurial stages. The unpredictable and ever-changing environment in which entrepreneurs live, leads the actors to shorter-term strategies and improvisations. In contrast, future-orientation is the basis of formal organizational strategies that by definition involves the planned future action of a firm [16]. This interpretation may obtain support from another finding. While each of the three variables of early-stage entrepreneurship showed significant associations with the normative attitudes, future-orientation did not have a negative coefficient with older entrepreneurial activities.

Following formal theory-driven models of intentions such as Ajzen’s Theory of Planned Behavior [17], we can argue that entrepreneurs have salient attitudes and values that are not necessarily shared with the non-entrepreneurs. Entrepreneurs do not aspire to the factual order. They develop conceptions and intentions for the “should be” or normative order. Later on, as shown by Bygrave’s model [18] of the entrepreneurial process, precipitating events are part of the process, but the intentions are important dimensions in the entrepreneurial process.

We found that group and institutional collectivism were both positively associated with the entrepreneurial activity variables, refuting our hypothesis that individualistic values should be more related to entrepreneurial activities than with collectivistic values. These findings corroborate the *cushion effect*, described above. This concept, borrowed from the literature on finance, contends that a collectivist society provides the individual with a safety net, making the individual less risk-averse. This explains why collectivism values rather than individualistic ones were found to be positively and strongly related with entrepreneurial activities. These results suggest that the link between individualism and entrepreneurship that is commonly assumed in the United States (e.g [19]) is not necessarily universal.

As Thomas and Mueller [1] state, perhaps influenced by Weber and McClelland, the ideal profile of the entrepreneur continues to reflect the characteristics of Protestantism and achievement, was primarily developed and tested in US settings. As a consequence, the US culture of individualism and

achievement has dominated the world view of entrepreneurship. Our findings regarding the relationship between collectivism and entrepreneurship question this contention.

Our findings refuted the hypotheses that uncertainty avoidance values in a society would be negatively associated with entrepreneurial activities. Uncertainty avoidance was not significant in any of the regressions.

Performance-orientation and uncertainty avoidance were deemed important to entrepreneurial activities, in general, both in their factual and normative forms. It might be that the cultural characteristics of performance-orientation (PO) and uncertainty avoidance (UA) need to be perceived as culturally context-dependent variables. Previous research leaned heavily towards US-based contexts and samples reflecting a singular orientation, while our results represent a more heterogeneous sample of 20 countries.

Arenius and Minniti [20] found that perceptual variables had an impact on new business creation across all countries using GEM 2002 samples from 28 countries. They stated that perceptual variables are powerful predictors of the likelihood of being a nascent entrepreneur. Our findings corroborate their findings and refine them, because normative values, such as assertiveness were found to be associated with the early-stage entrepreneurship but not with the activities in established firms. Moreover, Arenius and Minniti [20] also showed that the introduction of country-specific effects, though significant, did not reduce the cross-country importance of perceptual variables. In this vein, we also found that the introduction of our control variables of the GDP per capita and GINI index to the regressions did not reduce the cross-country importance of the cultural variables. Together, these findings may suggest that normative, cultural values could be determinants of entrepreneurial activities or at least encourage them.

Finally, methodologically this study benefits from using independent data sources for cultural practices and values, and for entrepreneurial activities. The independence of the measurement of cultural practices and values from the measurement of entrepreneurial activities lends credibility to arguments regarding linkages between these two areas of cultural values and entrepreneurship.

Engagement of Management and Employees in Enhancement of the Quality

Afrim Loku¹

¹Afrim Loku afrimloku@yahoo.com

“Undoubtedly one of the most challenging aspects for every manager is the dedication to the quality. In this article we will provide a research presentation which emphasizes some of the factors that influence the development and improvement of quality in management of human assets. Our approach will be oriented on presenting the ideas and results from the research that we have done. The reason for determining the necessary resources of an enterprise is done to achieve the necessary quality of the enterprise. The analysis process is imperative for identifying the readiness and the need for the requests that we can have for the human resources so that the enterprise can be ready to achieve the desired goals”

Keywords

Quality, improvement of quality in management, human assets, analysis process

1. Preface

Management of human resources is a process for securing that the appropriate people are working in a appropriate place and time. Management is about achieving the goals of the enterprise in an efficient and effective way through planning, leadership and control of the enterprise resources. Research of individuals and society that will be engaged during the process of production and economy is primary for a quality. Target groups in economy are clients where the purpose of the economy is to reach them. But, it cannot reach them if the production process doesn't function properly where the recombination of the different resources will be done towards achieving the final goal. Which individuals or which society is going to work with sources of limited natural resources? Here rise many problems and alternatives that the economy takes into account before it starts working with its business activity. In order to accomplish the objectives, enterprises or institution should secure not only material and monetary sources but also human sources, i.e. its personnel. Human sources have a vital importance for the success of the activity of every organization. Economy researches human sources because through that it achieves the increase of quality in all enterprises. Important economy ratings should be taken into account during the detailed and real analysis that we do in economy. We should choose the ways on how to attain the organization and planning of economic development. If we choose the wrong ways we will be stuck for a long time in the situation that we are now, i.e. with unorganized and non-functional economy.

2. Dedication to Quality

The issue that is related to the concepts and principles of organization/institution is dedicated to its quality. Regarding this issue the relatively neutral image was presented in answers of the surveyed persons.

Figure 1 Distribution of answers in engagement of the quality

Source: Survey of year 2009

In the aspect of the size of organization/institution, more positive answers are presented from the surveyed persons whose institution has 50 employees (80,0%) and 201-500 employees (70,0%). On the other hand, employed in institutions 51-100 employees and 101-200 employees only 28,4% and 26,0% respectively, have given the positive assessment of dedication to quality in their work environment. The highest negative assessment percentage for dedication to quality is presented to the employees in institutions with over 1.000 employed (56, 0%). This is followed by the category of surveyed persons employed in institutions with 501-1000 employees, where the percentage of negative answers was 63,7%. The small percentage of surveyed individuals that gave negative answers, are employed in institutions with 201-500 employed (2,0%) and the surveyed in whose institutions are less than 50 employed (10.0%). If we continue to compare the general answers with cyclic life of the institution where the surveyed persons are employed, we may notice some deviations. It is interesting to emphasize the high percentage (63,4%), of positive answers (modality 4 and 5) of the surveyed whose institution is 16-30 years and very low percentage (1.7%) of negative answers. The following results have been taken in proportion with employment sector:

Figure 2 Distribution in percentage of answers for assessment of engagement of quality of organization/institution in the aspect of employment sector

Source: Survey of year 2009

From given results we can see that the highest percentage of negative opinions for engagement of the quality is in the answers of the surveyed persons employed in health institutions. If the answers of the surveyed from the education sector are intercrossed with type of institution in accordance with the level of education we will see that the surveyed persons employed in institution of high education have higher results for engagement of the quality comparing with the employees in secondary schools.

3. Influence of Changes in Quality

It is up to the managers to decide when and what changes and controls should be made. These kinds of decisions are completely normal and unavoidable part of the managerial responsibilities, since no event or strategic plan or review can foresee in general all the problems or events that may happen. The time will come when every organization must change its action directions, to review and modify the strategy in order to find the way for more efficient application and functioning of the enterprise as entirety.

The process for implementation of changes depends on the concrete situation. In crisis situation, the approach of typical leadership includes gathering of main information, identification and assessment of different possibilities and preparation of many prior actions which are relevant for existing situation. Strategic directors usually meet with their subordinates and other individuals from lower levels and make a long discussion trying to build a quick consensus amongst members regarding their responsibilities and the common way of implementation.

If the agreement is not achieved, then the manager's task is very difficult to impose responsibility and to ensure support for their realization. When the situation allows the managers to decide easier what changes to make, then they are dedicated completely in planning each individual action part. Process through which the managers pass when they decide for changes, is the same whether it is about active or reactive changes and in general consists of: collection of basic information, wider and more detailed consideration and understanding of the situation, development of possible options and their detailed elaboration, offering of suggestions for ways of implementing the actions, building management consensus and in the end by achieving the complete agreement for manner of implementation of planned strategy.

Time needed to decide on changes of vision, strategy, ability, ways of implementation and application may include few hours, days, weeks or months depending on how complex is the situation for decision making. The success usually depends from complete analysis of situation and right justification for business.

A good test on how efficient is implementation of changes is considered when the organization has a good strategy and is carried out in a right way. If these two conditions are fulfilled then there are high chances for excellent financial and strategic results as well as for effective application of changes.

4. Improvement of Quality

When asked if in the institution / organization the team work is being encouraged in the last three years, we have got the below shown results.

Figure 4 General distribution in percentage of opinions regarding the collective work in institution / organization in the last three years

Source: Survey of the year 2009

Based on answers, team work was not developed entirely in public institutions. When we compare the general distribution of answers of those that were surveyed regarding the team work, with earlier

answers that were given about the encouragement of engagement with the clients and existence of responsibility in decision making processes, it looks like the employees attitudes about the basic objects based on which the general situation is established it is mainly in accordance. More precisely, constantly in their last attitude, they decide to choose a negative state of public institutions that do not fulfill reference points of excellence in the management of the organization and service offering.

5. Conclusion

In regards to the employment sector, answers of the surveyed that were employed in the health institutions were followed in the last three questions, meaning that the frequency of the answer with negative emphasis continues and they specifically express categorical disagreement (27.9%) regarding their chance of expressing ideas in their organization. From the gained answers about the stance that "Management values the ideas of the employees" we can conclude that, again, negative attitude of the employees regarding this statement is prevalent. This opinion is undoubtedly connected with the idea that the majority of the employees in the public sector are completely aware about the negative working conditions, but in fact, until now, reforms in this field were done to end the negative trends. Taking into consideration the possibility for expressing the ideas and their acceptance by the management is seen as negative, the surveyed are left in the attitude and statement that the atmosphere in the work where they accomplish their duties is unfavorable. Continually, more than half of the surveyed or 58.9% claim that the management doesn't value their ideas. Also a considerable number is undecided (28.9%), whereas positive answer gave only 12.9% of the surveyed.

Methods and tools for product innovation

Mimoza Luta¹, Edison Luta²

¹Lecturer Faculty of Applied Sciences in Business in Peja – University of Prishtina
mimosa.luta@gmail.com

²Master studies Economic Faculty- University of Prishtina, soni_luta@hotmail.com

Tools for innovation come in many different shapes and sizes. There are many useful tools such as mind-maps, collaboration software, modeling software, knowledge and idea management systems, etc. These all have a role in the innovation process but they are not innovation tools as they implement generic activities. Their usefulness is directly dependent on the methodologies employed, not on the tool itself. The tools of most interest to the innovator are those that directly enable, support and direct the right methods and practices for the innovation process. These are the tools that directly lead to the knowledge necessary for understanding the community, technology and solution domains from which value can be derived.

Keywords

innovation, motivation

1. Introduction

Globalization of competition and the evolution of financial markets have taken economic activities under a different framework than the one we knew as the establishment for the last decades.

Traditional methods of local development have left behind protectionism and artificial barriers to the world trade have been lifted long ago. The financial needs for global marketing, as well as mass production able to meet global demand, underlined the significance of the financial markets, transforming the production and distribution system into a credit system [1].

The incorporation of digital electronics with their accompanying software to all, products, distribution systems and production itself, under the umbrella of the financial markets, namely the “new economy”, gives the impression that things have drastically changed. From another point of view, there are no differences, since consumers are still seeking the maximum satisfaction from whatever they give their money for and remain producers themselves either as workers or as entrepreneurs, trying to maximize their revenue, in other words their source of money [2].

On the other hand, savings are the only source of capital that covers the expenses of enterprise creation and evolution, are driven to the most profitable destinations, taking into consideration the risk involved.

Widening the borders of capital movement, increasing the size of the enterprises and incorporating fast and secure communication, seem to make the economic activities more sophisticated and complicated. The intrinsic relations between the various factors remain the same, while the instability of the international financial markets gives enough ground to the reconsideration of development, seen as the local creation of wealth.

2. Nature of Innovation

Various definitions of innovation concentrate the attention on the various aspects of innovation or its use, so there is not a standard definition, which may have a universal application.

Common, in all definitions, is the aspect of something new, either a natural characteristic of a product, a production procedure, a sales network or technique, a new use of an established product or service, or even a new combination of product/service ensample?

The Webster dictionary indicates that innovation is:

“The act of innovating; introduction of something new, in customs, rites, etc

A change effected by innovating; a change in customs; something new and contrary to established customs, manners, or rites”

It is necessary to distinguish other similar terms, in the sense of their content and usual application.

Invention, seen as the original construction of something that did not exist before, is a part of innovation. Invention is the usual starting point of innovation [2].

Innovation is a marketable commodity, service or know-how. It can be examined as having separate or accumulative characters of:

- New products
- New production procedures
- New organization systems
- New methods of Selling
- New financial procedures

The purpose of innovation is profit creation by all parties involved, the result is the increment of local wealth, thus improvement of the living standards. Innovation has always been the driving force, the locomotive of progress, being the perpetual vehicle of both prosperity and civilization [1].

3. The need for Innovation

Competition, on one hand and the chaotic infinity of human needs and desires on the other, describe the environment in which economic subjects operate and live.

Competition is congenital to human nature (to all living organisms, as theorized) which is a satisfactory explanation of the economic cycles, as well as the life cycle of a product or service. Every economic subject is trying to perform better than others and it is beyond the limits of the present to examine why (there is a vast collection of literature, from Freud to Argyris).

Enterprises, in their competitive framework, are trying to innovate their products, in order to gain the consumer's attention presenting an alternative way to get more satisfaction by consuming them, their services, trying to convince the users that theirs are better than other available, their production procedures, trying to diminish costs and increase quality and so be cheaper, better or both, their marketing methods, trying to better meet the consumer desires, their financial scheme, in order to exploit the credit system and their organization, for a better performance[2].

Thriving to perform better than competitors, enterprises are seeking as much innovation as it is not risky for their established products, markets and profits. This is usually represented as a reaction to change, common to all profitable operations. Changes are not necessarily innovative, while innovation means a change itself. Reaction to change includes all parties, entrepreneurs, financiers, workers and managers alike. Reaction to change is obviously also reaction to innovation, since any change means to take the risk of failure, everyone is trying to avoid it. In the same time, any change is a turbulence of the equilibrium of conflicting interests with unpredictable results.

The market forces, even under protectionism, are feeding ambitions and drive innovation to competition with the establishment. Business ideas are created continuously, either as an imitation of success cases or as innovations. Investors are trying to balance between the risk of innovation and the security of the establishment. The less an investment comprises risk the lower are the expected revenues. The more an investment is based on speculations about the market reaction, the higher are the expected revenues, while this speculation is not based on documented forecasts but just on a hypothesis which may or not be verified. Uncertainty is not attractive to common investors, so speculation, when it is successful, brings back as high profits as much as the risk of failure, because of the lack of competitors in the initial phase. When it proves to be successful, many imitators follow, but innovators still have an advantage, having already created an establishment.

4. Innovation creation procedures

- Established firms use several methods of innovation creation, such as:
- They also buy innovation, instead of creating it, wherever it is available, using methods such as:

Research and Development is concentrating attention of businesses, as well as the government, as the source of innovation, because innovation is widely connected to technology.

Inventions are certainly necessary to the innovation of products and production systems, yet innovation is closer to a new use of existing knowledge, than the application of newly created knowledge. It all starts from a business idea, in the sense of an expected number of economic units (consumers, enterprises or public authorities) ready to pay in order to get the new product or service, obtain it in a new way, with unusual terms of payment, in a faster delivery time or with most desired standard characteristics, otherwise called quality.

Employees, managers, engineers, external collaborators, researchers and academic personnel are all individuals coming across innovative ideas. In spite of their connection or bounds to the enterprise, research institute or education unit, they all have the primary will to exploit the innovation which their brain has created. Some of them obtain a patent in order to safeguard their intellectual property and then start to market their idea. Most of those market ideas are never applied, for reasons that exceed the purposes of the present.

5. Application of innovation procedures in innovation creation

Innovation is a product of human activity. It is brainpower and knowledge that permit its creation, while “dreaming” of it is the real generating procedure. Being a product it has a commercial value, its commercialization means risk to lose the invested time and effort together with the money needed to finance expenses of going into detail, write proposals, meet the potential investors (or receivers) or obtain a patent and risk taking means expecting profits[4].

A “bottoms-up” approach of innovation creation may start from the fact that innovation is a product, so producers are the offer side, while investors are the demand side. This is applicable in all cases, from company employees to public servants, from politicians to academic researchers, from students to company managers and from housewives to academic teachers.

Traditional methods of innovation creation and implementation may need a revision using the same procedures, which are being used for the creation of innovative products and / or innovative production and marketing methods. Innovation as a result of creativity is now the major concern of management. In the traditional authoritative approach, it is the manager’s ability to promote the innovation concept among the people working under his guidance. It is his responsibility to assess the innovative ideas and adopt or drop them. Creativity and innovative orientation is then a result of leadership, effective in some extend[4].

Innovative business ideas need their own marketplace, which cannot be simply invented. The market rules derive from bridging the conflicting interests of the offer and demand sides. The demand side is always in search of better offers, while the offer side is advertising, in order to convince the demand side to buy, highlighting the most convincing characteristics of their product or service. Both sides are trying to make a profit out of these transactions. Sellers are trying to establish long-term maximum margins, while buyers are trying to maximize their long-term margins with optimal provisions[4].

Although the marketplace operates under formal and ethical rules, agreements that satisfy both the giver and the receiver sides are eligible, whatever their content. Public authorities and non profit organizations, as well as enterprises, have to create a marketplace of innovation. The creation itself of this marketplace may be considered as an innovation. If it will be limited by bridging offer and demand, then innovation vanishes after its creation. Looking back at the innovation creation procedures of the

enterprises, it would be rather a continuous innovation creation if the same methods were used, instead of a static act, even if it is a breakthrough[4].

Innovation, when examined as a product, has consumed human effort and money, put at a risky venture with the hope of a corresponding profit. Procedures that bring to surface and thus make evident the potential opportunities for the prospective receivers the creativity results of the individuals need the participation of the interested parties, givers and receivers, in order to adapt to the ever-changing expectations.

Brainstorming is an example of such a way of usage of the methods of innovation creation, which may lead to innovative procedures. Research is another way of obtaining similar results. Steering committees are used by social organizations and local authorities as an instrument of determination of development strategy. They may be used as the organizers of brainstorming and research about the procedures of creating innovation in development actions.

Firms should be aware of the value of the procedures of innovation creation, without confusing technology and development with it, just because in many cases technology is needed in order to apply it.

6. Conclusions

It is imperative to create awareness about innovation to peripheral enterprises; otherwise economies will end up with complicated logistical problems, if enterprises flourished only in the central points of the Regions.

Globalization, knowledge based economy, electronic society and all other components of what is being called “new economy” are promoted in order to create wealth and subsequently prosperity to the citizens. These components have at least two aspects; technological and economic. Basic research is needed as the platform of future technology. Applied research is needed as the platform of the creation of new products and / or services, as well as new manufacturing and organization methods.

Peripheral economies should concentrate their efforts to innovation rather than invention, based on laboratory research executed in the appropriate Institutes. Enterprises and local authorities in these less developed areas, if they try to create technological breakthroughs are in a great disadvantage against central economic entities. Enterprises are after profits and local authorities are after prosperity and social welfare. Their interests are common as common is the way of reaching their goals; take innovative actions for innovation creation.

Higher education institutions have a crucial role to play. They have attracted and recruited most of the peripheral brainpower, which has been driven to basic research motivated by academic incentives. It is not surprising that the academia personnel is motivated by economic incentives, while academia itself creates bureaucratic obstacles. This happens because academia is uni-disciplinary and concentrated in the scientific aspect, which has to be controlled otherwise academia, the compass to the future risks to lose credibility, if control of its personnel actions is lost. Once the innovation content and process is clear, it becomes evident that it is multidisciplinary, with an equilibrium between scientific coherence, feasibility compromises, profit expectations, cost/benefit consideration, social impact and collaborative in terms of scientific fields, personal, scientific and institutional authority, authenticity and superiority.

Involved parties will be rewarded according to their degree of acceptance of the contribution of all the others.

The Impact of Tourism Innovation on Visitor Expenditure – A Case Study from Eastern Finland

Teemu Makkonen¹, Timo J. Hokkanen²

¹Department of Geosciences and Geography, University of Helsinki, Finland, teemu.makkonen@helsinki.fi

²Centre of Economic Development, Transport and the Environment for North Karelia, Joensuu, Finland, timo.hokkanen@ely-keskus.fi

Tourism has gained an increasing amount of attention as a development tool, especially in rural areas where the conditions for success are relatively weaker for many other economic activities. Previous studies indicate that tourism can bring significant or at least fair amounts of outside expenditure to the local economy, thus revitalizing the local economic structure. Similarly, innovations are considered to be a crucial factor affecting the growth of regions. However, the research on tourism innovation has been relatively scarce up until the very recent years and the local economic impacts of innovation in tourism studies remain largely unexplored. This study aims to make a contribution to the field of tourism innovation and their impacts. The case addresses the innovative ICT application (a mobile game) in the Museum of Pielinen in Lieksa, one of the more peripheral towns in Eastern Finland. According to a pilot survey conducted in the summer of 2010 it, however, seems that the impact of the mobile game on the local economy is not as substantial as desired, because it is not well-known enough to draw in large numbers of tourists. Therefore it would be of utmost importance to develop the marketing of the innovative service due to the potential it can offer to meet the needs of tourists. However, the location itself in the Museum of Pielinen, has had a more positive effect than was expected on the tourist expenditure in Lieksa.

Keywords

Attraction, Innovation, Nordic Model of Tourism, Tourism, Tourism Expenditure

1. Introduction

The aim of this study is to examine the local economic impacts of an innovation in the field of tourism by using the expenditure method of the Nordic Model of tourism (NMT), a commonly used methodology in the Nordic countries. With the NMT the expenditure of tourists in the local economy can be estimated. The case study location is the innovative ICT application (a mobile game) in the Museum of Pielinen in Lieksa, one of the more peripheral towns of Eastern Finland. Mobile games are not new to the world, but the case in hand matches the description of an innovation as a market-based application of a new product. The town itself is suffering from outmigration and unemployment. Thus for Lieksa, as well as for many other rural and peripheral areas, where the possibilities of employment with another means are limited, tourism represents one of the few remaining economic options that has realistic growth prospects. The main research questions of this study are:

- Does the Museum of Pielinen have a significant impact on the local economy of Lieksa?
- Does the mobile game work as a significant tourist attraction?
- Does it have an impact on the tourism income of Lieksa?

2. Conceptual Framework

2.1 Tourism and Rural Development

Although, the notion has also received some criticism [1], tourism is commonly considered to be one of the fastest growing sectors in the world, mainly due to increased leisure time and standards of living for more people [2-3]. Thus, as the economic impacts of tourism are growing steadily and as the role of traditional livelihoods has decreased, tourism has been increasingly viewed as a tool for local development, especially in peripheral and rural areas [4-6]. At the local scale tourism is used to diversify the economic base of communities through the creation of positive income- and employment impacts. However, tourism can also have undesirable impacts on other local sources of livelihoods and detrimental environmental and socio-cultural impacts [7-8]. Thus, sustainable planning is needed to balance the benefits and costs of tourism [9-10].

As already mentioned above, tourism is extremely valuable for rural and peripheral areas, where the possibilities of employment with another means are weak and, where the services are not maintained only with the purchasing power of the local inhabitants. Indeed, in many remote or underdeveloped regions tourism represents practically the only form of viable economic activity which can bring realistic growth prospects for the future [11]. Still, not every rural locale in need of employment and income generation is a candidate for tourism [12-13]: there has to be something in way of locational assets to lure the tourists to the region i.e. attractions [14-16].

2.2 Innovation and Tourism

It is commonly acknowledged that innovations play a crucial role in the productivity and growth of firms, industries, regions, etc. [17], as demonstrated by the research on innovation which has boomed over the last few decades. Still, many authors have noted that there is a lack of academic empirical research on the innovation of the service oriented tourism industry [18-19]. One factor is the lack of data availability - commonly used indicators of innovation, such as patents, are not feasible in tourism [20]. However, the lack of innovation in tourism is more down to the fact that the service sector only innovates differently compared e.g. to manufacturing sector [21]. Therefore, the innovativeness of the tourism sector has gained an increasing amount of attention from academics in the recent years (for an extensive overview on the subject see Hjalager [22]).

Innovations in tourism are predominantly linked to innovative efforts undertaken in other sectors i.e. tourism businesses in general have been the main imitators and adaptors rather than innovators [23-24]. Still, tourism firms operate in a competitive sector: firms' competitiveness depends on their innovativeness in achieving higher quality outputs to meet the needs of potential customers and to introduce new products [25]. Furthermore, Mattson et al. [26] argue that in fact just the making of a scene is in itself an innovation. Innovation, thus, holds great potential for tourist destinations to attract tourists and to create tourism income [27].

In light of their various definitions, innovations are treated here as the market-based application of new processes, products or forms of organization [28]. The innovation in this study, as is usually the case in the tourism sector, is an application originally invented in other sectors, successfully adapted to meet the needs of tourists. Thus, although mobile games are not new to the world, they do fit the definition of an innovation as a market-based application of a new product.

2.3 The Nordic Model of Tourism (NMT)

Probably the most commonly used method for estimating the local economic impacts of tourism in Finland, is the NMT. In 1983 the Finnish Tourist Board published instructions for the utilization of the model, and since then many studies on the impacts of tourism in Finland have applied and reapplied the model. The NMT can be divided into two discrete parts, which can be used separately or together as complementary to one other. The expenditure method is used to survey the spending of tourists in a region with the help of questionnaires (or interviews) distributed on site and; using questionnaires, the receipts method is used to estimate the share of tourism revenue and employment of firms who benefit from tourism in the study region. Examples of the NMT's application can be found in e.g. Saarinen [29] and Rinne and Saastamoinen [30]. In this study the expenditure method of NMT was used. However, although the NMT has proven to be a valuable tool for evaluating the economic im-

pacts of tourism, the results attained are based on numerous variations that raise further questions about their reliability, repeatability and comparability [31-32].

3. The Case Study Location

Lieksa is a small, rural, and sparsely populated (population, 12 788; population density, 3.74 inhabitants/km²) town in the eastern part of Finland, in North Karelia (Figure 1). The town is suffering from structural changes and levels of unemployment (unemployment rate 17.2%) and outmigration are high (a negative net migration of 50–250 person per year). Tourism has a prominent role to play in the economy of Lieksa, which is home to the annual Brass Week music festival, Patvinsuo national park, Ruunaa hiking area and one of the most popular Finnish national parks in Koli. Previous studies, conducted in Ruunaa and Patvinsuo, on the economic impact of nature tourism in Lieksa have estimated that an average visitor spends about 50 € when visiting Lieksa [33-34]. In addition, the economic impacts of the Brass Week was studied in 2007 [35], and the results indicate that the visitors spent from 35.7 € up to 71.8 € per day in Lieksa (for a description of the evaluation tool used see Pasanen et al. [36]).

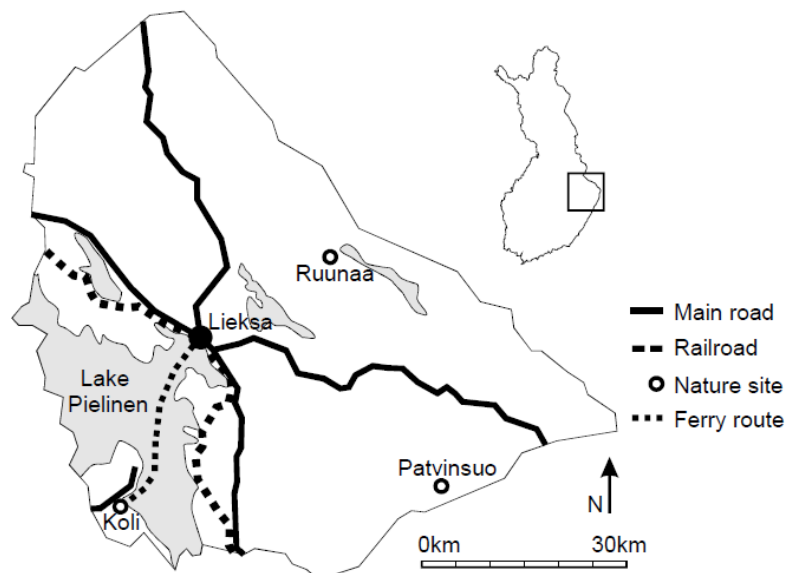

Figure 1 The map of Lieksa (main roads, railroads, ferry routes, and nature sites)

Situated in the centre of Lieksa (see Figure 1 above), the Museum of Pielinen, depicting the rural way of life and peasant culture in Eastern Finland, is the second largest open air museum in Finland. The museum had about 8 200 visitors in 2009 of which 16 % were foreigners. The museum offers an opportunity to use a mobile game to learn about the local history and everyday life of Finnish peasantry i.e. the purpose of the game is to bridge the physical- and virtual worlds to offer a new and exciting way of learning things with two story based games. The first storyline, situated in the end of the 19th century, challenges the visitor to learn about the daily chores of a housewife named Anna and the second, situated in the 1930s, offers an extensive view of the life of Jussi, a lumberjack working on a nearby logging site [37]. The mobile game has been developed by UbiqueLab team from Educational Technology Research Group at the University of Eastern Finland. A wireless web has been set up at the museum to allow the game play and visitors are provided with mobile phones, with the game installed, for loan during the summer season.

4. Results

A pilot survey was conducted in the end of the summer of 2010 to test the survey form and to get a preliminary overview on the impacts of the Museum of Pielinen and the purported benefits of mobile game to Lieksa's local economy. As mentioned above the survey form was constructed using a simpli-

fied version of the NMT's principles of the expenditure method and it also included specific questions about the mobile game. The personnel of the museum collected 50 answers from the visitors. About 60% of the respondents were female and the average correspondent was aged 42. The majority of the correspondents were mainly from other parts of Eastern Finland or from the Helsinki metropolitan region. The average group size of the respondents was about 4–5 persons and the average duration of the trip to Lieksa was about 2–3 days.

The Museum of Pielinen was the primary target of the trip for 11 visitors. Most commonly the museum was a planned site to visit during the trip (25 respondents), but not the only one, and for some the museum was an indiscriminate visit decided on the spot (14 respondents). What was discouraging is the fact that only a minority of the respondents had heard about the possibility to try out the mobile game in the museum. And what's more, from the handful of visitors who actually had a prior knowledge of the game, only a few acknowledged that it had had even a slight impact on the choice of destinations to visit (Figure 2).

Figure 2 The impact of the mobile game in the choice to visit the Museum of Pielinen (n=49)

The average visitor to the museum spent about 62 € during their stay in Lieksa. This result is in line with the previous surveys, but expenditure is slightly bigger than expected in comparison to the 50 € estimated by Eisto [33] and Heikkilä [34] and on the upper margins of the estimation by Mikkonen and Ristolaiinen [35]. Most of the expenditure was spent on groceries, retail trade and in cafes and restaurants (Table 1).

Table 1 The average expenditure of correspondents in Lieksa (€/person)

Refuelling and other station services	11
Local trips (e.g. bus, taxi, ferry)	5
Groceries and retail trade	19
Cafes and restaurants	14
Accommodation	7
Program- and recreational services (e.g. admission fees)	5
Other expenditure (e.g. equipment rents)	1
Total	62

As this is only just a preliminary study based on small sample we do not analyze the larger economic-multiplicative, and employment effects that the museum or the mobile game may be having on the Lieksa's local economy. The survey will be repeated on a significantly larger scale during the whole of the 2011 summer season. Subsequently, with a more extensive sample of visitors we assume that it will be possible to draw broader conclusions about the true economic impacts of the museum and the mobile game.

5. Conclusions

According to the results it can be concluded that, as a standalone tourist destination the Museum of Pielinen makes its own important contribution to Lieksa's local economy. The average visitor expenditure was higher than would be expected when compared with the previous studies about Lieksa's nature sites. However, on the other hand the mobile game had a negligible effect on the destination choice of visitors. Thus, according to our modest sample at least, it cannot be seen to have any widespread impact on the local economy. The reason for this is, according to the respondents, that the mobile game is simply not widely known enough to attract them to the museum. Thus, to maximize its impact, further developing the marketing of the mobile game seems obvious next step to us. As of now the mobile game has been without a larger audience, and therefore the potential which it offers, underutilized.

Sanitation presents even more problems than drinking water. Sanitation coverage in urban areas is almost the same as drinking water coverage. Urban areas have mostly combined sewage and storm water collection networks that discharge into near bay surface water-bodies. About 40% of the urban population has a sewer connection. In rural areas, only a small portion of the areas with piped water supply is equipped with sewer networks. Most rural areas have individual household wastewater collection systems, principally simple pit-latrines with no drainage pipes. Upgrading of sewer networks hasn't kept pace with the general development of infrastructure, and the materials and technology used haven't been improved. Presently, there's no treatment of wastewater in Albania; its discharge in water bodies, especially in coastal tourist areas and delicate ecosystems, is a major environmental concern for the government/business/community/wide public.

Albania faces a water distribution problem, not a water production problem. Studies indicate that available sources of supply could provide more than enough to satisfy the country's overall water demand. In many cities, water availability at the source is about 500-700 litres per capita per day, but leaks and waste mean that only a small fraction of water produced is consumed. Almost everywhere problems of water scarcity can be considerably mitigated through metering, leakage detection and reduction, network improvements, disconnection of illegal connections, and optimization of storage and supply patterns. The distribution problem also has a seasonal aspect: much more water is needed during the summer growing season; when rainfall is scarce, rural drinking water is often misused for irrigation; and the tourist resort areas use large amounts of water.

The main issues handled out in this presentation are: strengthening local government leadership and initiative; partnership between municipalities and NGOs; concluding all of these in the community-based approaches to infrastructure services and neighbourhood revitalization.

Keywords

Municipalities, NGOs, Urban Areas, Drinking Water, Social Leadership.

1. Community Drinking Water Treatment for Emergencies and Remote Locations

Almost everywhere problems of water scarcity can be considerably mitigated through metering, leakage detection and reduction, network improvements, disconnection of illegal connections, and optimization of storage and supply patterns. The distribution problem in Albania also has a seasonal aspect: much more water is needed during the summer growing season; when rainfall is scarce, rural drinking water is often misused for irrigation; and the tourist resort areas use large amounts of water.

On average, water is available only 3-4 hours per day, with certain areas receiving water only once in three days.

Blue future Filters introduces our latest offering slow sand and roughing filters: our patented SSF/x drinking water treatment technology in a flexible, shippable, storable tank. The SSF/x has been reliably treating surface water to potability worldwide for many years. This new version of the tried and tested technology makes clean water for small communities available literally out of a box. The filters come in a carton, weigh 39 lbs. They can be stocked for ready deployment without taking valuable storage space. They can be transported in numbers by truck, mule, on the back of a motorcycle or even a backpack. Once on site, they are loaded with 30 cubic feet of local sand and water from any surface source, immediately eliminating common pathogens. Water gravity feeds into the filter and can produce up to 1800 gpd, enough for a small village. Multiple units in parallel can accommodate hundreds of people within days or hours.

2. Climate Change and World View

The Earth's climate is changing and its atmosphere is warming. What might this mean for freshwater resources?

- *Rising water demands.* Hotter summers mean thirstier people and plants. Temperature increases will likely contribute to higher water demands. In addition, more evaporation from reservoirs and irrigated farmland will lead to faster depletion of water supplies;
- *Increased drought.* Scientific evidence suggests that rising temperatures in the southwestern United States will reduce river flows and contribute to an increased severity, frequency, and duration of droughts;
- *Seasonal supply reductions.* Many utilities depend on winter snowpack to store water and then gradually release it through snowmelt during spring and summer. Warmer temperatures will accelerate snowmelt, causing the bulk of the runoff to occur earlier—before crops can use the water—and potentially increasing water storage needs in these areas;
- *Long-term water supply reductions.* Many communities depend on seasonal water runoff from glaciers. Although shrinking glaciers create higher runoff (and thus more water) in the short term, the longer-term disappearance of glaciers threatens this important water resource.

Thinking about your local reservoir may conjure visions of water sports, fishing, or picnicking, but reservoirs serve a much more vital purpose. Reservoirs, or man-made lakes, are typically created by building dams across rivers (some also occur naturally).

Reservoirs even out the fluctuations in a water supply by storing water when it is abundant and releasing it later, especially when a water supply diminishes during drought.

Identify advances in detection, monitoring and modelling, analytical methods, information needs and technologies, research and development opportunities, and communication strategies that will enable the water supply industry and other stakeholders to further reduce risks associated with public water supply distribution systems.

Water towers, a familiar sight along nearly every highway in America, help to make sure that water deliveries remain relatively constant even during peak water use times. Their main purpose, however, is to elevate the water level high enough to supply adequate water pressure throughout a distribution system.

- *Water quality problems and issues are both local and regional as evidenced by a variety of reports included in, (Hydric Management, London 1989, 2003).*

Water quality assessments are in charge of the Department of Environmental Protection (PADEP), and testimony received by the committee. Some of these water quality problems are associated primarily with urbanization vicinity; some are associated with activity in the Allegheny River basins; still others are common to the predominantly rural counties.

Large differences exist among the sources of problems, their potential effects on Albanian public health and environmental quality, and their likely solutions.

Further, resolution of water quality issues is affected by other regional issues such as transportation, land use, and governance of the metropolitan area.

Small hydro is gaining ground across the Balkans. The small (municipal) Albanian investor is looking for medium-size hydro and dam companies who know how to tap special funds. This has been traditionally the arena of big players such as Siemens or *Alstom* with specific staff to handle the World Bank, the European Investment Bank and the EBRD. The Balkans show small funding is happening. Brussels and USAID also have small technical funds in the agricultural sector which can mesh nicely with reservoir building for irrigation and domestic water projects. American banks are also very active in Albania.

The extensive use of reservoirs for fish production as part of food security is expanding exponentially. There is a market for expertise on protecting big volumes of fish at the turbines, as well as fish ladders and other bypass schemes. Reservoir stocks for the market attract EU funding and may be worth tens of millions of Euros. Food ministers want clean river basin waters reaching the sea which will not damage high value shellfish beds and fish breeding grounds.

The significance of this is reflected in tensions between Italy, Croatia, Slovenia and Albania over their coastal stocks. One side of the Adriatic is only about 148km from the other, so the potential for pollution from the land is very high. In 1993 fertiliser land runoff coated 600km of the Yugoslav to Italian coastline with toxic algae. This cost several billion Euros in today's money through lost fish and collapsed tourism.

The existing pattern of water supply and water quality services in the region is highly fragmented, with more than 1,000 providers operating in the multicounty region area, like many other metro areas in the United States, large-special purpose authorities such as the Allegheny County Sanitary Authority (ALCOSAN) can achieve substantial economies of scale through joint management agencies.

Although private organizations may not have direct voting power in what mix of organizations is chosen to implement the plan, they could very well influence how the public and its elected and appointed representatives make these choices.

3. Conclusions and Recommendation

Planning for water quality improvement, especially where capital investment is substantial, must therefore reflect regional planning goals concerning economic development and demographic character, such as impacts of urban sprawl and (re)development.

Although no single unit of government has all the necessary power to implement the Three Rivers Comprehensive Watershed Assessment and Response Plan (CWARP) recommended and discussed in, (*Studies & Center of Economic CESS,2001;2004*) it is desirable to have some mechanism to facilitate continued oversight of regional progress (or lack thereof) toward clean water and its relationships to other regional goals and activities, and to help realize the benefits of cooperation.

The three poorest zones in Ecuador, with 80 percent of the canton population of 35.000 living below the poverty line mostly in rural parishes and scattered remote settlements. Lack of access to land and the ongoing process of fragmentation of family holdings have led to widespread poverty, prompting out migration.

To meet these daunting challenges, the canton democratized its planning and management procedures. This process allowed the canton to build consensus, prepare a development plan, allocate municipal funds equitably leverage additional resources and improve infrastructure and living conditions. The participatory municipal management improve infrastructure and living conditions.

The participatory municipal management process was institutionalizes ensuring representation of women and marginalizes groups.

Intrapreneurship: Challenge or new way of Working for Existing Organization?

Monika Markovska¹

¹Faculty of Administration and Information system management, "Ss. Kliment Ohridski", Bitola, Macedonia, monikamarkovska34@gmail.com

Francis Bacon (1561-1626) said: "He that will not apply new remedies must expect new evils: for time is the greatest innovator". In the latest time there is a growing need for innovation in the whole business world due to the rapid changes caused by globalisation. The dynamic nature of existing organizations, especially those competing in global market and the volatility of the existing organizations in our country setting make it imperative that organizations and their managers remain receptive to new ideas, approaches and attitudes.

According to Gifford Pinchot III and Ron Pellman (1999, p.11), innovation is necessary to differentiate one's offering, to find and fill unoccupied spaces in the market and to keep up with the soaring productivity of competitors. Rapid and cost-effective innovation is the primary source of lasting competitive advantage in the twenty-first century, leaving organizations no alternative but to innovate well or cease to exist. Pinchot III said: "Creativity and innovation are fuelled by the intelligence of people who have the freedom and right to express their ideas". The key components of entrepreneurship are creativity and innovation, which are often confused with each other. Some believe that they are synonymous, but in fact they are different. Creativity is a solitary, individual process and refers to the generations of new ideas. These ideas may have very little value to anyone else except to be creator. In fact, creativity can be defined as a process of being sensitive to problem, deficiencies, gaps in knowledge, missing elements, disharmonies etc.

Innovation refers to the process that follows the conception of a novel idea, and often involved many people who each offer different suggestions and contributions. With the increased emphasis on creativity and innovation in the world of work, existing organizations face the challenges of nurturing new ideas and effectively transforming this creative new into innovating products/ services.

Intrapreneurship can be seen: as a process by which individual inside organizations pursue opportunities without regard to the resources they currently control. Intrapreneurship includes the set of activities required to move a concept or idea right through to implementation. Existing organizations are looking for people who do more than thing of new things to do, but actually do new things.

An analogy for the intrapreneur would be the chess player, who may make a bold move yet understand the parameter of the game and anticipates the possible counter-moves. They are willing to take calculated risks because they have come to terms with the possible ramifications of the innovation. In fact, they feel comfortable with the uncertainty of the changes they are making. Intrapreneurs constantly seek innovative, even experimental, ways to watch, evaluates, sense, interact with, respond to, and anticipate customers. In this way, intrapreneurs not only are learning from marketplace but also are constantly educating it.

Pinchot III said that intrapreneurs are the "dreamers who do". In most organizations people are thought to be either dreamers or doers. Both talents are not generally required in one job. But the trouble with telling the doers not to bother about their dreams is that they dream anyway. When they blocked from implementing dream of

how to help the existing organizations they are dreaming dream of revenge. A mind is meant to imagine and then act.

It is not right to separate the dreamer and the doer. The important tasks of organizations, is to restore the place for vision in everyone's jobs. The intrapreneurs are people who are working very hard to realize the vision into profitable reality like new product/ service. New product/ service refer to the development of a product, from its initial idea until it becomes a commercial product available for public use. It will be usually use the term "venture" in lieu of the more lengthy "new product development project". A venture refers to the development project than to the new product itself.

Survival of the venture in the organizational environment is not easy. Often in the best of the conditions, venture is usually created within a culture that supports innovation and intrapreneurship. Even in the best managed organizations, intrapreneurs are facing with a number of obstacles and barriers, such as resistance to change, the inherent nature of large organization, lack of entrepreneurial talent etc. Intrapreneurial venture is completely different from the real practice at existing organizations. For surviving in organization it should be followed this set of rules: being innovative and resourceful in obtaining approval, finding and using allies, forming coalitions, persuading management to relax polices and procedures. It is therefore clear that organizations have the possibility to do things differently and better than they are being at the moment. Developing the intrapreneuship in organizations result in several advantages, including the development in the size and/ or diversity of the product and service range, and helping the organization to expand and grow. It also assists in the creation of workforce that can help maintain its competitiveness and promote a climate conducive to high achievement.

Keywords

existing organization, intrapreneurship, innovation, intrapreneurs, intraprise.

1. Introduction

Often in theory for term intrapreneurship can use synonyms: corporative entrepreneurship, corporative enterprise, intra corporative entrepreneurship, strategic reformation and etc. In fact, it means creation of new entity within existing organization, venture.

Intrapreneurship is a concept related with entrepreneurial orientation of organization. In fact, intrapreneurship is important for organizational existence, growth, profitability and reformation of existing organization. Innovation is common theme for all form of intrapreneurship. The use of innovation like mechanism for redefine and reformation of organization is forming essence of intrapreneurship. Intrapreneurship become term that it's use all the time in world of the business to describe organization that it's ready to recognize opportunities and then continues develop, initiate action and produce new product and/or service. These organizations can be corporations, non-profit organization, factories, schools and universities. The road of successful intrapreneurship is full of risks and difficulties. Like always, potential benefit in term for future successful organization indicates that it's worth to risks and hammer at. Involving the spirit of intrapreneurship in existing organization include changing of organizational culture across establishing goals, feedback and rewarding system oriented to results. Employees have to be encourages and supported in these efforts to develop and implement intrapreneurial projects. Actually, the organization needs to find ways for measure and reward intrapreneurship.

In 1985 Pinchot coined the term "intrapreneurship", short for intra- corporate entrepreneurship, whitin the organization. Intrapreneurship is increasingly becoming a term used in the business world to describe organization that are willing to pursue opportunities, initiate action and emphasize new, innovative products or services.

Due to the dynamic nature of modern organization it is imperative that organization and their managers remain receptive to new ideas, approaches and attitudes. It is therefore the belief that rapid and cost- effective innovation is the primary sources of lasting competitive advantage in 21-th century, leaving organization no alternative but to become intrapreneurial of case to exist. This thesis focuses

on this need and examines way in which intrapreneurship can be measured in organization in order to provide a benchmark for further organizational development.

New principles of organization are needed to produce an organizational brain that functions in a very different way from bureaucracy's vertical communication in a chain of commands. The structure of intelligent organization is not set by those in charge during periodic recruiting; instead, order emerges as a result of every one voluntary connection and more democratically determined direction. After research made on organizations in Republic of Macedonia there are data that enables to get a real picture about functioning and influencing of intrapreneurship in large organization. The new principles of working are dictating the new way with is different from the way bureaucracy works. According to the needs of the market large organization must be innovative, and open for innovating new products/ services. Therefore, this thesis is designed for developing intrapreneurship in large organization.

2. What does mean intrapreneurship?

There are many definitions for intrapreneurship. The basic definition for intrapreneurship gave Gifford Pinchot III who introduce this term. According to him: "Intrapreneurship is a method of revitalization entrepreneurial spirit, where is the best people and resources- in organizations".[1]

Jarna Heinonen argues that innovation wider defined is something that relates all forms of intrapreneurship. She also argued that using the innovation as a mechanism for redefining or reinvention the organizations, its position in the market and industry or competitive environment, it form the essence of intrapreneurship.

Nielsen, Peters & Hisrish (1985) argued that: "Intrapreneurship is development of internal markets within existing organizations and relatively small and independence unit designed to create, to make internal tests of the market and develop, to improve or innovate personal product/service technologies or method. In other words, this authors point out that intrapreneurship is organizational effort to improve internal working through internal market. This is a different way of working from the way that organization to do to improve and increase profitability.

But Antoncic and Hisrish (2001) describe four intrapreneurial dimensions that follow:[2]

- New business intraprise.
- Innovation.
- Self- renewal of the organization.
- Proactive.

New business intraprise is defined as a: creation of new business within existing organization no matter of the level of autonomy. According to them, it is meaningful dimensions of intrapreneurship because it evolves new business creation. New knowledge (new methods of working) creates possibilities for making new things in a new ways, which make old ways of working unusefull. New efficiency in creating and bringing knowledge means that we are living in time in which ability to innovate efficiency becomes primary determinant for success of the business. This means that organizations should give freedom to its employees which are more close to the entrepreneurs. Experiment in intrapreneurship has shown in many organizations which becoming new and more effective models for team working. Model through which organizations understanding and manage with the complex of the time. Intrapreneurship is original mix of managerial and entrepreneurial skills to accomplish innovation within organizational lining. Intrapreneurs have to be able for innovating within organizational culture, to govern with process and employees that it's result at environment of innovation and change. Innovation is process not just idea and also searching organizational support at senior management level, mentoring and team work for accomplish successful results. For example: at university can include enriching of student or academic community, public agreement or new development of technology, culture or organization. Intrapreneurship is risk but it's has to start somewhere. Consider it, intrapreneurship like concept for developing entrepreneurial spirit in existing organization has own advantages and disadvantages (shown in table 1). [3]

Table1 Advantages and disadvantages of intrapreneurship

Dynamic innovation is a key for long-term success of organization.	Possible conflict and dissatisfaction from relationship between colleagues.
Improving of individual or group performance.	Possible outfall of organizational resources (time, workforce, capital) if they are not managed appropriately.
Effective conclusion for change of market and unusually business environment.	Loading with work result with heavy innovation effort.
Quality of interpersonal relationship cooperativeness between colleagues.	Stress reactions, hierarchical conflict between employees obligations.
Attitudes with acquisition in direction of working.	Undefined environment for innovation.

The role of organization is:

- Establish framework that it's encourage, facilitate and support intrapreneurial process.
- Qualify a development of intrapreneurial skills.
- Incorporate outputs for develop business of organization.

Intrapreneurship is broad concept that it's consist of generating, development and continuing with implementing of innovating ideas within existing organization. This innovation can be new product, process or accomplishing goal, new service, system related with organizational business model. In fact, intrapreneurship is set of formal and non-formal activities in order to form business opportunities within organization across product/service, process, or develop of new market. All these activities can take place anywhere level of organization, business department, functional or project level with end goal, improving organizational performance and creating competitive advantage in front of all competitors in the market. Intrapreneurship is process in which every individual or group employees within existing organization create new organization or accomplish change or innovation.

2.1 Phase of intrapreneurship

During establishing venture exist different phase: [4]

- Solo phase.
- Project phase.
- Bootleg phase.
- Phase of formal team.

Solo phase. At the start intrapreneur establishes own vision. It is delicate thing to make decision when vision is complete for starting share with others. When idea is not form and fluid, the others who give suggestions for help often feels like striking. If it's let ideas to be coopting from others to fast maybe it's will be lost interest for them. Later, when idea become enough strong for intrapreneur, he face with suggestion of others without change it. It often help them to write before show the others and save discussion focused on desire direction and establish own authorship on idea.

Phase of project. When general idea is clear, most intrapreneurs share with friend at organization and with several customers. Form their reaction they learn more for strength and weakness of concept. In this phase, intrapreneur still does not lead the others in action but give them feedback and causal help. Surprisingly it is easy to get other together to take part in venture. To start, it is necessary to tell them they are respected experts.

Bootleg phase. Continuing the phase of the project some people gravitate in direction of helping with other rather than with words and facts. As far as, someone does not officially specified of venture, he start with develop of product or researching of market. This is crucial phase because it is happening different things. That is:

- Un-formal team is forming around idea. Intrapreneur is not alone anymore.
- Intrapreneur has a followers and than he has a responsible for leadership.
- Intrapreneur work with people and test them who can be member of officially team.
- Idea and skills for leadership are being tested without organizational background. Then advantages of idea and leadership are understood.
- Intrapreneur does something from creative work what will be does at venture. Team lending time and show productivity in simplifying of ideas.
- Intrapreneur creates micro-culture in venture. People learn how to act like team.

Phase of formal team. Some business can start with one smart individual who need army of people for executive his plan when business is growing. This model was represented in traditional way of working. Business that is creates entrepreneurs and intrapreneurs need complex accomplishment for one thinker and many work performers. Intrapreneur needs intrapreneurial team, member which complement vision and help for it execute.

3. (Not) enough identify conditions for development of intrpreneurship in organization

During different debate about intrapreneurship often is mentioned the word bureaucracy in existing organizations. Every organization has built "immunity system" against intrapreneurship, so it is necessary a lot of time and strengths to crush that immunity system and to start with realizing different projects. Most of the organizations are made on that bureaucratic model of working where there is routine activities and strong vertical hierarchy. It was different world, world of mass markets, uniformed products/ services and long term production process. But it is very clear that that kind of working doesn't work today. Today marketplaces need organizations which are creative and innovative. For that kind of work organization need intrapreneurs. And on the other hand for intrapreneurs is necessary to know the opportunities of organization if he/she wants to stay and t work in that organization. Intrapreneur should discover that part of the organization where exist conditions for execute different project. Furthermore, every organization integrates factors which will transform organization to become intrapreneurial.

Individuals in existing organization may give their contribution without becoming managers, through innovating. Many innovative organizations on this way creates second career path, where creative employees give their best. Intrapreneurs and entrepreneurs are not necessary for new products/services. Their involvement is in taking new ideas, even working on prototypes as well as their realization in profitable reality.

But, one thing is very important for organizations. They need to direct heir efforts toward generating new ideas and opportunities for development. It is necessary knowledge, creativity and innovation to put in a first place on the business agenda.

This research is focused on question for identifying of venture opportunities in organizations where can be implemented intrapreneurial activities.

So, in organization it is necessary to discover those parts where exist condition for establishing intrapreneuril activities, and it is also necessary for intrapreneurs to be empowered to realize their ideas to become business reality. Passing away from traditional to innovative organizational culture and developing organizational process of venture will ease way for establishing intrapreneurship in organization and in that way will bring the development of business and profitability of organization itself.

4. Identifying of the key elements for implementation of intrapreneurial activities in organization

It is suitable for the organizations which establish intrapreneurship to know which intrapreneurial activities will integrate in organization itself, to estimation of conditions for organization to become innovative. The necessary things that need to be done from the organization are to implement innovative process which will support innovation and intrapreneurship. Process of innovation is extremely detailed and complex. If organization wants to be successful in innovations, it is necessary to have its own model of innovation. In that direction collective actions of every participant will be coordinated, even people who resist will change.

In fact researching is directed toward identifying of input for intrapreneurship (resources, reward system, sponsors) for rational use and testing of transformation process in leadership, organizational structure, organizational polices, organizational culture, individuals and tasks which are in interaction and like that impact in improving innovativeness and inventiveness of organization.

According to the context explained before about intrapreneurship it was designed model which basics hypothesis for organization to become intrapreneurial is introduce innovation approach on individual and organizational level. Development and implementation of intrapreneurial activities needed rational and productive allocating of those input which are important to increasing of efficiency and effectiveness and improving the quality of working. For implementing intrapreneurial activities it is necessary to be establishes vision for "doing the new things on new ways." Vision regards to

introducing new products/ services, processes, business model and/or improving of existing products/ services. To accomplish that it's needed to reach degree of awareness for importance of innovation in organizational elements: leadership, organizational structure, organizational policy, organizational culture, individuals and tasks. All of those elements are interdependent to each other and toward development of intrapreneurship is necessary to be incorporated all of them together. In fact, it is necessary for innovation to be constituted in:

- Leadership,
- Organizational structure,
- Organizational policy,
- Organizational culture,
- Individuals
- Tasks.

Development of intrapreneurship in organization leads to development of innovativeness and inventiveness of organization, where will be generating opportunities for new ideas, exist vision for development and/ or improving new products/ services, processes, business model and realization of vision from beginning to profitable reality.

With designed methodological instruments were measured variables:

- Development of innovativeness and inventiveness of organization (*dependent variable*),
- Leaders characteristics of visionary and flexibility, strategic plan for accomplish vision, decentralizing of organizational structure, flexibility of organizational hierarchy, reward system for intrapreneurial behavior, polices that encourage creative and innovative approaches, independence of employees and teamwork, level of awareness for accepting opportunities and take risks from employees, demonstrate initiatives from employees, intrapreneurial qualities of employees, employees attitudes toward to change, risk and failure (*independent variables*).

Development of innovativeness and inventiveness of organization (*dependent variable*) was measured through:

- Launching of new products/ services,
- Dividing "firm in firm",
- Changing the existing firm in innovative.
- Independent variables were measured through:
- Innovative tasks,
- Employees- intrapreneurs,
- Flexibility and decentralization of organizational structure,
- Planed polices which encourage creativity,
- Intrapreneurial leadership,
- Intrapreneurial culture.

5. Interpretation of results in function of model for identify the key elements of intrapreneurship In Republic of Macedonia

Summarized results got from thesis led to interpretation of general thesis: If in the organization exist rational using of components of intrapreneurship (resources, reward system, support from manager) through institutionalize of innovation in elements of: leadership, organizational structure, organizationao polices, organizational culture, individuals and tasks then will be created conditions for implementation of intrapreneurial activities which means: innovation and invention in organization.

Which mean that is accept in a part of institutionalize of innovation in elements: leadership, organizational polices and organizational structure and it is declined in tasks as element. That is result from knowledge that individual level of tasks refers to the way individuals work. Furthermore, organizational culture and individuals they are input of basics determinants of intrapreneurship. In fact, organizational culture diagnoses level of innovativeness of organization, and individuals are carriers of innovation. Organizational culture and individuals in theoretical model are identified as elements where it's necessary to be institutionalized innovation, but empirical researching declined as elements and identifies as inputs or determinants of intrapreneurship. This data shows that it is necessary transformation of theoretical model in model which is appropriate in the practice in existing organizations in Macedonia.

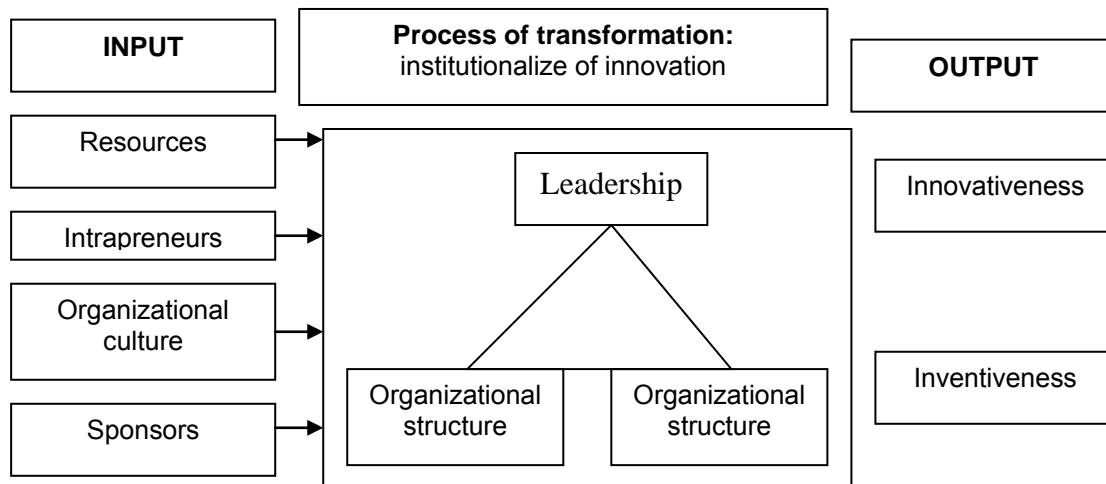

Figure 1 Practical model for development of intrapreneurial activities in existing organizations

6. Conclusion

Existing organizations manage of resources necessary for completing the job and working in organization. But it is necessary for employees to be rational in using resources able to the organization in a direction to generating and researching new ideas. Organization has employees which possess creative potential, knowledge and skills to do something new and useful for the organization. Intrapreneurs develop their own vision for new products/ services and vision how to realize idea in profitable reality. Intrapreneurs (may have experience in other organization) knows that every organization is unique. It is fact that employees will change themselves first, rather than organization itself. Intrapreneus must known well impact of organizational culture in organization where works. According to the attitudes, values and norms of behaviour accepted from employees in organization, intrapreneur must adjust its intrapreneurial behaviour. Organizational culture play very important role in development of intrapreneurship. In fact, organizational culture which support innovation, provide identity of intrapreneur, loyalty to ownership and organizational mission. According to organizational culture attend to explain and strength standards of behaviour.

Intrapreneurs create a new business within existing organization

Monika Markovska¹, Todor Kralev²

¹ Faculty of Administration and Information system management, Ss. Kliment Ohridski", Bitola, Macedonia, monikamarkovska34@gmail.com

² Faculty of Entrepreneurial business, University of Tourism and Management, Skopje, t.krlev@utms.edu.mk

Intrapreneurship is a method of working which will allow people to express their own potential more fully. Much of this potential is trapped within the hierarchy layers of organizations. Intrapreneurship is a step toward freeing individuals and organizations to build more meaningful and more productive lives. Intrapreneurs take responsibility for creating innovations of any kind within organizations. He/ she may be creator or inventor but is always the dreamer who turns an idea into a profitable reality. Intrapreneurs should research and find out the proper part of organization where exist the conditions for realize the venture. Working on the idea for the new product/ service is a first step in a building a new business. Furthermore, the idea develops in a business plan and then he/she realize that business plan into a profitable reality.

As an intrapreneur, the employee will act as owner of his/her own business. An intraprise is a business still legally owned by the larger organization but operated and controlled internally by one or more employees of the organization. An intraprise may serve internal or external customers or both. The new intraprise liberates the energy and intelligence of the employees. In that kind of organization, employees who have an idea are free to sell their idea as a product or service. The intelligent organization where creativity of the employees is important and respected is staying competitive at the global market.

Intrapreneurship is more actual in modern organization. Basicly, it means taking risk in developing new products/services. The risk is taken by employees who are so called intrapreneurs. There are differences between traditional managers and intrapreneurs. Intrapreneurs are known as: visionary, creative people and people who develop new products/services.

They are also taking venture and work at intrapreneurial teams. Opposite of this the traditional managers are protecting themselves and their workplace. They think that their work is good enough and there is no necessity for introducing innovation. If organization wants to become intrapreneurial it must encourage intrapreneurs and traditional managers must change their attitudes, and way of working. Peter F. Drucker said: "Every organization- not just in business- needs one essential competence: innovation". Entrepreneurship as a characteristic of human activity is known as well a human society. The man has to develop its ability for entrepreneurship, for providing his own existence. Entrepreneurship is often related with forming and starting new business. When we talk about who is entrepreneur, we can say that there is no person who doesn't want to have his own business once in his life. Every person wants to have freedom in decision making, be successful, have a lot of money, but those reasons are not enough for some person to be successful entrepreneur.

Entrepreneurs are people of new era they establish and develop their own business. But, when we are talking about intrapreneurship, this term is coined in 1985 from Gifford Pinchot III. He thinks that with establishing intrapreneurship in productive and

unproductive organization, they become more effective in their work. Intrapreneurs find out new ideas and make them in profitable reality. Intrapreneurship is a method of using intrapreneurial spirit where are the most good people and resources: at organization.

New knowledge (new methods of working) create possibilities for creating new things in a new way which makes the old way of working not effective. The new efficiency in creating and giving the knowledge means that we live in time where abilities for innovations are becoming determinant for the success in business. When competition makes innovations- it creates new product/ service or processes- one must innovate or die. That means that organizations have to give freedom to their employees and more close relationship and communication with entrepreneurs. There are many examples for organization and companies who use intrapreneurship as a method and a way of working like "Johnson& Johnson", "3M", "Citibank" etc. In competitive environment, it is necessary for the organizations to identify and search new business, ideas and possibilities. But researches show that organizations are facing with difficulties. Intrapreneurs want to achieve something but they have many obstacles in the organization itself.

There can't be innovation without taking a risk. Mostly, organizations don't want to take the risk. It becomes from managers who think that every mistake and failure is losing of precious time. But, mistakes have to be understood as a way of improving product/ service. That's why the success of intrapreneur is in his experience form which they are learning. They learn from their own mistakes. They are not afraid they are facing and looking for the ways how to solve them. The nature of intrapreneur is to research. They are doing that on the market with their own researches. The product/ service are giving to the customers who gave them feedback.

Intrapreneur is the person that has to find his own way in organization and to prove the managers that mistakes and failures bring improving the product/ service. Intrapreneur has to be flexible because he must realize his own idea. He realizes the idea with the help of the team members. All the aspects are important for realizing the idea from production, relation with customers and suppliers, different opportunities for sale etc. which is important for success of intrapreneurial effort for realizing innovation.

Keywords

Intrapreneurship, intrapreneurs, intraprise, new organization, venture.

1. Introduction

Intrapreneurship is often connected with existing organizations which lately puts great accent on intrapreneurial activities. Those organizations are directed onto creating an environment in which creative employees will continue with new way "of doing things", which will lead do generating new ideas for new products/ services in the organizations. Intrapreneurs sometimes are known as innovators, innovators which promote new products. Intrapreneurs carry out new processes with which are generated new products for markets. The reason for that is the fact that they are creative and they take risk so they left the traditional role in business. Intrapreneurs have courage to let their imagination and decisions to show them which directions should be taken.

Intrapreneur is employed in existing organization. In fact, intrepeneurs are happy when works in small teams with people with passion which have different abilities and skills. The key of whole working is in building the team. With appropriate training and organizational support, most of people are able to develop intrapreneurial mindset.

In existing organizations may be found many people which possess skills for mindset of entrepreneurs, which have desire to solve the challenges, results and difficulties till opening its own firms. They are very talented employees which haven't standard profile of employees, because their personal profile and working style are unusual. That's why they are named as intrapreneurs.

2. Who are intrapreneurs?

Often is indicated the question why is intrapreneur? There are too many definitions from different authors which give their own point of view on intrapreneurs.

One definition explains that intrapreneurs are:

“Persons who are focus onto innovation and creativity. They transform dreams and ideas in profitable venture, through acting in organizational environment.”

One of the reasons of existing of this definition in this paper is the meaning of the author *that intrapreneurs are visionary*.

Today workforce is consist from many un satisfied employees which are frustrated in working which is routine, not spiritual, not inspiring. They have necessity to be given to them opportunities which will hire their imagination, will connect their set of skills and will direct their creativity. Intrapreneurship is one of the ways to do that.

Gifford Pinchot III gave the definition in which are given the comparison between intrapreneurs and entrepreneurs:[1]

Intrapreneur: All “dreamers that do.” All of them take responsibilities for creating innovation of different kinds inside organizations. Intrapreneurs may be creators or innovators, but always they are dreamers who discover how to convert idea into profitable reality.

Entrepreneur: Somebody who make the role of intrapreneur outside organization.

Intrapreneurs found new ideas and convert them in profitable reality, so intrapreneurship can be diffined as process in whom: “are developed innovative products or processes through creating of entrepreneurial culture in already existing organization.”

Furthermore it will be explained how different authors define entrepreneurs. Some of definitions are:

“Intrapreneurs are persons who focus on innovation and creativity and it tries to transform his dream in profitable venture, through acting in organizational environment.”

Intrapreneurs have set of entrepreneurial skills which use it in organization rather than starting their own business. Mission that lead intrapreneurs in developing new products/services or processes give better explanation for previous definition. Intrapreneur is a person who accurately plans his work or career and believes that it is its own life mission.

There are some definitions from different authors.

“Intrapreneurs are employees who works in business with entrepreneurial capacity, creating innovative new products/ services and processes for organization”

“Intrapreneurs in organization promote innovative activities and minimizing negative effects of structure and system. It needs to be noticed that innovation that undertake means creativity as well as ability for realization and profitability of project.”

“Intrapreneurs are inside entrepreneurs which follow the example of founder of organization.”

Intrapreneurs constancy search innovative or experimental ways to look at, evaluate, feel, respond and forecast customers.

Similarity for intrapreneur is chess player which can do brave moves besides understandable parameters in the game and forecast possible opposition moves.

3. Characteristics of intrapreneur

Intrapreneur is included in process of intrapreneurship, which refers to developing new business inside organization, starting from initial idea till it become visible business. Intrapreneurs create new business and different ways of performing of things which results in innovative possibilities for organizations. They are pioneers and have a plan which needs to be followed. They can get the idea from different unconnected subjects and themes, and integrate them in their area of working in a way to bring the organization in direction of new managing. Intrapreneurs must be careful how they “move” inside organizational culture. If they are in a conservative culture, they will attract people or they will confront with them. They will attract those who have similar point of view with them and likes changes. They will confront with the people that don't like the changes and are satisfied with status quo. Intrapreneurs are people that are not favourite in organizations, and if behavior is not corresponding to the culture, they easily may become undesirable.

Many of their characteristics, which will be famed if they been entrepreneurs, but often they are not respected and organizational environment did not understand them. They are just “employed”, in specific time they can be seen from others as an impatient, unpractical, arrogant, unfounded, and aggressive.

There are many characteristics which are typical for intrapreneurs. Some of key characteristics are: [2]

- Entrepreneurial thinking. They are capable to see “what it can be”. They are focused of founding new solutions without searching explanation for the problems. They are inspired from the obstacles. They use creativity for generating new ideas for solving problems.
- Visionary leadership. They help others to see further from their typical aspects of thinking and go much further then they want. They are able to make relationship outside their departments for successfully making the projects. They are able to pass through organizational policy just to make things that are given to them.
- Passion. When they are obliged to something they do not except NO as an answer. They have huge level of energy... which is infectious or backwash and it depends from the organizational culture in which they work.
- Accelerator of changes. Always look how to capitalize opportunities for improving. Favorite question is “why not”. They are directed toward changes through connecting with others and simplifying the processes.
- Generator of values. They build bridges between theory and practice. They are able to use limited resources for accomplishing important results. They understand key business fundamentals and how to use solutions which helps the organization to make money nad how to keep money.

It is well known that intrapreneurs enabling ideas to become reality inside the organization. Intrapreneurs can be champions or team leaders. Lately it is known that everybody can be intrapreneur. Some author think that intrapreneurs should combine characteristics from entrepreneurs as well as from traditional managers because they have positive set of values, are directed and they should be loyal to the brand and business too.

According to Giford Pinchot III intrapreneurs have this attributes:

- They want free access to the resources of the company,
- They are self- motivated,
- They “manipulate” with the system,
- Have courage and self- confidence,
- Focused on customers,
- Wants modest risk,
- Do their own researches,
- Minimize risky projects
- Learning from mistakes.

It is clear that traditional managers are different from entrepreneurs because entrepreneurs use their abilities, its funds, building their own business design their own set of values and behavior.

intrapreneurs are some were in the middle as it was explained in the upper part of this paper. They need characteristics from entrepreneurs for as well as characteristics from traditional managers for easily handling with barriers in traditional organization.

Some of attributes of intrapreneurs are:

- Compact visionary and creators,
- Brave and with a lots of self- confidence,
- Flexible and innovators,
- Intellectual and curious,
- Have technical skills and knowledge for the market,
- Aim- oriented and self- motivated,

Intrapreneurship as a method for working in existing organizations require from intrapreneurs to have energy, self- confidence, optimism, courage, speed, clear vision, flexibility, persistence, enthusiasm, business, technical and knowledge for market, communication skills and ready all the time to use their hands for work. But there is another question here: How those characteristics may be developed?

The answer is that that is not easy, but it can be developed with openness and awareness. That is the way for people to understand more for themselves and for others, and in that direction they will establish and use better network.

At the figure 1 are shown important characteristics that are necessary for intrapreneurs, need for carry responsibility in their way of working.

It is possible different way of explanation on the individual qualities and characteristics for intrapreneurs. Those qualities are complemented with the characteristics shown in figure 1. Individual

quality of intrapreneur always comes out during his/hers working in organization. There are some qualities that are important for intrapreneurs like: [3]

- believing in innovation,
- creative, but pragmatic imagination,
- psychological safety,
- independent nature,
- vision oriented,
- self-motivation,
- oriented toward success,
- interpersonal skills,
- energy,
- sense for time

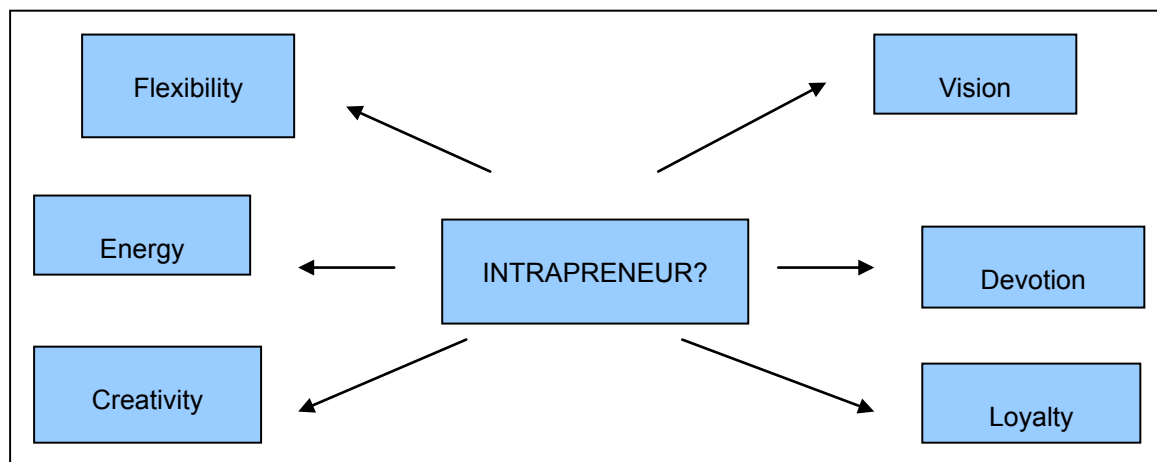

Figure 1 Characteristics of intrapreneur

Last three qualities are named as “killer instincts”, where intrapreneurs know where to go or when to stop. Combination of vision, self- motivation and “killer instinct” provide interesting image of secure, personalized, energetic, and pragmatic intrapreneur which will be proactive, but not forced from the managers or others employees in existing organization. intrapreneur of corporative entrepreneur, lately is seen as new business hero. Furthermore intrapreneurs their attention direct toward individuals and processes which produce new products/services in the organizational dedication.

There are many authors who explain different or similar characteristics of intrapreneurs which describe nature of intrapreneurs. People who are identified as intrapreneurs in organization usually show characteristics as activity and taking risk. Their behavior is characterized as clear breaking of existing practices in organization. Accenture identifies 5 key behaviors of intrapreneurs:

- Creativity and innovation,
- Ability to use creativity,
- Directed,
- Focused on creating of values,
- Taking risk.

4. Intrapreneurs v.s. entrepreneurs

Often intrapreneurs ask themselves: “Should I stay or should I left organization?” In the answers of this questions are showing intrapreneurship. If someone is intrapreneur, what he need to do? Should he/she take a risk? Intrapreneurship has a chance to help the organization to direct the future and it's existing. intrapreneurs should think about:

- reaching the moment,
- leaving opportunity, leaving the organization and becoming intrapreneur?

If decision of intrapreneur is to "catch the moment" is because he/she feel empowered, contrary from other employees which doesn't feel empowered. People from outside aren't connected with the quantity and quality of their work for success of whole organization, or for enlarging of payment. Nobody in organization isn't obligated to sell ideas to made profit, but intrapreneurs do that. Jack Raiton in its researches about intrapreneurship, makes comparison between characteristics of intrapreneurs and entrepreneurs. It is about differences and similarities in their motives, time orientation, skills and experience, behaving in environment, resources, mistakes and failures etc. This is explained in figure 2. In his researches intrapreneur is described as person who makes atmosphere for succeeding innovation. It's work is directed toward market through different approaches and different researching. It integrates in a small flexible firm but, it is well known interactive learning and hiding his work or so called "shunkworks".

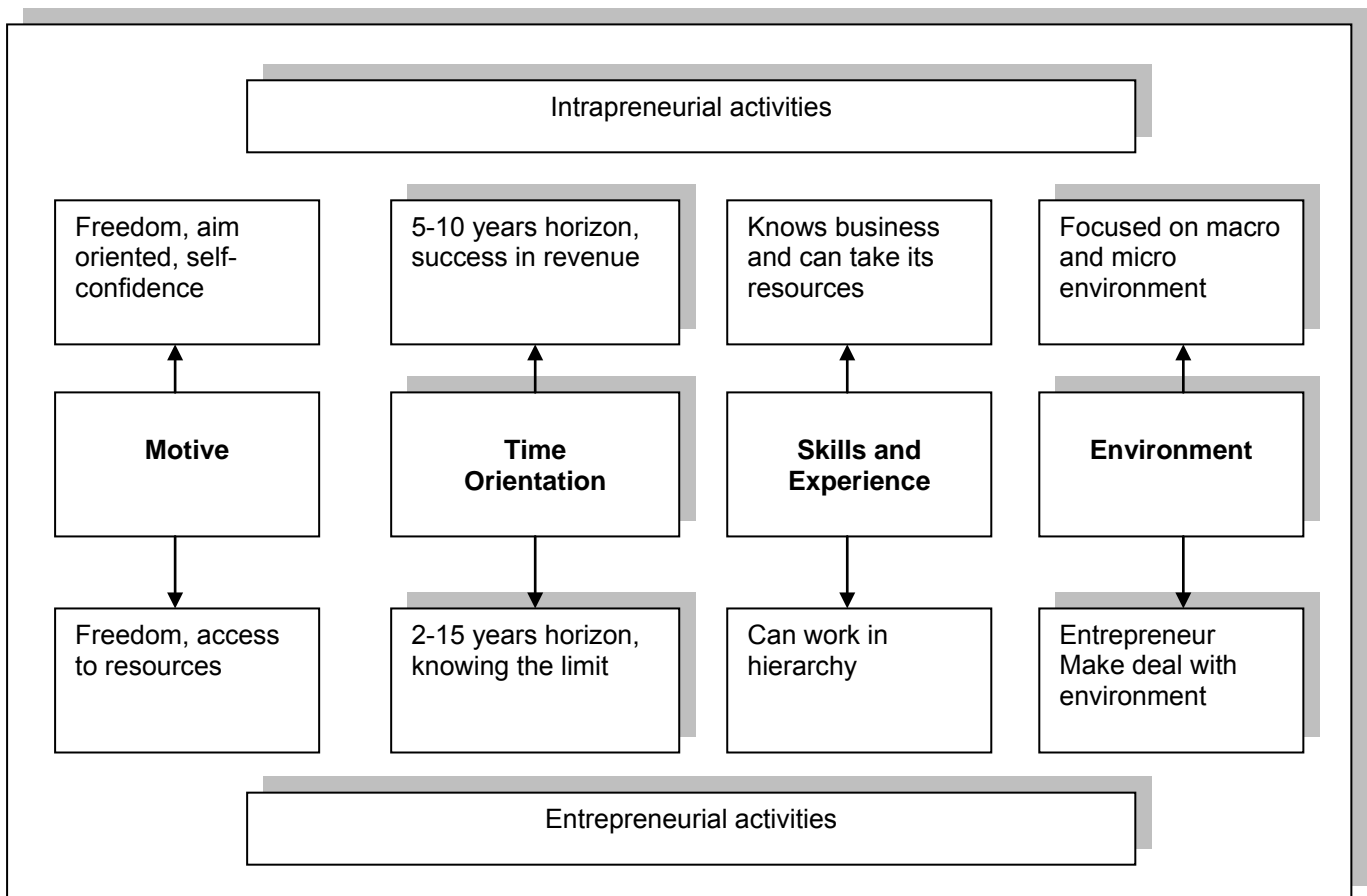

Figure 2 Comparison between entrepreneur and intrapreneur [4]

It is important to understand that entrepreneur as well as intrapreneur is directed toward innovation and both are ready to risk taking. Intrapreneur is directed to make innovation in the organization itself, different from entrepreneur who takes risk to start its own business with its own resources. Intrapreneur has harder work comparing to intrapreneur. Entrepreneurs have control over environment, especially internal environment. Financial risk has the organization where intrapreneur works, and on the other hand the financial risk has entrepreneur itself. Failure means bankrupt for entrepreneur and for intrapreneur means returning in the organization. Entrepreneur is a boss, but intrapreneur must cooperate with manager, must find sponsors, especially when he faces with internal criticism and resistance. Important for the style of behaving of intrapreneur crucial element is success. The best for organization is to be lead by intrapreneurs which will follow principles of entrepreneurship. Intrapreneur as well as entrepreneurs has potential to mobilize innovations and resources in some important projects.

5. Conclusion

Organizational climate must motivate individuals to take risks and then to be awarded those individuals. For this it is necessary policies and practices to be built in intrapreneurial atmosphere. The key is in reseating of rigid bureaucratic form in organization with all its rules and procedures which inhibits innovation and taking risks. That's why it is necessary for organization to look inside and find those people who has potential to develop business inside organization. It is also necessary to be included of employees in processes of thinking in organization, then empowering employees, giving them information about business and changing the system for rewarding.

To become intrapreneur is a state of mind. For that reason it is necessary to let own imagination and thinking to show the direction for researching. Those steps describe "birth" of intrapreneur in organization.

^{2,3} Department of Business Management, Unisa, South Africa, www.unisa.ac.za

Entrepreneurial activities are arguably effective contributors of economic growth, survival and stability of national economies. As such, educational institutions are directed at developing entrepreneurship curriculum that encourages entrepreneurship behaviour. University of South Africa (UNISA) which is an Open Distance Learning (ODL) institution unfortunately does not provide experiential learning to all their students. In contrast to the post graduation reality, skills and experience or lack thereof deprive graduates of available opportunities. Employment and poverty levels in Africa, particularly South Africa, calls for relevant interventions such as encouraging entrepreneurship behaviour. Indeed, the act of entrepreneurship behaviour lies in the formation of the intention to behave entrepreneurially. Whilst acknowledging the underlying determinants of entrepreneurship intentions in literature such as individual's human capital, individual's cognitions and motivations, and perceived self-efficacy, this study examines the impact of practical entrepreneurship project, the Student Business Initiative Challenge (SBIC) on future entrepreneurial intentions. The SBIC program is an initiative started by UNISA's College of Economic and Management Sciences students to encourage entrepreneurship behaviour. SBIC suggests that entrepreneurial empowerment to the students at tertiary is long overdue. SBIC also reports that students taking part in the program do not only benefit through exploring and learning entrepreneurial traits but also enhance their employability. In this paper we hypothesise that practical projects can intensify intentions of engaging in entrepreneurship. We also provide results in terms of student's experiences, key lessons, and aspirations that influence their future entrepreneurship intentions.

Keywords

Entrepreneurship; entrepreneurial intentions; experiential learning & SBIC

1. Introduction

Although it is widely accepted that entrepreneurship provides opportunities of economic growth, job creation and financial stability, and although Universities worldwide are constantly improving towards a contemporary entrepreneurship curricula, little understanding is known about the factors driving and affecting entrepreneurial intentions among students and distinctions between entrepreneurial intentions [48] & [48], attitudes and behaviours of students in different backgrounds such as culture, ethnicity, norms, family backgrounds and societal grounds [33]; [34]; & [42].

South African entrepreneurship education has focused more on offering education about entrepreneurship which is traditionally focused instead of offering education for entrepreneurship which produces entrepreneurs [4]. For economic growth; South African universities need to start producing entrepreneurs not just entrepreneurship graduates. [17] state that literature on experiential learning of entrepreneurs is limited. Moreover, they indicate that research on entrepreneurship itself continues to neglect the relationship between learning and entrepreneurship. They further point out

that more insight is needed in the experiential learning of entrepreneurs. [26] argue that real entrepreneurs should start businesses not look for jobs. Experiential learning can produce entrepreneurs the same way it produces nurses [5]. Even though entrepreneurship education can be encouraged by experiential learning ([2] & [8]), doing so poses many challenges ([5]; [10]; and [23]; [1]; [25] & [13]).

The purpose of this study is to determine the impact of Student Business Initiative Challenge (SBIC) on the future entrepreneurship intentions of South African students. SBIC is an initiative started by University of South Africa (UNISA)'s College of Economic and Management Sciences (CEMS) students. The purpose of SBIC is to instil practical entrepreneurship experience on students who participate in different initiative. SBIC fulfil this purpose through two approaches. These are: Actual Business-plan and Business Implementation Approach (ABBI) and Entrepreneurship Seminar Series Approach (ESSA). With ABBI, students who participate are given limited resources such as finance to draft a business plan and implement it. But, with ESSA, SBIC organises entrepreneurship seminars wherein people who are entrepreneurs are invited to speak about their practical experience. Students will then be invited to attend the seminars. The focus of the study is on the ABBI approach of SBIC.

The main objective of the study is to report on the impact that the SBIC challenge had in intensifying the future entrepreneurial intentions of students. Results are provided in terms of key lessons learned, the relevance of SBIC challenge and the confidence levels pertaining from SBIC challenge participation. This paper contains a literature review which summarise the logic behind SBIC challenge, the concept behind entrepreneurship, what it entails being an entrepreneur, their behavioural requirements and how entrepreneurs are categorised. The body of knowledge underlying entrepreneurship intentions with developed and tested models are acknowledged. The literature review is concluded by highlighting experiential learning and its impact on entrepreneurship education. The rest of the paper reports on limitations of the study, findings and conclusions.

2. Literature review

2.1 SBIC

As stated on our introduction, SBIC is an initiative started by University of South Africa (UNISA)'s College of Economic and Management Sciences (CEMS) students. The purpose of SBIC is to instil practical entrepreneurship experience on students who participate in different entrepreneurship initiative. SBIC fulfil this purpose through two approaches. These are: Actual Business-plan and Business Implementation Approach (ABBI) and Entrepreneurship Seminar Series Approach (ESSA). The focus of this study is on the ABBI approach of SBIC.

ABBI is a 5 weeks entrepreneurship practical project. This is an action oriented project. To be part of this project, students must write a motivation indicating why they would want to participate in the project. The selecting committee comprising of corporate sector professionals choose students with enough motivations. Selected students are then invited for face to face interview. The purpose of the interview is to determine entrepreneurship traits of the students. Through the face to face interview, the final candidates are selected. The final candidates are grouped into five (mixing them according to field of study and personalities) and candidates will undergo the mentorship sessions where reputable professionals provide guidance and business tips, followed by submission of business plan and then implementation. After the mentorship session, each group is required to draft a business plan. The groups are then given R500 to implement their business plans. And thereafter, a team of a panel consisting of entrepreneurs, academics, professionals assess and choose the best 3 teams for the award ceremony where certificates and prizes are presented.

2.2 ENTREPRENEURSHIP

Entrepreneurship is relatively new and flexible [19] and scholars are finding it difficult to define it due to its relation to economic and behavioural dimensions [23]. However, many scholars who have attempted to define entrepreneurship concurs that it enables individuals to develop their talents and creativity to achieve their dreams, to acquire more independence and a certain feeling of freedom ([6]; [18]; [15]; and [12]). Other scholars view entrepreneurship as a complex process [24] in a daily part of life [3] which involves pursuit of opportunities ([27]; [22]; and [16]), innovation [31], taking risks beyond security, and having the tenacity to push an idea through to reality combine into a special perspective that permeates entrepreneurship [16].

2.2.1 The entrepreneur

Defining the entrepreneur is a great challenge [13] and as a result there remain no agreed definition of an entrepreneur [12]. Having followed the origin of the term, which stems from the French verb “entreprendre” meaning to undertake; [12] went on to simply define an entrepreneur as someone who undertakes to make things happen, and does. Other authors ([25] and [19]) view an entrepreneur as someone with an entrepreneurial spirit, takes calculated risks, embrace innovation and takes judgemental decisions.

2.2.2 Behavioural requirements of entrepreneurs

[30] Suggest that there are 14 behaviours that are required by the entrepreneur, depending upon the situation in which he/she is to be found. They indicate that these behaviours can be learned. These behaviours are: (1) total commitment, determination and perseverance; (2) drive to achieve and grow; (3) orientation to goals and opportunities; (4) taking initiative and personal responsibility; (5) veridical awareness and a sense of humour; (6) seeking and using feedback; (7) internal locus of control; (8) tolerance of ambiguity, stress and uncertainty; (9) calculated risk-taking and risk sharing; (10) low need for status and power; (11) integrity and reliability; (12) decisiveness, urgency and patience; (13) learning from failure; and (14) team builder and hero maker.

2.2.3 Categories of entrepreneurs

[19] categorises entrepreneurs into three: (1) novice entrepreneurs: inexperienced individuals with no prior business ownership interests, and who currently own an equity stake in an economically active firm; (2) serial entrepreneurs: currently own an equity stake in a single economically active firm, and had previously sold or closed down similarly owned businesses; and (3) portfolio entrepreneurs: simultaneously own equity stakes in two or more economically active firms.

2.2.4 Entrepreneurship intentions

An entrepreneurial intention is the initial step in the evolution and in most cases process of venture development, the intention to start a business is a preceding element that drives the behaviour to engage in such activities [35]. The aim of intentions is that they focus a person's belief, attention, experience and behaviour towards a specific object or method of behaving [36]. Entrepreneurial intention is defined as the state of mind that guides and directs the actions of the entrepreneur towards the development and implementation of the business concept [37]. Also, [47] & [39] define entrepreneurship intention as a commitment to start a business once the opportunity is recognised; other authors agree that it is also a positive commitment of actions for future entrepreneurship engagement. Intentions are also influenced by personal factors such as skills and abilities and intentions are the single best predictor towards behaviour of executing the [38]. According to [38] such behaviour is often affected by the needs, values, wants, habits and beliefs.

The underlying determinants of entrepreneurship intentions in literature has been identified as namely individual's human capital, individual's cognitions and motivations, and perceived self-efficacy. *Self efficacy* is a person's belief in his/her capability to perform a task. It's an enthusiasm that drives decisions, goals, emotional reactions, attempt, managing and determination [39]. Self efficacy persuades whether individuals are optimistic or pessimistic or will either engage in self hindering or self fulfilling activities [40]. Studies by [41] revealed that increase in self-efficacy leads to an increase in identifying opportunities, thus entrepreneurship becomes a planned behaviour that is influenced by intentions [46].

Individual's human capital refers to the skills, attributes, qualifications that individuals possess. This human capital determines the individual's motivation and interest in following an entrepreneurial career path. Human capital has a direct influence on behaviours and attitudes of persons. *Individual's cognitions and motivations*: cognitions and motivation are generally rooted from the individual's societal norms, values, culture, ethnicity and background and involves influential variables of behaviours such as needs, growth, aspirations and motivations and other psychological attributes.

2.2.4.1 Emergence of entrepreneurial intentions

The interest of research in entrepreneurial intentions was influenced by the general aspiration that entrepreneurship will address the problem of unemployment and contribute to economic development

.The psychological literature of entrepreneurial intentions has classified intentions as the theory of planned behaviour from the two models of intentions were developed and tested in the literature namely Azjen theory of planned behaviour (TPB) and Shapero's model of entrepreneurial event (SEE).

2.2.4.2 The Theory of Planned Behaviour (TPB)

The theory of planned behaviour suggests that most of the human attitudes are intended and engaging in entrepreneurship activities is usually intended by the individual [42]. The hypothesis of planned behavior was proposed by Icek Ajzen in 1985. According to the theory of reasoned action, if individuals evaluated the suggested behavior as affirmative, and if they believed that peers behavior are recommending such behavior, this results in a higher intention and motivation and they are more likely to do so. Notably, there is an elevated relationship of attitudes and personal norms to behavioral intention. In essence, Ajzen argues that intentions generally depend on awareness of delicate personality, societal norms and opportunities.

Given the above literature review [42] concludes by noting that the theory of planned behaviour affirm that the intention to become entrepreneurial relies entirely upon the attitudes of aspiration of entrepreneurial occupation path, societal norms including apparent family anticipations, belief to perform the behaviour, maintain control and the ability to implement the actions of entering into the entrepreneurship career. And this aspiration were measured from the exposure to entrepreneurship education [43]; [33] & [34], exposure to entrepreneurship through family and direct experience [47 &44], and the role of ethnicity which was hypothesised that students belonging to different ethnic groups will possess dissimilar attitudes, societal norms and behavioural control [45].

2.2.4.3 Shapero's model of Entrepreneurial Event (SEE)

Shapero contends that entrepreneurial intentions are based on the perceptions of personal desirability, feasibility and propensity to act [46]. The models of entrepreneurial event clearly suggest that intentions are derived from perceptions of attractiveness and viability, and a tendency to act upon opportunities. In this model, perceived desirability is defined as the attractiveness of starting a business, perceived feasibility as the degree to which the individual feels capable of starting a business, and propensity to act as the personal disposition to act one one's decisions [48].

A counterargument against the high relationship between behavioural intention and actual behaviour has also been proposed as results of some studies do not show that behavioural intention always leads to actual behaviour because of circumstantial limitations. Namely, since behavioural intention cannot be the exclusive determinant of behaviour where an individual's control over the behaviour is incomplete, Ajzen introduced the theory of planned behaviour by adding a new component, "perceived behavioural control." By this, he extended the theory of reasoned action to cover non-volitional behaviours for predicting behavioural intention and actual behaviour.

2.3 Experiential learning in entrepreneurship education

There has been a rise in experiential learning (student learning by doing) in recent years (Daly 2001:204) and this is also evident in entrepreneurship education [5]. Experiential learning is said to be the teaching method that produces entrepreneurs [5] and it does so the same way it produces nurses, drivers and teachers. [31] define experiential learning as a process of constructing knowledge that involves a creative tension among the four learning modes. [24] views experiential learning as an experiential process in which knowledge develops through experiencing, reflecting, thinking and acting. Furthermore, many authors ([6]; [28]; [11]; [25]; and [1]) have concluded that experiential learning through venture start-up, real life learning, projects, practical experience, simulation and apprenticeship is the solution to the pedagogical problem in entrepreneurship education. Experiential learning provides many benefits to students, faculties and educational institutions, firms/owner/manager, researchers and government policy makers [11]. According to [21] experiential learning provides learners with fun, exciting and entertaining way of learning. Experiential learning gives students an opportunity to be real not pretenders [30]. In addition, experiential learning create the right atmosphere for learning, put value on students' knowledge, skills and experience, enforce sharing of ideas and increase synergistic learning of participants [25].

3. Research Methodology

3.1 Research design

The aim of the study was to examine the impact of practical entrepreneurship project, the Student Business Initiative Challenge (SBIC) on future entrepreneurial intentions. The sample was drawn from a pool of students and represented only a sample of 35 students. This sample arises from the following activities: The advertisement was placed all over for students to participate in this project. All applications were critically scrutinised against a set of qualifying criteria and up to 65 students were shortlisted. All the shortlisted candidates had to go through an interview whereby they had to convince the panel that they had to be selected based on personal goals, motivation to run a business, personal initiative. The shortlisted candidates amounted to a total of 25.

After critical assessment, the 25 students were selected and divided into groups of five representing 5 groups and formed groups whereby they had to initiate a business idea, implement it and earn revenue given a specified budget. This business initiative was converted into a competition at a later stage whereby the best group was evaluated through, profitability, business strategy, marketing, leadership, team work and business plan.

Approximately after six months of the competition, candidates who participated in the SBIC challenge were invited to participate in this study by completing a self-administered questionnaire. The questionnaire consisted of both open-ended and closed-ended questionnaires. The first part of closed-ended questions represented student's demographics and the second section represented questions on a 3-5 point Likert scale, questions explored and summarised the overall experience from participating from the SBIC challenge. The questionnaire also covered pre-SBIC questions which included students stating their exposure to entrepreneurship experience prior to the challenge. Open-ended questions allowed to do an exploratory study on future entrepreneurial intentions and included questions of whether students had intentions of starting the business in the next two years after participating from the program, and state if they acquired skills, knowledge and abilities to pursue the business in the future and also to highlight key lessons, experiences and activities which stood out from participating in this program.

Only 22 usable questionnaires were returned and the results are reported as follows:

Table 1 Students learnt something valuable from the SBIC challenge

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Agree	12	54.5	54.5	54.5
	Strongly agree	10	45.5	45.5	100.0
	Total	22	100.0	100.0	

Table 2 The level of confidence in attending the SBIC challenge

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Disagree	1	4.5	4.5	4.5
	Agree	10	45.5	45.5	50.0
	Strongly agree	8	36.4	36.4	86.4
	Not applicable	3	13.6	13.6	100.0
	Total	22	100.0	100.0	

The results clearly indicated that more than half of the students learnt something valuable from participating in the SBIC challenge and 36.4% strongly agreed that they developed more confidence in attending the workshop.

Table 3 SBIC Challenge relevance

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Very relevant	12	54.5	54.5	54.5
	Relevant to some degree	10	45.5	45.5	100.0
	Total	22	100.0	100.0	

About 54.5% students agreed on the relevance of SBIC challenge with the remainder 45.5% students agreed to some extent. 0% of the results indicated the irrelevance of the SBIC program.

Table 4 Increase in the level of motivation from the participation in the SBIC challenge

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid Average	2	9.1	9.1	9.1
Good	9	40.9	40.9	50.0
Excellent	11	50.0	50.0	100.0
Total	22	100.0	100.0	

More than 90% of the students believed that their motivation level increased whilst only 2% were on average not sure of their motivation levels given the experience from the challenge.

Results from future entrepreneurial intentions. More than 72% intend on starting their businesses in the next two years and reported that the SBIC challenge intensified their intentions in starting a business. The 22% percent highlighted that life circumstances in future will determine the need to open a business. This group was deemed as uncertain to participate in the study.

Key lessons learned from participating in SBIC project. Most of the skills, knowledge and ability acquired from this challenge were reported as communication skills, interpersonal skills, planning skills, business skills, marketing skills, sharing ideas, team work, research skills, time management skills, good relationships, patience, business plan drafting, risk taking, customer service skills, administration skills, professionalism and marketing intelligence.

4. Limitations of the study

All participants who participated in the SBIC challenge are from the black population however results of this study cannot be generalised to the whole South African population. Furthermore, it could be argued that the University of South Africa student statistics is majorly represented by the black students. The small sample size is also seen as a limitation as it provides minimal basis for analysis. However, the strict process in selecting candidates to participate in the SBIC challenge also provided a reliable sample frames as interviews were conducted prior to the SBIC challenge.

5. Conclusions and recommendations

From the results of the study, it can be concluded that indeed practical business project can intensify the entrepreneurial intentions of students in engaging in future entrepreneurship activities. Furthermore the practical business project identifies the necessary skills, and unknown skills of the students become exploited. It is therefore recommended that University adopt this initiative to encourage and intensify entrepreneurship intentions among its students.

Modern manufacturing enterprises are coping with an increasingly complex, dynamic and competitive environment thanks to globalization and rapid development of information and communication technologies (ICT). Manufacturing enterprises have to achieve sustainable competitive advantage through greater integration, information sharing, customization and flexibility. The purpose of this paper is to illustrate the model of just in time coordination and integration of internal supply chain (SC) activities based on radio frequency identification (RFID) in a digital enterprise. The innovation in RFID is not in the technology itself, but in its deployment in real-business situations. RFID implementation is a way to improve efficiency and effectiveness of enterprise. Integration of RFID technology with enterprise resource system (ERP) enables fully integrated enterprise system and improved information sharing and supply chain visibility. Thus a more effective and efficient business processes and real-time information about product movement visibility through enterprise system for management support in digital enterprise will be attained. Methodology applied is a review of the available literature about RFID, as well as practical experience. Research limitation is that validation of the proposed model is required through practical implementation in manufacturing sector.

Keywords

Enterprise resource planning system, Digital enterprise, Integration, Radio frequency identification

1. Introduction

Globalization and rapid development of information and communication technologies (ICT) have resulted in an increasingly complex, dynamic and competitive environment. Facilitating of efficient and cost-effective responses to the uncertainties in a global market is a major problem coping manufacturing enterprises. Information sharing can be considered as a source of competitive advantage and, for that reason, sharing information through enterprise and whole supply chain is very important. Enterprises tend to improve competitive advantage through greater integration, information sharing, customization and flexibility. Information must be timely, accurate, complete, adequate and reliable. It is necessary to share real-time manufacturing information and to coordinate all activities of business processes. Lack of accurate real-time work-in-process information may adversely impact the effectiveness, especially of just in time manufacturing (JIT) and supply chain planning. Using Radio Frequency Identification (RFID) technology physical objects (raw materials, parts, products, equipment, shipments and personnel) could be integrated by assigned identity (which is typically a number unique to each object) with the enterprise resource planning (ERP) system in the real time and that is very important for information visibility and information sharing in a digital enterprise. Thus a more effective and efficient business processes and real-time information about product movement visibility through enterprise system for management support in digital enterprise will be attained. The innovation in RFID is not in the technology itself, but in its deployment in real-business situations. Integration RFID with ERP is very important to the successfully sharing of up-to-date information throughout whole enterprise and the supply chain.

2. Problem description

Manufacturing enterprises of developing countries like Croatia are coped with problem of quality of production logistic with aim to increase capabilities for competitive response to demands of market or supply chain partners. Today, products become more complex with the increasing number of variants, shorter duration of production and product lifecycles. It becomes necessary to reduce production volumes and introduce a make-to-order production system in order to make products that satisfy customer specific needs. This can only be achieved by the application of production management information systems aimed at coordinating different manufacturing units. Enterprise application as ERP system provides managers with information and enables them to make the effective decisions. Also, ERP system has an important role in supply chain management.

Business processes of manufacturing enterprises are more and more information intensive. Control and monitoring of these processes is not easy. Coordination, integration and especially sharing information in real-time about resource constraints, plans and schedules through whole enterprise and supply chain partners is very important [1]. Variation in production affects downstream member of supply chain (e.g. supply of parts to assembly line). Without accurate real-time work-in-process information the current shop floor control and tracking process can not be efficient [2]. Croatian enterprises mostly use labor-intensive methods (enter data manually and using bar-code systems) for products-related data acquisition. Due to limitations in data acquisition and data interchange between shop floor and ERP system, data is often unreliable and uncomplete and needed production status information are unavailable at the right place and at the right time to make effective decisions. As a consequences of problems in existing methods of identifying and tracking parts and products, mislay of parts or products, schedule delay and late deliveries occurs and costs increase.

Automated data acquisition and integration of RFID and ERP system is necessary to enable real time information sharing, meaning delivery of the required information timely and to everyone whose need them through integrated enterprise system and supply chain.

2. RFID technology

Automatic identification and data capture technologies include barcodes, RFID, optic character recognition (OCR), magnetic stripes, smart cards and biometrics. RFID have advantages compared with others automatic identification technology: long reading ranges that enable automatic identification at varying distances, real-time read/write capabilities, data storage on the component, do not require line-of-sight for reading, enduring in harsh environment [3,4]. Radio frequency identification (RFID) is an automatic identification method that use radio waves to acquisition and transmit data from an integrated circuit tag attached to object through a wireless interchange to a host computer.

Basic elements of an RFID system are (Figure 1):

- RFID tag,
- a tag reader with an antenna,
- a computer.

The RFID tag includes a small microchip and an antenna. Data are stored in the tag, as a unique serial number EPC (Electronic Product Code). The RFID reader functions as a transmitter/receiver. The reader provides the tag with power required for operate. The tag transfers data to the reader via the antenna and then reader transfers data to a server. RFID automatically identify objects that are within given range and transform the physical flow of materials into the information flow. There are wide variety of applications of RFID technology (e.g. person identification and service control, supply chain and inventory tracking, payment application, product identification, monitoring and control of industrial production), e.g. [5, 6, 7, 8] and there is continuously growth in usage of RFID technology in different areas, according to IDTechEx Report the value of the entire RFID market will be \$5.63 billion in 2010., up from \$5.03 billion in 2009 [9].

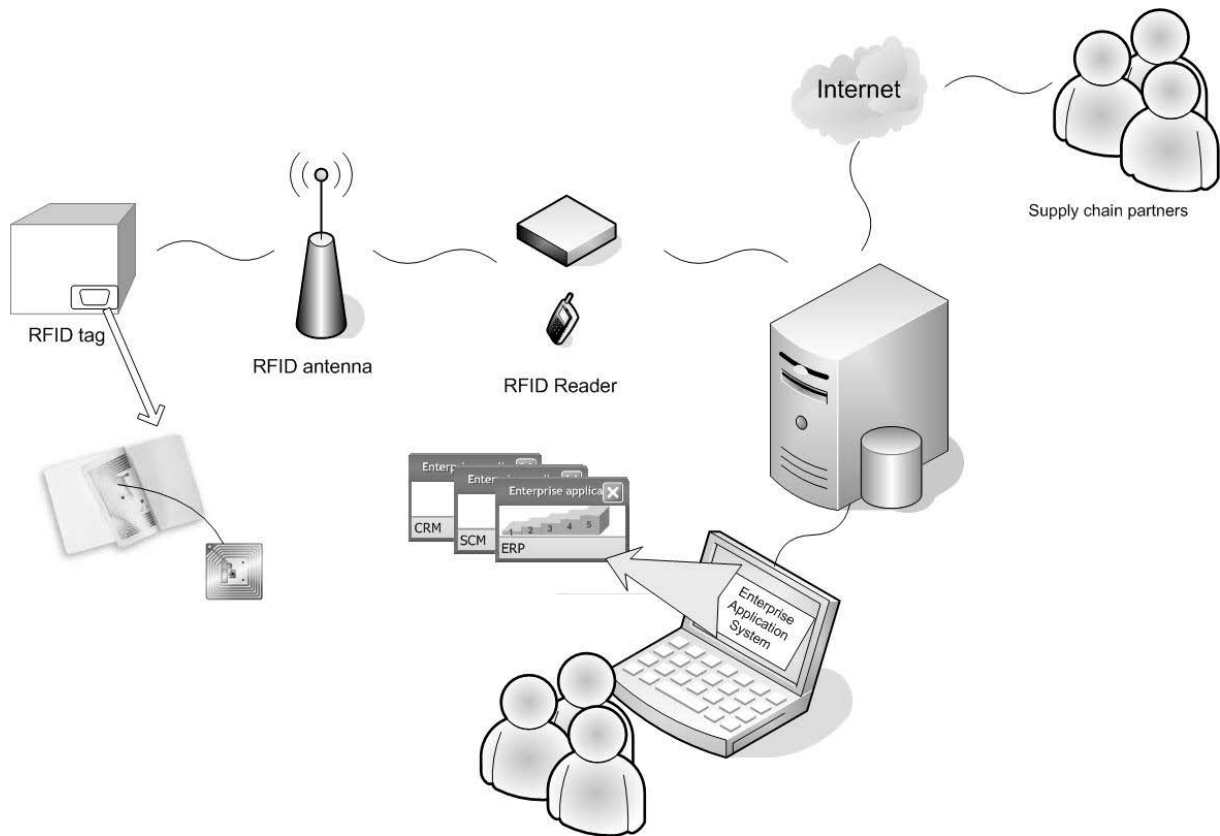

Figure 1 Components of RFID integrated with enterprise application system

The most of available literature about RFID technology is focused to application of RFID technology for warehouse management and supply chain, e.g. [10, 11]. Applications of RFID in EU enterprises are still relatively limited, 3% of enterprises on average used RFID in 2009. The highest shares of enterprises using RFID had the Netherlands (9%) and Finland (8%) and the lowest shares of enterprises had Greece, Cyprus and Romania (all 1%) [12].

According to the Croatian Bureau of Statistics for first quarter of 2009, there are 4% of all enterprises in the Republic of Croatia that use RFID technology (Figure 2), and that corresponds to the EU average [12, 13].

Figure 2 Enterprises using RFID in January 2009 [12]

4. Proposed Model

On the basis of practical experience and review of available published literature, the conceptual model that can facilitate the collection and share of information through whole manufacturing enterprise and supply chain was developed to support just in time delivery. The conceptual model is based on integration of ERP system and RFID technology.

The basic purpose of ERP system is shorten the duration of production preparation and production itself, reducing costs, flexibility compliance with market requirements and capability of readily alliance at new jobs and information sharing during realisation, that becomes indispensable in globalisation requirements [14].

Our model is based on just-in-time principles (produce and deliver products or services as needed by customer or required by hierarchically superior level in the right quantities, just in time and right place and avoiding storage, whenever possible or using minimal inventories).

Conceptual model of integration RFID with ERP system includes hierarchical planning model that integrates sales planning, assembly planning and production scheduling and generates plans which respond to the dynamic nature of the manufacturing system [15, 16]. The main goal in connecting three levels of planning by the application of just-in-time principle is increasing effectiveness of production, timely delivery of finished products/services to the customer or parts and subassemblies to a product assembly according to hierarchically superior level of plan.

In order to provide a just in time environment, status information of manufactured parts should be available to all who needs that information in enterprise in real time. Placing RFID tags on objects (as a parts, subassemblies, products, case of products, pallet, or shipping container) enables effective tracking of items in the production process. RFID technology enables fast data acquisition and transfers of data to databases as a part flows through shop floor and also across whole internal as well as external supply chain. There is a need for efficient and effective transformation of RFID data into congruently reports, and share information both internally within the enterprise and with supply chain partners.

The model of information sharing (Figure 3) includes the processes from customer orders through manufacturing and product assembly to delivery of the product to the customer. The hierarchically superior levels and subordinate levels of planning are interdependent in terms of the Japanese just-in time principle and coordination between the three levels of planning. One of the main objectives of hierarchical planning model is to keep the due date equal to the required date in order to meet customers' demands. The solution of a subordinate planning/scheduling level must meet the requirements at the superior planning level. Integration of RFID and ERP systems enables capturing data about real-time production status directly from production (e.g. accurate information about inventory levels, about start time and finish time of operation - then system calculates total real operation duration). That enables dynamic and real-time control of production and constantly adjustment of the production schedule to any disturbance.

The coordination of internal supply chain is completely realized when parts from manufacturing are transferred to the following phase (product assembly) right after it has been finished depending on the date required by the hierarchically superior plan at the level of assembly activities planning or sales department planning, respectively. Thus, integration of ERP system and RFID technology enables real-time information sharing, data accuracy, real-time tracking work orders, parts and products through internal and external supply chain.

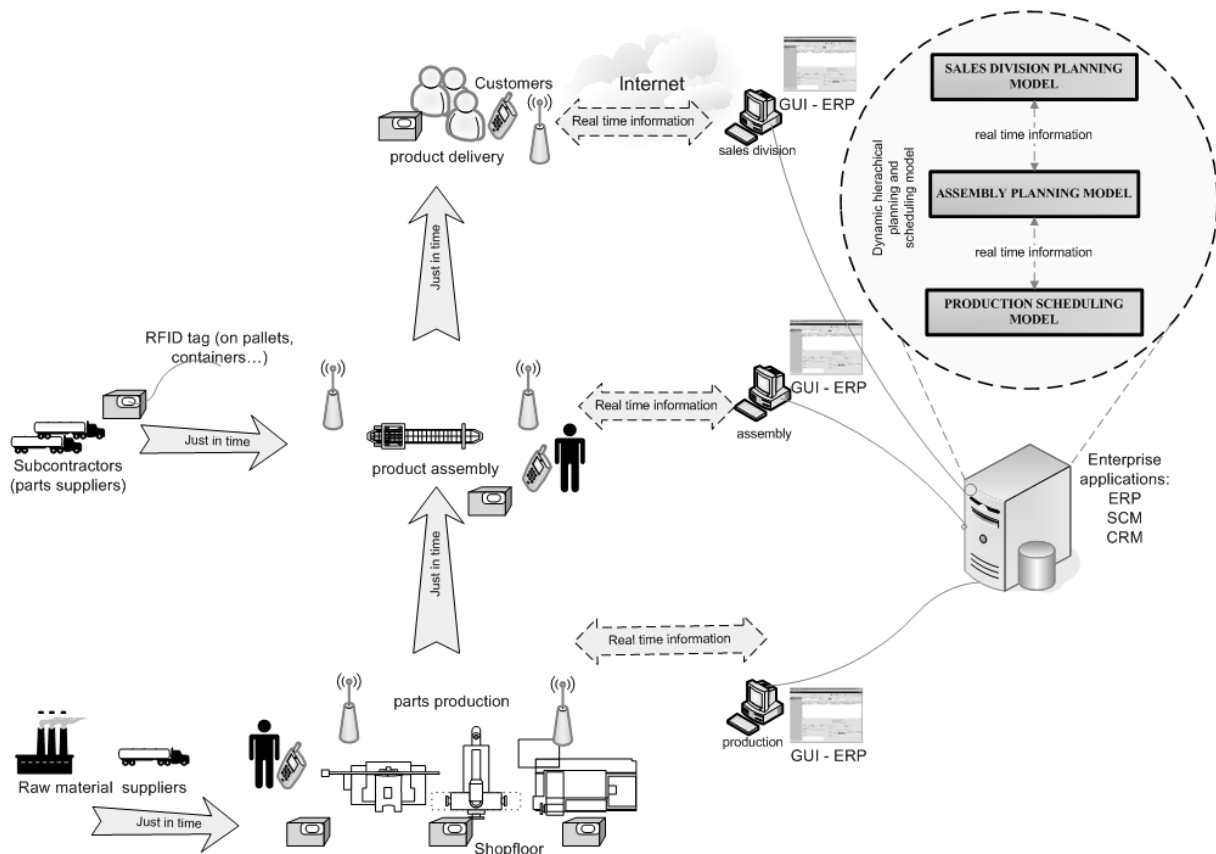

Figure 3 Model of information sharing enabled with RFID and ERP integration

5. Conclusion

Manufacturing enterprises by using modern automated identification techniques, like RFID, and by integration of RFID with ERP system, can now produce variants of a product, with small batches, down to a batch size of one piece. Integration of RFID technology with enterprise resource planning system enables fully integrated enterprise system and improved real time information. The main purpose of integration of RFID and ERP systems is to use real-time production status directly from production (e.g. ensure accurate information about inventory levels, about start time and finish time of operation - then system calculates total real operation duration). Thus a more effective and efficient business processes and real-time information about product movement visibility through enterprise system for decision making support in digital enterprise will be attained. Validation of the proposed model is required through practical implementation in manufacturing sector.

⁴ *META Group Slovenia, j.jurecic@meta-group.com*

Entrepreneurship and financial sources usually go hand in hand, especially when speaking about innovative, technological, potentially fast growing start-up companies. Lack of financial sources at the very beginning of the entrepreneurial growth, the so called “death valley”, is a common weakness of majority of the start-up companies. Venture capital is one of the financial sources, taking place on the path from the early stage to the maturity. However, there are several limitations and misunderstandings connected to the idea behind the Venture capital industry. This “equity gap” is caused by a number of interrelated factors: lack of information, a weak incentive structure for early stage investments, unwillingness to take risks, unfavourable tax provisions, lack of exit possibilities, etc. As a result of the “equity gap” fewer innovative enterprises are founded in Europe, and their prospects for growth are inhibited. Many bright and innovative European ideas end up being developed in the United States or elsewhere, where capital, know-how and the business environment are more conducive to their development and success.

In the paper we will present some theoretical and practical points of the Venture, and Seed capital industry as well as our own practical cases of managing public-private venture capital funds in Italy and, more recently, a new fund in Slovenia. This will present an initiative, interesting for the region of South-east Europe for leverage entrepreneurship and developing novel tools in the field of early stage financing. It will in addition represent a potential opportunity for local global born companies, entering Italian or Slovene market, looking for finance, partnerships and/or new opportunities.

Keywords

Financing, Knowledge-based entrepreneurship, Public-Private Partnership, Seed capital, Venture capital.

1. The Equity Gap

Private investors are known to be important sources of financing for Knowledge-Intensive Start-Ups (KISs). However, little has been documented about the nature or impact of financial and non-financial contributions that informal investors provide to businesses.

The way in which the issue about early stage finance is posed in much of the literature is that on the one side there is an entrepreneur seeking finance and on the other there is an investor seeking to employ capital profitably. The entrepreneur has ideas and, often, human skills, and the investor has money. The investor does not simply sit back and wait for returns to appear, there is active involvement in the development of the idea. Without that active involvement, investors perceive high risks and low returns from investment and entrepreneurs find themselves unable to raise capital. Entrepreneurs are therefore discouraged from applying for finance and costs of finance appear high. Therefore entrepreneurs and finance are apparently both in short supply.

Uncertainty and informational asymmetries that characterise “traditional” companies are amplified for KISs making it more difficult for them to access financing. First, the returns to really innovative

entrepreneurial activities are often skewed and highly uncertain. Second, entrepreneurs may possess more information about the nature and characteristics of their products and processes than potential financiers. Third, innovative activities are usually intangible thereby making the assessment of their monetary values difficult before they become commercially successful. Thus, financing KISs is very risky and uncertain, making it difficult to come up with a mutually agreeable financing contract.

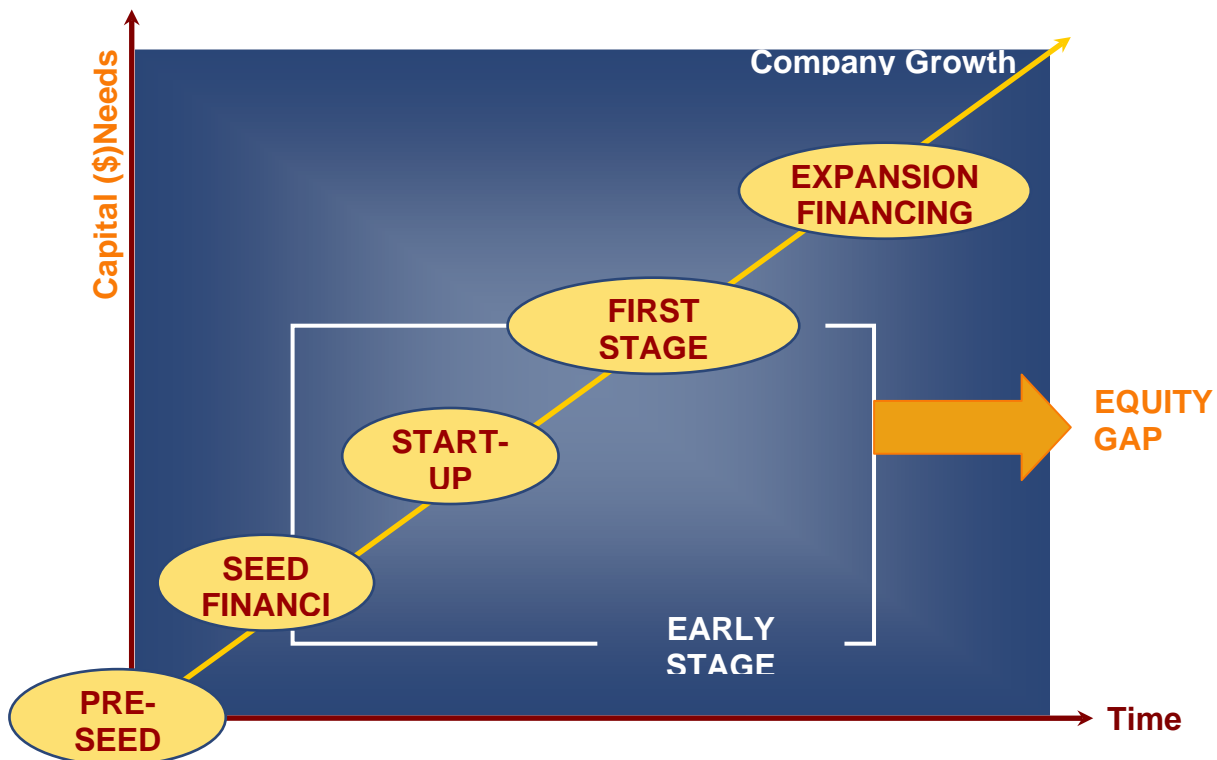

Figure 1 Different financing stages

Europe has witnessed a strong upward trend in early stage investments in Knowledge-Intensive Companies (KICs) during the last decade. Compared to the United States, however, the equity gap in early stages is still considerable in many European countries.

Too few new business ideas are developed. This “equity gap” is caused by a number of interrelated factors: lack of information, a weak incentive structure for early stage investments, unwillingness to take risks, unfavourable tax provisions, lack of exit possibilities, etc. As a result of the “equity gap” fewer KISs and innovative enterprises are founded in Europe, and their prospects for growth are inhibited. Many bright and innovative European ideas end up being developed in the United States or elsewhere, where capital, know-how and the business environment are more conducive to their development and success.

The difficulties of new companies to getting early stage financing are due to the inability of this category of firms to provide a sound track record to investors, the low level of guarantee and a long wait (some years) before generating a positive cash flow. All these barriers evidently increase with the degree of innovation involved such as strong presence of intangible assets, not previous managerial experiences of the team, business model not well defined (higher the innovation higher the risks associated).

In spite of there is still a resistance of the supply side in investing in the early stage, in the last years different equity tools are available but nevertheless the demand is relatively low and not qualified, “not investor ready”. The use of debt and equity is not either - or, but depends on the needs, development phase of the enterprise and the level of acceptance of entrepreneurs of third investors in the company. An important cause of the lack of demand is cultural: some business owners see the need to look for external finance as a sign of weakness and they are not ready to accept the control of this new partner. This cultural barrier is very significant in European countries. Networking with informal investors could be the reply to the equity and experience gap [1].

2. Early stage financial sources

Knowledge intensive start-ups are due to before mentioned barriers not appealing for traditional financing operators so new tools aimed at supporting the equity component have been created during last year: seed funds, business angels, venture capital funds.

2.1 Who are Business angels?

Business angels (BA) are private individuals who invest part of their personal assets in one or more start-up (becoming shareholders of the company) and also share their personal business management expertise and network of contacts with the entrepreneur. Business angels do not have any prior relationship with the entrepreneur. Angel intervention is long-term (so called patient capital) and may take a variety of forms.

Intervention by one or more business angels in a company generally takes the form of active involvement:

- As advisor
- On the Board of Directors
- As part of the management team

Business angels invest €25,000 to €250,000 in individual businesses – up to €400,000 in the United Kingdom. On average in Europe, business angel investment per deal averages €200,000 (by 2 to 3 angels per investment round). In some countries, business angels may invest up to €2.5 million when operating as part of syndicates or by leveraging their involvement through co-investment funds.

By doing so, they fill the so-called “equity gap”, period in which entrepreneurs have the hardest time to find funding for their young innovative company, lacking collateral needed for debt funding and not attractive enough to venture capital funds typically investing over 3 million€ per deal at the moment.

The graph is showing different stages of the capital needs for companies at different time scale of their growth.

Business angels are typically 35 to 65 year-old men and women (only 5% of the investor community) with considerable experience of the business world and the ability to invest time and money in companies. This activity is becoming more widely practiced and new business angel profiles are emerging [2].

2.2 What is a Venture capital fund?

Venture capital is the term used when investors buy part of a company. A venture capitalist places money in a company that is high risk and has a high growth. The investment is usually for a period of five to seven years. The investor will expect a return on his money either by the sale of the company or by offering to sell shares in the company to the public.

When investing venture capital, the investor may want receive a percentage of the company's equity, and may also wish to have a position on the director's board. Always remember that an investor who agrees to place venture capital in a company is looking to make a healthy return. He can demand repayment by the sale of the company, asking for funds back or renegotiating the original deal [2].

2.3 What is a Seed Fund?

Seed Funds are particular investment funds focused on investing in business ideas, projects or start-up companies for proof of concept, market search, or initial product development. Seed Funds are the result of the evolution of the international risk capital market and they represent an attempt of bridging the equity gap that is enlarging over time between angel investments and venture capital investments.

Seed funds are trying to respond to a market gap in the financial chain of players active in the development of new companies characterizing themselves as a separate asset class. The average amount invested by Seed Funds perfectly bridge the equity gap between business angles that generally do not invest more than 200,000 Euro, and traditional venture capital funds that invest on average more than 1,000,000 Euro. In fact, the average amount invested per deal by Seed Funds is aligned to the capital need of start-up companies in their first stages, with the 65% of the investments around 200,000 Euro and 800,000 Euro.

Table 1 Average amount invested per deal

Another important element of Seed Funds is that they usually have a regional dimension in the scouting of seed initiatives. A physical presence is not only necessary for “finding” the best ideas but also for supporting the entrepreneurs in setting up the strategy of the company and manage the business, similarly to what business angles do.

Moreover, Seed Funds are generally sector agnostic. To be more precise, while traditional venture capital funds are focusing more and more only on ICT, Biotech and Renewable Energies sectors, Seed Funds, thanks to their regional dimension and to the close collaboration with business angels that are typically ex-managers or professionals coming from various industries, are able to ignite fast growing start up also in more traditional industries, still guaranteeing adequate returns for investors. A strong network is important not only for the development of a solid deal flow of initiatives but also to find other private resources that could be used for investing in starts up companies. According to that, in some markets such as France and UK, in order to promote entrepreneurship and stimulate risk capital investments, the public sector created special co-investment funds that invest *pari passu* directly in the target company in conjunction with selected private investors, either institutional or informal, if certain conditions are satisfied. This kind of structure, commissioning the scouting and due diligence phase to private investors, are becoming an effective instrument to stimulate private investors in entering into new businesses.

Seed fund manager have a set of skills that are quite different from those required by a larger VC fund; they relate to the skills needed in evaluating and nurturing a company at the seed phase i.e. a small entrepreneurial team an untested product and a business plan that will probably change many times in the first two years. These skills are clearly biased on the capability of evaluating and supporting the team building plus a clear understanding of the market rather than on financials and technology.

Finally it is important to highlight the structural difference between “seed funds” i.e. funds with a size of 5-25 million € that invest mainly in seed phase and seed investment made by large funds of 50-500 million € dedicating a small percentage of their capital to the seed phase. The first type of funds are normally regional, sector agnostic invest between 0,3-2 million € and represent the average type of EBAN associate while the second would be normally sector specific, invest 3-25 million € and more and would normally be EVCA associate [2].

4. Case of Italy and Slovenia

Six seed funds in Italy and one newly established venture capital fund in Slovenia, all public-private funds, are managed by a private management company - Zernike Meta Ventures (ZMV). This is a financial company authorised by the Italian Exchange Office which operates in the risk capital sector for start-ups.

From 1996 the two ZMV shareholders, META Group Srl and Zernike Group Holding Bv, manage seed funds and start up funds with the aim to support the creation, first, and acceleration, then, SMEs high-growth potential. Building on the experience acquired at international level by the two above

mentioned partners, with around € 180 millions managed and investments in more than 500 start ups, ZMV provides the enterprises in its portfolio also with an extensive array of services for acceleration and internationalisation. The joint fund raising activity targets financial institutions, insurance companies, banks, the representatives of international industries, venture capitalists and institutional investors.

The funds management is based on the evaluation of the market potentials, the quality of the team and the viability of the proposed business model. Over the last 12 year the joint venture between META and Zernike has evaluated more than 2.500 knowledge intensive business projects.

Given the rich experiences of managing such funds, it can be clearly stated that such a financial tool is an important mechanism for enable innovative companies to grow fast, to enter global markets and to contribute to regional development and competitiveness.

4.1 Investment policy

In general the investment policy of the Funds is similar and based on the following criteria: i) The investments are targeted to projects having an innovative character or/and a high technology content and aiming at international dimension; ii) In the selection of enterprises the Fund prefers enterprises with a strong growth potential; iii) The investments tend to be directed toward the enterprises characterised by significant competitive advantages with a strong growth and development potential, strong professionalism and by a reliable entrepreneur project and potentially able to obtain positive economic results.

Each project must be illustrated by a business plan which allows the evaluation of the technical, economical and financial validity and the suitability with respect to the pre-established objectives. Funds invest in businesses that show a clear competitive advantage, address a demonstrated customer need and are expected to achieve positive cash flow within 18-24 months (as average).

4.2. Venture capital fund - Slovenia

Funds managed by ZMV are all public-private funds, with similar set ups. For example, venture capital fund in Slovenia is composed of 49% of funds provided by Republic of Slovenia through ERDF and 51% of private funds. The aim of Republic of Slovenia to introduce such an initiative was: to increase the VC market in Slovenia; to increase the entrepreneurial culture and understanding of VC investing in Slovenia; to accelerate new start-up and spin-off companies born; to attract foreign investors; to increase portfolio of knowledge based companies; to increase the portfolio/availability of equity financing in Slovenia. Having a more mature venture capital market will increase also the attractiveness of foreign companies to explore the Slovene market as well as foreign investors to scout for good investment deals.

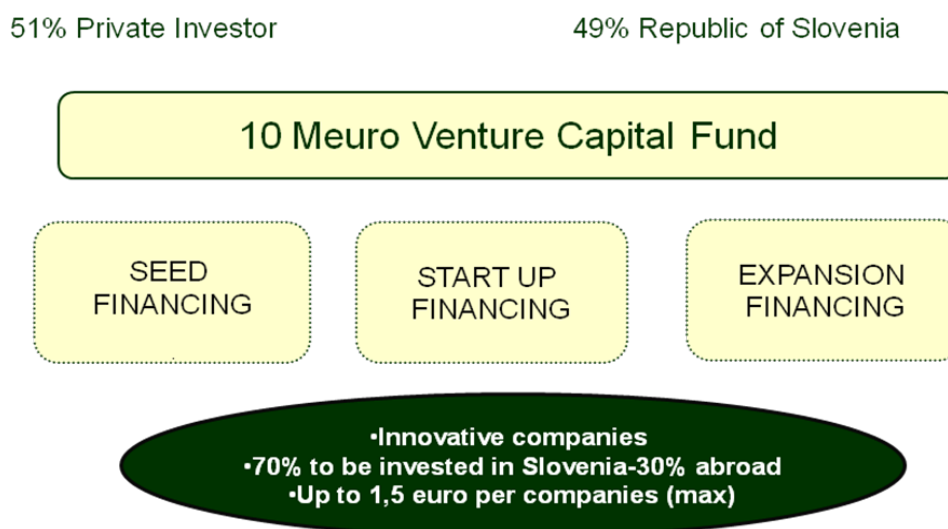

Figure 2 structure of Venture capital fund in Slovenia (Meta Ingenium)

5. Conclusions

In order to overcome the equity gap of knowledge-intensive start ups, such novel financial tools are of great importance for a sound development and competitiveness of the regions. A growing marketplace of early stage financial mechanisms has been stimulated by an increased awareness, Europe-wide, of the activity of early-stage investors and their contribution to the financing of high-growth innovative companies.

With the recent economic and financial crisis, this realisation has increased as both traditional sources of funding (debt funding through the banks) and traditional venture capital funds have either slowed down financing early- stage SMEs or have focused on their current portfolio. In particular, business angels and early-stage funds have been recognised as a vital source not only of seed capital but also of experience and knowledge available to innovative companies [3].

People with cerebral palsy have many problems and difficulties while executing everyday activities. Their wheelchairs are part of their every day to the rest of their life. In order to find a way to make living easier for these people, in collaboration with the Center for orthotics and prosthetics – Slavej extended research was conducted with the aim to design an ergonomic, multifunctional wheelchair which will fulfil and satisfy all requirements and standards for quality, comfort, therapeutic-medical aspects and will result as a reasonably priced wheelchair.

In this paper only one small part from the whole research is presented, emphasizing only the analysis of the capabilities of the Center for orthotics and prosthetics – Slavej in relation with the competitive companies and its marketing positioning on the Macedonian market for wheelchairs meant for children with cerebral palsy.

This center although is one of the few in R. Macedonia, has strong competition when it comes to production of wheelchairs for children with cerebral palsy from the producers from all over the world, present with their products on the Macedonian market.

Keywords

cerebral palsy, marketing positioning, product design, product development

1. Introduction

People with disabilities are population which in R. Macedonia is a little bit neglected in every meaning of the word. There are few Centers that provide daily care and services for people with disabilities, on the Macedonian market there is lack of availability of devices for assistance, and still public buildings are not available and the awareness of the whole nation regarding this issue is very low. This is one of the main reasons why more researches, papers and publications of this kind, treating people with disabilities in any manner, are needed.

People with disabilities differ regarding the type of disability. In this paper, only children with cerebral palsy are targeted. Cerebral palsy is damage of the brain which can be represented on the locomotion system with different level of paralysis. This occurs after the birth and it lasts for the whole life. This means that these children are bound to the wheelchair for their whole life. This evokes the need for creating special wheelchair which will fulfill/satisfy all needs of these children in the completion of their everyday activities. An extended research on this issue was conducted in a master thesis with main goal to design multifunctional wheelchair for children with cerebral palsy.

2. Analysis

Marketing positioning is a part from the marketing strategy that companies create in order to have successful product. Marketing strategy is in fact company's plan for achieving the goals that have been determined. One step of that process of creating marketing strategy is to position the company on the market which will give nice picture of the moment situation on the market regarding the competition.

This paper presents a marketing positing for the Centre for orthotics and prosthetics - Slavej, in order to understand the situation at the moment and to identify the possibilities for an improved new product. Slavej's core activity is taking care and treating people with disabilities, through therapies and production of different devices for assistance.

The expected result from this research is to develop a completely new product, wheelchair for children with cerebral palsy aged 7-14. Children with cerebral palsy may have additional health problems and to fulfil their specific demands the wheelchair should be adjustable and multifunctional.

Throughout all of the conducted research, few important characteristics of the wheelchairs were analyzed and according to the results a map of marketing positioning was made. The map has the role to assist in defining the needed changes in order to achieve the desired market position. The research was conducted on 50 children. This is a special sample and it was randomly chosen from the whole population of children with cerebral palsy. In this paper 11 producers of wheelchairs for children with cerebral palsy were analyzed. The producers were chosen because of the similarities of their key functions with the new wheelchair that Slavej wants to produce. The propulsion for these wheelchairs is manual. Most of these wheelchairs are not directly sold in R. Macedonia but they are available to order.

2.1 Customer's ranking of the characteristics according their importance

The first step in the conducted research is to rank the characteristics of the wheelchairs according their importance. For that matter a list of characteristics of wheelchairs was created, and the task of the respondents is to rank the characteristics according importance based on their subjective opinion. The characteristics in the list are not chosen by accident, but according to another research which was conducted only for that matter to see which characteristics of the wheelchairs are most important and have biggest influence on the buyer for purchasing them. Most of the characteristics are regarding the comfort, adaptability and therapeutically effect, given the fact that these children with cerebral palsy spend all day in them.

List of characteristics:

- Comfortable seat,
- Adjustable seat height,
- Adjustable seat width,
- Adjustable seat depth,
- Adjustable height of the back rest,
- Lumbar support,
- Head support,
- Adjustable height of the head support,
- Adjustable width of the head support,
- Leg support,
- Feet support,
- Compartments for storage of spear parts and luggage,
- Table for various activities,
- Reliable,
- Durable,
- Affordable price,
- Additional elements for entertainment,
- Low cost for spare parts,
- Variety of colors and materials.

From this list few characteristics were taken and some new were created which combine few old ones, and these characteristics were used in the research. Here is the list of the chosen characteristics:

- Good design,
- Comfort,
- Reputation of the company/producer,
- Low cost for spare parts,
- Durability,
- Price.

We determined by ourselves the ranking scale in this case we use 7 graded scale, where the number 1 stand for the least important characteristic and number 7 stand for the most important characteristic.

Table 1 Rank of the characteristics according their importance

Characteristics	Grades						
	1	2	3	4	5	6	7
Good design				7	12	11	20
Comfort				10	20	10	10
Reputation of the company	2	3	10	5	5	12	13
Low cost for spare parts			3	5	5	27	10
Durability						13	37
Price					7	10	33

2.2 Calculation of the relative importance

After conducted ranking of the characteristics according to their importance, grades for every one of the characteristics are collected.

Example: Good design $4*7+5*12+6*11+7*20 = 294$;

Where the multipliers (4, 5, 6, and 7) are grades that the respondents gave to the characteristic good design and the other multipliers (7, 12, 11, and 20) represents the total number of respondents which gave points for every characteristic accordingly. In the table 2 total points for every characteristic are given.

Table 2 Total importance of every one of the characteristics of the wheelchairs

Characteristics	Total
Good design	294
Comfort	270
Reputation of the company	246
Low cost for spare parts	286
Durability	337
Price	326

From this table the relative importance can be calculated for every characteristic. Relative importance is result of the division between the total of some of the characteristics and the total of the all characteristics.

Example: Good design $297/1759 = 0,167$;

Where the dividend 297 is the total for the characteristic good design and the divisor 1759 is the total of the all characteristics, 0,167 is the coefficient of relative importance.

Table 3 shows the total for every characteristic and their coefficient of relative importance.

Table 3 Coefficient of relative importance of every one of the characteristics

Characteristics	Total	Relative importance
Good design	294	0,167
Comfort	270	0,153
Reputation of the company	246	0,140
Low cost for spare parts	286	0,163
Durability	337	0,192
Price	326	0,185

2.3 Rank of the producers of wheelchairs for children with cerebral palsy

Next step in the process of creating map of positioning is ranking of the wheelchair producers according their products. The ranking is done by the respondents according to the characteristics discussed above in the text. Before the respondents start with the ranking they are introduced with the producers, their wheelchairs for children with cerebral palsy and their specifications. The ranking is with 7 degree scale, where number 7 stands for the characteristic which is the most satisfied by the defined wheelchair and 1 stands for the characteristic which is the least satisfied by the defined wheelchair.

In the table 4 are given the average values of the ranking given by the respondents.

Table 4 Average ranking of the wheelchair producers

3. Results

After the conducted analyses, the results are collected and calculated for every wheelchair producer in order to create the map of positioning. The calculation is done by multiplication of the coefficients for relative importance for every characteristic (table 3) and the average values from the ranking of the wheelchair producers (table 4).

Example: Good design (Chunc) – $0,167 * 7 = 1,169$;
Comfort (Convoid) – $0,153 * 6 = 0,918$

Where the first multipliers (0,167; 0,153) are the coefficients for relative importance, the second multipliers (7; 6) are the average values from the ranking of the wheelchair producers. The results (1,169; 0,918) are the coefficients for the wheelchair producer (Chunc; Convoid) for the given characteristics.

In the table 5 the coefficients for every characteristic for every wheelchair producer are given.

Table 5 Coefficients for every wheelchair producer

Characteristics	Wheelchair producers											
	JCM Seating Solutions	Chunc	Convoid	Drive Medical	Leckey	Sunrise Medical	Sung Seat	Thomasshilfen	Timoteos	O.3. Slavej	Nicecare	Comfort
Good design	1,169	1,169	1,002	1,002	1,002	0,835	1,169	1,002	1,002	0,167	0,334	0,334
Comfort	1,071	1,071	0,918	0,918	0,918	0,612	0,918	0,765	0,918	0,459	0,459	0,459
Reputation of the company	0,840	0,840	0,840	0,840	0,700	0,840	0,700	0,700	0,560	0,560	0,420	0,560
Low cost for spare parts	0,489	0,489	0,326	0,489	0,326	0,163	0,163	0,489	0,652	0,978	0,815	0,815
Durability	0,960	0,960	0,768	0,960	0,768	0,960	0,768	0,576	0,768	1,152	0,960	1,152
Price	0,185	0,370	0,370	0,555	0,185	0,370	0,185	0,370	0,740	1,129	0,740	0,740

In order to create map of positioning we need two characteristics of comparison, not six as we have consider in the analysis. This is why we need to classify these characteristics in two groups, and those two groups are: cost efficiency and image.

Table 6 Division of the characteristics in two main groups

Cost efficiency	Image
Low cost for spare parts	Good design
Durability	Comfort
Price	Reputation of the company

For the creation of the map we need one characteristic from each one of the two groups. In this case the two chosen characteristics are good design from the group image and price from the group cost efficiency (table 7).

Table 7 Considered characteristic for the positioning of the wheelchair producers

Characteristics	Wheelchair producers												
	JCM Seating Solutions	Chunc	Convoid	Drive Medical	Leckey	Sunrise Medical	Sung Seat	Thomasshilfen	Timoteos	O.3. Славеј	Nicecare	Comfort	
Good design	1,169	1,169	1,002	1,002	1,002	0,835	1,169	1,002	1,002	0,167	0,334	0,334	
Price	0,185	0,370	0,370	0,555	0,185	0,370	0,185	0,370	0,740	1,129	0,740	0,740	

While creating the map of positioning the characteristic of the wheelchair producers, the characteristics of the group cost efficiency are put on the y-axis, and the characteristics of the group image are put on the x-axis.

Graph 1 Positioning of the wheelchair producers

4. Discussion

According to the results from the conducted analysis it may be concluded that the Centre for orthotics and prosthetics - Slavej with the present wheelchair are top ranked according the price or cost efficiency, but when the design or the image is considered, Slavej is on the very end of the list or lowest on the graph. In order for this to change, Slavej has to make changes on the existing model or develop a completely new one, either way the design has to be entirely changed. That way they can try to achieve the top middle of the graph for the beginning, and as the time goes by maybe the top right corner of the graph, which will mean that they will have the most cost efficient and best looking wheelchair on the market in R. Macedonia.

Metrics and Optimization of Technology Transfer Channels between Universities and Firms

Laurent Miéville¹, Georges Haour²

¹Technology Transfer Unit Unitec, University of Geneva, Switzerland, laurent.mieville@unige.ch

²Innovation Technology Management, IMD, Lausanne, Switzerland, haour@imd.ch

In what is often called the “knowledge economy”, two actors, universities and firms, play a leading role in creating new knowledge, products, services and jobs. Through efficient and smart partnering models, firms can now leverage their innovative capacity and access valuable knowledge and insights from Universities. Engaging in Knowledge and Technology Transfer activities has become a must for companies relying on innovation to develop and defend their market share.

We have been studying good practices world-wide [1] in order to define the best ways of managing the main formal channels for knowledge and technology transfer from universities and public laboratories to firms: collaborative research and licensing, including spinning out start up companies.

Despite a world class research activity established decades ago, Switzerland has only recently become a top ranked country in technology transfer. The key elements responsible for such a progression remain the subject of debate but we suggest that carefully selected technology transfer metrics may point out a concomitant increase of licensing activity from Universities to firms, in particular spin-offs, could explain the rise in international rankings. Finally, a parallel increase of staffing level of professional technology transfer agents may be responsible to the observed progression in research partnering ranking, due to improved associated transaction costs.

Keywords

Collaborative research, Knowledge and Technology Transfer, Licensing, Spin-offs, Universities and Firms partnering.

1. Introduction

In what is often called the “knowledge economy”, two actors, universities and firms, play a leading role in creating new knowledge, products, services and jobs. Through efficient and smart partnering models, firms can now leverage their innovative capacity and access valuable knowledge and insights from Universities. Engaging in Knowledge and Technology Transfer activities has become a must for companies relying on innovation to develop and defend their market share.

One central element pertaining to the study of knowledge and technology transfer is the notion of metrics. The goal is to provide more information on the performance achieved by Universities and firms in transferring and developing new innovative products.

Some metrics are subjective and are based on interviews with key stakeholders; others are objective such as counting the number of transfer transactions or patent applications. With such a wide diversity of metrics any attempt to evaluate a particular performance falls short if the results are not benchmarked with similar metrics obtained through other approaches.

The goal of this report is to provide for the first time a comparative study that includes different metrics associated with knowledge and technology transfer performance and their evolution as function of time.

Since most of the metrics are based on the performance at national level, we selected Switzerland as the country for which we based our study. The Swiss innovation ecosystem is well characterized and

as one of the top innovator country it provides a series of interesting metrics data related to knowledge and technology transfer.

2. The main channels for knowledge and technology transfer

Knowledge and Technology Transfer channels are multiple and we will focus on the main formal ones, namely the University – Firm research collaboration (research partnering) and the transfer of research results and technology from Universities to firms (either existent or newly generated in case of spin-offs).

- *Technology Licensing* which consists in the transfer through licensing/assignment of research results from the PROs to the firms. The firms (either established or just starting-up) buy new technologies from Universities in exchange of royalties or other financial considerations.
- *Research Partnering* activities which are established through collaborations between a firm and a Public Research Organization (PRO) around a common research project. Through direct interaction, firms can get access to know-how from the PROs and obtain exploitation rights to technologies that may be generated during the execution of the project.

These two channels are often active in parallel in a firm-University relationship. They consist also in the bulk of the work that technology transfer organizations realize for their University. One very important channels of knowledge transfer is the training of young graduates that are hired by firms. It is however very difficult to have any meaningful metrics aimed at measuring its importance and evolution.

3. Rankings and metrics of Switzerland in technology transfer

Switzerland is enjoying a particular (but somewhat unknown) success in the worldwide innovation rankings with a 1st place in the latest European Scoreboard Summary Innovation Index (2010). In terms of competitiveness, it ranks 1st in the Global Competitiveness Index (World Economic Forum 2010-2011) as well and 4th in the World Competitiveness Scoreboard (IMD, World Competitiveness Yearbook, 2010).

Figure 1 Worldwide Innovation Rankings

In terms of knowledge transfer and research collaboration between firms and Universities, the position is also excellent with a 1st and a 2nd rank for the IMD, resp. WEF rankings (figure 2).

Knowledge Transfer between Companies and Universities

Source: World competitiveness yearbook 2010, IMD

University - Industry Research Collaboration

Source: Global competitiveness report 2010-2011

Figure 2 Swiss rankings related to University-Industry partnering

Figure 3 Evolution of Swiss rankings related to University-Industry partnering as a function of time

Figure 4 Evolution of active staff in Swiss Technology Transfer (swiTT)

The progression of the Swiss position within these two rankings is impressive. In about 10 years span, Switzerland progressed from a rank from 10th to 15th to the top spots (figure 3).

What were the main factors responsible for such an improvement? As a practitioner we see a general formalization/professionalization of knowledge and technology transfer that has occurred for the last 10 years in Switzerland mainly through the establishment of dedicated teams working for or within PROs. This is exemplified by the number of Technology Transfer professionals in Switzerland, as shown on figure 4 (in full time equivalent – FTEs).

Of course such an increase may simply be the consequence and not the source of the intensification of knowledge and technology transfer but clearly it has played a role in providing a clear path for companies to establish partnerships with PROs and for researchers to get clarity on their institution' guidelines when establishing such partnerships. Of course the quality of such personnel is key.

We now focus on studying the metrics pertaining to each of the two considered knowledge and technology transfer channels.

3.1 Research partnering metrics

Among the indicators at hand which is related to research partnering is the number of co-publications of firms (located in a chosen country) with PROs, per million of population. As depicted on figure 5, Switzerland ranks first for this metric.

The density of the Swiss research with regards to its population clearly provides an advantage here. It would however be more meaningful to measure the share of co-publications with firms in comparison to the total number of publications in order to control for research intensity. This indicator is however interesting in the sense that it also includes not only technology but also knowledge transfer between firms and PROs.

Source: European Innovation Scoreboard, 2010

Source: European Innovation Scoreboard, 2010

Figure 5 Public-private co-publications per million population (based 2008 data)

Figure 6 Evolution of public-private co-publications per million population

As depicted on figure 6, Switzerland has been a leader in regards to public-private co-publications metric for several years. No increase in terms of comparative performance with other EU countries is found (EU mean value remains at 18% of the Swiss mark throughout the years). For this reason this metric cannot explain the progression observed on figure 3 where Switzerland improves its rank compared to other innovative countries.

Another metric related to intensity of research partnering is provided by the number of funding requests for matching funds scheme of the Swiss government through its Commission for Technology and Innovation. This widespread tool aims at incentivize firms (in particular SMEs) to engage with PROs and consists in providing matching funds to the firm's own R&D investment in a Research Partnership project with a PRO. The PRO contribution to the project (usually close to 50%) is funded by the government. Figure 7 lists the number of such matching project requests of Swiss firms engaging with Swiss PROs. Except for an increase in 2009 due to the introduction of more flexible funding criteria, the amount of project funding requests remain stable.

Source: Commission for Technology & Innovation

Source: Swiss Federal Statistical Office

Figure 7 Number of funding requests for Swiss firms-PROs projects to CTI.

Figure 8 Amount spent by Swiss firms on R&D projects with Swiss PROs.

The same is true for yet another research partnering metric, namely the amount spent by Swiss firms on “extra-muros” R&D mandates to Swiss PROs (figure 8). This metric is collected every fourth year by the Federal Statistical Office, together with *economiesuisse*, an association of Swiss firms. Here again no increasing trend in the last 10 years has been reported.

In summary, intensity of research partnering metrics do not provide an explanation for the rise in ranking in research partnering depicted in figure 3. Private-public co-publication intensity, matching fund requests for University – firms collaborative projects or the amount spent by firms on R&D collaborative projects with Universities remain stable during the period at hand.

If not the intensity, it is the quality (eg the transaction costs of research partnering, framework conditions) of the relationship that has improved. This observation is in line with the figure 4 and the establishment of dedicated teams of technology transfer professionals active in formalizing research partnering activities. Alliance managers from firms are able to engage with a growing number of professional knowledge and technology transfer agents from the Universities.

3.2 Technology licensing metrics

On the side of technology licensing channel, the Swiss technology transfer association (swiTT) provide since 2005 an annual survey comprising several metrics. Due to a variable participation of certain institutions from year to year, we focus the analysis on the data provided by Swiss Universities in these surveys.

Figure 9 depicts the evolution of invention disclosures (black) made by the researches to their institution. This number increases about 30% during the four years span at hand.

Despite the fact that the amount of executed licenses remains stable (figure 9 gray) a rather strong increase in spin-offs creation (60%) is observed during the same period (figure 10).

Source: Swiss Technology Transfer Association

Figure 9 Number of inventions disclosures received (black) and licenses executed by Swiss Universities (gray) in function of time.

Source: Swiss Technology Transfer Association

Figure 10 Number of spin-offs (license based) from Swiss Universities as a function of time.

Overall we observe a growing trend of the technology licensing metrics which could, at least partly, explain the increase in the rankings enjoyed by Switzerland.

Another element which concurs with such positive results is the fact that knowledge and technology transfer offices are more efficient in converting inventions disclosures into licenses than other European countries as shown on figure 11.

Figure 11 Average number of licenses per country for Europe [2]

4. Conclusion

We have examined in this study a broad range of metrics pertaining to research partnering and technology licensing activities in Switzerland. These metrics focus on the intensity rather than the income generated from these activities. It is important to note that more important than generating income, technology transfer aims at maximizing the speed and the likelihood to obtain innovations on the market.

Metrics aimed at measuring the intensity of research partnering remains stable as a function of time for the period considered. As a consequence, the progression observed in innovation related metrics covering University – Industry collaboration could be explained by a more qualitative (rather than quantitative) improvement. This result is in line with the progression of professional dedicated staff active in technology transfer offices and the associated reduction of transaction costs as well as a clearer framework in which these relationships take place.

In terms of technology licensing, we observe an increase of intensity combined with a high level of efficiency, which is in line with the related progression observed in innovation related metrics.

Based on these findings, policies focusing on increasing the intensity of research partnering and further developing technology licensing should contribute to maintain Switzerland in a leading position.

Insurance Companies as one of the Drivers of Entrepreneurship in Developing Countries

Nada Milenković¹, Dragana Ikonić², Nina Arsić³

Although insurance companies are mainly associated with the development of financial markets, they also represent important factors in the development of entrepreneurship. Namely, the development of small and medium-size enterprises is widely threatened in developing countries primarily due to the impact of competition of multinational companies. And, on the other hand, one of the important influential factors on their course of business is a high level of economic and political risk that is and will be present for some time in developing countries. In order to increase their competitiveness, SMEs decide to credit insurance with insurance companies, thus reducing the credit risk and also the cost of credit (interest rates). Therefore, these companies can gain in competitiveness in comparison to large enterprises, multinational companies. The insurance companies are thus becoming the key factor in the process of financing by providing security in a volatile business environment and contributing to the competitive advantage of SMEs in transition countries.

Keywords

Entrepreneurship Credits, Entrepreneurship Development, Insurance Companies.

1. The importance of SME and entrepreneurship

The developing countries, which released themselves from the shackles of socialism rather late, should encourage the development of small and medium enterprises as a *conditio sine qua non* for the development of their economies. Namely, after the abolition of socialism, in developing countries, there was an influx of foreign capital due to privatization of state enterprises. In those situations, economies in transition countries can easily come to a position to depend on big multinational companies, which, driven by supranational motives, often use vague legislation of transition countries to make as much profit as possible. So, it is in the national interest of all developing countries, to achieve economic growth and development on the grounds of domestic production incentives and, primarily, the creation of the independent economy. The best way of accomplishing such objective is to invest in the development and strengthening of small enterprises, and particularly in the medium ones.

The main problem of small and medium enterprises are the undefined legislation, complicated administration, inadequate management, lack of information, and the last but not the least, insufficient financial resources. On top of these problems is the unfavorable business climate in developing countries which have, for quite some time, favored the public sector and large economic systems that have entirely different business strategy that the one used by small and medium enterprises. But despite these difficulties, the advantage of developing countries is that they could learn from the developed countries that the main and key factor of economic development is the creation of competitive and export oriented SME sector. An interesting fact is that currently there are about 20 million SMEs in the European Union, in fact they make up about 99% of companies in the European Union and contribute to the creation of more than half of the extra value in the European Union.[7]

Although the development of SMEs in the European Union is at high level, a lot of effort is put into the improvement of this sector, and the new trends that have occurred concerning the issue are oriented towards standardization in this area.[5] The SMEE sector in Serbia has more than 300,000 companies and shops, and makes up 66% of employment, 55% of GDP and 40% of export in Serbia.[8] From today's perspective, a lot of effort has been made to encourage development and strengthening of the sector of small and medium-sized enterprises in Serbia, but there are still some crucial problems, which do not subside, but under the auspices of the global economic crisis they only deepen.

2. Analysis of the situation of SMEs and entrepreneurship in Vojvodina

To fully understand the problem that SMEs have, it is necessary to analyze their current situation. The data obtained from the analysis conducted in Vojvodina over the period from 2008-2010 [1] indicate that, despite the numerous results achieved by various measures in this sector, there are still some difficulties that are more or less manifested in their business and, in times of crisis, can ultimately lead to their disappearance.

The analysis conducted in 2370 companies in Vojvodina provided interesting data about the SMEE sector, but for the purpose of our analysis we will present only the relevant data.

As for the market and competitive business in SMEs, they are mostly active in the domestic market, while the share of their business activities in foreign markets is minimal. As for the issue, certain measures should be taken to increase export activity of these enterprises. In addition, the fact obtained from a questionnaire where the respondents confirmed that 26% of the market is unstable and 40% is subject to seasonal changes [1,14]. Bearing this in mind, there are certain measures that need to be taken to increase share in the foreign market by means of export credits. As one of the limiting factors is the cost of financing, insurance companies could be the solution to the problem since they could provide credit insurance.

Among the problems SMEE face in their business, the leading problem is lack of funds which should be recoverable through state aid since financial institutions' credits for small and medium-sized enterprises and entrepreneurs are too expensive. Following lack of financial resources, is another big problem, those are still unregulated regulations or legislation in the field of SMEE business. Strengthening the private sector and creating more favorable conditions for in the form of legislative and institutional framework is crucial for the development of SMEE sector, in that way conditions are created for the sector to get new employees and thus reduce the unemployment rate, which is the most important problem in the country. Overview of the critical areas of SMEE sector is given in the following figure:

Figure 1 Overview of the critical areas of SMEE sector in Vojvodina [1,26]

As you can see from the above, lack of funds is undoubtedly in the first place. In recent years SMEE sector in Serbia has received support from many financial institutions that encourage development, it should be pointed out that the funds have been distributed steadily across regions. Some of the recent development programs that have supported the development of SMEE are: [10] the BAS program of

EBRD which has supported 214 SMEEs so far, and the project is going to run until November 2011; the funds were approved by the International Investment Bank EIB and in 2010 they amounted to 60 million euro's; then 56.3 million dollars from the Revolving Fund of the European Agency for Reconstruction; and many other projects.

The problem with these support programs is that in most cases there is no feedback on whether the funds were specifically spent, then SMEEs are not informed about the possibilities of obtaining funds on favorable conditions and hence, in most cases, they use their own capital as the main source of financing. For these reasons, supporting the companies through credit insurance would be an adequate means of incentives. For the credit funds to be spent specifically insurance should be narrowed down to the export credit insurance, in that way, by increasing exports, apart from stimulating the development of SMEE, external balance deficit could be decreased, i.e. the balance of payments would be improved. They would increase their awareness if they merged in clusters, through which SMEs and entrepreneurs would be informed and get policies easier.

3. Insurance companies as an incentive factor for SMEEs

Starting from the facts that the lack of financial resources hampers development of SMEEs, and that most SMEEs is financed from its own sources, that they do not meet requirements for obtaining credit and operate in volatile markets, there is an obvious need for government intervention in this area. The state and international institutions can grant a credit at more favorable terms in order to help those enterprises, but a more efficient means of support is insurance of the previously mentioned export credits.

In addition to economic risks affecting SMEEs there is a political factor that is present in the countries in transition in Southeast Europe and makes it harder for enterprises to enter foreign markets because it increases business risk, it is linked to higher costs, especially financing, and hence the enterprise loses the competitiveness. This issue of economic and political risk, primarily creates problem of financing SMEEs, therefore the government needs to find a way to assure conditions for enterprise products to be competitive in foreign markets. Insurance company, being the representative of the State, should solve this problem.

In most cases, no private insurance company would agree to take export credit insurance due to the high level of economic and especially political risks. Therefore, by hiring insurance companies as a representative the State needs to insure export credits. In that way two problems could be solved, on one hand, the problem of external trade deficit, and on the other, the problem of obtaining financial resources for SMEEs, which indirectly contributes to the development of financial markets by strengthening the insurance sector and increasing activities of the bank sector. This proves that involvement of insurance companies as State representative has multiplied effect on the development of the country.

The system of export credit insurance has proved to be successful in many developed countries where private and public insurance companies cover the risk for exporters. When it comes to small and medium-sized enterprises, due to the lack of development and willingness of insurance companies to insure the credit, the government should be the one to take the initiative. The risk for small and medium-sized enterprises is higher because the total assets of these companies are smaller, so when borrowing they usually don't have their assets which would be used as collateral or mortgage, and it hampers obtaining credits for the purpose of starting manufacture. For all the above reasons, insurance would considerably reduce the cost of financing these companies.

In developed countries this system works for years and has proved to be a successful means of increasing export activities of SMEEs. The crucial thing is that insurance premium is relatively low, compared to the high cost of financing. Taking the advantage of insurance, there would be a possibility for insuring a financial credit, or insuring export business, depending on the requirements of a company.

An important emphasis of the Federal Government's work should be to promote the interests of small business. This is also true of the export insurance scheme. The advisory and information services would be particularly tailored to the needs of small and medium-sized enterprises and to issues of relevance for them. Small and medium-sized exporters, in particular, are only able to fulfill orders from high-risk countries in many cases with the help of insurance. They are much less able to absorb possible bad debt losses than larger companies. Three out of four applications for cover in developed countries come from the small business sector. In many cases these are for small transactions on short credit terms. But small firms are regularly involved as subcontractors in large-scale projects as well.

Only transactions which are eligible for cover and in which the risk is justifiable can be covered. Most export business in Serbia would be eligible for cover. The criteria should be, for example, whether the export transaction safeguards or creates jobs whether it maintains presence in markets, as well as its relevance for overall foreign, developmental or structural policy.

A guarantee can only be granted, however, if the risk is justifiable. The Government Committee should stipulate the requirements for cover for each country. These take into account the financial strength and economic policies of the country concerned, as well as macroeconomic and political factors. In addition to this, the foreign buyer's creditworthiness and his payment record are scrutinized. Even if a buyer is insufficiently creditworthy, it may be possible to cover the transaction if a state or bank guarantee is forthcoming. No cover can be given, however, in cases where there is a high probability of loss.

Benefits obtained by the use of insurance are to make it possible to open up difficult markets, protection from non-payment, make export financing easier, create a level playing field in international competition etc.

Types of insurance that would be of interest for SMEs in transition countries, which have proven successful in the EU would be medium and long credit term supplier credit cover as well as buyer credit cover for the financing of export deals with tied buyer credits. These types of cover would be suitable mostly for individual export transactions. Also there is a wide range of cover options available for export transactions on short credit terms (payment periods of up to two years): wholeturnover policies and wholeturnover policies light insure exports on short credit terms of an exporter who supplies several buyers in different countries. Revolving supplier credit guarantees and revolving buyer credit guarantees provide protection against bad debt losses in cases of repeated deliveries to one buyer. One-off transactions can also be covered with an export credit guarantee on short credit terms. [6]

When raw materials, semi-finished goods, components, consumer goods and spare parts are supplied, the accepted credit period should be normally only up to a six months maximum. For high-value components and consumer durables the acceptable credit period should be 12 months. In these cases of short credit periods the cross-border supplies would be covered under short-term supplier credit guarantees.

The cover would be taken effect with the shipment of the goods and/or the commencement of service, and would be ended with full payment of the covered amount owing to the SME. For the provision of cover the insurance company would charge the SME an administrative fee and a premium, the amounts of which depend on the order value. The premium level would depend on the foreign buyer's credit rating, the general country risk and length of the credit period.

Take a form of credit insurance and its benefits for SMEs. Suppose that the credit relationship and export business was carried to a credit scheme given in Figure No. 2

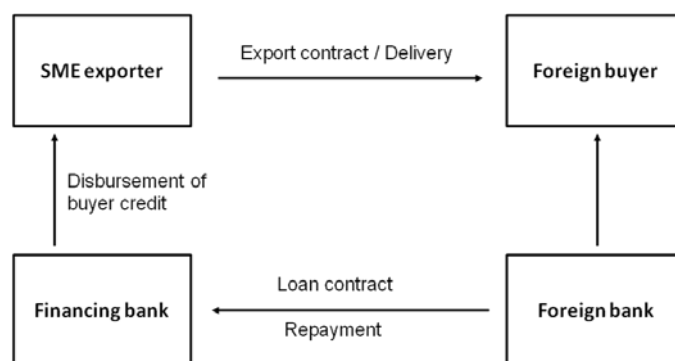

Figure 2 Business processes

On the basis of the scheme one can see that the entrepreneur applying for export credit insurance can insure a credit line or they can insure export business. Some major enterprises have the possibility of insuring manufacture costs so that the enterprise could enter the secure export business and establish credit relations. Insurance as such, on one hand, encourages SMEs to start transactions with a foreign partner, and on the other, it facilitates the funding process. By insuring credits or export business, SMEs obtain credit (funds) more easily since the bank, owning the policy, is willing to grant a credit without any further collateral by means of personal and real property. When it comes to credit costs, they are reduced, since they are the reflection of bank loan risk. Hence it is better for SMEs to pay the

insurance premium and reduce the cost of financing through insurance, bearing in mind benefits and advantages of the insurance policy. The insurance premium is variable, depending on the experience with the guarantee applicant, the risk and size of export business and the risks of the country they export to.

As already mentioned the basic types of insurance which have shown to be useful to encourage SMEs in developed countries, which could be applicable in countries in transition are wholeturnover policies and wholeturnover policies light insure exports on short credit terms of an exporter who supplies several buyers in different countries and revolving supplier credit guarantees and revolving buyer credit guarantees which provide protection against bad debt losses in cases of repeated deliveries to one buyer. For supplier credit guarantees and revolving supplier credit guarantees SMEs pay administrative fees and premium for cover. The administrative fee depends primarily on the order value. The premium rate is also determined by the country risk category into which the country of the buyer falls. Besides, the premium rate is influenced by other parameters such as the term of the contract, status of the buyer (public or private) and, where applicable, the percentage of cover.

The premium for wholeturnover policies and wholeturnover policies light is calculated on the basis of monthly declared turnover. For wholeturnover policies the premium is fixed on the basis of the risks covered in each individual policy, while fixed premium rates apply to wholeturnover policies light. For both types of policies the premium rates will be adjusted in accordance with the claims experience under a system of no-claims bonuses/risk surcharges, which results in premium reductions or increases in subsequent years. However, both types of cover are normally cheaper than an individual supplier credit guarantee.

3.1 Fundamentals of wholeturnover policies

In the developed countries the wholeturnover policies is often used by SMEs. In particular semi-finished goods, consumer goods, raw materials and agricultural produce are usually traded on short credit terms. For all companies with a turnover that qualifies for cover amounting to at least EUR 500,000 and a number of foreign buyers in several countries the obvious choice would be a wholeturnover policy as comprehensive cover. It protects SMEs from bad debt losses due to foreign buyer insolvency, non-payment of receivables within six months following due date as well as due to political risks, especially lack of hard currencies or restrictions on the international payments system.

In most cases wholeturnover cover can be provided at a much more favorable price than supplier credit guarantees for individual transactions. Besides, there are no individual applications or handling fees. The premium amount is determined mostly by the country risk and the terms of payment that the SME agreed with the buyers. The higher the risk attached to countries and buyers included in wholeturnover policy, the higher the premium rate will be. On the other hand, the premium will be the more favorable, the better the risks are balanced. The flexibility of wholeturnover cover is proven by a great variety of options for inclusion. The SME can have receivables from business with all private customers in all other countries included in wholeturnover cover. They can choose freely which countries they want to include in the cover. They can apply for limits (maximum amounts) for commercial and political risks respectively for each buyer, which will be fixed without any extra costs. Hence they can always know which of their customers are included in the cover and with what amounts [6].

In addition, they can optionally include certain types of receivables for the entire policy period and exercise these options on a country-by-country basis. Receivables due to foreign subsidiaries from foreign customers can be included in the wholeturnover policy irrespective of whether the goods are delivered by subsidiary to a third country or an end buyer within the country it is domiciled in.

3.2 Fundamentals of wholeturnover policies light

Wholeturnover policies light are ideal for exporters whose annual turnover in export business is less than one million Euros and who normally agree short credit terms of up to four months. Hence they are aimed at small and medium-sized companies whose turnover from export business is not yet big enough to qualify for normal wholeturnover cover. A wholeturnover policy light is even easier to handle than a standard wholeturnover policy but does not offer the same comprehensive options for inclusions. The wholeturnover policy light also runs for one year, however, all insurable business has to be included in the policy. When cover commences, the premium rate will be fixed for two years,

afterwards the premium may be reduced due to a system of no-claims bonuses/risk surcharges depending on the loss experience [6].

In particular customized goods should be insured because it may be almost impossible to sell them to another buyer if they cannot be delivered. Manufacturing risk cover includes the actual prime costs incurred. These are estimated in advance by SMEs and form the basis for the maximum cover amount given. If an insured event occurs, the actual amount of the loss is ascertained by a specially prepared expertise. The guarantee covers all political and commercial circumstances in the buyer country which prevent the completion or the dispatch of the goods. The risk of an embargo being imposed is also covered.

3.3 Fundamentals of revolving supplier credit cover

Revolving supplier credit guarantees cover repeated deliveries of goods and the provision of services to one foreign buyer on short credit terms of up to 24 months. Their scope of cover and the premium rate are the same as for short-term supplier credit cover, however, it is much easier for SME to handle. If a positive decision is taken on the application for a revolving supplier credit guarantee, SMEs receive a policy in which the maximum liability accepted ("maximum amount" or "limit"), the permissible payment terms and other general conditions are specified. Because of this limit, which is fixed at the outset, the amount freed can be used up once the covered shipment has been paid for further supplies – the policy "revolves". There is no need to file separate applications for supplier credit cover for each order and that helps SMEs to react much more flexible to market trends. The Government continues to be liable for these covered trade receivables even if the revolving supplier credit guarantee is not renewed upon the expiry of the policy year [6].

3.4 The real state of credit insurance in Serbia

The current issue of SME's credit insurance, in turbulent business conditions and trends caused by global economic crisis, is becoming more and more important. On 30th September 2010. insurance companies balance 117.4 billion dinars, which, compared to the third trimester 2009, presents the 19.1% increase [9]. If one observed premium structures of the insurance companies sector in the third trimester 2010, they would see that the premium share coming from credit insurance accounted for 0.08% of the total sum, which indicates that the awareness of credit insurance and its positive effects on the development of enterprises in Serbia needs to be raised.

A step forward to raising awareness of the benefits of insurance is the establishment of guarantee fund which is a nonprofit organization. The Fund provides bank credit lines by reaching an agreement on business cooperation with banks that are willing to support program activities of the Fund and to adapt credit conditions (interest rate, term and of repayment) to the conditions defined in the Fund program and the tenders that the Fund holds; the tenders for granting guarantees for the purpose of granting credits intended for financing certain economic activities [4].

The guarantee fund was established in Vojvodina as well. Its main goal is to help SME business in Vojvodina. Fund activities in 2009 were as follows:

Activity	Guaranteed amount employed (RSD)	EUR=95.89 RSD	Number of guarantees	Effect of the activity
Agricultural machinery	192.688.797,70	2.009.502,65	54	56 units of agricultural machinery
Women entrepreneurship –start up	6.822.736,11	71.152,58	6	16 new jobs
Women entrepreneurship – women who perform activities for less than 3 years	47.661.528,04	497.050,00	24	101 new jobs
Total	247.173.061,85	2.577.705,23	86	

Table 1 Guaranteed amount employed by allocation in 2009 [2]

As one can see from the table, during 2009 the Fund issued only 86 guarantees, while in the same year in Vojvodina there were 23,066 active companies out of which 22,933 are categorized as SMEs [3]. To assume that in 2009 the 86 guarantees were given to various companies would be rather bold, but it would mean 0.37% of SMEs took the advantages that the guarantee fund gave.

4. Concluding remarks

Given the above, the situation in the credit insurance area in Serbia is at an early stage. Although there is a possibility of insuring credits for SMEs, there are many difficulties due to the entrepreneurs' lack of knowledge about procedures for obtaining an insurance policy and the like.

A possible solution to this problem might be SMEs association in clusters which would enable them get the information and obtain insurance policies easier. Associating in clusters or associations, they would cooperate with insurance companies which, being the government representative, would insure export credits. Hence, by means of clusters, they would obtain information and secure placement of funds, since the State, over continuous cooperation among clusters, would enhance the security in terms of credit solvency of enterprises they grant funds to. However, joining a cluster or an association, shouldn't be a precondition for obtaining a policy, but its purpose would be the reduction of bureaucracy i.e. procedures and the increased knowledge i.e. the awareness of the need for credit insurance especially in the case of export business.

Countries in transition have the possibility to apply the model that the developed countries have used for a longer period of time, which proved to be a good instrument of facilitating the business for SMEs, and an incentive for their export activities. By insuring credits or business of SMEs, funds are directed towards achievement of macroeconomic goals of the state that ultimately help the global economic situation in the country to improve. If there is an insurance company is state representative, it would encourage development of SMEs, increase exports, achieve higher employment rate, on the other hand it would influence the financial sector development since the banks would grant credits to entrepreneurs with greater security and, hence, increase their business volume.

Methodology for analyses and selection of Best Practices in the area of embedded systems and industrial informatics

Nikolay Milovanov¹, Antoni Slaviniski², Ivan Bogomilov³

¹*Department of Telecommunications, New Bulgarian University, Sofia, Bulgaria, nmilovanov@nbu.bg*

²*Department of Telecommunications, New Bulgarian University, Sofia, Bulgaria, aslavinski@nbu.bg*

³*Department of Telecommunications, New Bulgarian University, Sofia, Bulgaria, ibogomilov@nbu.bg*

The paper describes a methodology for elaboration, selection and analyses of the Best Practices (BPs) from the numerous gathered good practices (GPs) related to the transformation of research into innovation. The methodology has been developed by Foundation for New Bulgarian University as part of an I3E funded project. The project goal is identification of numerous good practices in the area of Embedded Systems and Industrial informatics from the region of South Eastern Europe (SEE). The methodology is part of Work Package 4, activity number 4.2. Within this activity, it has been necessary to identify a short list of the 30 BPs from the 120 GPs gathered within activity 4.1.

The proposed methodology contains guidelines and criteria related to the thematic area of GPs, description forms of research achievements, technological innovations and applied financial mechanisms. It could be used as a template with very few adaptations for BP selection from many GP in other European Union funded projects. The selection of the 30 Best Practices is particularly important for the next project phase 4.3. This activity has to elaborate how the research results of the 30 BPs to be transformed to innovation and to describe the process in a document called Methodology Guideline for Innovation.

Keywords

Methodology for analyses and selection of Best Practices from many Good Practices, Embedded Systems, Industrial Informatics, I3E

1. Introduction

One of the project objectives, within the WP4, is the development of methodology guidelines for elaboration, selection and analysis of a set of Best Practices. This Methodology describes how the analysis and selection of GPs will be carried out and provides guidelines for the project partners to analyse the gathered GPs following a defined set of criteria and on bases of a comprehensive analysis to select a number of GPs which are related to the transformation of research into innovation on the areas of Industrial Informatics and Embedded Systems.

The I3E project envisages collecting at least 100 GPs within the activity 4.1, which has to be finished until June 2010. At the teleconference held on August 31st, 2009, when WP4 was kicked off, it was agreed that each project partner should collect at least 10 GPs in accordance with the given recommendations and presentation templates. Each of the GP examples should clearly present the applied financial mechanism that enabled the transformation of research into innovation.

Based on that, in activity 4.2 a subset of a minimum 30 BPs from the gathered 100 GPs will be selected. This document will define a methodology and the criteria to be used in the assessment

process. After that each of the BPs will be further analyzed through a detailed SWOT analysis. Finally the results will be used in the next 4.3 activity of the project for the preparation of one of the major project deliverables the - Methodology Guideline for Innovation. In this document based on the outputs from 4.2 a methodology guideline is developed describing how research results may be transformed into innovation and which financial tools make it feasible.

2. Methodology description

2.1 Overview

The objective of Activity 4.2 is to assess and select a subset of a minimum of 30 BPs from the gathered 120 GPs. The document defines a methodology and the criteria used in the elaboration process. Then each of the BPs will be further analyzed through a detailed SWOT analysis. At the end the results will be used in the next activity of the project 4.3 in which a Methodology Guideline for Innovation will be prepared. In this document based on the outputs from 4.2 a methodology guideline will be developed describing how research results may be transformed to innovation and which financial tools that make this feasible.

The methodology is based on several criteria – financial, impact, realisation, innovation, social, etc. Each one will bring a certain number of points to each GP. It is possible that some criteria apply to specific GPs, and other does not. In order to have a clear and meaningful elaboration process it is important for each GP to provide as detailed information as possible. The inputs that are needed for the elaboration process are described below.

Each GP will be assessed by 3 project partners. Two of the partners shall be organizations different from the one that has submitted the GPs and the third partner will be the leading project partner and organizer.

2.2. Needed Inputs

In order to elaborate and analyse the gathered GPs they shall contain two major groups of input information. The first group is more important for the assessment process.

- Group 1
 - GP description
 - Description of the R&D team
 - Description of the financial mechanism that was used during the transformation of research into innovation
 - Accomplished benefits for R&D team, institution, SME
 - Sustainability after the financial aid
 - GP evaluation
- Group 2
 - GP theme and objectives
 - Location: country, region, place, institution
 - Evaluation of GP in terms of additional explanation of the reason why the proposed GP is considered an example of GP
 - Contacts for R&D team. Optionally contacts for the financial facilitator if he is different.

2.3 Complementary Information and Non-applicable Criteria

If necessary the reviewer will have two options for specific manoeuvres. Both of them must be used in limited cases after careful appreciation.

During the evaluation of GPs the reviewer can decide that some complementary information will facilitates the fair and detailed evaluation of the GP. In this case the reviewer might request the additional information from the responsible partner. If the answer is received in a reasonable time the complementary information might be used for the final evaluation.

In some specific cases the reviewer might decide that some criteria are non-applicable to the certain GP. In this case the reviewer has the possibility to extract this criterion without a decreasing of the final evaluation. Details will be given below.

3. Grading System

Based on the cases of the criteria below, a system of grading will be applied. Each GP will be evaluated against several criteria. Each criterion is subdivided into several sub criteria. Each sub criteria brings a certain number of points between 0 and the maximum for the particular criteria described in paragraph 4. The evaluator shall fill the scores in the table in Annex A. The final score is calculated as a percentage determined from the GP points score (from all the applicable for the particular GP criteria) divided by the possible maximum score. Some criteria / sub criteria might not be relevant to certain GP. In this case, described in paragraph 2.3, the evaluator shall extract the maximum scores for these criteria from the total maximum score but not less than 85 points. The most difficult task for the evaluator is to decide which criteria are non-applicable for the particular GP.

4. BP selection criteria

4.1 Financial criteria:

15 points max

- Attractiveness for investors: expected benefits (influence over the market, long term profit, short term profit, taxes decrease and value for money). If certain GP has:

6 points max

- Influence over the market - 2 points;

Long term profit - 1 point;

Short term profit - 1 point;

Value for money - 1 point;

Taxes decrease - 1 point.

- Financial diversification: all types of financing (corporate, seed, government and private funds, personal) must be present; combinations of two or more types of financing are preferable.

4 points max

- GPs that provide attractive financing mechanisms that support the other market players in the field of embedded systems and Industrial informatics. For example a bank or a fund offering a scheme for financing research and development of the SMEs part of the sector in SEE.

5 points max

4.2 Applicability/Impact criteria

15 points max

- International validity: application in the country of origin, distribution among all SEE countries, distribution in EU, distribution over the world.

6 points max

- Wide range of participants: GP's which are good for SME's, large industrial companies, universities, small research groups, individuals.

4 points max

- International synergy of intellectual resource: which are the possibilities for cooperation between participants (private and state companies, universities, retailers and wholesalers).

5 points max

4.3 Realisation

15 points max

- New idea realisation: time span, approximate cost, team (approximate number of staff members – belonging to one company or university, belonging to different companies / universities). If a company or organization complies with those criteria the innovation and commercialisation of that idea should be recent.
7 points max
- New technological realisation through a novel means of existing idea: results (better parameters / characteristics / efficiency, lower cost / size / weight, more functional use)
5 points max
- Improvement/novelty introduction to well-known technology: same as 3.2.
3 points max

4.4 Innovation

15 points max

- Innovation shall be recent (preferably from the last 1 or 2 years). It might be a product, process, service or even a financial mechanism. Note that a new version or repackaging of an already well-accepted technological solution does not qualify as an innovation.
- Recent GPs that have achieved something beyond the current state of the art in the area of embedded systems and Industrial informatics.
5 points max
- Novel ideas that have achieved a real innovation in its market niche despite the relatively low R&D effort/cost behind them.
4 points max
- Innovative prototypes ready to enter the market.
6 points max

4.5 Time & life criteria

12 points max

- Expected use of GP: less than 3 years (1 point max), 3 - 5 years (2 points max), and more than 5 years (2 points max).
4 points max
- GP sustainability and potential for growth.
2 points max
- Energy saving GP with classical energy sources.
2 points max
- Environment friendly GP
2 points max
- Use of new energy sources (wind, solar energy, bio energy, thermal energy)
2 points max

4.6 Social criteria

10 points max

- Creating new work places.
4 points max
- Oriented to handicapped people.
2 points max
- Enhancing of personal qualification.

- 2 points max
- Number of trained staff in areas related to embedded systems and industrial informatics.
2 points max

4.7 Transferability

10 points max. Transferability criteria elaborate GP that has achieved results that might be easily transferred to other players from the SEE region. That criterion is particularly important for the project since one of the project goals is to build a network and to transfer knowledge between the different GPs. Thus practices, by which the results were transferred to more than two places, shall score 10, to two places - 7, and to one – 5. The possibility for transfer has to be scored with 2 and by its lack - 0 points.

4.8 Overall reviewer impression

8 points max. Since it is quite difficult to make fair criteria for assessment of so many different good practices an additional criterion will be added. It gives opportunity to the reviewer to provide its overall impression from the Good Practice. This criterion gives a maximum of 8 points. Since this criteria is quite subjective the reviewer shall specify in the notes section of Annex A why points as per this criteria are/ or are not given.

5. Results

As a final result 30 BP were selected among the initial 120 GPs. The country representation is shown on Table 1 and on Table 2 is presented the representation as per Industrial areas.

Table 1 BP country representation

Country	GP 120		Original Data	
Greece	21	17.50%	9	30.00%
Austria	23	19.17%	6	20.00%
Italia	11	9.17%	5	16.67%
Bulgaria	20	16.67%	4	13.33%
Slovenia	14	11.67%	2	6.67%
Serbia	11	9.17%	2	6.67%
Ukraine	10	8.33%	2	6.67%
Romania	10	8.33%	0	0.00%
	120	100.00%	30	100.00%

Table 2 BP country representation

Industrial Area	Original Data	
Industrial informatics	13	43.33%
Nomadic environments	4	13.33%
Private spaces	4	13.33%
Public infrastructures	9	30.00%
	30	100.00%

6. Conclusion

The proposed methodology for elaboration and selection of Best Practices among many Good Practice examples was successfully implemented into this I3E funded project. Due to its close following and execution from all the partners were selected 30 BPs among 120 GPs. The methodology had its pros and cons. The pros were that it has selected BP from almost every country and those BPs were from all the Industrial domains of Embedded systems and Industrial Informatics. The cons was that it was relatively difficult for the evaluators to determine are some of the criteria applicable to certain Good practice. The final results were accepted by all partners and the project continued in its next phase. In this one the partners has to further elaborate the chosen BP and to perform a SWOT analyses of the BP's.

Audit of the Information Systems (IS) as a tool for continuous improvement of the performance of an organization

Robert Minovski¹, Valentina Neshovska²

¹Faculty of Mechanical Engineering, Ss. Cyril and Methodius University, Skopje, Macedonia, mrobert@mf.edu.mk

² Faculty of Mechanical Engineering, Ss. Cyril and Methodius University, Skopje, Macedonia, valchnesh@gmail.com

Today information systems and information technology (IS and IT) are essential components for the operation of any organization. Their importance in providing support to business and operational processes, as well as management activities for tactical and strategic operations, has dramatically increased over the last 15 years. As IT has become an essential component of any business, it is not just an additional expense for the organization, but also a means for generating additional income and achieving business goals.

With its widespread use, possible misuse of information becomes a major concern. Data security and integrity are of primary importance for any organization. Information management involves identifying what information should be kept, how and where it should be stored, and who should have access. The quality of this process affects the quality of the information submitted to management, which directly affects its decisions, which in turn are essential for the survival of the organization in the global market. Additionally, some further topics are enhancing the complexity to the topic. One such example is alignment of IT with business, known as 'IT strategic alignment', which is becoming one of the major challenges of managing IT and business in general in the last period. From here stems the importance of checks and audits of information technology as a key mechanism for ensuring the integrity of information, with a view to the continuous improvement of the organization [2].

In this paper the example of IT audit in certain organization is given. COBIT is used as a basic audit methodology. The main goal of the paper is to show that the IT audit should be viewed as a tool for fostering the continuous improvement and IT strategic alignment.

Keywords

Audit, Information Systems, COBIT, Continuous Improvement of Business Process, IT Strategic alignment

1. Introduction

Today successful organizations such as Google, Apple, T-Mobile, etc., are doing more than simply collecting and storing large amounts of data and information. By managing this information, they develop competitive strategies. Professor Thomas Davenport explained that such organizations are analytics competitors or competitors with the analysis [3]. It is clear that the IS and IT are facing new challenges that are making them more and more complex and difficult to manage. Besides the generic demands to obtain the right information to a right place in a right time in right format (in order to obtain management by facts), globalization and rapid development of the technology brought up additional questions/demands concerning the IS and IT, like security, strategic alignment of IT, etc.

Although the idea of management by facts is seemingly a simple process, in its application most organizations face three problems [3]:

1. Collecting relevant and reliable information,
2. Finding relevant information in vast amounts of available data, and
3. Transforming the data into information and knowledge.

Alignment is the correct positioning of components in an organization and their continuous adjustment to achieve the defined objectives. IT Governance is achieved by [4]:

- Strategic alignment of IT with business,
- Implementation of IT systems in business,
- Risk management of IT systems,
- Management of IT resources, and
- Measurement of the performance of IT systems

Since the IT and IS audit is one of the tools to evaluate the condition of the IS and IT, it is obvious that they have to cope with all these issues. For example, although SAIT should be among the primary objectives of IT audits, today audits are focused more on the technical part and less on the substantive one, the reason being that they are executed by IT experts who are not very familiar with MIS (Management Information Systems). The goal of this paper is to show the benefits that can be gained when audits also check whether systems are aligned with both the organizational needs and the business goals of the organization. This should improve the potentials of the IT audit in direction of the continuous improvement of the organization as a whole.

2. Audit Methodologies

IT audit is an objective process of collecting data for evaluation of information systems, operations and their functions. The evaluation of the collected information indicates whether the information systems store data securely, maintain the accuracy of the information and work effectively to achieve the goals of the organization. IT audits must answer the following general questions [5]:

- Do the computer systems work at all times when needed? (Availability)
- Are the data systems available only to authorized personnel? (Confidentiality)
- Is the data in the systems always timely, reliable and accurate? (Integrity)
- Are the operations of the systems effective? (Operations)
- Do the systems work in accordance with the user requirements, organizational policies and procedures and applicable laws and regulations? (Compliance)

Audits are carried out in phases / stages. According to [6], phases for running audits can be divided as follows:

1. Planning
2. Field work (executing)
3. Reporting

2.1 Planning

When planning an IT audit, the IT systems to be taken into consideration have to be associated with the organizational strategy. As things stand now, the methodologies for IT auditing that are mostly implemented in praxis are not suggesting analysis of the strategic documents, like strategy and strategic goals of the organization, IT strategy and its goals, etc. So, in the real life the consultation of those strategic documents in this important phase of the audit is left on the knowledge and experience of the auditors themselves. Auditors can choose the systems based on observations and on analysis of the risks. If the auditor (or the whole team) has no information on the strategic needs and goals of the company, the results of the audit will be inadequate. By using this approach, mathematically speaking it is possible to find the "local maximum of the function" without getting a synergistic effect on the results obtained. This important connection should yield an optimal solution which would lead to the realization of strategic goals of the organization. Therefore, the company's strategy and goals must be among the major inputs in the planning of IS audits.

2.2 Field work (executing)

The field work phase involves the execution of the audit. An important aspect of the audit, which should be determined before the field work begins, is to define the assessment of the level of fulfilment / compliance with the standards. This is a process in which the data processes or products are compared with certain defined criteria and evaluated to determine the extent to which they met the relevant criteria and whether corrective action is needed. Table 1 ([7]), gives one possible way of to carry out such an assessment; it is used in the case study.

Table 1 Compliance assessment

Supported by documentation	Conducted in practice	Degree of implementation
Yes	Yes	Fulfilled
Yes	Partly	Partially fulfilled
Partly	Yes	Partially fulfilled
Partly	Partly	Partially fulfilled
No	Yes	Partially fulfilled
Yes	No	Unfulfilled
Partly	No	Unfulfilled
No	Partly	Unfulfilled
no	No	Unfulfilled

2.3 Reporting

After completion of the audit, the auditor must report the findings to the clients. The audit report is a very important document which should be skilfully written so as to be understandable to all levels of management and staff.

3. Case Study of Implemented Audit Methodology

We will present the practical implementation of an audit of the functions of an IS in a global nonprofit organization. More precisely, the audit was carried out in the department which deals with the execution and follow up of different projects of the organization (in the following text the department is addressed as organization). The audit was done in accordance with COBIT, ISACA and IIA standards and methodologies; more specifically, we used ISACA methodology for planning, COBIT methodology for conducting the audit and IIA standards for reporting.

The first step was planning the audits of the organization's information systems.

For the audit we needed an auditor with knowledge of IT and SDLC (Systems Development Life Cycle) methodology. The duration of audit activities for carrying out the planned tasks was three weeks plus one additional week for writing and communicating the audit report.

Besides the ordinary documents that has to be analyzed in this planning phase, like IT plan, IT inventory, etc. [9], in order to exploit the SAIT we intended to consulte the mission, vision, general strategy and the IT strategy of the organization. Surprisingly the department had mission, vision and IT strategy (probably due to the fact that most of the documents are in electronic format), but had no written general strategy at the moment of auditing (this is one of the serious remarks noted in the final report). We therefore analyzed the mission, vision and the IT strategy of the organization. The mission of the organization is to expand its capacity and the capacity of its partners for the timely implementation of projects (cases) and activities. Working in some of the harshest environments and conditions in the world, the vision of the organization is to always provide its clients with services and results that meet the highest standards of quality, speed and efficiency.

From this we conclude that for the organization to achieve its mission and vision it requires a stable IT capacity that will enable efficient use of resources and will give accurate results. The key words from the mission and vision are expand, quality, speed and efficiency. In other words, the audit, concerning the SAIT had to answer the question(s), like "Are the information systems capable to "follow" the growth of the activities (in terms of new locations and new projects), obtaining good quality of data, in a short period of time and with acceptable costs?"

According to the size and importance of the systems, the audit objectives are defined as follows:

Primary objectives:

1. Is there a system for management of ICT resources?
2. Are there appropriate policies and procedures for strategic planning and management?
3. Are the roles and responsibilities clearly defined for effective and secure execution of ICT operations?

Secondary objectives

1. Is access to critical data and programs is secure and solely available to authorized people?
2. Is the network physically and logically secure?
3. Are there change management controls in place?
4. Are there implemented procedures for correct, complete and timely processing of data?

Considering the inventory / list of all automated applications, the organization uses the following information systems:

- An application for correspondence (CorLog) - where all the organization's internal and external communication is logged
- A time monitoring system – monitoring the amount of time employees spend per project
- A case management system – monitoring all the organization's on-going projects/ cases
- A database for issuing and monitoring recommendations (RecTrack) – such recommendations are issued as a result of completed projects/ cases
- An electronic telephone directory (Tel.directory) – a database of all employees

Analysis of identified IS risks used a method based on a scale of 100 points, as shown in Table 2 [8], where extra criterion (SUIT) was added in correspondence with previous discussions.

Table 2 Risk Assessment of the applications in the organization using the model of 100 points

Category	Description	Max.	Tel. directory	Time Monitoring	Case Management	CorLog	RecTrack
A	Criticality	20	5	20	20	15	15
B	Complexity	20	5	20	20	10	5
C	Technology	10	5	10	5	5	10
D	Control environment	15	10	10	15	5	5
E	Integration	15	10	5	10	15	20
F	SAIT	20	5	20	20	10	10
Total		100	40	85	90	60	65

From the risk assessment table we see that the systems for case management and time-monitoring are the most critical applications in the organization, because they maintain all the important information on the projects. Hence, the risks associated with using these systems are the greatest.

Both information systems are accessed locally (there are local servers) in Locations 1, 2 and as well as some other locations (7 and 8), while other locations have access via Citrix, as shown in Figure 1.

Audit of all technical elements of the systems was done by assessing the degree of fulfillment: evaluating responsiveness to the requirements of the standard to determine to what extent they meet the relevant criteria and whether corrective action is required.

Secondary objectives of the audits were pursued with respect to the following elements; the results are summarized in Table 3.

Due to the limited space in the paper we will only list the summarized findings for the COBIT elements while we will provide a detailed review for the third COBIT element.

Element 1: Installation and configuration of the Application System and the general ICT environment

Audit results: Technical aspects of the application system have been properly configured and implemented however the application performance is very slow in some locations.

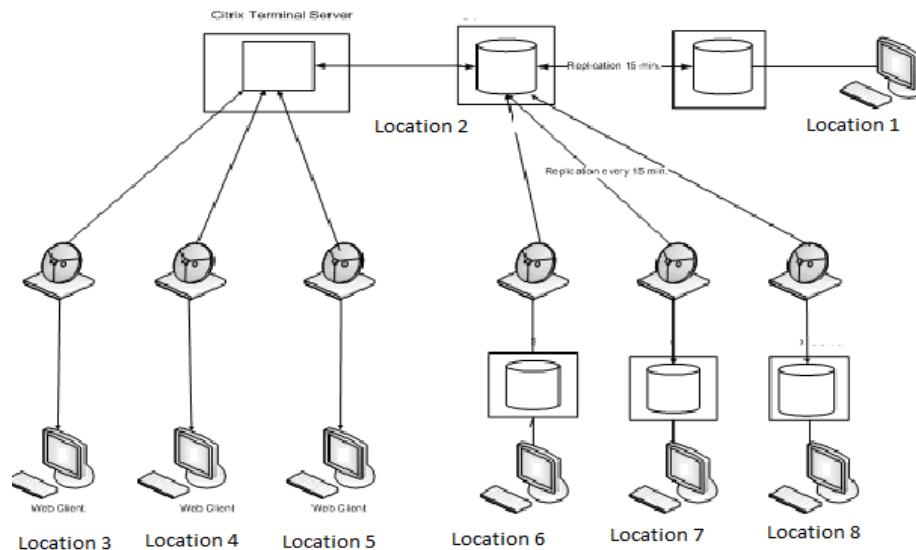

Figure 1 Architecture of the system for projects

Element 2: Processing

Audit results: The system is following the organizational workflow however there are no effective automated controls to ensure authorized, accurate and complete transactions from input to processing modules to the output of information.

Element 3: Data ownership

Objective of this element: To determine whether data owners have a clear understanding of their roles and responsibilities in ensuring the quality of data and the effectiveness of the application system.

We have expanded the audit with an analysis of the strategic alignment of IT. The new role of IT audits should be to reveal whether the IT and IS provide information that corresponds to the strategy. Currently, the organization has an IT strategy that has been developed taking into account various parameters including but not limited to the operational requirements of users, feedback received from users and potential areas for IT development. However, the following is not covered in this document:

- Definition of the IT services requested / required from service providers (SLA - service level agreement)
- Legal risks and requirements
- Best practices
- System for monitoring the reliability of data
- Electronic data protection and
- Policies for password creation

It is important to emphasize that there are no internal documents signed with providers that define the contracts for IT services and IT policies (SLA) given that the information system currently being used by the organization is maintained by the IT department in location 2.

From the analysis of the IT strategy, we can see that the organization has internal mechanisms for coordination of IT initiatives but no effective mechanism for supervision and coordination of IT programming and administrative activities, and therefore no proper forum for:

1. Establishing and ensuring that effective and efficient use of IT investments has been achieved;
2. Holding discussions to determine what resources are needed for IT support of IT activities and explaining the requirements for additional IT resources;
3. Recommending appropriate IT policies and procedures for business continuity plans for critical systems, security and replacement of systems or development of new systems that comply with standards;
4. Overseeing and coordinating the development of new IT systems;
5. Acting as an IT coordinator for the organization to ensure that all relevant directives are distributed to employees;
6. Ensuring that the IT needs of individual departments are met.

Long-term and short-term IT plans establish IT tasks necessary to fulfil the strategy and meet the needs of the organization. Such plans are important because they provide the basis for allocating and

monitoring the use of resources, information to interested parties about how the IT strategy will be delivered and a demonstration of how to prioritize IT activities to meet the needs of the organization. These plans should be used for calculation and analysis of investments in information technology. Audits found that, in the absence of such plans and a list of initiatives to support the process of project management, the organization cannot clearly show how IT resources are effectively used.

As a consequence:

1. Alignment of IT activities that include the terms and details of staff responsible for performing IT tasks is not visible within the organization;
2. Decisions on IT services are not planned but are determined according to current needs (on an ad-hoc basis). It is obvious that there are financial constraints in the organization, but this also means that the organization does not get a full picture of whether IT meets its business needs;
3. There are no controls to ensure that IT goals and short- and long-term plans are meeting organizational goals and plans;
4. There is no formal mechanism to assess whether and to what extent existing information systems meet the requirements for the automation of business processes, functionality, stability, complexity, costs and benefits.

According to the organizational structure, the IT unit is in the administrative department. The audit has no evidence to determine that this structure is based on sufficient analysis of the nature of the necessary IT services and the staffing and financial resources required for effective performance of functions. The audit proposes the establishment of an IT unit; for its efficient performance it is necessary to first define:

1. Description of the structure, functions and duties of all staff working in the IT unit;
2. Description of reporting lines, roles and responsibilities of staff in the IT unit.

The audit found that the organization has dedicated staff to provide software services, including troubleshooting and installing hardware and software. While some support requests are received by e-mail, the organization does not have mechanisms to store and analyze requests, including phone calls, or to analyze the nature of the requests. Because of this, the organization cannot develop a comprehensive list of equipment and systems problems and is not able to generate a list of frequently asked questions to establish the training needs of staff, which could strengthen the IT skills of employees in general.

The organization informed the audit that there is lack of funding for IT activities, which restricts the upgrade of IT equipment and technology. However, accurate information about how much is spent on IT is not available because the organization has no policies and procedures to ensure that IT costs are reflected in the budget in a consistent manner. The audit is of the opinion that this information is essential to allow the organization to explain and justify the need for IT investments necessary to support the organizational mandate. It is necessary to establish an IT fund, preferably within the administrative budget, which will help in collecting and reporting on IT costs and will facilitate analysis of investment in the use of IT applications and support for additional funding.

Element 4: Change management

Audit results: New releases and upgrades have been properly reviewed and staff has received adequate training.

Element 5: Logical access control

Audit results: The application system does not maintain appropriate confidentiality and integrity of data. There are no logical access controls and procedures to protect the system and information from accidental or intentional misuse.

Element 6: Data retention/backup/recovery

Audit results: There are effective controls for backup and recovery of data during the process of data storage and retrieval however the system does not have detailed audit trail.

Table 3 Evaluation of the elements of the system

Elements of the system to check	Level of fulfillment			Remarks and suggestions for improvement
	Fulfilled	Partially fulfilled	Unfulfilled	
1. Installation and configuration of the Application System and the general ICT environment		X		Installing Domino servers in each location that will replicate the main Server in Location 2
2. Processing			X	New integrated system, it is not productive to improve (change) the old
3. Data ownership			X	To establish an IT department that will be composed of about three people and be responsible for IT support
4. Change management	X			Fulfilled
5. Logical access control			X	New system
6. Data retention/backup/recovery		X		The system is missing a detailed audit trail

The audit found that existing systems do not meet the needs of the organization and that there is a requirement for a new integrated system for tracking cases, timing and issuing recommendations. The systems showed significant pitfalls concerning the processing and logical access control and certain pitfalls concerning data ownership and data retention/backup/recovery. This kind of shortcomings can significantly affect the fulfillment of the mission and vision of the organization – expansion of the missions, timely carrying out and monitoring of the cases (projects), etc.

Using the gap analysis the audit defined a detailed list of specifications that the new improved system has to have in order to meet the aforementioned requirements. Due to the space limitation, here we will pinpoint just few of them only to have the picture of the level of details, Table 4.

Table 4 Functionality of the document management

Feature Group	Requirement id	Requirement description	Current	Future
Collaborative Editing	FN_CM_001	1. Some of the document types are multi-part documents, where each section of the document may be authored / edited / reviewed / approved by a different set of people. Therefore, the following use-case scenario describes the necessary functionalities:	NO	YES
		1.1 It should be possible for the users to check-in / check-out individual sections of a multi-part document separately. This will ensure that multiple users can work on different sections of the same document in parallel.	NO	YES
		2.1 It should be possible for the document owner to define access rights (read, write etc.) and metadata elements for each section of a multi-part document. This will ensure that the users have the appropriate level of access based on their task assignment.	NO	YES
		3.1

The development and implementation of the system should follow established organizational standards and procedures. Two basic options are available to replace existing systems (the decision on this issue is beyond the frame of the audit):

- Buying a commercial system (off-the-shelf) based on a relational databases, or
- Developing a new system within the organization with existing staff or by hiring consultants.

4. Conclusions

Audits of IS systems are of great importance and benefit in ensuring the quality of economic activities and business processes within organizations. Through the audit process it is possible to check the quality of data and information, the way data is obtained from the systems, how to use the data and whether the data contributes to the improvement of the organization's decision-making process. This paper confirms the theories about the importance of information and IS and demonstrates how their accuracy and timeliness is essential for the organization. It also shows the importance of SAIT and its verification.

Globalization, technology and diverse organizational structures have made business very complex. Audits should help the organization gain competitive advantage in the market. Properly planned and implemented, the recommendations of the audits can have far-reaching consequences and benefits for the organization and can provide meaningful results that are visible at every level in an organization.

Audits, no matter how well conducted, may miss their aim and issue invalid recommendations if they do not take into account the organizational strategy. Audits should give guidance for improving the performance of organizations, making better products, gaining higher profits and better return on investment and obtaining a competitive advantage. Audits of IT and business processes can be seen as a way to improve performance of the organization, which will result in competitive advantage.

In this paper we have shown how significant and far-reaching conclusions can be derived from the IT audit. Detected significant deficiencies in existing information systems can have serious implications for the (none) implementation of the strategic goals of the organization. From this we can conclude that it is necessary to (1) clearly define the organizational goals, (2) connect them with (translate them into) IT objectives, (3) continuously compare the performance of existing business processes and IT (where audit is one of the basic tools) to determine directions for future improvement in the organization. Moreover, it is irrelevant whether it is for profit or non-profit, product or service, small or large organization - the process is the same, it only vary in its complexity.

Entrepreneurial intentions within business and non-business studies

Riste Mishe¹, Jaka Vadnjal²

¹*Government of the Republic of Macedonia, Cabinet of the Minister for Foreign Investments
V.Samak, Skopje, Macedonia, riste.mishe@gs.gov.mk*

²*GEA College of Entrepreneurship, Ljubljana, Slovenia, jaka.vadnjal@gea-college.si*

Along with the changing nature of work and the prevailing global value being placed on entrepreneurship, the development of an 'enterprise culture' has become a primary objective for many countries. It has been argued that an enterprise culture depends upon a population of individuals who are 'enterprising', and who have the ability to take action, (as employees or employers), using creative and innovative approaches. Enterprise education operates on the premise that individuals can be taught to be more enterprising, and aims to develop in young individuals a set of skills that will allow them to be both job creators and job seekers – and so contribute to the enterprise culture.

Although extensive research evidence has been available on different scopes of entrepreneurship in Macedonia, not much has been revealed about the entrepreneurial intentions of the senior students within business and non-business studies and their interest in the field of entrepreneurship as a possible future career. Furthermore, some anecdotic evidence would propose, that there would be more ambitions for traditional jobs in larger industries and public sector rather than pursuing entrepreneurial career.

Preliminary results show that the economic and business students are more likely to start their own company and have more knowledge for starting a new business rather than the students from technical faculties which is due the fact that students from the economic faculties usually attend more economic courses during their studies. It is very likely to be confirmed that the student entrepreneurial intentions are less the case of their personal characteristics but they lay in their knowledge and abilities acquired through their education and also working experience. Thus, higher interest for entrepreneurship career is more likely to be associated with higher level of knowledge on how to run a business rather than level of innovativeness and other entrepreneurial prerequisites.

Keywords

Entrepreneurship, entrepreneurial intentions, entrepreneurship education, business studies, non-business studies

1. Introduction

Although extensive research evidence has been available on different scopes of entrepreneurship in Macedonia, not much has been revealed about the entrepreneurial intentions of the senior students and their interest and ambitions in the field of entrepreneurship as a possible future career.

Furthermore, some anecdotic evidence would propose, that there would be more ambitions for traditional jobs in larger industries and public sector rather than pursuing entrepreneurial career. More specific emphasis will be given to the entrepreneurial intentions of the students from the technical colleges apart from the students of economics and business colleges.

Thus the essential part of the research is focused on the student's entrepreneurial intentions towards establishing new companies and the assessment of the quality of educational system and entrepreneurship teaching programs towards supporting entrepreneurial culture among the student population. Research was performed through a survey carried out among the students Republic of Macedonia from both technical and economic colleges in which students will be asked whether they will establish their own company after graduation. More than 600 students participated in the research.

2. Literature and hypothesis

2.1 Literature

The fundamental reasons why students give a lot of importance to education (Pais, 2001), researchers point out, come from their beliefs of open possibilities of transition from one social class into another – therefore, the educated youth have great expectations in a parallel line with their level of education [1]. When young people are in a deciding position on their future career, in most cases, they have a poor image about what that sort of a vocation offers them and what are the consequences from that decision. For instance, students who enrol a faculty of pedagogy they decide to become pedagogues/teachers, most commonly based upon their own observations, their own thoughts and their already formed model of a teacher. This type of a teacher is usually based on the blurred memories from the kindergarten teachers of their past while attending it, which sadly, is a very narrow-minded thinking when it comes to making a decision like this [2].

Life, family and working experience affect our behaviour and intentions to a large extent, even though they are dependant on how we respond, i.e. our own reaction to those experiences. Similarly, in the entrepreneurship, experiences affect to a large extent on entrepreneurial behaviour and intentions. Education also affects entrepreneurial behaviour to a great extent [3].

Potential entrepreneurs are most often frightened or marvelled by entrepreneurship, depending on the prototype of the entrepreneur they represent. If individuals learn about entrepreneurship, their behaviour and intentions considerably change. Via entrepreneurial education, they have an opportunity to shape themselves as a broader and a richer model of an entrepreneur, as well as to present themselves more optimistically as entrepreneurs. Generally, individuals form different models of entrepreneurs. Thus, past entrepreneurial experiences are related to more realistic views about them as entrepreneurs [2].

Numerous researches conveyed in developing countries, especially the countries which in the process of transition into free enterprise economy gave high priority to the development of entrepreneurship and to the small and medium businesses, show great disproportions in the motivation and ambitions among the students of technology and social sciences. Namely, students from the faculties of economics display great motivation for power compared to their colleagues from the faculties of technology, while the ambitions of the students of technology are much greater from the ones the students of economics have [4].

These pieces of research show connection and similarities between the results from the research from both groups of students, and the reason is due to the assumption that those students when in secondary school, right before the choice to continue their education, whether to study economics or social sciences, they do not receive sufficient information that would help bringing the right decision and initiating their brilliant future and career.

On the other hand, the imperfection of the labour market expressed by the unsynchronized educational programs with the staff unrelated to their appropriate vocations and professions, as well as the claims and the needs of the realistic business sector for specific new professions and staff with a deficient character, imposes the need for active policy on planing human resources according to the labor market needs, implementing and promoting new educational programs, as well as implementing entrepreneurial education and development of entrepreneurship in all levels of formal education as a mean for stimulating self-employment and filling the gap between the supply and the demand for the labour market.

2.2 Hypothesis

H1: Students of economics are more likely to start their own company than the students from technical faculties.

Most researchers [5], [6], [7] point out that greater the number entrepreneurial subjects included in the syllabuses of faculties, affects on the greater number of founded companies. Hence, the students from the economic faculties usually attend economic and business classes for four years while in some certain departments entrepreneurship is taught as a mandatory course. Despite the mandatory course of entrepreneurship, some departments in the faculties of economics also include entrepreneurship as a facultative course in their syllabuses. On the other hand, at the technical faculties students usually attend technical courses only, mainly because of the unavailability of economic or business related courses in their studying programs.

H2: Students of economics have more foreknowledge for starting a new business than the technical faculties' students.

I assume that the students of economics upon attending classes on economics are more confident in their knowledge and skills acquired in the field of entrepreneurship rather than the technical students who on the other hand didn't have an opportunity to take any classes in business or economics. Namely, the previously conveyed researches indicate that people who have and are confident in their knowledge, skills and abilities are eight times more likely to become entrepreneurs than the people who don't [8].

H5: Students who during their studies have acquired some practice or worked for a private company are more inclined to set up a company.

Many students from the Western European countries during the studies have the opportunity to take practice in the private enterprises and as well to work in real work environment with regular job responsibilities and duties. These practices offer the opportunity to acquire additional skills and capabilities and as well invaluable working experience which in major extent will bring them more benefit later on in the regular employment. Listen

Dictionary - View detailed dictionary

Thus, some of the latest researches show that the safest way for integration with the labour market is the so-called "dual system" where education takes place simultaneously with the practice because it allows the students to become insiders in the market while they are studying [9]. In Germany, Denmark and Switzerland this system is compiled and implemented by cooperation of the companies and the appropriate faculties. It is considered that it is beneficial for all the three parties: the students increase their employment options, the educational institutions widen their program range, the companies maintain contact with the potential young employees who might be employed in the future. As a result, around 82% of the graduates in Germany land their first jobs within the first 6 months after graduation [10].

3. Methodology and sampling

3.1 Methodology of research

3.1.1 Data source

The major data source is the questionnaire on students' entrepreneurial intentions, taken as an example from the previous preformed research in Slovenia aimed to evaluate the entrepreneurial profile of Slovenian people [11]. The questionnaire was compiled of 5 sections – the first section deals with the questions on the students' entrepreneurial intentions while the second states the reasons for starting a business answered only by students who intend to start a company. The third section of the questionnaire defines the reasons for not starting a company, answered only by students who do not intend or do not know whether in the future will start a company. The fourth section generally deals with the values, interests and standings while the fifth deals with the demographical characteristics. As from the first question in the first section students immediately specify whether they intend to start a company or not, while the questions in the other sections ascertain the intentions, motives, behavior, values, interests and standings of the youth.

3.1.2 The objective of the research

The objective of the research is to study the enterprising of the youth from the aspect of whether young people consider an entrepreneurial career as a possible future employment occupation. As research sample for our research we have included senior students enrolled in the final academic years, having in mind that they are one step away to finishing their studies and assuming that their thoughts are directed towards a future career and occupation decision making. Additionally to our general research we have also included research sample of two groups of students, one from the faculties of technology and the technical faculties and one from the faculties of economics and the business faculties, using them to make comparisons in terms of their entrepreneurial intentions.

3.1.3 Data processing

The data collected from the questionnaire is being processed and analyzed by the SPSS 15.0 software program for Windows and Microsoft Excel 2007 program. The procedure of processing analysis contains the following phases: (1) Targeting and classification of the population; (2) Design of both on-field an on-line versions of the questionnaire; (3) Carrying out the poll process within the two types of faculties; (4) Processing with the SPSS statistics program; (5) Analyzing of the final results.

In order to check the hypothesis I have been using the CHI-square test with values in the interval of $[0, x_{2max}]$ as well as the Cramer's coefficient defined in the interval of $[0,1]$ in order to show how strong is the connection between the nominal variables. For confirmation or rejection of the hypothesis I have also used the CROSSTABS subprogram as a part of the SPSS software program.

4. Results

4.1 Entrepreneurial intention among students

Research results show that the interests among students for founding a company is huge, however it is only stimulated by the future wish for setting up a company and not the real possibility and the current situation to which students are faced with at the moment of their decision. Hence, most of the students choose to set up a company in their later lives and solely after five years of graduation, which is due to the logical decision to either continue their education and temporary escape or postpone the decision about their future career choice or either to choose to be employed in private or public sector, and thus avoid the unemployment and leave the idea for founding a company still opened couple of years after the first employment. Accordingly, the number of students who wish to form their own companies after the first 12 months of graduation is close to 4 % which shows poor students' readiness to put their acquired skills and knowledge into practice by forming their own companies and thus capitalizing their intellectual effort at the same time. Main reasons that contribute to the results mentioned above are: the lack of knowledge, lack of experience, no encouragement and support from the stakeholders of the entrepreneurial environment (their professors, parents, relatives, media) and mostly lack of financial resources. Thus the fact that only 2.6 % of the students have their own company only additionally emphasis the strong influence of the reasons mentioned above.

Table 1 Entrepreneurial intentions among students.

Type of faculty	Already have own company	Intention to establish company next 12 months	Intention to establish company 1-5 years	Intention to establish company 5-10 years	Intention to establish company after 10 and more years	No intention to establish a company
Business faculty	0.6%	1,6%	22.2%	13.8%	5.5%	6.3%
Technical faculty	1.9%	2.1%	15.0%	14.4%	3.4%	13.1%
Total	2.6%	3.7%	37.2%	28.2%	8.9%	19.4%

If we compare the same parameters between the business faculties and the faculties of economics against the faculties of technology and technical faculties we can reach the following conclusions:

Only 6.3% of the students of the business faculties and the faculties of economics do not intent to set up their own company, while twice as many (near 13%) of the students of the faculties of technology and technical faculties have chosen not to set up their own business.

There is a more serious intention in founding a company at the students of business faculties and the faculties of economics with the quarter (22.2%) of them who are planning to set up a company in period of 1-5 years; 13.8% that are planning to form a company in period of 5-10 years; 5.5 % that are planning to set up a company in period of 10 and more year, 1.6% that are planning to set up a company in period of 12 months, while only 0.6 own their company.

Opposite to the results at the students studying at the business faculties and the faculties of economics, 15% of the students studying at the faculties of technology are planning to set up a company in period of 1-5 years; 14.4% are planning to form a company in period of 5-10 years; 3.4% are planning to set up a company in period of 10 and more years, 2.1% are planning to set up a company in period of 12 months, while only 3.4% own their company.

In terms at situation, the results are surprisingly interesting. As we were pretty much convinced into defining the basic hypothesis that in the fact that the students of the business faculties and the faculties of economics are more focused toward forming a company than the students studying at the faculties of technology and technical faculties, it turns out that such an argument is in accordance with the received results. Namely 93.1% of the students of the business faculties and the faculties of economics have intentions to establish company in future, while 85 % their counterparts from the faculties of technology and technical faculties have such intentions.

On other hand regarding the results about the state of the already established start-up companies, the students of the faculties of technology and technical faculties are showing much sustainable successful entrepreneurial stories than their counterparts from the business faculties and the faculties of economics. This is mainly due to the fact that most of the students of the faculties of technology have more innovative and technologically based ideas that affect to better sustainability of their business model which is more or less dependable upon the upstream development trend of the information and communication technologies (ICT) industry and the growing market of ICT services.

But, as we have already said in the theoretic part of the research, these results picture the following statements:

- Students of the business faculties and the faculties of economics study more economic subjects
- Students of the business faculties and the faculties of economics have more prerequisites and are more talented for founding a company but they don't have authentic entrepreneurial ideas.
- Students of the faculties of technology and technical faculties are very good technically, and frequently have very strong product ideas. However, they are weak in the area of commercialization and marketing.

4.2 Entrepreneurial experience among students

One of the most important factors which affect the students' entrepreneurial profiling, apart from being a member in student organizations, parents' support, the professors (the quality of the educational system) and the state support is of course the possibility to work and have a practice in a company during the course of their studies.

Table 2 Internship (part time job) during studies

Type of Faculty	Yes, by personal engagement in seeking of open internship or vacancy	Yes, by intermediation of the temporary employment agency	Yes, by intermediation of the student organisation	No
Business faculty	23.5%	0,5%	2.6%	23.5%
Technical faculty	24.3%	2.1%	4.4%	19.3%
Total	47.7%	2.6%	7.0%	42.7%

The previous results show that many of the students (58 %) had the opportunity to do a practice or to work for a company, against those with the percent of 42 who didn't have the opportunity to do that, because of the hardness of the study courses. Though the previous numbers look impressive, it is still surprising a fact that more than 83 % of those who said that they did some kind of practice during the course of their studies, applied that they did that on their own initiative.

In the questionnaire, I also inserted the question about the necessary knowledge, skills and experience needed for a student to establish a company. If he wants to set up a company, the entrepreneur must be familiar with the all main functions of the company and the way it operates. They especially need knowledge about sales, economics of enterprise (finance), organization of enterprises, human resource management, principles of law and so on.

Table 3 Entrepreneurial knowledge to establish a company.

Type of faculty	Yes, enough	No	No, but trying to educate themselves on their own initiative (seminars, workshops etc.)	Not sure
Business faculty	4.5%	4,5%	32.8%	8.1%
Technical faculty	9.7%	10.0%	19.3%	11.0%
Total	14.2%	14.6%	52.1%	19.1%

As it can be seen more than 66% from the interviewees said that they didn't possess the necessary knowledge and did not have an experience, 19 % said that they were not confident enough in their knowledge and experience, while 14 % said that they had enough knowledge, skills and experience to set up and manage their own company. Regardless of the large number of 66% of inexperienced entrepreneurs (without the necessary knowledge, skills and experience) it is still favourable a fact that 78% of the inexperienced students are willing to become educated on entrepreneurship their own initiative (reading literature in the field of entrepreneurship, attending seminars, workshops and so on). If we compare the results on different levels of students (the students of the faculties of economics and the business faculties versus the faculties of technology and technical faculties) the situation will be as it follows:

1. More than 74% from the interviewed students of the faculties of economics and business faculties answered that they didn't possess such an experience and knowledge, 16% were not sure in their own skills and experience, while 9% said that they did possess the knowledge, skills and experience needed to establish their own company.
2. More than 58% from the interviewed students of the faculties of technology and technical faculties answered that they did not possess such an experience and knowledge, 22% were not sure in their own skills and experience, while 19% said that they did have the knowledge, skills and experience to form their own company.

It can be concluded that the students studying at the faculties of technology and technical faculties stressed they think they have better knowledge, skills and the necessary experience to form their own company, while most of the students studying at the faculties of economics and business faculties stressed that they are more self-educated in the field of entrepreneurship rather than their counterparts from the faculties of technology and technical faculties.

This is a reflection of the fact that students of the faculties of technology and technical faculties frequently have very strong product ideas and technical expertise which arise from their profound theoretical knowledge of computer programming, mechanics, machining, 3D modeling and designing etc. which makes them more confident in their acquired knowledge which can be more market payable and market materialized on labour market as well. But this doesn't make them more entrepreneurial friendly than their counterparts from the faculties of economics and business faculties since the students of the faculties of technology and technical faculties usually lack of knowledge in the area of commercialization and marketing which are of major essence for the entrepreneurial success.

4.3 Entrepreneurial education among students

Support for starting a business can be given by teachers as well, which to a large extent influence the individuals who think about entrepreneurship as a possible career. Schools that include entrepreneurship and innovation programs in their curriculum are the ones that create entrepreneurs and are one of the creators of entrepreneurial environment. For example, the bigger number of entrepreneurial subjects in school, the bigger possibility those students to start their own business in the future [7].

According to previously quoted I've decided to evaluate the educational system regarding the level of involvement of entrepreneurship as a subject in the overall academic curricula. For that reason I've asked interviewees to give their more general mark about the degree to which Macedonian formal educational system encourages the entrepreneurship through a fivefold Likert scale. Additionally, the interviewees were given a chance to give reasons for their answers through a further use of conditional questions.

Table 4 Level of which formal educational system encourages entrepreneurship

Type of faculty	Not enough	Little	Moderate	Much	Enough
Business faculty	5.2%	8,9%	20.7%	3.6%	11.7%
Technical faculty	12.1%	11.7%	16.0%	2.6%	7.6%
Total	17.3%	20.6%	36.7%	6.1%	19.3%

Hence, the results are as they follow:

1. Near 75 % of the interviewees gave insubstantial, low and moderate mark about the degree of implementing the entrepreneurial skills in our formal educational system. Or more precisely 37 % of them gave a moderate mark, 20 % a low mark and 17 % insubstantial mark in their evaluation. If we neglect the statistically neutral moderate mark for which usually the interviewees go for, it can be concluded that the formal educational system received mostly insubstantial to low grade (38%) in implementing the entrepreneurial skills in the formal education.
2. 25 % of those, whose mark was very good to excellent, based their grades on the following criteria: having a good educational program (subjects) which encourages the entrepreneurship, encouragement by the professors, the existence of extracurricular activities and lectures by proven entrepreneurs.
3. 75 % of those whose mark was insubstantial to good, based their grades on the following criteria: lack of practice, extracurricular activities, lectures by proven entrepreneurs, and appropriate subjects which encourage the entrepreneurship.

5. Conclusions and implications

5.1 Conclusions

The results from the contingency table for H1 showed that the percentages of students from faculties of economics and business faculties who intend to establish a company is 54.3%, while that percentage of students from faculties of technology and technical faculties is 45.7%. Accordingly, we can confirm H1, i.e. students of faculties of economics and business faculties are more inclined to establish an enterprise than the students of faculties of technology and technical faculties. This is mainly a result from the theoretically proved statements:

- Students of the business faculties and the faculties of economics study more economic subjects
- Students of the business faculties and the faculties of economics have more prerequisites and are more talented for founding a company but they don't have authentic entrepreneurial ideas.
- Students of the faculties of technology and technical faculties are very good technically, and frequently have very strong product ideas. However, they are weak in the area of commercialization and marketing.

The results from the contingency table for H2 showed that different faculties provide students with different level of foreknowledge of the business area. From the results can be concluded that the students studying at the faculties of technology and technical faculties stressed they thought they have better knowledge, skills and the necessary experience to form their own company, while most of the students studying at the faculties of economics and business faculties stressed that they are more self-educated in the field of entrepreneurship rather than their counterparts from the faculties of technology and technical faculties.

This is a reflection of the fact that students of the faculties of technology and technical faculties frequently have very strong product ideas and technical expertise which arise from their profound theoretical knowledge of computer programming, mechanics, machining, 3D modeling and designing etc. which makes them more confident in their acquired knowledge which can be more market payable and market materialized on labour market as well. However, this doesn't make them more entrepreneurial friendly than their counterparts from the faculties of economics and business faculties since the students of the faculties of technology and technical faculties often lack of knowledge in the area of commercialization and marketing which are of major essence for the entrepreneurial success. In terms of the training (working) students are differently inclined towards setting up a company, i.e. we can accept the conclusion that students who worked in a private company or acquired some practice during their studies have a greater inclination to founding a company. The previous results show that many of the students (58 %) had the opportunity to do a practice or to work for a company, against those with the percent of 42 who didn't have the opportunity to do that, because of the hardness of the study courses. Though the previous numbers look impressive, it is still surprising a fact that more than 83 % of those who said that they did some kind of practice during the course of their studies, applied that they did that on their own initiative. This situation in one hand shows quite high degree of students' self initiative as one of the major factors and stimulus for establishing a company, but at the same time also shows not enough efficiency in the work of the student organizations and does not justifies the purpose and the aim of their existence at the same time.

5.2 Implications

Even though students' general interest for founding an enterprise is great (nearly 3/4 from the polled students) it is stimulated only by the desire to establish a company, but not as well by the realistic opportunities and the current situations which students face at the moment of decision making. Namely, apart from the high personal motivation and desire to set up a business, the lack of required knowledge, lack of experience, lack of support and stimulation by the rest of the stakeholders of the entrepreneurial environment (teachers, parents, relatives, media etc) and the lack of financial funds additionally postpones students' decision of setting up a business immediately upon graduation, i.e. in the following 12 months. Instead of that, students choose to start a company in some later point of their lives, in a period of 5-10 years after their graduation which reasonably is a result of the students decision whether they want to continue their education by enrolling postgraduate studies or to become employed in the public or private sector where they can be acquired with the needed working experience so that again, when they would be 27-32 years old they would try to reconsider the possibility of founding a company.

The previous findings only confirm the general image of the quality of the educational system in Republic of Macedonia and the measures taken in entrepreneurial education. That is to say, the non-decisiveness of starting a company immediately upon graduation, i.e. in the following 12 months is a direct reflection of the inadequately passed and acquired knowledge and skills in the educational process and the insufficient experience of their practical application in the real life.

Correspondingly to this situation students choose the path that leads to the temporary or long-term unemployment (those who try to find a job but unfortunately fail), to the temporary or long-term employment (those who have found a job and used the possibility to acquire training and practical knowledge on the working place) and the path to continue their studies (those who temporarily postponed the choice of becoming unemployed or employed).

On other hand regarding the evaluation of the educational system in Macedonia and the level of involvement of entrepreneurship as a subject in the overall academic curricula it can be stressed that it will be a real challenge to build inter-disciplinary approaches, making entrepreneurship education accessible to all students, and where appropriate creating teams for the development and exploitation of business ideas, mixing students from economic and business studies with students from other faculties and with different backgrounds.

Although courses and activities on/about entrepreneurship for all categories of students, in any field of study, provide basic business skills and raise awareness of entrepreneurship as a potential career

option, the teaching process needs to be additionally tailored to the specific needs of different categories of studies where more emphasis will be placed on one aspect or another, for instance:

- Entrepreneurship within business schools and economics studies should be more focused on business start-up and new venture creation, and on the management and growth of SMEs. Students of economics should learn to work with students from different fields (engineering, scientific studies, etc).
- Entrepreneurship within science and technology studies on other hand should be especially concerned with the exploiting intellectual property, creating spin-off companies and venturing, and as well to offer courses on issues such as:
 - management techniques;
 - marketing, commercializing and selling of technology based ideas;
 - patenting and protecting technology based ideas;
 - financing and internationalizing high-tech ventures.

Capital Budgeting – A Tool for Improvement of Operations of Small and Medium Enterprises

³Higher School of Professional Business Studies, Novi Sad, Serbia, dajana_vindzanovic@yahoo.com

Capital budgeting is a planning process that determines whether a company should pursue a specific long term investment into new equipment, plant, product or improvement of existing ones. The movement to new products, services, or markets must be preceded by capital expenditures and capital budgeting decisions which define company's strategic direction and therefore are very important for survival and success of the company.

The allocation of capital in small and medium enterprises is often more important than in large companies due to the fact that funds necessary to finance projects may be difficult to obtain. Also, small and medium enterprises may not have luxury to correct a mistake. Yet small and medium companies make less extensive use of capital budgeting techniques than the large ones. If a small business fails to use capital budget methods because its managers are not well trained or informed, it may be putting itself at a serious competitive disadvantage. Therefore, in order to compete effectively with big companies, small and medium enterprises must attain knowledge in capital budgeting methods.

This paper will explain and demonstrate capital budgeting methods in order to help entrepreneurs to make prudent decisions about what, where, and how much money to allocate to new facilities or improve existing ones in order to ensure long-term success.

Keywords

Capital budgeting, Capital budgeting methods, Cash flow, Discount rate.

1. Introduction

When a company makes a capital investment, it outlays cash in the expectation of long term future benefits. Examples of such capital investments include the purchase of new or replacement of existing manufacturing equipment, plants, products and so on.

An investment proposal should be evaluated in terms of whether or not it provides a return equal to, or greater than, that requested by investors. Capital budgeting methods that are the most commonly used for such evaluation are payback method, net present value, internal rate of return and profitability index. In practice, often a combination of these methods is used.

2. Capital budgeting methods

One of the basic methods for evaluating investment project is payback period, which is the period needed for the return of initial project investment by cash flows. [2] According to this method, the projects that return their investment earlier are considered more attractive, and all realized cash flows after the return of initial investment may be regarded as the profit realized on the basis of this project. Likewise, the project that returns the invested money in a short period of time is less risky because a

significant risk component is the probability of enterprise to lose certain or total amount of money invested in the project.

Actual payback period = $I - CF_1 - CF_2 - \dots - CF_t$ [3]

I – capital investment in a project,

CF1, CF2...CFt – annual cash flows from the project.

When the enterprise uses payback period as the criterion for accepting or rejecting the project, it determines the maximum payback period and accepts the projects covering the investment before the agreed deadline.

The enterprise do not normally use payback period as the primary criterion for the selection of projects but this method has a secondary additional rule for decision-making. Thus, the enterprise may set out a rule stipulating that every project having return on capital of at least 20 percent and payback period shorter than ten years will be accepted. If the investor must select one of the projects with the same return on capital, they will opt for the one with a shorter payback period.

The pitfalls of this method are the fact that time dimension of money (i.e. this method uses nominal cash flows) is not taken into consideration and that cash flows are ignored completely after the initial investment is returned. Besides, this method cannot be used if the investment is distributed in several periods of time or when there is no initial investment at all.

The net present value (NPV) method calculates the expected monetary gain or loss from a project by discounting all expected future cash inflows and outflows to the present point in time, using the required rate of return. [4]

$$NPV = \sum_{t=0}^n \frac{CF_t}{(1+r)^t} \quad [5]$$

CFt – the cash flow in the period t,

r – the discount rate,

n – project time period.

This method is the difference between the initial capital investment and the present value of all future cash flows generated due to the project exploitation by discounting the cost of the project capital. The minimum condition that the project must meet in order to be approved is to have the NPV greater or equal to zero. If this condition is not met, the project should be rejected. If the NPV is equal to zero, the cash flows of the project are sufficient for paying off the invested capital and providing the required rate of return on capital.

The limits of the NPV method refers primarily to the need for long-term and precise projection of the net cash flow and salvage value (See 2.1 The projection of the cash flow from the investment project.) of the project, not only regarding the amount but also time distribution of the cash flows. Potential inaccuracies may lead the investor to wrong conclusions.

Internal rate of return (IRR) method is a method of ranking investment proposals using the rate of return on an investment, calculated by finding the discount rate that equals the present value of future cash inflows to the project's cost. [6] That means that IRR is the discount rate which forces the present value of project's inflows to equal the present value of its costs.

$$NPV = \sum_{t=0}^n \frac{CF_t}{(1+IRR)^t} = 0 \quad [7]$$

The minimum condition that the project must meet in order to be approved is to have the IRR greater or equal to the cost of the project capital. Conversely, the project is rejected if the IRR is lower than the cost of the project capital. If the investors take two projects into consideration, whereby the IRR is greater than the cost of the capital in both projects, they will choose the one with a greater value of the IRR provided that the projects are mutually exclusive, or both of them will be approved in the case of independent projects.

When the investor considers independent projects, the NPV and IRR lead to the same decision about the acceptance or rejection of the project. When the investor, however, considers mutually exclusive projects, the NPV and IRR may lead to different decisions in the case of a considerable difference in the size of the project and/or timing differences between cash flows of the project. When evaluating mutually exclusive projects, especially those that differ in scale and/or timing, the NPV method should be used. [8]

Profitability index is the ration between the sum of present values of all future cash flows in the expected period of project exploitation and the amount of initial investment. [9]

$$PI = \frac{\sum_{i=1}^n \frac{CF_t}{(1+r)^t}}{I} \quad [10]$$

This method transforms the absolute sum of the profitability obtained by the NPV into the index and enables the assessment of the relative profitability of the project. The minimum condition for the acceptance of the project requires the profitability index equals 1.0 or better in the case of independent projects, whereas the project with the greatest profitability index is accepted in the case of mutually exclusive projects.

2.1 Projection of cash flows from the investment project

Incremental cash flows, or the additional operating cash flow generated when the enterprise decides to invest in the certain project, are used for the purpose of the assessment of the project by discounting. The projection of the cash flow of the certain investment project must be based on the forecast of the three key elements: [11]

- Net capital investment,
- Net residual cash inflow and
- Net cash flow from investing activities.

Net capital investment includes the outflow needed to make the investment ready for operation and generating the expected profit. These expenditures include the fixed assets increased by all dependent costs, installation costs and the costs relating to the rise in the necessary operating costs, such as cash, receivables and stock.

Net residual cash inflow is the expected cash inflow that the investor will receive after the end of the project time period from the sale of fixed and working capital used during the operation of the project.

The projection of net cash flow from investing activities is complex and implemented in three steps:

- Projection of income and cost for every year of the project time period,
- Determination of accounting earnings based on the projected income and cost and
- Transformation of accounting earnings into net cash flows for every year of the project time period.

It is impossible to forecast income and cost of the certain period with one hundred percent certainty due to various factors, such as: forecast mistakes, technological advancement, reaction of competitors, interest rate changes, etc. There are three ways for income and cost forecast of the certain project: [12]

- Forecast based on experience,
- Market testing in order to assess potential demand and income,
- Use of the method of economic scenario analysis.

The enterprise that constantly commences the same type of the project may forecast the income or cost of the project on the basis of experience or historical data.

If the enterprise forecasts the income and cost of the project referring to new products, services or market, it is necessary to carry out the market research or testing in order to forecast the interest for the purchase of that product or service.

When the enterprise is exposed to uncertainty owing to external factors that cannot be controlled despite the good knowledge about the market, it may consider different scenarios with their certainty, income and cost.

In order to reach accounting earning from forecast, it is necessary to classify the planned cost into operational and capital (Operational cost is the expenditure relating to generating the income in the current period of time, whereas capital cost has effects during a longer period of time. Operational cost are deducted from the income of current period, and capital cost is amortized or depreciated during a longer period of time.). Then, it is needed to depreciate or amortize capital expenditures over time and allocate fixed expenses of the company that cannot be traced to a specific project, such as general sales and administrative expenses (GS&A), that can be allocated to a project based on the measure such as project's revenues.

$EBIT = \text{income} - COGS - GS\&A - \text{depreciation and amortization}$ [according to 13]

EBIT – earnings before interest and taxes,

COGS – cost of goods sold.

Also, the investor has to consider the tax effect that is tax liability created by the operating income projected. Therefore, EBIT must be adjusted for the tax influence multiplying by the factor (1-t), where t is the interest rate applied on net income.

In order to get from accounting earnings to cash flows, the investor has to add back non-cash expenses like depreciation and amortization, subtract cash outflows which are not expensed (capital expenditures) and transform accrual revenues and expenses into cash revenues and expenses by considering changes in working capital.

Non-cash expenses reduce accounting earnings, but not cash flows so it is necessary to add them to the net income when calculating the cash flows. However, some non-cash expenses, such as amortization and depreciation, reduce tax liabilities of the enterprise and result in tax benefit (tax benefit=depreciation * tax rate).

Conversely, there are non-cash expenses that are not tax deductible, as with ration of goodwill. Such non-cash expenses do not enable tax reduction and do not have the influence on the cash flow.

Investments in working capital are cash outflows since money invested in inventory or accounts receivable cannot be used elsewhere and therefore, it represents a drain on cash flows. It has to be recognised that cash flow drain is reduced to the extent to which some of these investments can be financed using supplier's credit, or account receivables. Also, any decrease in working capital increases cash flow in that year. It is important to have in mind that at the end of the project life working capital investments need to be salvaged.

Within investment analysis it is important to observe incremental cash flows, or cash flows that the project achieves for the enterprise it takes. Namely, some cash flows for investing activities are incurred and it is not important for them if the project will be undertaken or not. Those cash flows are called sunk costs and they are excluded from the acceptance analysis for an investment project. A typical example for sunk costs is research and development expenditures for considering a project.

2.2 Discount rate

The discount rate of the project is one of the basic inputs for the dynamic methods of capital budgeting. The discount rate must reflect the level of project risk so it is important to investigate whether the project risk differs from the enterprise risk when determining it.

If all the projects of the enterprise have a similar exposure to risk and belong to the same field of activities, the cost of equity (The cost of equity is the rate of return required by the owners of ordinary shares so they will have an interest to purchase and keep the shares of the enterprise. It must be pointed out that the free cash flow to the equity is the cash flow discounted by the cost of equity while using the dynamic methods of capital budgeting, and it represents a cash flow available to the owners of ordinary shares obtained on the basis of the project, which ceases when all business expenditures are incurred, all necessary investments into working and fixed assets are made, the interest rate is paid and the payment of the principal of the debt is completed.), i.e. the cost of the total capital(The cost of the total capital takes into consideration all the sources of the capital and is obtained as the weighted average cost of all sources of the capital of the enterprise. Free cash flow to the firm is a cash flow before incurring the debt and after taxation, which measures the funds made on the basis of the project for all creditors, after all re-investing actions to the enterprise are incurred. Free cash flow is discounted by the cost of the total capital of the enterprise by using dynamic methods of capital budgeting) is used as the discount rate of the enterprise and beta of the enterprise may be used as a beta of the certain project. This approach may be used for the enterprises involved in one activity and implementing homogeneous projects.

When the enterprise is involved in different activities, and the projects within each activity have a similar level of risk, it is possible to calculate the cost of equity or the cost of total capital of each activity and use it as the discount rate of the project. It is clear that riskier activities have a higher cost of equity than less risky activities do. If the weighted average cost of capital is used for all projects, notwithstanding what field of activities they belong to, there will be gradual excessive investment into riskier activities and the rise in the total risk of enterprise operations.

When calculating the beta of each project, or each activity of the enterprise, it is possible, in addition to the historical market beta(Historical market beta is calculated on the basis of the

formula $\beta = \frac{COV(R_A, R_M)}{\sigma_{R_M}^2}$. [13]), to use pure play method and accounting beta method. In the pure

play method, the company tries to find several single-product companies in the same line of business as the project being evaluated, and it then average companies' betas to determine the cost of the

capital for its own project. [14] This method can only be used for major assets such as whole divisions. An additional problem with this method is the difficulty to find pure play proxy firm.

Accounting beta method is a method of estimating a project's beta by running a regression of the company's accounting return on assets against the average return on assets for a large sample of firms, such as those included in the S&P 400. [15] In practice, accounting betas are calculated for divisions or the large units, not for single assets, and divisional betas are then used for the division's project.

Likewise, the project of the enterprise may have different exposure to risk regarding both the common projects of the enterprise and the field of activities it belongs to. Therefore, if the project is large, the price of own funds or total capital necessary for running the project is separately assessed. The assessment of the cost of equity or cost of total capital can be done by the use of a beta enterprise that implements different projects or by the use of inter-sector regression of beta on fundamental variables. [16]

3. Conclusion

The investment of scarce capital is connected with uncertainty and risk. The bigger amount of such long term capital investment, which will be in accordance with strategic orientation of the company, will bring the greatest benefit to the company.

All companies should use capital budgeting methods since capital investment requires huge amount of financial resources and therefore has a long term economic consequences. This is especially true for small and medium enterprises because a wrong capital investment decision often leads to their bankruptcy. In order to compete effectively with big companies, it is crucial for small and medium enterprises to attain knowledge in capital budgeting methods.

4. Example

Company XYZ is developing new type of extruder and it already spent 3 million EUR in research and development. These expenses have been capitalized. Company decides to proceed with commercial introduction of the product and the company will have to spend an additional 5 mil. EUR for a new plant and production equipment. Salvage value of new plant and production equipment at the end of the life of the project is projected to be 700.000 EUR.

Capital maintenance expenditures are required in the amount of 30.000 EUR in year 1. After that, it is projected that capital expenditures will grow at the same rate as inflation (which is assumed to be 3% per year) until the end of the life of the project.

The sale of the product is expected to begin in the first year. Also, it is expected that company will sell 25 machines each year until the end of the project's life. The machines will be priced 200.000 EUR each. The price is expected to grow at the same rate as inflation.

Based upon past experience, company anticipates that variable expenses will be 72% of the revenue each year.

Initial investment in working capital is projected at 300.000 EUR. Salvageable fraction of working capital at the end of the project life is 100%.

The discount rate for the project is projected at 11,54% (beta of the project is 0,9, riskless rate 4,2%, market premium 8,5% and debt ratio 30%).

The project is expected to have a useful life of 10 years. The corporate tax rate is 10%. Company uses straight line depreciation to estimate depreciation each year.

Should the company undertake a project?

Answer: It can be seen from Table 1 that all major capital budgeting indicators favour the undertaking of the project. According to a payback period the investor will need 4.02 years for an investment's revenues to cover its costs.

Net present value is 3.213.188,11 EUR and since it is positive investor should undertake the project according the NPV rule.

According to the minimal requirement of internal rate of return, IRR should be higher than the cost of capital of the project in order to accept the project. In this case the IRR=22,90% and cost of the capital is 11,54%, which means that investor should undertake the project.

Profitability index is 4,97 and it is higher than 1, which is minimal requirement according to the profitability index rule.

Development of PIFC in Albania - a step on the road to European Integration

Hysen Muceku¹, Albana Gjinopulli²

¹ Director, General Department of Audit, Ministry of Finance, Tirana, Albania, h.muceku@yahoo.com, hmuceku@minfin.gov.al

²Head of unit, Methodology and Training, General Department of Audit, Ministry of Finance, Tirana, Albania, agjinopulli@yahoo.com, agjinopulli@minfin.gov.al

The concept of Public Internal Financial Control (PIFC) has been developed by the European Commission in order to provide a structured and operational model to assist national governments in re-engineering their internal control environment and in particular to upgrade their public sector control systems in line with international standards and EU best practice.

The democratic changes affecting all areas of life in the last years, have led to reforms in the management of public finances of the public sector in the Republic of Albania.

On the road to our accession to the European Union we are in the process of important conceptual, legislative and structural reform of the Public Internal Financial Control framework with the aim of strengthening the managerial accountability of the managers of public sector organizations and further develop independent internal audit.

Actually the Ministry of Finance is completing the legal framework for FMC and IA in compliance with the EU requirements. Now, we have prepared and approved "The Law on Financial Management and Control", Law "On Public Financial Inspection" and amendments in the existing Law "On Internal Audit in Public Sector". Such laws and other by laws, professional guidance and regulations create the legal frame where PIFC System is based for implementation.

In order to ensure the transparency of public resources' management and spending, the legislator has introduced the requirement to the Council of Ministers (through the Minister of Finance) to report on an annual basis on the status of internal control in the Republic of Albania to the National Assembly.

This paper includes findings from the annual reports on the status of financial management and control (FMC) and internal audit throughout public sector in Albania. The paper summarizes the self-assessment made by the managers of public sector organizations and the internal auditors regarding the state of FMC and internal audit. It also includes information about the activity of the Central Harmonization Units (CHUs) and respectively, for financial management and control and for internal audit at the Ministry of Finance, which are directly engaged in the harmonization of the internal control in the public sector of Albania. The paper aims to give some key issues regarding PIFC development in Albania such as: the level of transparency regarding the status of the financial management and control and internal audit in the public sector; the awareness of the Heads of public organizations about the importance of sound financial management and control and to enhance their managerial accountability; information about the self assessment of the heads of public sector organizations on the adequacy and the effectiveness of internal control and about the progress made. It also outlines the weaknesses, solutions and development opportunities based on the assessment of the status of the financial management and control systems as well as of the internal audit. Through conclusions it summarizes the main directions in which the Albanian institutions must be focused in the future for further development and improvement of management of public resources. The development of the new model of public internal financial control in Albania demands

from all the participants in the process, leading to effective action in accordance with their roles and responsibilities. Only proper implementation of new legislation and efforts by all stakeholders can lead to achieving the goal - to create a modern system, reliable and functioning of public internal financial control. In this regard the CHU/FMC will outline specific measures related to strengthening managerial accountability and updating of legislation and methodology in the field of internal control in accordance with EU legislation and best practices. As one of the "three pillars" of the of Public Internal Financial Control System, Internal Audit has developed and continuously improved in order to take its modern role as advisor for the assessment and systems and contributing to the achievement of strategic and operational objectives of the organization, always in accordance with international standards and best practices. In this context, CHU/IA, CHU/FMC and the Minister of Finance are responsible to develop and implement all measures necessary for the successful implementation of the PIFC model and achievement of high professional standards in the field of internal auditing in the public sector.

Keywords

Public Internal Financial Control, (PIFC), Internal Audit, Financial Management and Control, Internal Audit Units and Public Entities, Risk Management.

1. Introduction

1.1. PIFC system in Albania

PIFC (Public Internal Financial Control) System contains a comprehensive and consolidated control system, including the structure, method, administrative procedures and internal audit which is set to achieve management objectives based on principles of transparency, legality, efficiency and effectiveness. PIFC system focuses on three main pillars:

- Sound financial management and control systems (FMC) as a primary responsibility of managers in each unit of public expenditure.
- Independent and objective function of Internal Audit (IA), to support management and to provide reasonable assurance that control systems are established in accordance with rules and standards, according to the principles of a sound financial management.
- Central Harmonization Units (CHU) in the Ministry of Finance (MoF) - to design and implement a methodology, to harmonize and standardize the quality system for FMC and Internal Audit.

The main actors of the current PIFC system in Albania are: the Minister of Finance, CHU/FMC (Central Harmonization Unit for Financial Management and Control) and CHU/IA (Central Harmonization Unit for Internal Audit). The Minister of Finance is responsible for establishing internal control systems to all public general government entities and fulfilling his duties in the field of FMC supported by the CHU. The CHU/FMC is responsible for the implementation of public internal audit as the basis for monitoring and control of public finances. CHU/IA initiates and supports the process of creating a functionally independent internal audit service, in the ministries and at different levels of local government.

2. Financial Management and Control

2.1. Concept of Financial Management and Control

Financial Management and Control is a system of policies, procedures, activities and controls, which are established, maintained and regularly updated by the head of public unit and are put into practice by all the personnel aiming to address risks and to provide sufficient assurance that the objectives of the public unit are achieved through:

- efficient, effective and economic activities

- compliance with the existing legislation and internal regulations and contracts;
- reliable and complete operational financial information;
- Safeguarding of information and assets.

Financial Management and Control in the public sector is achieved through: (i) creating an efficient and effective control environment, (ii) effective risk management, (iii) proper implementation of control activities, (iv) information and communication; (v) monitoring of the control activities of the public sector entities.

2.2. Assessment of FMC components in the Albanian public sector

- The self assessment questionnaire on FMC components

In order to collect information about the FMC status in the public sector, a self assessment questionnaire on FMC components for all public organizations – central and local government units was prepared and delivered.

The scope of the questionnaire was to address the level of fulfilment of the main requirements of internal control framework related to the five components of FMC – control environment, risk management, control activities, information and communication and monitoring. The self assessment control tool is intended to be used as well by the public sector entities in order to help them to identify the aspects of internal control in the respective organization where additional awareness and training needs to be targeted. The total number of the public sector organizations to which the self assessment questionnaire has been sent for reply is 434 and precisely 305 communes, 67 Municipalities, 12 Regional Councils, 50 Central Government units including line Ministries. Only 135 completed questionnaires have been received, which represents 31% of the whole organizations. However, most of central government units and big municipalities have replied. Most of local government units are represented by very small communes. Out of the Central government organizations completed questionnaires have been submitted by 12 ministries, 24 agencies and other relevant structures. Out of the local government organizations – municipalities, communes and regional councils - completed questionnaires have been submitted by 39 Municipalities, 12 Regional Councils and 48 communes.

- Analysis of FMC self-assessment questionnaires

2.2.1 Control Environment

The first group of components of internal control describes the basic conditions, completion of which is important for creating an appropriate control environment in a particular institution. The control environment provides our organization, by influencing the control consciousness of its people. It is up to the foundation where all other components of internal control structure as it raises and decides discipline. The control environment is the key to good management of public funds and other elements of financial management and control. The section of control environment in self-evaluation questionnaire contains 31 questions, divided in five subsections, and respectively: setting goals, personal and professional ethics, and the management style of work, organizational structure, human resources policies and procedures.

- **Objectives Setting**

General estimates indicate that most public institutions have designed the mission, and strategies that have been distributed to all staff or at least to the management level of the unit. More detailed results shows that there are about 36% of institutions that do not have the mission statement or the strategy for determining the priorities of the institution. This phenomenon is verified in the local government units, especially in small communes. Central institutions and a large part of the municipalities, which cover about 51% of institutions, have responded to the mission statement, have adopted strategies and action plan for achievement of their goals in accordance with the requirements of Law no.9936, "On management of budgetary system in the Republic of Albania ". The following chart reflects some statistics about mission design, strategy, action plan in public institutions and distribution of them to all employees.

Conclusions and recommendations: Considering that for this component have a number of institutions which have a negative response, the primary objective remains that the requirements of the 9936 Law "On budget management system in the Republic of Albania" to be applied in all local government units. All local government units must have their parts of the program budget medium-term budget in

accordance with procedures approved by the Minister of Finance as well as ongoing monitoring of their implementation.

- **Personal and Professional Ethics**

With regard to personal and professional ethics, the managers have stated positive results in implementing the existing legal framework with regard to ethics. During the analysis of responses to questionnaires, we may conclude that the legal framework in force is known and applied from most of public entities. The legal framework is represented by the: Law no.8549, date 11.11.1999 "On the Status of civil servants" and Law no. 9131, dated 09.08.2003 "On the Rules of Ethics in Public Administration. A part of the institutions, mainly the central ones, have made progress by drafting their own code of ethics, or include ethics elements in their internal regulation document. Despite the large number of institutions that claim they apply the Code of Ethics, or special rules of ethics included in their institutional regulations, in 58% of institutions there is no promotion procedures and updating knowledge of staff with these rules. It also displayed a pronounced weakness in terms of reporting violations. It is responsibility of managers of institutions to determine the development and implementation of procedures for reporting violations of ethics rules. Regarding the existence of procedures for reporting errors, fraud and irregularities - 53% of institutions state that currently do not have such existing procedures, but planning their presentation;

- **Managerial style of work**

With regard to management style of work, there is a positive element of best practice, the held of regular management level meetings to discuss about main issues of the organization. In some institutions, the frequency and manner of organization of the meetings are described in internal regulations of the institutions. One of the elements essential components of managerial style is the delegation of tasks. Currently noted shortcomings in this regard, especially in nonexistence of written procedures for delegation of duties and description of the way the powers could be delegated. Institutions declare that the delegation of duties is realized in practice, but this element is not reflected in job descriptions.

- **Organizational Structure**

With regard to the organizational structure, managers consider that in their organizations there is good organizational structure, and there are job description for employees approved and updated on regularly annual basis. Requirements of Law no.9936, "On management of budgetary system in the Republic of Albania", regarding the appointment of Authorizing and Executing officers result as fulfilled by the majority of authorities (90%). However, we noted that in practice this functions are not always covered by the high level managers and their direct subordinates. Leadership interaction between institutions and internal audit results effective. Only 5% of institutions have provided negative response in these indicators and this percentage is represented mainly by communes.

- **Human resources management policies and procedures**

There are good results in terms of existence of job description and review of the same in central government and large municipalities. Regarding local government, and specifically in the communes, most of them replied that there does not exist job description in written form. Despite legal framework requirements for preparation of job description for each position, still these requirements are not applied. The results show that in terms of the control environment, managers are confident they have created good conditions for the basic functioning of the institutions they manage.

Conclusions and recommendations

The focus for increasing the effectiveness should be in determining the mission, strategy and objectives, and in designing specific action plans which should include deadlines and responsible persons for their implementation. Must be reviewed the assignment of the positions of executing officers. With the new draft financial management and control law, it is intended to clarify the roles and responsibilities of the key actors of the system.

2.2.2 Risk Management

Risk management is the process of identifying, evaluating and monitoring the risks facing the organization in achieving its objectives and performance of controls necessary to keep exposure to risk at a level acceptable to the institution. This section of the self-evaluation questionnaire contains a few questions (four in total) since it is considered that risk management is a new concept for our public

administration. In this context, more than 50% of institutions state that they do not possess any procedure regarding identification, analysis and control of risks that impede the achievement of the goals of the institution, specifically during mid-term budget planning. But while there is no written procedures for identifying risks, they are subject to continuous discussion and evaluation between the stakeholders and employees in order to minimize risks and make possible the achievement of the objectives. The results shows that 67% have responded very good, 24% good, and only 9% replied that do not assess risk or take measures for its mitigation.

Conclusions and recommendations: Some positive side in this regard, as the existence of a good practical discussion on the possible risks during the process of setting objectives are noted. However, based on comments received from institutions, conclude that even in cases where there are risk management procedures, they focus more on financial risks and not in all kinds of risks that could prejudice the achievement of goals.

2.2.3 Control Activities

Control activities are the rules, procedures and actions aimed at reducing the risks with a view to achieve the objectives of the organization and promote the implementation of decisions of the head of the entity. The results of the self assessment questionnaires replies, define this element of financial management and control rated as very good in many institutions, central and local ones. The heads of state institutions that have met the minimum legal requirements and have put in place appropriate controls in the following areas: the existence of rules/guidelines for the description of internal key operational and financial processes, including documents and information flow, decision-making, setting the activities of internal controls, the double signature system, safeguarding assets and segregation of duties, documentation of all operations, activities and financial transactions. As highlighted weaknesses of the system, results in the lack of support of information systems technology and above all in the local government units. With regard to training needs, over 87% of institutions have expressed their need for training for managers and specialists, in the field of financial management and control. It is the responsibility of CHU/FMC to identify needs and develop an appropriate training strategy for public sector employees.

Conclusions and recommendations: The emphasis and focus in the future should be the development of IT systems to improve control activities. Also, each unit must have internal regulations which should summarize the description of all procedures for the activities conducted, provide access to information and assets from the right people, developing IT systems to support control activities.

2.2.4 Information and Communication

The fourth group of components of internal control issues related to information and communication. Information is the basis of communication required for effective performance of assigned duties. Information and communication system must provide identification, collection and distribution of the information in the appropriate form and terms in order to allow the performing of duties. From the graphical presentation of answers to questions in this component of FMC, is found that over 28% of institutions have no written guidelines regarding the mode of communication within the institution, 18% of these institutions have a good level and 54% of institutions have internal regulations including communication rules (this mainly in the central institutions, regional councils and large municipalities). More than 48% of institutions declare that their IT system is not developed in those levels to support the monitoring of targets. The central institutions and precisely 43% of them, have answered "very good", 27% good and 29% poor. Feels towards the establishment of procedures necessary to provide real information, for appropriate, timely implementation of some activities within the institution. This need is evidenced in more than 75% of responses to questionnaires.

Conclusions and recommendations: The responses show that, public sector instintities has not yet a adequate system of communication and information. This prevents the daily work of staff and managerial decision making. It also creates complications in the achievement of the objectives of institutions (known as the weakness in the "control environment"). In this regard is noted that in some central institutions, especially those created recently, they created several electronic databases and some others are in process, in order to provide better information.

2.2.5 Monitoring

Monitoring is the process of reviewing the entire activity of the organization, which aims to provide reasonable assurance that control activities operate according to the purpose for which they were created and remain efficient with the passage of time. As a strong point of this component results the line of reporting; its regularity is a good practice. About 88% of managers consider that the progress towards achieving goals is regularly monitored and the reasons that may impede their fulfilment are analyzed. Following the line of interaction with auditors, there is a high percentage of institutions (70%), which states that they respond appropriately to internal audit recommendations.

Conclusions and recommendations: A good part of the management state that they review financial management and control not only on an annual basis. Some of them are involved in the regulation of their internal performance indicators, monitoring tools and regularity in reporting. However, establishing a new legal framework for FMC, will create strong basis for improvement of this component.

2.3. Findings

Positive Aspects

- The existence of a sound control environment in a good part of its components elements.
- The requirements of Law no.9936 "On management of budgetary system in the Republic of Albania" are met, especially regarding the drafting of mission, strategies and objectives. Generally in all public organizations results that, structures are suitable for the dimensions and character of the organization activity.
- The existence of job description and review, mainly for managerial positions in all central and local government institutions.
- Has been appointed in almost all public entities the Authorizing officers and executing officers in accordance to the requirements of Budget law.
- Dominant part of heads of public entities testify the proper functioning of lines of reporting; regular management-level meetings to discuss crucial issues for organization management.

Identified gaps

- Lack of analysis, documentation and management of risks that impede the achievement of the objectives in public organizations.
- Lack of awareness at the right level of managers and staff to the concepts of financial management and control.
- Lack of codes / rules of ethics for every organization.
- Lack of practices and written rules for signaling irregularities.
- Delegation of duties turns out to be good practice but not regulated by normative acts, or included in job descriptions.
- Managerial supervision focuses mainly on financial aspects than on monitoring objectives or efficiency.
- It is required to intensify training for heads of entities in order to improve the use information.
- Communication within the unit is not uniform, and the staff is not always aware of the product/ outcome of the processes in which they contribute.

2.4 Objectives for the future

The following directions need to be addressed in the future:

- Strengthening managerial accountability and changing the mentality of the managers responsibility to see top-down, by consolidating the legal basis and awareness seminars.
- Improve and increase the financial management methodology and control, including development of: Guidelines for the development of risk management, asset management, guidelines for the preparation of a statement of quality and report son FMC existing system,
- Identify the needs for training and support to training institutions and professional conduct in the field of financial management and control of senior officials and managers of public sector institutions;
- Strengthening the capacity of CHU/FMC staff through training and on-job training,
- Increase awareness regarding new FMC concepts in central and local administration.

3. Internal Audit

3.1. Sources of information on IA activities in the public sector

Information about the internal audit activity in the public sector is collected on the basis of audit reports and annual audit reports for 2009, 2010 received from IA units. This information has been received from 13 central institutions, five subordinate institutions, four Independent Institutions and part of the audit of Local Government structures. Likewise, a supplementary form titled "Questionnaire for annual tests" was delivered to IA representatives of IA structures in the public sector, and the 40 replies received served as source of information for this paper.

3.2. Establishment of IA functions in the public sector

- **Establishment of new IA Units**

Internal audit function should be implemented by all public sector institutions as requirement of Article 2 of Law no.9720 "On Internal Audit in Public Sector (including all central and local government institutions, other institutions, central and local which provide public services and, independent institutions). Audit Procedures Manual further defines the criteria for job creation and operation of the internal audit structures and it highlights the fundamental principles on which this activity is exercised. Implementing the above framework, by the end of 2009, 119 units were created (internal audit structures), which exert their function at the level of central government (in all line ministries except the Ministry of Integration), subordinate institutions, local levels (municipalities and communes), and independent institutions. In 2009 the number of structures of central government audit units was 69, compared with 52 existing in 2008; this represents an increase of 32%. In the case of local government, the increase was of 28%. This rising trend is a positive indicator for the development of auditing systems, which show a greater expansion of practical implementation of the Law on Internal Audit. Despite improvements made in this direction, there are still issues that have a significant impact on creation and implementation of institutional capacity of internal audit. The CHU/IA in his role as leader and coordinator of all activities of the internal audit system, determines that these issues continue to be vulnerable. The most important issue is related to the fact that high level management in public entities did not understand properly the role of internal audit and its mission. Thus in many subjects has not yet established the internal audit unit. Also, some entities do not respect the criteria of establishing audit structures. Within the IA units established the principle of independent function, but there are frequent occasions when these units are required to act as control structures, thus exercising the function of financial inspection. Currently there is no clear division between the role of functionally independent internal audit and financial inspection, as one of the basic requirements of European standards in the field of auditing. With regard to the respect of deadlines for the establishment of internal audit units, the most significant weaknesses are in the area of local government units.

- **Administrative capacity of IA units.**

Another important element in the progress of audit activity, in addition to creating the structures, is meeting the needs of human resources with integrity and professional competence. Because of the very delicate nature of the internal audit profession, which includes not only evaluation of control systems (financial or other), but also provides recommendations, the auditors should possess and demonstrate in the context of their activities, appropriate professional knowledge and integrity to ensure proper presentation of the effectiveness of the audit tasks. By analyzing the completeness and composition of the audit structure, we note that by the end of 2010, from 416 positions for internal auditors (based on organizational schemes adopted), has been hired 406 auditors, of whom 277 certified auditors, 58 in the process certification and 71 still not certified. In 2009, among 119 Audit structures, 106 of them are completed of staff. According to the data, progress is made in recruiting internal auditors in the past two years. In 2009 the number of employees rose by 34.4% against 2008. In addition during 2010 the number of IA Units was increased with 11% achieving 132 IAU in total. General Directorate of Audit continues to implement the training program "Certification of Internal Auditors in Public Sector" to four relevant curricula and modules: Audit, Governance and Control, Accounting and Legislation. Organization, management and development of training for certification "Internal Audit in Public Sector" are a direct product of collaboration between GAD and Training Commission, as the bodies responsible for this process.

3.3. Evaluation of performance and reporting of internal audit units

The Audit Units mainly consider the following as areas with the greatest risk:

- Financial management systems,
- Dependent entities which have responsibility for significant amounts of public funds coming from several financial sources,
- Strategic Investment projects working
- Subjects or areas that have significant weaknesses in internal control systems,
- Human Resource Management,
- Units and areas with low levels of knowledge and use of information technology systems.

Based on the assessment of areas with higher risk mentioned above, audit units have set their priorities. The main sources are committed to audit units or high-risk areas, with allocation of sufficient time and technical expertise and other resources to the needs identified. However, it was conducted additional missions at the request of management audit, as a result of updating the risk assessment during the year and in cases where the management sees fit such a mission. When assessing the risk level was high, was appointed and length suitable for tracking recommendations. In this way, internal audit is not only intended to find the conditions, consequences and responsibilities, but above all, improvements and prevent repetition of such phenomena in the future. Generally, the total number of audits planned and implemented also has increased year by year, and this indicator can be seen that if combined with other factors (cost / benefit), shows a process for improving increase the effectiveness of audit work. However, given the observed deviations in fact opposed the plan, as well as trends over the years concludes that they are almost the same factors influence that consists of:

- Changing the priorities in the activities of the entities audited,
- IA missions overlap with audits conducted by other audit institutions, especially the SAI;
- Interference management in implementing audit plans seeking audits,
- Lack of capacity to audit and frequent change of audit staff and sometimes the heads of IAU;
- Performance of the auditor's disappointing, especially the staff employed recently.

Specifically for internal audit structures in prefectures, it is considered as fundamental problem the collisions between the specific functions provided in the law "On the Institution of the Prefect" regarding financial control and, internal audit functions according to the IA Law. One of the most important issues relates to typology of audit engagements. Currently, the Internal Audit Law in force, does not have a clear distinction between audit and consulting services and insurance, respectively, providing the kinds of commitments are not listed.

3.4. Audit findings and recommendations

The overall assessment for internal audit activities is positive, as significant improvements in the country, but at the same time, some important factors have a negative impact on achieving the objectives of the audit and should be handled properly so to improve future results. In general, the same gaps are found in almost all supervised entities to which summarize as follows:

- The quality of preparation of materials is estimated to be at the level required by standards. Reports are incomplete and rarely heard work of the unit itself.
- There is sufficient knowledge for the presentation and setting up controls as part of the activities of the organization. Thus, auditors have difficulty in evaluating internal control. When evaluation of control provided, it is usually theoretical, without any of the concrete process of auditing and assessment of inherent meaning and control risks.
- Lack of clarity on these facts limit the role of the auditor; he/she acts just like the facts and the register fails to provide useful recommendations to improve systems in terms of preventing adverse events, and in enhancing the effectiveness, efficiency and economics of the process that is audited.
- Frequent deviations from plans, audits required by management to increase the risk of impact functional independence of the auditor, expressed exactly the independent planning, execution as well as impartial, objective assessment of audit evidence and provide an independent opinion.
- Besides the unsatisfactory level of preparation of reports, there are many gaps in the procedure for communicating the audit results with management.

- The status of some structures remains unresolved audit. There are still facilities that operate within the internal audit, but they are called, respectively, control units and perform the duties of inspection.
- Low levels of knowledge of the management of new and modern role of internal audit within the PIFC system recently has been an obstacle to the proper functioning of the Internal Audit in the public sector.

3.5. Further developments regarding IA in the future relate to:

- Improving the awareness of managers regarding PIFC, FMC and IA.
- The low level of awareness is the issue of non-compliance of the basic principle of functional and organizational independence of internal audit
- Specific activities should be undertaken in order to create an environment full legal and procedural training to conduct the internal audit function.
- Building administrative capacity of the units that IA and quality of internal audit remains to be done in terms of professional training and capacity of auditors.
- Guarantee stability of the professional staff is an issue that is often found in structures, especially the audit of public entities or other levels of local government. Changes unfounded trained staff brings not only loss of the acquired professional experience, but they also have an impact on the quality of audits.
- Create and implement a specialized program for the purchase of practical skills will contribute to increase the quality of internal audit structures

4. Overall conclusions

The development of the new model of public internal financial control in Albania demands from all the participants in the process, leading to effective action in accordance with their roles and responsibilities. Only proper implementation of new legislation and efforts by all stakeholders can lead to achieving the goal - to create a modern system, reliable and functioning of public internal financial control. Specific measures related to strengthening managerial accountability and updating of legislation and methodology in the field of internal control in accordance with EU legislation and best practices should be outlined. As one of the "three pillars" of the of Public Internal Financial Control System, Internal Audit has developed and continuously improved in order to win its modern role as advisor for the assessment and systems and contributing to the achievement of strategic and operational objectives of the organization, always in accordance with international standards and best practices. In this context, responsibility to develop and implement all measures necessary for the successful implementation of the PIFC model and achievement of high professional standards in the field of internal auditing in the public sector remains the most important issue to be addressed during the future developments in Albania.

2 Goals with one shot: Promoting entrepreneurship among students in secondary school can beat academic failure and increase future employment chances

Jordi Naval¹, Oscar Sánchez², Paul Kidd-Hewitt³, Audrey Damas⁴

1. Introduction

During the past decade many countries have been faced with several problems such as population growth, lack of improvement in economy, difficulties of the labor market to absorb the new graduates and government policies to downsize its structure. These problems have forced those countries to find a solution for the unemployment problem of graduates, alternative preparation for the labor market and providing further opportunities for learning.

Through appropriate training methods, societies can create entrepreneurs who will develop new business and maximize the economic potential of an area. At this point, schools, colleges and universities can function as a catalyst. The United States has the longest tradition of fostering entrepreneurship at universities and schools, comparatively to any other country. Unfortunately, in Europe, the development of entrepreneurship education has been much slower. Regarding Europe's welfare system, people are less willing to take risks.

All these problems and crisis have caused us to pay more attention to entrepreneurship as a fundamental issue and have brought about an increasing demand in entrepreneurship education. Thus entrepreneurship must be regarded as one of the necessities in development of countries. In this regard, a number of initiatives for promoting entrepreneurship at school by means of mentoring students to create their own micro-companies have been promoted by European Union and individual governments.

Spain, and the Autonomous Region of Catalonia, face some of the fundamental problem's of today's development in the European Mediterranean area: an uncontrolled unemployment rate of 20% (and growing), and an amazing 30% of kids not finishing secondary school. (1) Specially, the rate of youth unemployment in Spain, which has been in the OECD's fastest growing percentage since the beginning of the crisis, is forecasted to remain above 40% for at least 2011, according to projections. (2) On the other hand, Catalonia has been described as one of the most active regions in the world by number of entrepreneurship projects by population: according to the Global Entrepreneurship Monitor 2010, 6,38% of the adult population was involved in 2009 in early-stage entrepreneurial activity(3). Historical economic and social reasons and the situation of Catalonia and especially of its capital city, Barcelona, have helped to promote and maintain this high rate of entrepreneurship spirit.

Table 1 Statistical Study in Europe

	Europe-25	Spain	Catalonia
Population	501 millions	48,3 millions	7,3 millions
GDP per Capita (in Euros)	24,700	23,500	27,500
Total rate of unemployment	9.6%	20%	17. 3%
Unemployment rate amongst young people	12.6%	40%	40%
% Students not finishing secondary school	22%	38.9%	31.5%
Entrepreneurial rate according to GEM	8,6	5,2	6,8

With this grim scenario in sight, the clear need exists to further promote entrepreneurship in Spain, and especially in our region, Catalonia, where the potential irradiation of wealth to the community can be maximized. For this reason, we have decided to focus on the role of entrepreneurship and on its development as an academic discipline with a strong emphasis on programs that encourage independence and self-development for young students in secondary school.

2. Convergence of Stakeholders in one common goal

The Foundation Escola Emprenedors is a non-profit entity founded in 2008. The Foundation's purpose is to promote the entrepreneurship and innovative spirit among young students (14 to 20 years old) in Catalonia, Spain. It has been created and managed by seasoned entrepreneurs, and involves the participation of key stakeholders in the community.

The Foundation collaborates with outstanding university partners in order to develop programs that seek to build a sustained capacity in entrepreneurship. The Foundation Escola Emprenedors has established a partnership involving some of the best business schools in the world, as IESE or ESADE, and works thanks to the enthusiasm and altruistic collaboration of entrepreneurs of our country who want to share their time and experience with the youngster in the education process. We believe that it is the best way of transmitting the values of excellence, innovation and responsibility to build up a more fair and wealthy world.

As a result of the economic and social situation described above, the Autonomous Government of Catalonia has decided to improve the level of entrepreneurship education of students in secondary school, high-school and professional training.

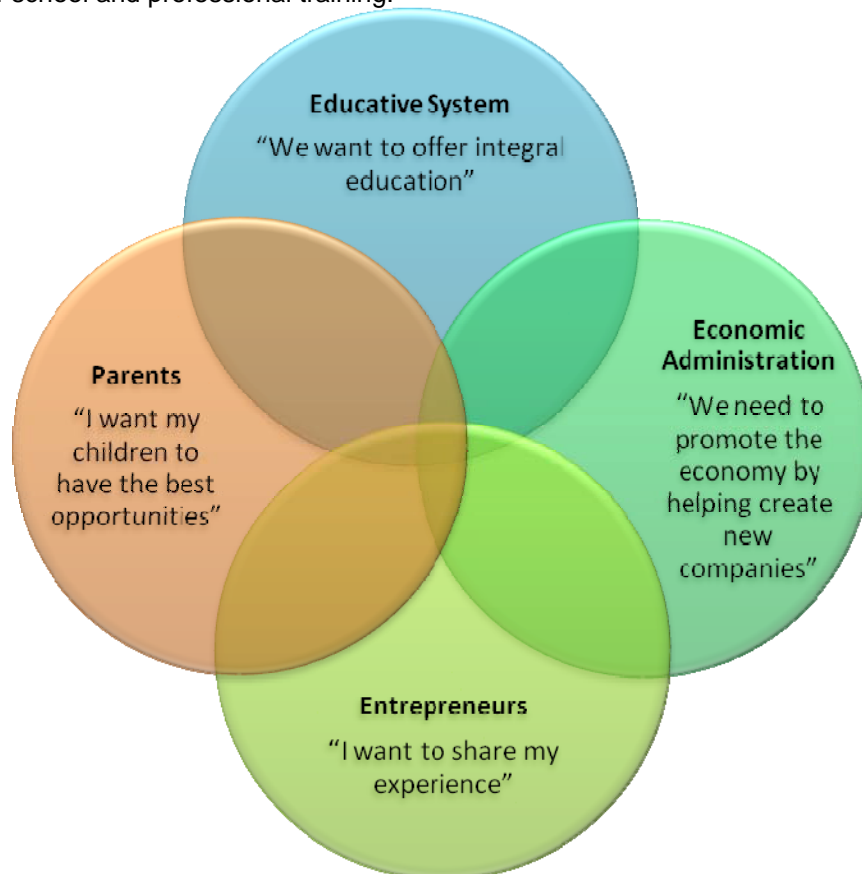

Figure 1: Stakeholder involvement and interests in promoting Entrepreneurship in our country

2.1 The "Be an Entrepreneur" program

The Foundation Escola Emprenedors, in collaboration with the Department of Education of the Autonomous Government of Catalonia, has created the "Be an Entrepreneur" program, as a means to

systematically promote entrepreneurial spirit among students in secondary schools. The program has the following characteristics:

- It is oriented to groups of 20-30 students, typically the average size of a class group in Catalan schools in secondary education.
- The program is delivered in 12 sessions of 1 hour each, during a full Quarter
- Classes are mandatory for students, and are held during normal school time.
- Besides secondary school (14 to 16 years old), the program can be applied to College Students (16-18 years old), Professional and Technical Education (16 to 20 years old), and first University courses
- Sessions are conducted in English
- Teachers are external to the School, and are paid and trained by the Foundation Escola Emprenedors
- In the first session, the students are divided freely in groups of 4-5 persons. Each group will develop its own project.
- The 12 sessions' program includes conceiving, designing and fully developing a Project Plan, whether by creating a new company, a new product or a social entrepreneurship project.
- Team learning is encouraged
- Communication skills (powerpoint, public-speaking, presentation skills) are strongly trained and encouraged
- Community Entrepreneurs are encouraged to participate as guests speakers in some of the sessions. For example parents of students are invited to present their Entrepreneur project to the class.
- Normal teachers of the School are intimately involved in the project by assisting to the classes, coordinating the teamwork, and providing support to the Foundation teachers.
- Students have to work regularly at home between the sessions, in teams, for preparing materials and ideas.
- Sessions are 20% Theory, and 80% Learning-by-Doing activities.
- The students have to finalize the program by creating a 5-10 minutes public presentation with Powerpoint and a presentation Video. All students present a part of the developed project.
- Project Plans developed by the students are presented in formal public sessions in presence of the rest of the class and the teachers. When possible, parents, guests and external entrepreneurs are invited.
- The Projects do not end in a Contest, and prizes are not awarded. Being able to present the project in public is the final goal and achievement.

When designing and developing the Be an Entrepreneur program, our goals have been to focus on the acquirement of personal competences and entrepreneurial skills:

Personal attributes and skills	Business Skills
<ul style="list-style-type: none"> • Creativity • Team working • Problem-solving skills • Taking calculated risks, and confronting risk • Communication skills • Assertiveness • Leadership 	<ul style="list-style-type: none"> • Understanding how a business works, and how wealth is created • Entrepreneurial thinking and generation of business ideas • Basic economics • Experience of key business functions • Developing market research • Developing a business plan

<ul style="list-style-type: none"> • Critical thinking • Self-confidence • Taking initiative • Assuming responsibilities • Autonomy • Taking individual and group decisions • Time management, and keeping deadlines • Setting goals; • Negotiating skills; • Project management; • Use of Information and Communication Technologies (ICTs); • Public speaking and presentation skills • Analyzing and planning own activities; • Improving own learning and performance. 	<ul style="list-style-type: none"> • Human resources management • Financial literacy • Budgeting and allocating resources • Raising finance through shares, sponsors, loans • Calculating product cost and profit • Accounting • Marketing • Entrepreneurial thinking and generation of business ideas • Advertising a product/service • Putting on an exhibition, and taking part in a trade fair • Sales and purchasing techniques • Developing and managing business contacts, interacting with the local community
--	--

The Entrepreneurs Program is unique in the use of innovative methodologies for training. The Program, in its very ideology, offers for the first time student's protagonism with the possibility of an education to learn to be entrepreneurs, an offer which is neither elitist nor boring. Actually, the main axis of the activity program is the participation, but with an intention that goes beyond the exclusive playful character. When facing individual challenges when the pupils do exhibitions, the objective is to reinforce the teamwork while they decide aspects of the project

The steps through which the program runs and students are guided include:

1. Describe the main idea of the product, service or company
2. Identify the people's need the project will serve
3. How the product will be produced? This is a very light approach, as we accept inventions not necessarily doable, like for example a chewing gum that substitutes all main meals providing same nutrients
4. Identifying the basic finances, just by listing the costs and the possible future income
5. Identifying the basic "departments" of any organization, and making the kids identify with one of the roles (Director, Marketing and Sales, Production, Finances, Research, Logistics, etc)
6. Marketing and planning a product launch, striking good if possible, with commercials (TV and press) to do.

All of the above will depend on whether the business consists of setting up a video games company, a hotel, a community service or, why not, a high-tech company.

Table 2: Content Distribution during the Program

Week by week, each group has to share with the other groups how their company is evolving, by short presentations in English to the rest of the groups, as one of our goals is to get students used to speaking business English in public. If the boys put a shirt and a tie on and girls wear business suits, the credibility is increased and surely the entertainment value is as well.

Ideally, the Program tries to warn about the loss of values such as the effort and the sacrifice between the new generations, where young people are at a critical step and in front of a society that does not promote entrepreneurship because it gives everything chewed up to the youth. Our Program offers a solution. It seeks to prepare youth to be responsible, enterprising individuals who become entrepreneurs or entrepreneurial thinkers. With the help of an entrepreneurship spirited educator and the educational institution, the responsibility for learning transfers to the students and activity will take a more important role instead of passive receiving. The aim of entrepreneurship education is to teach the students the attitude, skills and information that are needed later on in working life regardless of whether one works for someone else or as an independent entrepreneur. It's a way to immerse them in real life learning experiences where they can take risks, manage the results and learn from the outcomes.

Regarding teacher training, the emphasis of the teachers' role is in achieving the entrepreneurship education targets. It's important that the teacher's attitude and perception of life are entrepreneurial.

Finally, the "Be an Entrepreneur" program is based in the "Learning-by-doing" methodologies. It's not sufficient simply to have an experience in order to learn. Without reflecting upon this experience it may quickly be forgotten or its learning potential lost. It is from the feelings and thoughts emerging from this reflection that generalizations or concepts can be generated. And it is generalizations which enable new situations to be tackled effectively. Similarly, if it is intended that behaviour should be changed by learning, it is not sufficient simply to learn new concepts and develop new generalizations. This learning must be tested out in new situations. The learner must make the link between theory and action by planning for that action, carrying it out, and then reflecting upon it, relating what happens back to the theory.

2.2 Results

The Foundation Escola Emprenedors has implemented the "Be an Entrepreneur Program" in 34 schools between 2008 and 2011 in the Autonomous Region of Catalonia, i.e., for three complete academic years (2008-2009, 2009-2010, 2010-2011). A total of 56 programs have been implemented (average of 1.6 programs per school), as there is a variation between the number of individual groups (classes) in each school, i.e., some schools have only 1 group of students of 4th of Secondary School, while others have 4. All schools were Public schools.

The total number of students has been of 2570.

Number of Participating Schools	50
Average number of groups (classes or lines) in each school	2
Average number of students per Group	30
Total number of students	3000
Average course where the program was implemented	4th year of Secondary School
Average age of students (min, màx)	15 (13-19)
Mean number of sessions per program	12-15
Average duration of the program	4 months
Average % students of immigrant origin	20%
Number of schools in low-income areas	12
Number of schools in medium-income areas	36
Number of schools in high-income areas	2

Table 2: Reality of the “Be an Entrepreneur” program in Catalonia, in 2008-2011

The type of Project presented by the students could be defined in the following way: leisure and entertainment (30%), social (20%), tourism (20%), Internet, programming and technology (10%), Educative (10%), and Services (10%).

2.3 Opinions of teachers and alumni

When measuring the results it should be remembered that some of them are visible in the short-term and some in the long-term. The evaluation study of the Be Entrepreneur’s Program was carried out in the following way: a questionnaire was used in evaluating the programs conducted in 2010.

Although no systematic evaluation of the results was conducted in terms of improvement of academic failure of the alumni, due to lack of data and resources, surveys were conducted to alumni and teachers, with the following global qualitative results:

- A total of 250 questionnaires were sent to students.
- 85% of the respondents fully or somewhat agreed that they have learned new issues on entrepreneurship. Moreover, for them, the perception of entrepreneurship changed to being more positive as a result of the training.
- Alumni were happy to have the opportunity to make their projects real, with the help of the trained teachers, in the framework of the “Be an Entrepreneur” program
- Alumni valued the team-building spirit, and the chance to be able to present their business cases in front of a real audience
- Teachers valued the good team spirit, and the innovative climate that was created. They also evaluated the normal use of English.

All the 30 schools expressed their wish to repeat the program in the following years.

4. Conclusion

We think that implementing the Be an Entrepreneur program in Secondary School in Catalonia has been a success. Students learned the basics of creating projects of their own, increased their self-esteem, learned communication skills while improving their English level, in a dynamic and constructive environment. All the students participated in the activity, thus demonstrating its widespread application. Teachers showed a high degree of satisfaction with the activity. Plans are in progress to extend this program to more schools in Catalonia, and authors are open to help expand the experience to other countries.

Diffusion of Innovation by Rate of Usage of Internet

Borislav T. Nestorovski¹, Radmil Polenakovik², Bojan Jovanovski³, Trajce Velkovski⁴

⁴National Centre for Development of Innovations and Entrepreneurial Learning, NCDIEL, Skopje, Macedonia, trajce.velkovski@ncdiel.mk

The paper examines correlation of Innovation in the firms in Macedonia and Internet. Today, Internet is recognized as one of the most important economic indicators. This indicator creates structural position for innovative potential. It is noticeable that countries that have highest penetration of broadband Internet in the same time have highest indexes for innovation, competitiveness and technological development. Through survey of representative sample of Macedonian companies, after validation 1.979 forms were taken into consideration. The survey followed general OECD guidelines set out in publication known as the Oslo-Manual. For the purposes of field research two stratification criteria have been adopted: economic size (in terms of employed workforce), and business sector.

The survey collected information about product/service innovation, as well as processes, logistics and marketing innovation, and other key variables, during the three-year period from 2006 to 2008. By performing statistical analysis comes out that there is implication on usage of Internet on innovation in the firms. It has been found that there is moderate positive correlation between innovative activities in the firms and usage of Internet or innovation is more rapid in firms that use Internet than the firms that not use Internet. Also, as a summary output of regression statistics could be found that 14,5% of variation in the number of innovative activities is explained, by the variation in the number of access of employees to the Internet and 27,5% by variation in the number of average usage of Internet in the company. Thus, second conclusion has been drawn that there is positive correlation between implemented innovations in firms in Macedonia and employees access to the Internet and frequency of usage of Internet of those employees.

Keywords

Innovation, Diffusion, Broadband Internet, Correlation

1. Introduction

Globalization represents trend which irresistibly destroys local and national borders, thus causing sharp competition on the world markets. Only those who have access to the key information and could follow on timely manner world-wide trends and exchange information could be in struggle with fierce competition in the world.

In order to realize full potential of the country it is required to exploit all possible resources and in the same time to create possibility for new growth of economy. Taking into consideration that development of electronic communications networks and especially fast Internet (broadband Internet) are basis for technological platform for introducing information society, from which clearly emerge critical role that

this technology has. Internet connects consumers, businesses, governments and speed up social interactions. It is more than obvious that policy for broadband Internet access represents vital instrument for providing competitiveness of the countries. According to Statistical Indicators Benchmarking the Information Society (SIBIS) research from November 2003, "Broadband Internet is probably the single most important enabling technological development on the present time and it is, therefore, imperative to measure who has access to it, and what it is being used for." p. 23. [1] Services on this platform like E-Commerce, E-Health, E-government, E- Education, create added value, new ideas and they are key source for new jobs. ICT not only provides products which are innovative by themselves, but they are main promoters of changes in modern economy, economy based on knowledge.

As much as households and businesses have access to the Internet, that much they are increasing capabilities for access to the worldwide information and possibility for business. Recognizing connection between Internet and business, in 2000 European Commission (EC) recommended to all member countries to provide accessibility to broadband Internet with low price, interconnected networks and development of advance information technologies. Furthermore, in 2003 EC recommend development of national strategies for access to the broadband Internet, thus to significantly increase number of such connections with ultimate aim to stimulate innovation in member countries, and finally with Europe 2020 strategy aiming "broadband access to all by 2013". [2]

Today, Internet penetration is count as one of the most important economic indicators. This indicator creates structural position for innovative potential. According to the Organisation for Economic Co-operation and Development (OECD) 2007 statistics for penetration of broadband Internet in enterprises as well as comparison with European Innovation Scoreboard (EIS) 2007 and World Economic Forum (WEF) indexes, global index for competitiveness from Xavier Sala Martin, and Business Index for competitiveness of Michael Porter [3-7] it is noticeable that countries that have highest penetration of broadband Internet in the same time have highest indexes for innovation, competitiveness and technological development

2. Framework and Hypotheses

"Innovation could be defined as a process which lead towards adoption and spreading of new technologies, with ultimate aim to create new processes, products and services. While term adoption represent final phase of innovation, spreading is related on offering new services and commodities." EIS 2005, page 7. [8] According to Freeman and Engel, Innovations refer to process which starts with new idea, and ending with introduction to the market. [9] Pioneer in innovation Van DeVen (1986) suggests simple definition for innovation "Innovation is development and implementation" [10]. This definition allows for any kind of change in the organization to assign innovation, if change is manageable. Concept of innovation has many characteristics. It could be classified as radical or incremental. The last one includes step by step improvement in the current technologies, while radical innovation is related to introducing of new technologies and discontinuity from previous one.

According to Berkhout and others [11], in order field of innovation to be successful several aspects must be included, as it is: science, product development and entrepreneurship which play the key role. There is no innovation without entrepreneurship. Aralica and others [12], while discuss experience of Croatian companies stated that measurements and analysis of innovative activities as well as influence on micro and macro level is very difficult, burden with conceptual and applicative difficulties, especially in the countries in Central and Eastern Europe. Competitiveness of countries is now more and more technologically oriented. That is one of the reasons that current statistics for measurements of Innovations activities in the era of globalization is inappropriate stated Collecchia [13]. A lot of international organizations initiate new indicators which realistically will show the level of Science Technology and Innovation (STI) in the countries thus helping in bringing new national policy for development and growth. Porter and Stern [14] proved that R&D variables are important determinant for innovation and growth of productivity. Countries in EU through continuation of Lisbon Strategy for growth and new jobs, with Europe 2020 Strategy [2] established advance politics and reforms, specially designed in order European regulation and economic frames to be as much as friendly towards smart growth, fostering knowledge, innovation, education and digital society. One of the key goals which have been established was the level of 3% from GDP in each EU member states to be dedicated for research and development. EU Members States have introduced system for monitoring of progress in innovation as a significant indicator for country performance. In that national framework for innovation "Trend Chart on Innovation" [15-17] they consider strong and weak side of each

member states under different indicators for innovations. Taking into consideration importance of innovations, EU dedicated significant time and resources in order to define global politics towards innovations, to identify main reasons why total potential is not used and how could be achieved advance innovative economy in EU 27 Member States. In Aho report [18] as a main remark has been directed that EU countries must develop much more friendly business environment for innovation.

Strategy for development of innovation includes all stakeholders: business community, public sector, and of course, consumers. This is obvious because process of innovations includes not only business sector, but also public administration on national, regional and municipality level, public sector and consumers. Innovation strongly depends from consumers and citizens and their needs for innovative products and services. That is the reason why besides creation of optimal frames and capabilities for innovation, it must be created friendly market for innovation and needs for such products and services. Innovation comes in different forms, besides technological innovation, in this category belongs organizational innovations, process innovation, innovations in services and marketing innovations.

Republic of Macedonia must take serious steps with the aim to improve innovation in public and private sector. In order to follow, analyze and improve politics related to competitiveness of national economy it must be established national system for innovation and indicators which will reflect the real situation of innovation in the country. Polenakovic and Pinto in their paper clearly stated that “Republic of Macedonia missing well defined National system for Innovation with clear and well defined connections between science, technology and innovation and their connections with economic development.”[19]

Besides well-defined system for innovation must be examine relations between several input and output factors of this system. In other words it must have better efficiency in exploitation of resources for science, technologies and innovations.

Advance usage of IT tools led towards a wide range of technological innovation for firms. ICT also have major impact on sales channels, marketing approaches, as well as creating new potential for logistics and communication and finally organization.

Very little academic research has been focused upon the relationship between ICT implementation in the small and medium enterprises and innovation in any form. Specifically, focusing of usage of broadband Internet and relationship with innovation could results in specific recommendation which could help in growth of SME. Diffusion of Innovation in Oslo Manual [20] is defined as “the way, in which innovations spread, through market or non-market cannels, from their very first implementation to different consumers, countries, regions, sectors, markets and firms.”

Hypothesis1: It is proposed that innovation is more rapid in firms that use Internet than the firms that not use Internet

Hypothesis2: It is proposed that innovation is more rapid in firms that usage of broadband Internet is spread through all employees, rather to those that only need to perform work and the usage is more frequent.

3. Methodology and Operationalizations

The data was collected as part of wider survey “European Innovation Scoreboard 2010 for Republic of Macedonia” Polenakovic, Nestorovski et al [21]. The survey was administrated during May 2010 – September 2010. The objective of the survey was to generate statistical data necessary to carry out the analysis of Innovation and Entrepreneurship drivers in Macedonia.

In order to consider an appropriate sample design, it was first useful to look at the total population of companies:

Table 1 Total number of registered companies at the end of year

Year	No. of companies
2006	91.104
2007	94.112
2008	98.270
2009	101.323

Taking into consideration number of active companies in the country it has been agreed to limit the research to 3.000 invited firms as a representative Macedonian sample. After the validation of returned surveys, 1.979 forms were taken into consideration which means in total 1.979 firms provided usable responses and this represents a 66% response rate. The high response rate was explained by

the fact that the process of interviewing of companies was initiated by official e-mail invitation and the Questionnaire. Companies were given the opportunity to choose the mode of interview:

- filling the questionnaire in person with interviewers or
- filling the questionnaire electronically and sending it back to designated e-mail address

The companies that did not answer the first e-mail were contacted by telephone and were given extensive information about the survey and the reasons for their participation. Finally, letter from the Minister of Economy has been sent to all participants in order to given higher importance of the survey and to achieve higher response rate.

Data were collected in accordance with Macedonian laws and the survey was carried out under the agreed set of international rules as laid out from the OECD, Community Innovation Survey (CIS) 2008 including new 2008-1010 methodology [22], and Eurostat recommendations. The survey followed general guidelines set out in publication known as the Oslo-Manual. [20] This document offered suggestions for realisation of innovation surveys, including statistical procedures and a review of the range of concepts that fall together under the umbrella term innovation. The CIS deals with the innovation activities of enterprises within EU Member States. The business classification used for the survey is based on the Statistical Classification of Economic Activities in the European Community (NACE Rev. 2) excluding sectors L and Q.

The random stratified sample was taken from the Central Registry of Republic of Macedonia. For the purposes of field research two stratification criteria have been adopted: economic size (in terms of employed workforce), and business sector. The total population consists of all active companies registered in the Central Registry of Macedonia (to have done business in 2006 or 2007 or 2008) and to have existed for at least three years. The database was divided in 8 groups according to Macedonian statistical regions: Skopje, Pelagonia, Polog, Eastern, South-Eastern, North-Eastern, South-Western, and Vardar. The coverage is therefore organized in a two-dimensional matrix of cells defined by one of the possible intersections Number of Workers * Sector. The sample of companies is then selected by the individual cells, thus ensuring adequate representation of heterogeneity in the field of observation.

The survey collected information about product and service innovation, as well as other type of innovations and other key variables, during the three-year period from 2006 to 2008. Most questions cover new or significantly improved goods/services or the implementation of new or significantly improved processes, logistics or distribution methods and marketing innovations.

Other information gathered mainly concerns:

- the kind of technological innovation introduced;
- the influence of government policies in enhancing the innovation climate;
- expenditures on innovative activities carried out by the company;
- the share of turnover generated by new products;
- the impact of enterprises' innovation activities

The survey takes into account other aspects of the innovation process such as: the factors that restrict or prevent enterprises from developing innovation activity, the public support of innovation, cooperation agreements, sources of information on innovation, and the propensity to use patents or other forms of intellectual property protection. There was set of questions in order to determine each category of innovation.

New products have been counted if any significantly improved or new product development has been performed, regardless of being new only for the market of the company or only new to the firm. The same applies to the service innovation. Process innovation describes new methods relating to the firm business practices either internally or in external, including new relation. The following aspects have been taken into consideration:

- to reduce time to respond to customer or supplier needs
- improve ability to develop new products or processes
- improve quality of goods or services
- reduce costs per unit output
- Improve communication or information sharing within your enterprise or with other enterprises or institutions

Organizational innovation is described as:

- New methods of organizing work responsibilities and decision making
- New business practices for organizing procedures
- New methods of organizing external relations with other firms or public institutions

Innovation in Logistics is described as new or significantly improved logistic, distribution or distribution method for the input materials, products or services, while marketing innovations have been represented through implementation of a new marketing concept or strategy that differs significantly from the enterprise's existing marketing methods and which has not been used before. This kind of innovation implies significant changes in product design or packaging, product placement, product promotion or pricing. Seasonal, regular and other routine changes in marketing methods are excluded from the concept of marketing innovation.

4. Results

The enterprise system in Macedonia is characterized by small-sized firms in terms of both turnover and employees. These are companies with low turnover and limited staff. Due to the difficulty in sizing the sample, from the economic point of view, it could be useful to use, by analogy, as sizing depends on the number of employees declared and their variation from 2007 to 2009. In 2007, the percentage of enterprises with 0-5 employees was equal to 51.8% (down to 49.6% in 2009). In general, the majority of companies are set in a size range below 50 employees (with 77.7% of companies in 2007 and 78.70% in 2009). By analyzing the information from geographical point of view, the smallest enterprises (0 to 5 employees) are located in the northeast regions (68% in 2007 and 62% in 2009) and in the southeast (64.8% in 2007 and 62.8% in 2009). Larger companies (over 51 employees) are mainly located in the eastern region. Besides these problems, enterprises are highly isolated in terms of relationships with other companies and towards target markets.

4.1 Diffusion of Innovation in Firms by Internet Usage (Internet Access)

Out of 1.979 respondent, 1.596 firms use any kind of Internet, which represent 80,6% from total population count. From the other side Innovation in the companies has been defined as an innovation in products, services, method of production, logistics, organizational innovation and marketing innovation. Total number of enterprises that have any kind of innovation is 1.520 or 76.5% from total population.

Diffusion of Innovative activities significantly differs from region to region, showing that Skopje and Southeast region has been more innovative than other regions. The same fact applies for the usage of Internet. Dominant technology for using broadband Internet is ADSL and it is count for 58,5% from total population or more than 72,6% from those that use Internet.

Concerning importance of Internet in the growth and productivity, *correlation analysis* has been performed in order to estimate relation between independent variable "usages of Internet in the firms" with dependent variable "innovation in the firm". By performing such statistical analysis coming out that *there is implication on usage of Internet on innovation in the firms*. A computed value of coefficient of correlation is 0.525, showing *moderate positive correlation*. By computing coefficient of determination has been explained proportion of the total variation in the "innovative activities in the firms" by the variation in the independent variable "usages of Internet in the firms". Coefficient of determination is 0.275 or 27,5 % of the variation in the number of innovative activities is explained, or accounted for, by the variation in the number of firms which uses Internet. Table 2 summarizes innovation activities by firms in Macedonia.

Table 2 Innovation in small and medium companies

New or significantly improved products	24,9 %
New or significantly improved services	23,1 %
New or significantly improved method of production of goods or services	22,5 %
New or significantly improved logistics	22,8 %
New or significantly improved supporting activities for organisational processes	22,7 %
New or significantly improved marketing methods	34,6%
Total of any kind of innovation	76,5 %

Innovation activity is count either that activity is new to the market of the firm, or only new to the firm. By this hypothesis is confirmed that *Innovation is more rapid in firms that use Internet than in those that does not use Internet, or the rate of diffusion of Innovation is increasing for firms that use Internet compared to firms that not use Internet.*

4.2 Diffusion of Innovation by Rate of Usage, Access and Purpose of Usage of Internet

Based on collected data investigation of relation between innovation and usage, access and purpose of usage of Internet has been performed.

In the last three years, in average of 34% of companies have increased internet access speed, with the maximum number being in Skopje (54,5%) and in the south-western region (44,6%). Increasing access speed is connected with increased Internet activities. *More than 96% of companies that increase access speed have implemented some innovation in the last three years.*

Out of 1.596 firms that use Internet, 81,1% use Internet every day (Table 3); while in 30% in the companies that use Internet all employees have access to the Internet (Table 4).

Table 3 How often internet is used in the enterprises

		Everyday	A Few days in week	Rare	I don't know	No answer	Total
Total	a.v.	1.294	178	67	10	47	1.596
	%	81,1%	11%	4,2%	0,6%	3,0%	100,0%

a.v. – absolute value

Table 4 How many employees have access to the Internet

		Only management	All employees	Most of the employees	Only part of employees for which Internet is necessary in their work	No answer	Total
Total	a.v.	591	480	227	269	29	1.596
	%	37,1%	30,0%	14,2%	16,8%	1,8%	100,0%

By performing linear regression analysis using the "least squares" method at 95% confidence interval has been analyzed single dependent variable "any kind of innovations". Values of dependent value is checked whether is affected by the values of one or more independent variables, "average usage of Internet in the company" and "how many employees have access to Internet". As a summary output of regression statistics could be found that 14,5% of variation in the number of innovative activities is explained, by the variation in the number of access of employees to the Internet and 27,5% by variation in the number of average usage of Internet in the company. Those figures *show moderate correlation* between analyzed variables. E-mail correspondences are most widely use activity in the companies that used Internet. More that 85% used this tool, while 66% of the companies seeking new business opportunities through Internet. Only 14,8% of all companies that use Internet have used this application for selling and buying products and services. This could be explained due to very low penetration of credit cards with possibility for Internet trading, Internet security and low training and education for such business model. (Table 5)

Table 5 Purposes the companies do you most often use Internet

	Yes		No		Total	
	a.v.	%	a.v.	%	a.v.	%
For e-mail	1.368	85,7%	228	14,3%	1.596	100,0%
For seeking new business opportunities	1.053	66,0%	543	34,0%	1.596	100,0%
For performing working tasks	1.053	66,0%	543	34,0%	1.596	100,0%
For professional education	551	34,5%	1.045	65,5%	1.596	100,0%
For buying or selling products or services	237	14,8%	1.359	85,2%	1.596	100,0%
For data transfer including video, pictures	426	26,7%	1.170	73,3%	1.596	100,0%

	Yes		No		Total	
	a.v.	%	a.v.	%	a.v.	%
and music						
For other Internet applications	347	21,7%	1.249	78,3%	1.596	100,0%
For software downloads	240	15,0%	1.356	85,0%	1.596	100,0%
For news and information related to yours business	487	30,5%	1.109	69,5%	1.596	100,0%

Regarding the possession and use of web sites, 60,4 % of enterprises do not have a website and only 10% use the company's web site to support their business operations. (Table 6)

Table 6 For which purposes are internet web sites used

Answers	Yes		No		Total	
	a.v.	%	a.v.	%	a.v.	%
Our company have no own web site	963	60,4%	633	39,6%	1596	100,0%
For advertising and information of our company	396	24,8%	1200	75,2%	1596	100,0%
For direct sale of products and services	88	5,5%	1508	94,5%	1596	100,0%
Education and training	29	1,8%	1567	98,2%	1596	100,0%
Support of business	160	10,0%	1436	90,0%	1596	100,0%
I don't know	24	1,5%	1572	98,5%	1596	100,0%

There is positive correlation between implemented innovation in firms in Macedonia and employees access to the Internet and frequency of usage of Internet of those employees. Diffusion of Innovation is higher in firms that usage of broadband Internet is spread through larger number of employees and the companies use Internet more frequently.

5. Conclusions

The survey results show that the diffusion and adoption of Innovation varies with geographical region, Internet access, rate of usage, as well as who is using the Internet.

Hypothesis 1 is supported by findings that *diffusion of innovation is greater in firms that have Internet access*, illustrating that the diffusion of innovation occurs in those firms that have access to more information. The survey clearly shows that companies beside e-mail which is by far most usable application 85,7%, use Internet for seeking new business opportunities 66%, performing daily work 66%, but also to find news and information regarding their business 30,5%. All these companies have access to more information and obviously use them to implement some type of innovation in their daily business. Continuous increase of adoption of Internet suggests that companies appreciate the power of ICT and are able to find resources to adopt it.

More in line with expectations is the fact that the firms in which Internet is spread wider through employees and rate of usage is more frequent, is likely to have more innovative activities in the firms, thereby supporting Hypothesis 2.

The current level of Internet Access is high, but still there is room for further expansion, especially considering Europe 2020 goal of broadband to all by 2013. Future expansion decisions are likely to concern upgrading of existing Internet Access, governmental intervention in rural areas, and further growth of penetration into the firms due to some legal requirements.

To conclude, data analyzed in this paper has been drawn from national survey of Macedonia. It is already proven that innovations increase competitiveness of the firms. In order to increase competitiveness of the country, all aspects of innovation should be taken into consideration. Further examination of employee's ICT skills in order to increase innovations could provide important insights. Also, correlation between different management styles and diffusion of innovation in the firms could exploit new horizons. Finally, how investment in ICT results in innovations activities and how those innovations impact firm's financial results could explore new important facts, which would help in further increase of competitiveness of the companies.

Existence of “Urban canyons” as the innovative solution for better quality of life and business developing in Podgorica city

Aleksandar Nikolić ¹

¹DOO MONTINSPEKT, Podgorica, Montenegro, tipotek@t-com.me

Introduction: Communal noise is common nuisance that affect people in their homes and offices. Construction of tier buildings along the main traffic roads or streets could increase the people quality of life and make opportunity for business developing.

Objective: Analysis presence of communal noise in residential and business premises settled along Boulevard Sava Kovacevic in Podgorica city. Propose solution for solving negative effects and developing business.

Methods: Tier building was selected for the experiment. One hour noise measurements, on five positions inside the building and three positions outside, during three different periods (7-8h, 15-16h, 20-21h) were performed according to Montenegrin legislative for environmental noise exposure and occupational health and safety at work.

Results: Outdoor measurements (positions near Boulevard) showed that traffic noise exposure exceeds limits for 5dB. Difference, between measurements on ground level position and noise level on seventh floor position, was negligible (0.5dB). Situation caused by presence of “urban canon”. Results for all indoor (working) positions exceeded limits for about 5 dB. As the main sources for such noise were detected heating/cooling system and frequent traffic.

Conclusion: Experiment results show that communal noise represent nuisance that negatively affect people in business and residential premises across Boulevard Save Kovacevic - Podgorica. Pollution is caused by very frequent traffic and industrial noise sources (generators, climate units). Pollution problem could be solved by providing activities on better traffic regulation (roundabout instead of traffic lights), “green barriers” implementation and some technical improvements. Best way for noise problem solving will be assignment of residential and office premises strictly for commercial purpose (home stores, markets, etc.). This solution offer best opportunity for increasing people quality of life and business development.

Keywords:

Business development, communal noise, innovative solution, quality of life.

1. Introduction

National technological development brings benefit to all citizens who are generally pleased with the progress and the things that this technological development brings. A typical example of this progress can be seen throughout the development of means of transport, different machines and devices that make life enjoyable to modern man. The consequence of this rapid progress has been rapid growth in both the environmental noise and noise at work environment, which results in stagnation and quality of life decreasing. City of Podgorica is an ideal example of rapid technological development and progress, which results in increased communal noise which adversely affects the quality of life of citizens. The application of urban-technical measures can eliminate the negative effects that noise has on the quality of life. Application of measures to eliminate excessive noise inevitably requires

additional financial resources, which call into question the economic viability and do not guarantee a permanent problem solving due to the fact that the noise level is constantly increasing. Problems with increased levels of communal noise are particularly pronounced in the residential and business areas located close to the frequency traffic roads. A common practice is to build tier buildings next to the city's boulevards, which are used as residential and commercial (office) space. The existence of such facilities on both sides of the city boulevard, which performs very frequent road traffic, has resulted in the production of so-called "urban canyons" that eliminates the effect of noise attenuation with increasing distance from the source. That resulted in the presence of noise which is almost identical within building regardless of the number of floors and the distance from the road marked as a source of noise. In order to practically confirm the above facts, traffic noise assessment was performed in Boulevard Sava Kovacevic-Podgorica. The goal is to effectively check the noise levels generated in the "urban canyon" along the Boulevard, and to determine whether we have the existence of excessive noise that adversely affects the quality of life, interferes with the living and working activity, and find an innovative solution that permanently solves problem.

2. Choice of facility for the noise measurement

Commercial building located in a metropolitan area with very frequent road traffic, with the obvious presence of other sources of community noise (air conditioning, industrial sources, etc.) represented an ideal choice for carrying out the experiment. Other forms of transport (air and rail) are not present in this part of the city. Selected building is adjacent to the Boulevard "Save Kovačević" on the north side. On its east side is adjacent to residential-commercial buildings, and on the south side is a parking space.

3. Selection of measurement sites

Given that the north side of the building directly exposed to noise coming from the direction of the Boulevard is determined by five positions. Three positions inside residential part and two positions inside office part of building, in order to measure the value and impact of noise generated by very frequent traffic. Selected the three measurement positions in the flats on the second, fourth and seventh floors, two positions on the ground floor and first floor used as office premises. To determine the effect of noise on the building facade were chosen positions close to the main entrance on the ground floor, and two positions close to the Boulevard were used to determine the value of traffic noise. Therefore, the impact of noise was measured at eight different positions in order to encompass the entire impact of all sources of noise which the utility business and residential building exposed.

4. Choice of instrument for measuring, measurement intervals

Noise is measured by precision modular analyzer Brüel & Kjaer 2250 that meets the prescribed standard IEC60804. Tuned frequency range from 6.3 Hz to 20 kHz frequency range corresponds to 1/3 band noise analysis. Degrades gracefully is A- weighted frequency weighting curve for the fast response time of 0.125s. Dynamic range of the instrument for a tone frequency of 1 kHz is set for maximum value of 140 dB. Before and after the monitoring device was calibrated with a sound calibrator, model Brüel & Kjaer 4230, which produces noise levels of 94 dB at a frequency of 1000 Hz, with an accuracy of ± 0.25 dB. During the measurement used is "free-field" microphone size of 0.5 inches, the working range of 2.6 Hz to 20 kHz. During measurements of weather conditions were good, sunny and quiet time. In selecting the measurement interval was followed instructions from Article 6 Ordinance on the methods and tools of measurement to be met by the organization to measure noise. Under this Ordinance changing the noise level is measured at three intervals during the day (06-22h) and two intervals during the night (22h-06h). Given that this is a residential-business building and that it was not possible to measure the night, all measures within the building carried out in three day intervals for a period of 1 hour: The first measurement interval from 07:30 h to 08:30 h; second interval measurement from 11:30 h to 12:30 h; third measurement interval from 15:00 h to 16:00 h. Measurements in front of the building were performed in three intervals of 30 minutes: The first measurement interval from 08:00 h to 08:30 h; second measurement interval from 15:00 h to 15:30h; third measurement interval from 21:00h to 21:30h.

5. Applied legislation

States of Montenegro's declaration of the Law on the Protection of Environmental Noise (Official Gazette No. 45/06 of 17.07.2006.) regulates noise in the environment, identifies measures to combat the harmful effects of noise on human health, precise data on permitted levels of environmental noise and ensuring their availability to the public. Article 9 this Law, defines the obligation of a competent government authority to issue regulations for limited values of noise, methods of assessment and measurement methods. Ministry of Health, Labor and Social Affairs adopted the Regulation on the methods and instruments of measurement noise (Official Gazette nr 24/95, 42/2000, 25/2003), which is used as a reference for making this work. Besides these, we used Regulations used to check the limit values of environmental noise (Official Gazette of 08/12/2006 nr.75/06) and Regulation on measures and safety standards of noise in work areas (Official Gazette SFRJ nr.21/92).

6. The results of performed measurements

The results of noise measurements performed at the monitoring positions are classified in three categories. The first category is the results of measurements that show the obtained values of the equivalent noise level during the measurement interval. These results are shown in diagrams and tables, and presents values for the total equivalent noise level - LAeq. The second category is the results which represent the cumulative distribution of noise level during the entire period of measurement. Tables shows the values of parameters LAF1, LAF10, LAF50 and LAF90 which represent the percentage prevalence of noise during the measurement and are used in the statistical analysis of the excess over the permitted level of noise. The cumulative value of these parameters for the total period of time defines the impact of background noise (L90) or impulse noise (L1). The third category of instructional results represent the results of sound pressure level at a given frequency range at certain frequencies. This category results will be used in the analysis of noise in those areas where measurement is to determine whether the obtained values do not exceed allowable limits. Analysis results determine: Is the value obtained at selected measuring points exceeds the value of exposure to noise in the environment; Do values obtained at selected measuring points exceeds the value of exposure to noise at work.

For the measurement position within the work premises is necessary to determine if the results exceed the permitted levels defined in the Regulations on the safety standards of noise in the workspace (Official Gazette of SFRJ 21/92). In accordance with these rules allowed noise level is determined based on the type of work being done on the said working position. Employees in these positions perform work that requires concentration, right speech and telephone communication, and has allowed noise level of 50 [dB]. For the assessment of noise levels we used the method of assessment of noise by normative curves. As the allowable noise level is 50 dB, it is a normative curve represents the reference value curve N-45. Allowed values of sound pressure at the reference frequencies are given in Table 1 and for the normative curve N45 are:

Tabel 1 – Sound pressure levels on referent frequencies for the normative curve N45

Frequencies (Hz)	31,5	63	125	250	500	1000	2000	4000	8000
Permitted (dB)	86,0	71,0	61,1	53,6	48,6	45	42,2	40,0	38,3

The results obtained by measuring on the first selected position in a time of 7:30 to 8:30 pm are presented in Figure 1:

Figure 1 – Results obtained by measuring on the first selected position in a time of 7:30- 8:30 pm

Frekvencija	Hz 31,5	Hz 63	Hz 125	Hz 250	Hz 500	Hz 1000	Hz 2000	Hz 4000	Hz 8000
L _{AF}	42 dB	58dB	63dB	73dB	85dB	90dB	89dB	75dB	75dB

After analyzing the measurement diagrams and reading results for all three terms, we compared measured values with acceptable values for the curve N45 (Table 2). In accordance with the Regulations on safety standards of noise in the workspace (Official Gazette of SFRJ 21/92), the measured values of sound pressure for each frequency level, must not exceed the values given as a reference, or in one of frequency levels. If the value of even a single measured sound level for a given frequency exceeds the permissible level, it is considered that the noise exceeds the limit. To compare our results with reference values allowed for the curve N45, points to the fact that almost the entire frequency range measured values significantly exceed the permitted limits in all three terms of measurement. In the field of lower frequencies there is no deviation from the allowed value, which indicates that the Boulevard traffic of heavy vehicles is minimized. The measured values of sound pressure at frequencies of 1 kHz, exceeding allowable by approximately 30dB-45dB. The difference is particularly strong. Therefore, it is evident that the above mentioned position measuring noise level does not meet the criteria defined in the Regulations on the safety standards of noise in the workspace.

Table 2 Comparison of measurement results in all three terms, with the permitted values for the curve N-45

Frequency	Hz 31,5	Hz 63	Hz 125	Hz 250	Hz 500	Hz 1000	Hz 2000	Hz 4000	Hz 8000
Permitted level	86,0dB	71,0 dB	61,1 dB	53,6 dB	48,6 dB	45 dB	42,2 dB	40,0 dB	38,3 dB
Measurement results 7:30-8:30h	42 dB	58dB	63dB	73dB	85dB	90dB	89dB	75dB	75dB
Exceeds	No	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Measurement results 11:30-12:30h	38 dB	52dB	68dB	74dB	78dB	82dB	88dB	72dB	60dB
Exceeds	No	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Measurement results 15:30-16:30h	44 dB	55dB	60dB	65dB	88dB	72dB	90dB	70dB	65dB
Exceeds	No	No	No	Yes	Yes	Yes	Yes	Yes	Yes

Almost identical data were obtained for the second working position, which was selected as the second test point for which comparisons were made of the measured and allowable values of noise at work. From cumulative diagram for Position 2 (Figure 2) in the period from 7:30 to 8:30 leads to the conclusion:

Figure 2 – Cumulative distribution of noise levels for the period from 7:30 to 8:30 pm

- At 72.3% of total recording time, a condition that the noise would be below 50 dB was satisfied. If one takes into account the term morning shooting noise ratio and percentage of satisfying a given criterion of 72.3%, expressed as a time duration of about 43 minutes, it was concluded that the increase in noise caused by the arrival of the position of employees and their mutual communication after terms of 08:15 h.
- The value of L1 = 64.1 dB points to current events (1% - 6s) pulse character whose influence is negligible in real terms;
- The value of L10 = 55.7 dB points on the noise from the environment. The only source of noise is the environmental transport in the Boulevard.
- The value of L90 = 42.1 dB, the background noise by 7.9 dB lower than allowed. This low value of the background noise is explained by the size of the room where the high walls and open space, noise impact of air conditioning and IT equipment does not come into play.

In order to verify the accuracy of the conclusions would compare the value of L1, L10, L90 for the remaining terms of measurement noise on Position 2. The document results are given in tables(Table3).

Table 3 - Values of L1, L10, L90 for Position 2 at all terms of measurement

	L1[dB]	L10[dB]	L90[dB]
Term 1	64.1	55.7	42.1
Term 2	70.3	61.5	47.6
Term 3	70.8	62	42.6

It is clear that the value of L90 is almost the same for terms 1 and 3. The value of L90 in the term 2 is higher by about 5 dB which is attributed to the activation of all computer and printer in the room during working hours. It is evident that the value of L10 = 62 dB in term 3, is consistent with the fact that in

this period is increased traffic and the impact of traffic noise as a source of noise from the environment. We see that the level of L10 in term 3 is higher than in term 2 and the term 1.

In order to be comparing the measured values in positions that are located within residential premises used by the Regulations on Limit Values of Environmental Noise (Official Gazette of br75/06 12/08/2006), in which the equivalent noise in the visitors' room at no time of day exceed a value greater than 45dB for daytime. Obtained values of equivalent noise at all three positions in all three terms were above the allowable amount of 7-15dB (Table 4) depending on the terms of measurement, which indicates the need to apply appropriate measures to eliminate or reduce noise

Table 4 - Equivalent value of the measured noise in residential areas

	Pos.3 L _{Aeq} [dB]	Pos.4 L _{Aeq} [dB]	Pos.5 L _{Aeq} [dB]
Termin 1	59.2	60,3	58,7
Termin 2	55.1	54,3	53,8
Termin 3	52.5	53,8	51,7

What can be noted from Table 4 is that values of measured equivalent noise in all three terms in all three positions are approximately the same. It is evident that the values at the measuring position 5 is slightly less (0.5 dB) compared to the other two positions, although as a rule be as Position 5 on the seventh floor of the building. Cause of this phenomenon would be presence of "urban canyon" that eliminates the effects of reducing noise by moving away from its source.

Measurements that were conducted in three daily terms for a period of thirty minutes on the positions in front of the building, gave results that exceed the limit value of the equivalent noise level for residential and business zone of day of 65dB. Measurement results presented in Table 5 supporting the fact that the facilities built next to the road traffic are exposed to increased noise, and specific values indicate the excess in the range of 2.5 dB to 5dB. What is characteristic for all three terms of measurement at all three measurement points, is the fact that in any case we do not have a result less than or equal to the allowed values of equivalent noise of 65dB.

Table 6 - Equivalent value of the measured noise in front of building

	Pos.3 L _{Aeq} [dB]	Pos.4 L _{Aeq} [dB]	Pos.5 L _{Aeq} [dB]
Term 1	70,3	70,1	69,7
Term 2	68.8	68,2	68,9
Term 3	70.8	70,6	70,7

7. Solutions for problem elimination

Analysis of the results of measurements on the selected measurement positions, which also represent the working position, showed that the conditions defined in the Ordinance on the measures and safety standards of noise at work areas are not being met. To obtain an adequate working environment it is possible to implement the following measures and activities: relocate or isolate computer equipment from offices, implement an additional layer of monolithic glass on existing glass facades or make corrections to the facade of the building by a glass facade that will be replaced by facade of solid materials with higher degree of noise insulation, examine the possibility of installing a central ventilation system for an office building in order to eliminate the way of natural ventilation by opening windows. The elimination of noise in residential areas can be performed with better facade windows, which will eliminate the penetration of noise that exceed the allowable value of 2.5-5dB. A permanent technical solution for the problem would be installation of central ventilation and facade windows fixed to avoid the penetration of natural ventilation and noise in the living room. Unfortunately in this particular case it is not feasible and economically viable. Measurement results, related to the measurement sites in which the problem is noise from the point of environmental protection, have

shown that the present environmental pollution would be noise generated in the Boulevard. Measures to eliminate noise could be noted by better regulation of traffic flow, because the traffic is regulated by light signals, which inevitably causes long delays in the Boulevard especially during rush hour. One possible solution is to regulate traffic throughout the roundabout. Construction of roundabout to reduce congestion along the Boulevard and inevitably led to the elimination of traffic noise that has a pulse character (audible warning, move quickly from the station and emergency braking). Reduction of traffic noise implementation of artificial barriers in this case would not produce satisfactory results due to the presence of "urban canyon". It would lead to an increase in noise level of 3-7 dB with increasing altitude of the object relative to the barrier. Natural barriers (form of trees) are completely acceptable and represent the most effective form of struggle with the noise coming from the direction of the Boulevard. Implementation of green barriers achieves good result but only to a certain height, because of the presence of "urban canyon". All these measures for the elimination of excessive noise are mostly technical in nature and require significant investment. What is evident is that regardless of the implementation of these measures, there is no permanent solution, and the facts point to the certainty of escalating the level of noise increases the number of qualifying vehicles. Innovative solutions such as introducing the electrically-driven vehicles are now a distant future. As the only solution imposed by the implementation of planning and zoning measures that would stimulate business development, and all through the introduction of innovative policies to a major thoroughfare to build multi story commercial type facilities (supermarkets, furniture showrooms, art salons, bars, restaurants and the like.). Regarding the aspect of improving quality of life and eliminating the harmful effects of noise, this solution is absolutely acceptable, because objects on the road would be an ideal sound barrier for the facilities that would be built behind them, and used in residential / commercial purposes.

8. Conclusion

The presence of communal noise in the facilities are located close to city road is a health concern that affects the normal limits of human activity. Noise pollution is evident, and indicates the commitment to implement the measures for its elimination or reduction to the level allowed by law. There are a number of technical solutions that can be implemented but it calls into question the durability of such solutions and economic viability. The only permanent solution, which also stimulates business development and improve quality of life of citizens, are planning and zoning measures to introduce a rule that is the only major thoroughfare build multi story buildings that will be used for commercial purposes.

The Macedonian labour market and the role of university business incubators

Dimitar Nikoloski¹

¹Faculty of economics-Prilep, University "St. Kliment Ohridski", Bitola, Macedonia,
dimitar.nikoloski@uklo.edu.mk

The aim of this paper is to assess the perspectives of the Macedonian labour market with respect to the dynamic changes in the higher education system and, particularly the role of the university business incubators. During the two decades long period of transition Macedonian labour market has been characterised with depressed conditions manifested by high and persistent unemployment rate, strong labour market segmentation and prevalence of long-term unemployment. In such circumstances, the higher education system in Macedonia has been challenged to change its role in the society. During the period of transition we have witnessed a dramatic evolution of the Macedonian higher education system that has been characterised with proliferation of university centres, growing number of study programmes and development of new concepts such as introduction of dispersed studies, clinical education, compulsory internship etc. In this context, the role of the universities as generators of knowledge and promoters of entrepreneurial spirit has been repeatedly emphasised by both academics and policy makers. Although the idea for university business incubators in developed western economies is not new one, Macedonian higher education system is lacking sufficient experience about their role and socio-economic implications. In order to fill this gap, the focus of the applicative part in this paper will be development of a model for appropriate university business incubator. Hence, we would like to explore the feasibility of this model for developing entrepreneurial skills among students and to evaluate its potential impact on the Macedonian labour market. As a consequence, we will formulate suitable policy recommendations as guiding principles for policy makers in designing more competitive higher education system that would respond to the needs of the Macedonian labour market.

Keywords

Business incubator, Entrepreneurship, Higher education, Labour market

1. Introduction

One of the most important development goals of economic policy is the goal of full, productive and sustainable employment, *i.e.* employment for all those who are able to work, wish to be employed and actively looking for a job. This commitment becomes even more pronounced in the case of transition economies where economic shocks have contracted the level of employment and redistributed wealth. Having in mind the social implications of persistent open unemployment manifested in rising poverty and social exclusion, all transition countries have placed unemployment reduction among their most important macroeconomic goals. However, policy measures intended to reduce unemployment have to be based upon previous comprehensive analyses of the labour market characteristics and have to be implemented by credible governments.

In the circumstance when unemployment is high, the policy measures should simultaneously focus on both demand and supply side of the labour market [1]. This means that efforts for creation new jobs in the economy should be accompanied by accumulation of appropriate knowledge and skills of the workers and potential labour market entrants. In this context, almost all transition countries have paid

particular attention to reforms of their education systems in order to provide more competitive and marketable skill generation. Alongside the introduction of compulsory secondary education, we are witnessing dramatic changes in the higher education system in Macedonia that are still subject to criticism. One form of reconciliation of the demand and supply labour market policies is by creation of university business incubators as viable tools for development of entrepreneurial skills and creation high quality jobs.

Given the Macedonian labour market conditions and the on-going reforms of the higher education system, in this paper we aim to develop an appropriate model of university business incubator and to assess its potential impact on the labour market performance. Hence, with this research we intend to fill the gap in our literature about the implementation of university business incubators. For this purpose the paper is structured as follows. In the second section we will present the main features of the Macedonian labour market as a contextual framework of the research. A critical elaboration of the higher education reforms in Macedonia will be given in the third section. In the fourth section we develop an appropriate model of university business incubator for the case of Macedonia with giving emphasise to the potential stakeholders, supporting services and phases of incubation. Finally in the fifth section we conclude and formulate some policy recommendations.

2. Macedonian labour market performance

The main source of data for the Macedonian labour market is the Labour force survey. The first Labour Force Survey (LFS) in Macedonia was conducted in 1996, and since then we have detailed data concerning labour market trends [2]. The LFS is one of the most valuable sources of information regarding trends in the labour market. This survey is conducted according the methodology recommended by the International Labour Office (ILO) and the recommendations of the European Statistical Bureau (Eurostat). The goal of the LFS is to provide comparable data concerning the size and the structure of the active population with respect to international standards. According to the LFS the general trends in the Macedonian labour market are presented in Figure 1.

Figure 1 General trends in the Macedonian labour market

From Figure 1, we can notice that the unemployment rate in Macedonia during the period 1996-2010 is high and persistent. Moreover, the unemployment and employment rates manifest procyclical changes throughout the whole period of transition. Based on the LFS data, the unemployment rate in 1996 was estimated to be 31.9 percent, followed by period of steady decline until 2001 and a sharp increase thereafter. The unemployment rate steadily declined since 2006, but recent economic downturn has again reversed this trend. The unemployment measures based on the registered number of unemployed is even higher than the unemployment rate estimated from LFS. For instance, registered unemployment in 2000 peaked at 44.9 percent of the total labour force, which to our knowledge represents the highest registered unemployment rate among all transition countries.

The Macedonian labour market is characterised by a relatively stagnant unemployment pool that has been translated into increasing long-term unemployment[1]. For instance, long-term unemployment accounted for 80.7 percent of total unemployment in 1996 and it grew steadily until 2005 when it accounted for 86.7 percent of total unemployment. Moreover, the so-called very-long-term unemployment comprising the unemployed who look for jobs for more than four years is outstandingly high [3]. For instance, in 2005 the proportion of very-long-term unemployed accounted for 65.4 percent of total number of Macedonian unemployed population.

Long-term unemployment has significantly contributed to an erosion of skills and motivation of unemployed workers, making them less employable over time [4], [5]. The deterioration of skills further reduces the attractiveness of the labour force and contributes to a blurring of the difference between the states of unemployment and non-participation. After remaining unemployed for a long period of time, a considerable part of unemployed workers stops looking for jobs and quits the labour force. This is known as the phenomenon of 'discouraged workers,' a characteristic for depressed labour markets where labour demand is insufficient and unemployed workers face poor employment prospects. Discouraged workers do not fulfil the requirements of job search as a precondition to be counted as unemployed. On the other hand, they can easily re-enter the labour force if, conditions on the demand side of the labour market improve. The empirical literature has recently documented the problems that statistical offices in transition countries encounter in estimating the unemployment rates in the presence of large numbers of discouraged workers [3], [6]. How to categorise those that lie on the borderlines between unemployment on the one hand side, and employment or inactivity on the other side, may significantly influence the officially calculated unemployment rate.

Although we are unable to undertake a separate analysis, we also acknowledge the existence of underemployment. The term underemployment is used to designate the state of those workers who are able to find employment only for short periods of time, such as involuntary part-time workers, seasonal workers, day or casual workers, whose relative shares in the total workforce typically increased during transition [6]. In Macedonia this is the situation not only for many legally employed workers, but also for those who work in the informal sector. The category underemployed also includes workers whose level of education and professional skills make them overqualified for their jobs. This is the case of the workers with a strong educational background forced to perform various types of 'unfavourable' jobs in order to secure their basic existence [7]. Therefore, two basic forms of underemployment are persistent: visible underemployment, which is characterised by insufficient working hours and, invisible underemployment, associated with productivity losses due to insufficient use of human capital.

Having in mind the above-mentioned characteristics, we can argue that the labour market in Macedonia is affected by striking segmentation, meaning that certain social groups such as: youths, less educated workers, and women, face a much higher risk of unemployment and/or non-participation than the rest of the labour force [5]. This conclusion is in accord with the findings for some other transition countries [8], [9]. The high Macedonian unemployment rate has enormous social implications such as rising poverty and income inequality. For example, the estimated percentage of the population living below the poverty line in 2003 was 21.7, whereas the Gini coefficient in the same period stood at 0.373 [10]. Long spells of unemployment often leads to the degradation and dehumanisation of individuals in society, causing social exclusion and increasing the burden for the government of providing the necessary safety net. Consequently, the problem of unemployment is not only a personal problem for the people who experience it, but it has become a problem for the economy as a whole. Today, the Macedonian government bears a big part of the responsibility for the poor labour market performance that can be partly improved by undertaking appropriate policy measures. In this context, we next examine the reforms in the higher education system in Macedonia.

3. Challenges of the higher education system

Having in mind the depressed characteristics of the Macedonian labour market, the higher education has faced a challenging task to become a generator of competitive and marketable skills for students in order to promote greater employability. On the other hand, the insufficient demand on the Macedonian labour market prevents the policy makers from getting relevant feedback of the reforms efficiency. During the two decades long period of transition in Macedonia we have witnessed a variety of changes in the sphere of the higher education. The main features of this transformation will be briefly explained as follows.

First, the most striking feature of the higher education in Macedonia has been a proliferation of a number of new institutions and study programmes. For instance, twenty years ago in Macedonia

existed only two state universities and total absence of private initiative, whereas today there are 5 state universities and about 18 private higher education institutions [11]. Alongside this process, the existing universities have permanently diversifying their curricula by offering new and more competitive study programmes. The rising number of higher educational institutions and study programmes has contributed to increase of competition and creation of critical academic climate. As a consequence, the number of enrolled students in higher education in Macedonia marks an increasing trend which can be noticed from Figure 2. Recently, the number of enrolled students in higher education exceeded 60000 students per year, opposed to only 25000 students enrolled each year at the beginning of the 90's.

Figure 2 Number of students in Macedonian higher education

Second, all universities in Macedonia by 2010 have adopted the European credit transfer system and adhered to the Bologna process whose goal is 'to create a European space for higher education in order to enhance the employability and mobility of citizens and to increase the international competitiveness of European higher education'. This trend has been crucial for the process of harmonisation of the Macedonian higher education with the common European standards. However, the recent evaluation of this system shows a number of weaknesses that imply needs for further revisions and improvements.

Third, the adoption of the new 'Law for higher education' in March 2008 and the latest changes and additions in February 2011 have brought a number of novelties among which the most prominent are dispersed studies and compulsory study programmes in English [12]. Most of these reforms are dubious in their nature since they are not initially engendered from the academic milieu and are not widely supported by all members of the academic community. For example, the model of dispersed studies has been criticised because of its detachment from the concept of concentration of knowledge similar to that applied in university campuses. Taking into account that dispersed studies in Macedonia have been launched without providing the necessary technical and personal equipment, this model of studies is discriminatory in nature because it deprives the students in dispersed classes of their basic academic needs.

Finally, clinical education and compulsory internship have been promoted by the Ministry of education and science in Macedonia as most prominent ways for achieving a greater competitiveness of the higher education. However, these changes have not been accompanied by appropriate analysis of the capacity of Macedonian economy to serve/host all students for such forms of practical education. Having in mind that most of the Macedonian companies are small and medium in size and in the same time permanently face financial, technical and personal problems, it is clear that these intentions should be realised with more soundness for the current economic performance.

4. A model of university business incubator

From the previous section it is evident that higher education system in Macedonia has been recognised as an important factor for generation of essential knowledge and skills that give students advantageous position in the labour market. However, as previously noticed, the higher education system in Macedonia is lacking an establishment of suitable relationship between the practical needs

of the students and capacities of the Macedonian economy real sector. Therefore, in this section we propose a particular strategy consisting of establishments of university business incubators (UBI) that would help enhancing the students' entrepreneurial skills and, in the same time, would corroborate with the functioning of Macedonian economy.

Historically, incubators appeared in developed countries in the early 1980s, whereas in developing countries they are a quite recent phenomenon [13], [14]. Incubators can be differentiated according to several criteria such as: their mandate (for profit or non for profit), the type of sponsorship (private, public or mixed), their focus (mixed use or niche), geographic area (rural, urban, suburban) etc. The goals of the incubators may also vary but, generally encompass economic development and generation of new jobs, property venture development, fostering entrepreneurship in transition countries, development of export production etc. [15], [16].

An university business incubator is a particular type of incubator because it has a purpose to bring together various stakeholders in order to offer a variety of services to the students who have potentially successful business ideas and help their start-ups to get established and evolve to the point where they can operate independently. To our knowledge, such type of business incubator in Macedonia has still not been established hence, in our effort to develop a suitable model of UBI we address the experiences from similar types of incubators in developed countries and use the best proven practices around the world.

The role played by universities consists of linking research, technology, capital and know-how to leverage entrepreneurial talent, accelerate development of new technology-based firms and speed up the commercialisation of technology [17]. The evidence from the developed countries shows that university link to the incubator reduces the probability of new venture failure [18]. In particular, the UBI should provide a number of support services for students business projects and assist them toward becoming sustainable business entities. The potentially successful business projects should pass through several phases starting with selection, tenancy, reviewing of graduation and eventually leaving the incubation process. The conceptual framework of the proposed model of UBI is presented in Figure 3.

Figure 3 A model of University business incubator

From Figure 3 we can notice that our model of UBI generally consists of three building blocks namely, potential stakeholders, supporting services and phases of incubation. In what follows we separately analyse each of these elements.

4.1 Potential stakeholders

Alongside the universities as potential stakeholders in the university business incubator may appear the government authorities and private businesses. Therefore, in order to meet the interests of all potential stakeholders, we recommend that personnel should have mixed background ranging from academic, local government and business area. The management function should be delegated to a

director who is full time university professor and has considerable experience in the domain of business advising. In this context, UBI would help strengthen interactions between university and industry, promote research commercialisation, and give opportunities for university staff and students to better utilise their capabilities [19].

Particularly susceptible partner in this model of incubation are local government authorities that can contribute to the functioning of the UBI by providing a variety of services such as premises and other logistic support. In return, the benefits of a well-managed UBI for the government can be viewed in the fact that incubators help overcome market failures, promote regional development, generate jobs, incomes and taxes, and demonstrate political commitment to small businesses.

Private businesses may also cooperate with the business incubator in finding potential partners, engage in research-based technology, developing new products etc. In return, businesses can benefit from UBI by developing opportunities for acquiring innovations, supply chain management, and helping them meet their social responsibilities.

4.2 Supporting services

According to experience from several successfully established UBI their main goals include providing variety of services such as office space, shared facilities, business consulting, access to capital, networking and, resources, so that the companies within the incubator learn how to develop and grow their business in order to be competitive in a market economy. Furthermore, the proposed model of UBI may allow two types of incubation i.e. physical and affiliate incubation. Students involved in full incubation would receive physical space, whereas affiliate businesses would receive all of the services except physical space. Students in the affiliate program may not be ready to occupy physical space in the incubator or the nature of the business may not warrant physical space.

Since, all beneficiaries of the UBI will be enrolled full time students, the university may gradually incorporate the UBI activities as an extracurricular programme. Once accepted into the UBI programme, students will be required to participate in variety of activities that we shortly describe. First, as part of the learning process, programme staff needs to be able to review the financials of the company with the student in order to assist in their growth and strategic planning. Second, students have to select and attend relevant seminars to his/her business offered by the university. If the student needs specific course which is not offered, it would be provided by outside consultants. Third, periodically all UBI tenants will meet to hear a guest speaker, network and discuss their ongoing business endeavours. Finally, each tenant will be required to meet with the UBI director individually according to a previously prepared schedule.

4.3 Phases of incubation

Process of incubation consists of several phases starting from selection, tenancy, review of graduation and eventually exit from the incubation and starting post-incubation period. The phase of selection is one of the most sensible parts of the incubation process since it largely determines the outcomes of the incubation. In order to make correct selection decision, the process of selection should be done by a competent committee consisting of several experienced members. The applicants should have opportunity to apply on a regular basis once or twice a year, whereas the projects will be evaluated according to a number of indicators.

The period of incubation or tenancy should be limited to one year with or without possibility to be extended after the reviewing of graduation. As successful businesses will be classified those who demonstrate potential ability to operate in a market environment without supporting services from the UBI.

The assessment of the performance of business incubators has been stressed as a critical element to its success [20]. With an effective assessment the incubator may continually improve its functioning, attending and exceeding the expectancies of all the players involved in the process. For this purpose we propose a number of indicators for the assessment of UBI such as indicators of pre-incubation process, indicators of selection process, indicators of residence period, indicators of the graduate companies and indicators of the management of the incubator.

5. Conclusions and policy recommendations

From the previous analysis we can draw several concluding remarks that can be used as guiding principles for policy recommendations. First, the depressed characteristics of the Macedonian labour market impose needs for creation of global agenda for fighting high and persistent unemployment. Having in mind the pronounced labour market segmentation, the measures have to target mainly the disadvantaged labour market segments. Second, the reforms of the Macedonian higher education system have not been proven to have significant positive impact on the labour market performance. As a consequence, we stress the importance of undertaking a large scale empirical assessment of the reforms with purpose to identify the existing gaps. Third, the concept of university business incubator that so far has not been tackled in Macedonia may play crucial role in the reconciliation of the labour market policies that should be simultaneously undertaken on both demand and supply side. Having in mind that university business incubators as a target group have younger and educated population, they can be used as alternative strategy for creation new productive jobs and fighting youth unemployment.

As a suitable strategy we recommend launching a pilot project of university business incubator that can be utilised in assessment of strengths and weaknesses of the proposed model. In this context, the policy makers have to be aware of the modest entrepreneurial potential in post-transition countries and adequately to project the potential development scenarios. The potential effects from implementation of UBI can be divided into direct or short-term and indirect or long-term effects. Among the direct effects the most important are creation of new companies and jobs, increased generation of revenues from taxes, decrease of unemployment etc. On the other hand, the improvement of the business climate and creation of entrepreneurial spirit are most important spin-off effects that on the long run may exert positive influence on the Macedonian economy.

From this perspective, the adoption of the model of UBI as a standard in both state and private higher education institutions in Macedonia will have large positive impact on the Macedonian labour market performance in several manners. First, creation of new and sustainable businesses will absorb a part of the young and educated labour force that would otherwise remain unemployed. Since, the young and educated segment of the labour force marks a continuous growth, we hope in the near future to see at least substantial decrease of the unemployment rate for this segment of the labour market. Furthermore, increased budget revenues from taxes, if adequately utilised will improve the infrastructure and further exert positive impact on the investment climate. In this way, the economy would enter the so called 'virtuous circle' that reinforces itself through a feedback loop and has favourable results in terms of moving the Macedonian economy from the sub-optimal to an optimal equilibrium. Finally, increase in the awareness of self-employment opportunities will stimulate the entrepreneurial endeavours and induce creation of new jobs.

PPP experience in Macedonia

Marjan Nikolov¹

¹Center for Economic Analyses-CEA research think tank, info@cea.org.mk and Integrated business faculty, marjan@fbc.edu.mk. Preparation of this paper is supported by the Open Society Institute Think Tank Fund Budapest.

According to the World Bank, in the period 1990-2001 year, the world invested about US\$754 billion annually for PPP projects. In 2009, 241 infrastructure projects (include primarily medium-size and large projects) with private participation reached financial or contractual closing in 42 low- and middle-income countries. These projects involved investment commitments of US\$83 billion. Studies from international financial institutions indicate that although the authorities provide various subsidies to the private investors, still there is restraint among investors to invest in developing countries, because involuntarily are accepting part of the commercial, financial and political risks. In such circumstances, central governments are developing special funds in order to provide reduced transaction costs, increased transparency and consistency in evaluation and allocation of public support. Here should be considered that the PPP as an option for increasing the quality of the services and range of people who use these services requires increased awareness of this instrument, first strengthening the partnership between central and local governments, and then between the public and private partners.

However, it is necessary for Macedonia to strengthen the legislation, not so much for the concessions as for the private finance initiatives, taking into consideration, how Macedonia is organized and what is the intergovernmental legal framework. At central level economy Macedonia has macroeconomic stability as public good that can be used as an argument for attracting investors and private partners. Financial capabilities of local governments are generally modest, and there can be considered establishment of a fund for investments in infrastructure who will not only provide funds but will assist as knowledge centre in the preparation of tenders and contracts for PPP.

This paper will give overview of the legislative and institutional set up of the PPP in Macedonia, the challenges and needs for PPP and the experience and lessons learned so far by analysing the few PFI attempts in Macedonia.

Keywords

Public private partnership, public sector comparator, public services, risk management, value for money.

1. Introduction

According to Private participation in infrastructure – PPI database of the World Bank, while remaining strong, private activity in infrastructure declined and became more selective in 2009. Investment commitments to infrastructure projects with private participation in 2009 were at their third highest level, but most of the new activity was concentrated in projects of US\$1 billion or more and in a few countries. Brazil and India saw a strong growth in investment and they attracted half of the total investment in 2009. If Brazil and India are excluded, total PPI investment to developing countries would have fallen by 26% in 2009 compared with 2008.

In Macedonia, the Public Investment Programme – PIP 2009-2011 [1] consists of 90 ongoing investment projects. The total cost of these projects is estimated at 2,492 million EURO. A part of the costs, amounting to 533 million EURO has been executed by the end of 2008. The fulfilment of certain investment activities, estimated at 478 million EURO, will be shifted beyond 2011. It is said in the PIP

that the Government's imperative is to engage foreign investments primarily through concessions, donations, public private partnerships – PPP, direct and joint ventures. PPPs are mentioned in the main text of the PIP for projects in the following sectors: hydro power plants and road network construction. In the PIP there is also a priority list of PPP projects in the sectors of energy and health in amount of value of 381 million EURO.

In the Fiscal strategy 2010-2013 [2] PPP is mentioned in the context of the local self government-LSG: *"...a proper effect is expected from the initiative of the private sector in the public sector through the PPP as incentive to improvement of the local service quality and increase of the revenues"*. Center for economic analyses'-CEA study [3] on the role of LSG in economic development and macroeconomic stability from 2007 shows that only 7 out of 13 municipalities (at that time only 13 municipalities have had viable strategic plans to analyse) have defined medium-term capital expenditure framework with explicit estimates of their fiscal needs. Most projects are focused on improvement of the infrastructure, employment creation, agricultural and tourism development, support of local businesses and entrepreneurship, social inclusion activities.

The investment needs in Macedonia both at central and local level government are already confirmed not only by the World Bank PER documents [4] and domestic researchers [5] but with the anecdotal fact of lesser satisfaction with the public services quality by the citizens of Macedonia. The needs for investment are relatively high given the relatively low fiscal space at the central and LSG budgets and low domestic and foreign direct investments-FDIs in Macedonia. The donors are downsizing their engagement in Macedonia, the capacity to utilise the IPA is weak and it seem that the PPP can be the instrument to settle the often contradictory goals among the government, investors and consumers. This paper will not go into the definitions of the PPP or deeper into the needs of it instead will give an overview of the strategic institutional and legal set up needs so that Macedonia might attract more structured investors interested in PPP opportunities.

2. Legal and institutional set up of PPP in Macedonia

The concessions and the PPP concept were institutionalized in Macedonia with the Law on concessions and other types of PPP ("Official Gazette No. 7/08,139/08, 64/2009 and 52/10). There is a draft new law available at the Ministry of economy web site for almost 2 years (<http://www.economy.gov.mk/WBStorage/Files/Predlog%20zakon%20za%20JPP.pdf>) but not yet adopted by the Parliament.

The Law on concessions and other types of PPP regulates separately concessions from PPP and allows for institutional and contractual PPP. The state help is not allowed in PPP case. Institutionally the Law regulates establishing a PPP Council for: *"...efficient policy making of the Government in the area of PPP"*. The Council should prepare suggestions, opinions and initiatives that should be the base for preparing the Strategy for realization of PPP and concession projects in Macedonia.

Members of the Council are representatives from the central government and the local government and two experts of which one in law and the other in economy. The experience is that the Council was established but apart from the one meeting they had that I am aware of nothing else has been done so far. Its role is also blur and of less need the way it is prescribed in the law.

The strategy should be adopted by the Macedonian Parliament upon Government's proposal but not one has been prepared so far. There was one attempt for preparing PPP Strategy with a help from USAID [6] but it was not successfully ended by the Ministry of economy.

The new draft law has been prepared after thorough considerations from the Sigma project [7] especially lining it with the Law on procurement and introducing the appeal as a right for the private partners. The new draft law propose establishing a unit within the Ministry of economy which among other things should manage a PPP register for implemented PPP projects and record for started but not implemented PPP projects as well. The Ministry of finance will control the collection of the concessions. It is also prescribed that the public partner should ask for approval for the annual financial obligations that arise from the PPP contract from the Ministry of finance. Thus, the law is prepared by Ministry of economy but it seems that there is significant role of the Ministry of finance as well. Given the experience of coordination (in)efficiency in coordinating the economic sectors in Macedonia this set up of PPP responsibility is challenging for Macedonian PPP law.

As a result of the draft law it is expected the following by laws to be adopted: elements and contents of the PPP feasibility study, the content of the PPP contracts, the framework and content of the registry and proper reports for PPP.

3. PPP implementation and challenges in Macedonia

There are challenges to PPP implementation in Macedonia. Sigma project [7] emphasises the lack of understanding and expertise in project financing, which is an essential requirement for many PPP structures and that public bodies in Macedonia do not have the expertise to negotiate a PPP project.

The EBRD report [8] is ranking Macedonia in the middle, with medium compliance of the Law on concessions and other types of PPP compared with the international concession standards and principles.

When considering the PPP effectiveness in Macedonia we must take into account the fact of lower than potential economic growth, slow transition to efficient market economy, relatively high poverty and unemployment rate in Macedonia. Given this set up, there are few questions we should at least discuss:

- Is there political will and champions for implementing PPP in Macedonia?
- Does Macedonia have needs assessment at local and central level as a precondition to discuss PPP or it is just pushed forward as a latest political toy?
- Do we have the right legislation and by laws at place?
- Are the projects commercially attractive to financial institutions and commercially attractive to private partners and are they affordable to the public partner?

Discussion follows upon these questions.

As for the political will and champions we cannot identify neither will nor a champion that can foreseen the strategic importance and ask for system approach to make the ambient for PPP in Macedonia more transparent. There are few examples from our experience. First are the often questionable initiatives of public partner to go for/initiate PPP without proper feasibility study stating that the PPP study is just unnecessarily expense? This of course is because of the lack of knowledge and awareness of what PPP is exactly and that PPP requires trust and real partnership between partners, sharing risks and proper expertise to allocate risks, circle the financial structure and foreseeing all the aspects systematically in the contract. At all the times PPP has been seen in Macedonia as a “pocket bank’ where the public sector can take money from the private partner so that the public sector can continue to work as usual and more, stigmatizing the private partner if searching for profit. Another example is when the private partner does not receive the PPP compensation from the public partner on time as agreed and by that not only not complying with the contract but also creating liquidity problems for the private partner. The private partner, in order to attract attention to the public partner, stops delivering the service and the public partner treats to raise formal charges against the private partner. This of course, is not best practice of PPP in Macedonia. Recommendation here is that there is a need for one minister at the government to lead an all encompassing system for PPP implementation starting first with training on what PPP is for decision makers. The public sector in Macedonia, both administration and politicians should know that PPP is not and cannot be used by politicians to transfer liquidity problems of public sector to private sector. This will ruin the credibility of the country and will detract potential investors both domestic and foreign.

On the question if Macedonia has central and local level intergovernmental relations for introducing smooth PPPs the experience is not so good. The decentralization in Macedonia is more of a deconcentration than devolution type. For example, if a municipality wants to go for a PPP say for kindergarten, the municipality can use in theory the block transfers from the central government for child protection for its best use. The risk arise because if the public partner pledge the block transfer to the private partner in order to achieve value for money the private partner cannot employ people in the newly kindergarten as it must wait for Ministry of finance’s approval for those new employees and also, if it is privately run it is under risk that this kindergarten will not be considered in the fiscal plans for block transfers for the next fiscal year. In that way the quasi devolution of the fiscal decentralization creates such risks that makes risky and/or practically impossible to exercise PPP at local level for “decentralized” competencies such as education and child care in Macedonia.

Next issue is if there is really a proper needs assessment at central and local level for infrastructure projects in order to make pre-feasibility PPP assessment as of what project are affordable and what projects provide good value for money so that it can be considered as PPP projects. One modest attempt is made with the PIP (even though not transparent and without knowing under what criteria or analysis the list of priority PPP projects are selected in the PIP) but at local level the author is not aware of systemic analysis of strategic plans of municipalities in direction of identification of what projects can be considered as PPP projects. Recommendation here is again for the top decision makers to identify one champion for PPP that can drive the necessarily reforms especially for

decentralization and proper needs assessment for PPP. Maybe to make the PPP identification a part of the budget process both at local and central level government i.e. part of the preparation of PIP could be a good start.

As for the legislation and institutional aspect of PPP we are still waiting for the new law, the council is not operational, the registry does not exist, there is no strategy adopted etc. Next I will discuss one important strategic issue about how PPP national unit should be organized: one unit or in nodes. As it is envisaged in Macedonia the idea is to have one unit at Ministry of economy (with significant involvement of the Ministry of finance). In the next table I give overview of the pros and cons as if it can be organized as nodes or as one national unit.

Table 1 Pros and cons for establishing a national PPP unit versus PPP departments (called “nodes” or “cells”).

PPP unit	PROS	CONS
Nodes/Cells at ministries and LSGs	<p>It can provide more efficiency through existing specialization and sector knowledge</p> <p>Can easier identify, prepare and offer sector PPP projects to investors.</p> <p>Can easier work with Project development facilities-PDF</p>	<p>Usually keeps important information to itself until it is too late</p> <p>Not good for “approval activities”</p> <p>No formal network with other nodes/cells</p> <p>Not good for functional development (technical, legal, procurement)</p> <p>Not good for standards, manuals</p>
National at Ministry of economy	<p>Private developers work best when they can negotiate with one single governmental committee or representative group, rather than having to pursue completely separate negotiations.</p> <p>Infrastructure project financing can be politically controversial; a high level of political leadership and clout is usually needed to head the government’s steering committee. Placing existing infrastructure line ministries in charge of this process themselves is a conflict-of-interest that can result in projects failing to be completed or implemented.</p> <p>Project financings involve a different kind of evaluation of government risk exposure (over the entire term of the project), and as such our Government can get the best results when we can retain experienced outside line ministries PPP government specialists to help them with the large and specialized tasks of analyzing, structuring, tendering, negotiating, and contracting for project financings.</p> <p>PPP don’t require sovereign guarantee and they appear more “affordable” to the line ministries. Ministry of finance can more efficiently monitor and calculate the affordability of government PPP payments to the private sector thus, it can provide consistent management and monitoring of the PPPs and keep the macroeconomic stability</p> <p>Can easier make needs assessment for training, research and analysis of the PPP status in the country.</p>	<p>Doesn’t have the sector knowledge</p> <p>Can be too administrative and bureaucratic in a fiscal devolution set-up</p> <p>More expensive PPP-knowledge archiving</p> <p>More difficult to measure the key part of its performance on the actual PPP transactions completed, not just on promotional and capacity-building activities. Line ministries can do it better</p> <p>Not good for ‘promotional activities”</p> <p>Not good for sectoral development (energy, roads)</p> <p>Look only on the budget and not on the long run development</p>

At this moment it is difficult to give clear cut recommendation on what is proper for Macedonia. The criteria to make a choice can be if we have more information and proper analysis about the level of knowledge in PPP in the country, the commitment of the decision makers, the needs assessment of the infrastructure and services needs assessment, the government priorities, political will etc.

Next important issue is the financial aspect and establishment of so-called project development facilities-PDF. Usually PPP requires well prepared PPP pre and feasibility studies that on the other side require knowledge in project finance, PPP finance structures, sectoral knowledge, tender and

contract preparations etc. At the moment in Macedonia there is no PDF for PPP. Having PDF requires a clear commitment and seriousness about implementing PPP at higher scale in Macedonia. Such a PDF can work as a knowledge centre as well and giving trainings, paying and matching costs for studies and research in PPP etc. So far, the municipalities are paying out of own budgets and/or with donor help PPP studies but this is incidental and there is no track record from the central government or the association of LSG – ZELS about the PPP initiatives, contracts, on-going projects, projects stopped etc. The central government on the other side also pays out of the budget or through IFIs feasibility studies.

Last but not least is the political acceptability of PPP given the level of poverty and unemployment in Macedonia and especially the bad experience with the privatization we had. In that regards what can be done in Macedonia at least is: Clear pro-poor targets for the private partners, proper pro-poor tariff systems if needed, PPP linked to performance output, credible, transparent, independent, experienced and knowledgeable regulatory agency for regulated sectors. Also, proper risk allocation might bring good value for money (risk adjusted Public Sector Comparators-PSC) that can be used to mitigate adverse effects of poverty.

3. Conclusions

The need for modern infrastructure and better services is evident in Macedonia. The lack of proper fiscal space both at central and local level budgets makes the PPP an opportunity to meet the citizen's needs for better services and value for money for the taxpayers money. On the other side there is a risk in going for PPPs if there is a general lack of political will and proper legislation at place. In Macedonia few issues should be considered. First, it is not enough to have proper law (which by the way Macedonia do not have) if there is lack of awareness and knowledge of what PPP is and if there is a lack of accountability from the central and local governments and lack of performance culture at the public administration. Then, there is a need for knowledge centre that will be immune of political appointees and that can help in preparation of tenders, studies, researches, contracts and training materials for PPP. The mixed competencies between Ministry of economy and Ministry of finance in the area of PPP especially when there is a lack of proper law and by-laws creates additional risks especially given that PPP is off-budget category that can create macroeconomic risks.

Innovative Entrepreneurship – basis for getting involved in the globalization and regionalization processes

Ljubisha Nikolovski¹

¹Agency for Entrepreneurship Support of the Republic of Macedonia, Skopje, Macedonia,

The economy of the Republic of Macedonia, if it persists in remaining competitive, needs to rely on the competences of its entrepreneurs, i.e. the small and medium enterprises. When describing an entrepreneur, the most commonly used characteristic is the readiness to undertake risk with a desire to make profit. However, the basic characteristic of the entrepreneur and entrepreneurship in general, is the innovativeness and readiness to apply innovations. The application of innovations enables the entrepreneur to offer something new on the market, be competitive and increase his market share. In this context, innovative entrepreneurship is central in the market oriented economies. Numerous examples of technological and economic transformation in the world confirm the big role of the entrepreneur, his creativity, determination and persistence.

The paper will also review the activities of the Agency for Entrepreneurship Support of the Republic of Macedonia, directly connected to the relevant subject.

Keywords

Competitiveness, strategy, human resource, small enterprises, training

1. Introduction

The openness towards the world market and the inclusion in the globalization processes and regionalization is certainly the road towards economic development of a small country like the Republic of Macedonia. Today, technology erases economic boundaries, thus nations, if they insist on remaining competitive, have to rely on the dynamics and ability of their entrepreneurs. In spite of the fact that multinational companies used to play the key role in economic growth and development, today small and medium enterprises (SMEs) are becoming ever more so significant in all industrial economies.

The most frequent feature used to describe an entrepreneur is the readiness to undertake risk in order to make profit. However, the thorough analysis of the entrepreneur, and/or entrepreneurship, points to innovativeness and readiness to accept innovation in the broadest sense of the word. Innovativeness enables the entrepreneur to offer something new or better and:

- Be competitive,
- Extend the market,
- Be a step forward compared to others.

Thus, the entrepreneur is a person who, by applying innovation on the market and by accepting the business challenge makes an attempt to make profit. We say “makes an attempt to make profit” because the absence of profit does not mean that someone is not an entrepreneur. There are a large number of successful people who did not make their dream come true in their first attempt.

Joseph Alois Schumpeter, a representative of the Austrian school, has placed the entrepreneur in the centre of economic development and considers the entrepreneur to be the force causing that development. In his theory of creative destruction, the innovative entrepreneur is the main cause of the market imbalance. In contrast to this theory, the neoclassical theory understands a systematic activity on the market, i.e. the sellers and buyers by adapting to the supply and demand react to the

change of prices and in this way establish the market balance. The latter is called by Schumpeter a "circle flow process" where the entrepreneur is unnecessary because economic life goes on always in the same way.

It is with the entrepreneur that development takes place, which practically means disruption of the circle flow. According to Schumpeter's theory, the entrepreneur brings innovation to the existing markets which destroys them by creating new demand. Development includes introducing innovation which Schumpeter considers the same as new combinations of production sources:

- Introducing new doctrines,
- Introducing new production methods,
- Opening new markets,
- Conquering new markets for raw material supply or semi products,
- Introducing new organization.

The entrepreneur is the person introducing new combinations, i.e. he/she is the one with the innovative role.

2. Innovation and company growth

In contrast to the importance of innovation, small enterprises have a rather limited possibility for their implementation and even smaller possibility to invest in the necessary research which precedes them. In this sense, this inability needs to be compensated for by public institutions and organizations for supporting businesses. On the other hand, small enterprises do not have information and knowledge on the research which is being done by the academy, universities, faculties and institutes. This gap must also be overcome by the public institutions. In this sense, the Agency for Promotion of Entrepreneurship of Republic of Macedonia (APERM), being one of the leading institutions at local level, provides this information to their end users through a network of local and regional centers, company incubators and other business support organizations.

Enterprise development as a long or short term process, is primarily a necessary and indispensable response to the changes which take place daily in the company's surrounding. If there is no adequate response to the market change, or there is no response for a certain period, possible negative implication for the company will occur, which may result into the need of serious efforts.

Each enterprise has its own life cycle. Depending on the stage of the life cycle, adequate interventions are necessary, i.e. elements of suitable restructuring which will result into suitable development. The practice points to the following:

- Small company managers most often decide to design and implement their own business development plan,
- The relevant decisions for achieving the planned development are most often based on insufficiently valid data and information.

Within the given information one should also have in mind that the institutional network for SME development is in the process of continuous capacity improvement and increase. In these conditions, one can say that in many cases the entrepreneurs' behavior to approach the establishment and development of their businesses on their own is acceptable. On the other hand, the entities included in this institutional network accept the challenge of permanent training and education in order to achieve a higher level of skills in providing quality services. The latter needs to be positively accepted due to the fact that each of these institutions are also in the stage of their own development in line with their clients' requirements and the market demand. What needs to be achieved in the upcoming period is higher level of transparency of information for the various opportunities offered by these institutions. This is more so because it is recently the case that entrepreneurs do not know how and where to find certain information.

The business support offered by the AESRM in their work so far provided for the possibility of successful SMEs development in the state. By supporting SMEs development, APERM contributes to the improvement of the overall social and economic environment in the Republic of Macedonia.

Innovative enterprises is one of the latest trends in Europe. It means that innovative approach is used in the management and leadership in order to achieve better results, both regarding profit and human resource relationships. According to Peter Drucker "innovativeness is an economic and social category rather than a technical term". German economists J.H.Pichler, J.H.Pleitner, K.H.Schmidt, point to the fact that "innovativeness includes all improvements, enhancements and novelties in the processes and works in general which result into a concrete economic and social benefit."

It can be concluded that innovations are in the essence of the entrepreneurial process and are defined as being the main changes aimed at:

- Improving competitiveness and
- Enhancing the ability or know-how for further development.

The following stages are distinguished from innovation idea to its commercialization:

- Innovation idea,
- Concept,
- Product/process elaboration,
- Pilot product/process
- Idea-innovation marketing or commercialization.

Without the last stage (implementation/commercialization) we cannot speak of innovation.

While going from one to another stage (transfer point), there is threat of ceasing or impeding the process due to:

- Understanding the idea,
- Lack of adequate concept,
- Lack of adequate knowledge, methods and other capacities for initiating and successful end of the pilot stage, and
- Failures in the designed promotion and marketing activities.

The following obstacles for introducing innovation may be accompanied by others, but these will be the main ones:

- Emotional impediments,
- Cultural impediments,
- Environmental impediments, and
- Impediments regarding the individual's ability to manage the process of implementing the innovative idea.

In conditions of overall globalization, the product life cycle is continuously shortened. On the other hand, there is a need for permanent innovation – improvement in every stage of the company life cycle. This is exactly why only companies with innovative staff and creative culture will survive. This particularly refers to the stages of company development, i.e. its management and fitness, a stage in which the company, if managed successfully, may stay for a long time.

Numerous young organizations, including those which are in the aging stage, have the following in common:

- Flexibility, i.e. inclination towards change, and
- (in)ability to control the organization.

Figure 1 Flexibility and control with growth and aging

Young organizations are characterized with high flexibility (prone to change) and inability to control. Aging organizations are characterized with low tendency towards change (with falling flexibility) and growing control. The achievement of top form is practically a combination of the mentioned typical features. This is a permanent challenge of any managerial or management structure.

When the company growth and development, i.e. competitiveness, are discussed, the following elements are very important:

- Research and development (know-how design),
- Innovation (know-how implementation, i.e. commercialization).

Unfortunately, the companies in the Republic of Macedonia tend to believe that resources devoted to research and development (R&D) are considered to be a waste. These funds are never treated as investment or anything that would improve the business in the future.

3. Agency for Entrepreneurship Support (AES)

AES is a state agency and important institution at national level for the implementation and coordination of domestic and international support for the small economy sector.

In the following text I am going to highlight some of its priorities in the period 2004 – 2010:

- Self-employment support, a project by the government of the Republic of Macedonia: Credited self-employment and grant self-employment,
- Expert assistance in the transfer of new technology, know-how and resolving difficulties in small and medium size enterprises in their operations,
- Incentives for counseling and assistance through a voucher program for giving advice to unemployed people and small active enterprises,
- Information services for entrepreneurs from “info point“ organizations for business support,
- Raising SME awareness of the value of introducing quality standards.

3.1 GTZ – technology transfer

The aim of this project was to provide expert assistance in the implementation of the transfer of technology and know-how and resolving challenges in 10 small enterprises in the following production areas: rubber production, furniture, food, chemical products, construction, and machinery and equipment production.

3.2 SME support – project of the European Agency for Reconstruction (EAR)

This project helped over 100 mainly small companies with domestic and international experts and trainers to implement know-how in certain production conditions. The results were multiple, not only for the beneficiaries, but also for the experts and the public sector, i.e. the institutions which were involved in the process of supporting entrepreneurship in general.

3.3 European Information and Innovation Centre in Macedonia (EIICM)

The government of the Republic of Macedonia is permanently proposing a large number of activities to help small and medium size enterprises in their operations and in this respect is implementing a large number of projects and measures to enhance the business environment. One of the projects related to SMEs is the support for the one-stop shop system for small and medium size enterprises – the European Information and Innovation Centre in Macedonia (EIICM).

EIICM was established in 2008 as part of the Enterprise Europe Network. The Macedonian small and medium size enterprises were thus provided with the opportunity to network and achieve cooperation with over 400,000 enterprises in EU and companies from other non EU member states which are included in this network. The objective of the project was to enhance SMEs' competitiveness and innovativeness, increase access to information on doing business and improve their technological level. Since the network, in addition to enterprises, also includes scientific and research institutions, a large number of applied scientific and research projects will be implemented, which is beneficial not only for the SMEs, but also for the academic and research potentials of the Republic of Macedonia.

EIICM is a key instrument for the implementation of numerous projects related to competitiveness and innovativeness not only in the domain of SMEs, but elsewhere too. This Centre is directly linked to the European Commission, and provides for the opportunity to implement a lot of joint programs and projects. Enterprise Europe Network, is also a key tool for the implementation of the Competitiveness and Innovation Framework Program (CIP) of the European Union.

The project in the Republic of Macedonia is managed by a Project Consortium composed of four partners, one of them being the APERM. The following is a presentation of the activities related to the transfer of know-how, technology, innovations and research and development:

- Promotion of programs and funds for funding innovation;

- SMEs support for finding/offering an innovative technology through: profiling (profiles placed in the internal base of the network), company missions, multilateral broker meetings, fair exhibitions etc.,
- Support for other target groups (academies, scientific and research centers, large companies, innovators) to find partners for joint projects for innovative development;
- Conducting technology audits of SMEs, innovation management training, intellectually property rights;
- Cooperation with other organizations for innovation in the state, and support for young companies through product development training, innovation management etc.;
- Information for SMEs about EU programs for research and development (FP7 program);
- Stimulation for SMEs to take part in the research and development programs by distributing calls for project proposals, project proposal design training and support in finding potential partners for EU programs through the Net.

4. Conclusions

It is indisputable that the SMEs sector is one of the main pillars in the economy of any country. The SME and entrepreneurship development in the Republic of Macedonia is accompanied with all challenges, problems and directions of movement as part of a global and long-term strategy. Within these processes the Agency for Entrepreneurship Support has established a position in the past period which is becoming stronger and is recognized both in the Republic of Macedonia and abroad. On the other hand, entrepreneurs and SMEs' needs are sizeable and require a high level of professional approach in providing various types of support for their development. In this respect, it is necessary that the APERM is in the future more involved in increasing opportunities for entities to enhance their participation in the network already established.

Innovation support framework for SMEs in Serbia

Dejan Ninković¹, Igor Svetel²

¹Faculty of Mechanical Engineering, Belgrade, Serbia, dninkovic@mas.bg.ac.rs

²Innovation Center, Faculty of Mechanical Engineering, Belgrade, Serbia, isvetel@mas.bg.ac.rs

Recent EU effort in building a knowledge-based society revealed problems connected with the utilization of R&D results within production facilities. Unwillingness of researchers to work closely with production facilities, and SME's lack of resources to track technological development were two main causes of this situation. Answer, which provided a good solution to the problem, was the establishment of Innovation Relay Centers. The mission of the IRCs is to support innovation and transnational technological co-operation in Europe with a range of specialised business support services. The initiative was successful and soon spread among more than 33 countries. Enterprise Europe Network (EEN) was developed as the integrating framework that incorporates all local initiatives and provides unified gateway to all required information.

The paper illustrates innovation support framework for SMEs in Serbia. The first phase of framework's development was the formation of the IRC Serbia, through gathering of interested domestic partners around Innovation Centre of Faculty of Mechanical Engineering (ICMF) along with signing of Consortium Agreement with chosen partners. The second phase was development of EEN-Serbia by formation of the Consortium, successful submission of the project proposal (ref. ENT/CIP/07/0001a), followed by signing of the Contract with EU Commission. Today activities of IRC Serbia and EEN-Serbia are coordinated. The IRC Serbia has developed and maintains Content Management System that provides all necessary services for EEN-Serbia Web portal. The EEN-Serbia continually disseminates information, raises awareness among SMEs, and organizes meetings among interested parties. Their joint efforts resulted in the growing presence of Serbian firms on relevant fairs, matchmaking events, and online partner search databases.

Keywords

Innovation, networking, IRC Serbia, EEN-Serbia

1. Introduction

Division onto so called "white" and "blue" collars was very well noticed within industrially developed countries. Studies conducted to investigate reasons for that dichotomy demonstrated that the major obstacle lies in the decreased flow of scientific and technical achievements from R&D institutions into the production, due to the unwillingness of researchers to work closely and/or within the production facilities themselves [1]. Answer, which provided a good solution to the problem, was the establishment of Innovation Relay Centres (IRC) [2].

The mission of the IRCs is to support innovation and transnational technological co-operation in Europe with a range of specialised business support services. IRC services are primarily targeted at technology-oriented small and medium-sized enterprises (SMEs), but are also available to large companies, research institutes, universities, technology centres and innovation agencies. The first Innovation Relay Centres were established in 1995 with the support of the European Commission. The aim was to create a pan-European platform to stimulate transnational technology transfer and

promote innovation services. Today, 71 regional IRCs span 33 countries with 240 partner organisations and 1200 consultants.

Methodology of IRCs work is depicted in Figure 1, with the main forms being Technology Offer (TO) and Technology Transfer (TT), which, after preparing, are being posted and exchanged between the network members.

Figure 1 Methodology of IRCs work

Formation of EU, made apparent other issues concerning new legislative, establishment of cooperation, new markets and regulations linked with them, financial instruments and their availability, etc. Generally, information considering new and ever changing business environment were needed. This implies especially to SMEs, which represent 99% of all legal persons in EU, generating 47% of the income. The answer was founded in creation of Europe Information Centres (EICs). Still, both networks have showed certain shortcomings. Mainly, there was no one place to get all of the needed information and support, again predominantly needed by SMEs.

Through combination of these two networks, along with added value for the clients, with the utilization of “no wrong door” concept, a new network (Enterprise Europe Network-EEN), providing full range of the services to its clients, arose. Today, this network is constituted by more than 580 member organisations across the EU and beyond, whose role is to provide full support to the clients, dominantly SMEs.

2. Framework development in Serbia

The realization of the activities started with the preparation of National Strategy of Innovations and the project “Feasibility study for the founding of scientific-technological parks in Serbia”, no. TR-7026A financed by the Ministry of Science and Environmental Protection. Through these activities following issues were identified:

- Building of infrastructure for innovations in Serbia is at the very beginning, and there is small number of organizations within it: few incubators and scientific-technological parks (NTPs), with constituted Business-Technology Incubator of Technical Faculties of Belgrade University.
- Restructuring of Serbian economy along with the transition towards market economy implies the necessity of more innovative oriented company behaviour. Lack of knowledge on available technologies, as well as the knowledge on mechanisms for market realization of own technologies, is present.
- Lack of knowledge on how innovative system in of one economy functions, along with its mechanisms is widely spread. Non existence of appropriate infrastructure with the role of

supporting the innovative system and its functioning is one of the major constraints in further development.

- Especially difficult situation is within the sector of SMEs, which do not possess personal, material and financial resources to develop and/or obtain the technologies needed for further improvements.

These reasons created a need for the implementation of proven solutions, which led to the innovation project "Development of the infrastructure for Innovation Relay Centre in Serbia". Project's success led to the second project "Support of the innovation society development process in Serbia by capacity enhancement of the IRC Serbia." Both projects were financed by Ministry of Science and Technological Development - Republic of Serbia.

Creation of infrastructure for offer and demand of technologies and innovations is an important segment of innovation infrastructure and way of promotion of the culture of entrepreneurship and innovation activities within the Serbia's society and economy. It is a constitutive part of realization of the National strategy of building of national innovative system. Formation of IRC Serbia initiated gathering around Innovation Centre of Faculty of Mechanical Engineering (ICMF) of interested domestic partners, along with signing of Consortium Agreement with chosen partners. The project enabled following results:

- Creation of data bases on national innovative resources and results of innovation work
- Promotion and offering of technological solutions and innovations of domestic R&D institutions and individuals, in Serbia and abroad – through the IRC network in EU
- Infrastructural support to technological development of SMEs within the process of choosing the necessary technologies for their field of engagement
- Promotion of their own technological solutions and innovations, on domestic and foreign markets through the IRC network in EU.

Through the realization of the project, the following was and is being set up:

- Part of the missing infrastructure within the economy of Serbia
- Process of learning and knowledge transfer on innovation activities in the economy of Serbia
- Mechanisms for providing help to SMEs in the organization of their technological development

Successful implementation of the IRC Serbia enabled formation of the EEN-Serbia. After formation of the Consortium, and successful submission of the project proposal (ref. ENT/CIP/07/0001a), followed by signing of the Contract with EU Commission, formation of EEN-Serbia, began. Macro organizational structure of the project is depicted on Figure 2. The work, itself, is divided into three modules (A, B and C). Generally speaking, Module A represents information dissemination (area of the EICs network), and the load it carries is approximately 47%; Module B represents technology transfer (area of IRCs) enriched with the business cooperation and carries approximately 47% of the engagement; while Module C represents offer of support to clients in connection with EU programmes, such as FP and CIP, and present approximately 6% of the total project engagement.

The main project objective is establishment of integrated services in support of business and innovation for SMEs in Serbia, as the main client, in order to help them increase their competitiveness on EU and domestic market, and the enhanced information access considering EU and domestic RTD possibilities. Specific objectives are:

- Raise awareness about technology transfer opportunities and increase competitiveness
- Raise awareness among SMEs regarding Community policies and opportunities
- Participate in the creation of the Europe-wide network of excellence

Special emphasis is on:

- Support to the female and young entrepreneurs
- Stronger regional cooperation in Western Balkans
- More uniformed regional development across Serbia
- Promotion of innovation culture through the SMEs
- Building capacity for applied R&D, innovation and technology transfer

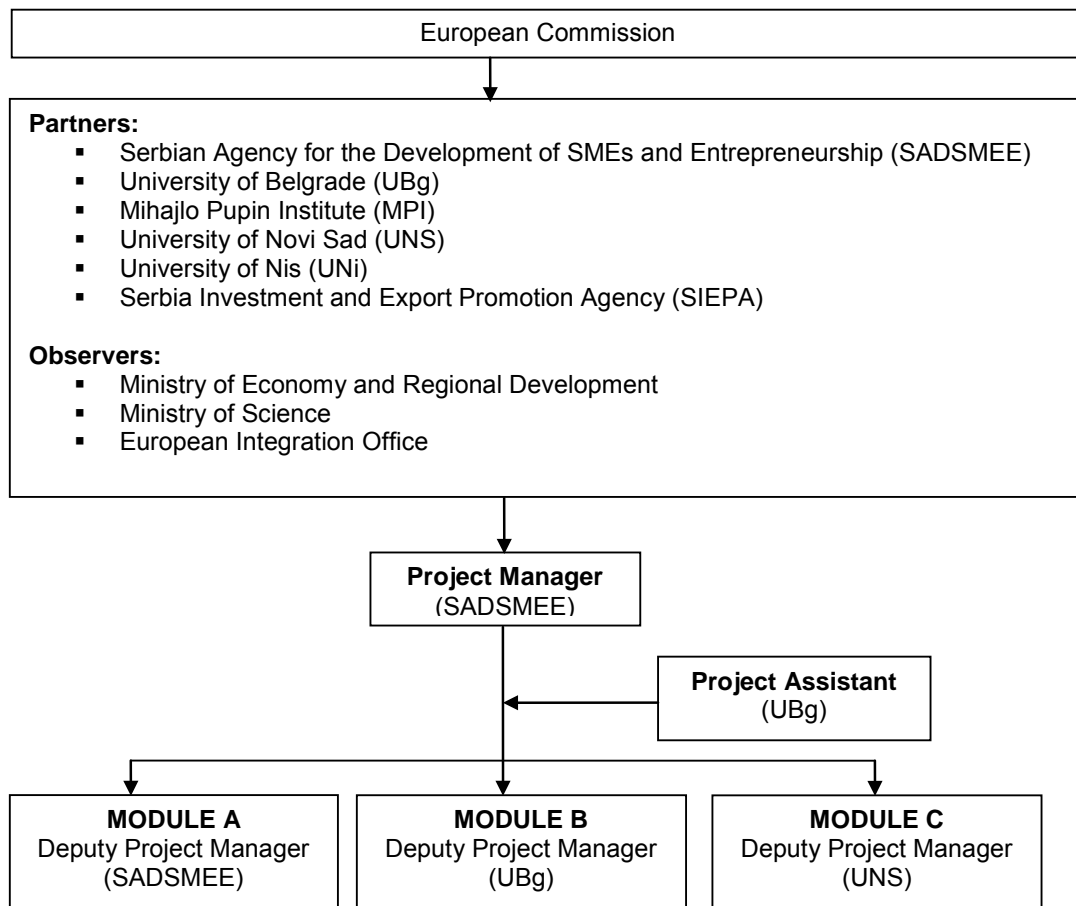

Figure 2 Starting macro organizational structure for the project realization

Since the official start of the project in Serbia, January 01, 2009, activities of the Consortium vent into two directions. First direction was defining of the micro organizational structure and defining of the work methodologies and procedures and their bringing into accord with EU Commission. Parallel with this, endeavours to promote the network were undertaken. Such actions were comprised of printing of the promotional material, participation on TV and radio shows, publishing of articles, etc. Second direction was the work with clients, either through direct approach for promotional purposes, or through particular services, such as: providing the information on EU directives, recommendations and regulations, presentation on possibilities provided by EU market, and markets of other countries included into the Project, presentation on possibilities for business cooperation establishment, providing information on the programs and funds available to SMEs, creation and posting of technology and business request and offer profiles. In January 2011, the list of EEN-Serbia partners is enlarged with the Serbian Chamber of Commerce.

The ICMF developed Web content management system that is used to operate EEN-Serbia Website [3]. The site regularly provides information on upcoming events, innovations, and R&D news. The site also maintains internal database of domestic SMEs interesting in collaboration, and keeps their portfolio.

The EEN-Serbia continually disseminates information, raises awareness among SMEs, and organizes meetings among interested parties. Their joint efforts resulted in the growing presence of Serbian firms on relevant fairs, matchmaking events, and online partner search databases.

3. Gained experience

The innovation system is the concept that fits needs of the developed economies [4]. When facing markets emerging from centrally planned economies the concept faces many obstacles. Innovation is mainly a bottom-up process [5], and actors in those markets expect top-down directed business approach. That way they often confuse activities of IRC and EEN network with supposed controlled

business approach and consequently they underestimate need to develop their own innovation capabilities. Both innovation projects conducted so far and regular EEN-Serbia activity solved many problems arising from the implementation of innovation strategy in Serbia, but also they generated new questions.

The first innovation project implemented core of the future innovation infrastructure in Serbia, and created following questions:

- The need to expand the number of clients
- Unsatisfactory awareness on the need and advantages of using the newly developed innovation infrastructure, and accompanying networking mechanism.
- The lack of information on the possibilities to find relevant business partners and to develop cooperation with interested parties.
- General ignorance of the opportunity of acquiring EU funds.
- Insufficient knowledge of the mechanisms of the establishment and realisation of the cooperation, with significant legal implications.
- Lack of ability for real-time information monitoring.
- Inhibition from the appearance on the foreign technical-technological and economical arena and lack of realistic self positioning.
- Absence of tendency and practice of grouping and/or common appearance on the market in the legal sense.

The second innovation project provided mechanisms for coping with above mentioned problems and revealed new questions that will be addressed in the future:

- Association with value-added partners based on the projected compatibility and self positioning.
- Commitment to single innovators and persons.
- Application and adherence to the HSE (Health Safety Environment) concept.
- Intellectual property protection
- Technology audit

3. Conclusions

Despite that innovation system is established concept with worldwide implementation the literature on innovation studies is still struggling to understand the linkages between innovation networks, the performance of the firms that participate in these networks, and all relevant variables [6]. Based on our experience on developing innovation framework in Serbia it is evident that any particular solution does not lead to complete elimination of the related problem, but only defines successful mechanism that provides answers to the needs of the existing interesting groups, i.e. it provides established instrument to cope with the needs of relevant target group.

These results are consistent with the nature of the innovation process that strives for continual development and improvement, and it is evident that both related framework and accepted methods should follow same strain of continued enhancement to provide relevant support for all interesting parties.

4. Acknowledgments

This work was supported by the Ministry of Science and Technological Development - Republic of Serbia under grant 391-00-00027/2009-02/46. It is a part of the project 'Support of the innovation society development process in Serbia by capacity enhancement of the IRC Serbia.' The project director is Dr Dejan Ninković.

Composite Index for measuring level of introduction of an Integrated Product Policy in countries under certain circumstances

Teodora Obradovic-Grncarovska¹, Vladimir Dukovski²

¹Ministry of the Environment and Physical Planning, Bul. Goce Delcev bb, 1000 Skopje, R.Macedonia, t.grncarovska@moepp.gov.mk

Integrated Product Policy (IPP) is an approach which seeks to reduce the life cycle environmental impacts of products from the mining of raw materials to production, distribution, use, and waste management. IPP focuses on those decision points which strongly influence the life cycle environmental impacts of products and which offer potential for improvement, notably eco-design of products, informed consumer choice, the polluter pays principle in product prices. It also promotes instruments and tools which target the whole life cycle of products.

The aim of this paper is to propose methodology for developing of Composite Index for measuring level of introduction of an Integrated Product Policy in countries under certain circumstances,

Composite index is developed as a mix of pressure and response indicators derived from available data combined with the set of proposed IPP indicators from the literature. Special response indicator for countries under certain circumstances is proposed, as a sum of the levels of transposition of relevant IPP related directives into legal system.

Composite index aims in measuring, monitoring, analyzing and comparison of the level of introduction of an IPP policies in countries.

Keywords:

Integrated Product Policy (IPP), indicators for IPP

1. Introduction

Integrated Product Policy (IPP) is an approach which seeks to reduce the life cycle environmental impacts of products from the mining of raw materials to production, distribution, use, and waste management [1 to 7]. The driving idea is that integration of environmental impacts at each stage of the life cycle of the product is essential and should be reflected in decisions of stakeholders. Strategic documents adopted on the EU level regarding IPP are several [8 to 11].

IPP focuses on those decision points which strongly influence the life cycle environmental impacts of products and which offer potential for improvement [16,17,18], notably eco-design of products, informed consumer choice, the polluter pays principle in product prices [23,24,25]. It also promotes instruments and tools which target the whole life cycle of products.

In this article countries under certain circumstances refers to the countries with status candidate countries for full membership into EU, which has to transpose all relevant EU legislation into their national legal system on one hand but they have very limited data and no system for systematically collecting of data at the other hand. Some interim approach for measuring the level of introduction of an Integrated Product Policy was proposed combining available data and selection of the proposed indicators for IPP in the literature. The weigh for each area was chosen as an equal (0,25). Scoring

was proposed based on deviation from the set values of proposed variables. Margins of tolerance for scoring were proposed based on the deviation from the EU levels for proposed variables.

2. The IPP Approach

The IPP approach [3,6], which has been developed gradually over the last decade, is now generally recognised as being a potentially very effective way to address the environmental dimension of products. This approach is based on five key principles:

1. Life-Cycle Thinking – it considers a product's life-cycle and aims for a reduction of its cumulative environmental impacts - from the "cradle to the grave". In so doing it also aims to prevent individual parts of the life-cycle from being addressed in a way that just results in the environmental burden being shifted to another part. By looking at the whole of a product's life-cycle in an integrated way, IPP also promotes policy coherence. It encourages measures to reduce environmental impacts at the point in the life-cycle where they are likely to be most effective in reducing environmental impact and saving costs for business and society.
2. Working with the market – setting incentives so that the market moves in a more sustainable direction by encouraging the supply and demand of greener products. This will reward those companies that are innovative, forward-thinking and committed to sustainable development.
3. Stakeholder Involvement – it aims to encourage all those who come into contact with the product (i.e. industry, consumers and government) to act on their sphere of influence and to encourage co-operation between the different stakeholders. Industry can look at how to better integrate environmental aspects in the design of products while consumers can assess how they can purchase greener products and how they can better use and dispose of them. Governments can set the economic and legal framework conditions for entire national economies and also act directly on markets, for instance by purchasing greener products.
4. Continuous Improvement – improvements can often be made to decrease a product's environmental impacts across its life-cycle, whether in design, manufacture, use or disposal, taking into account the parameters set by the market. IPP aims for a continuous improvement in these rather than setting a precise threshold to be attained. As a result, companies can set their own pace and can focus on the most cost efficient improvements.
5. A Variety of Policy Instruments – the IPP approach requires a number of different instruments because there are such a variety of products available and different stakeholders involved. These instruments range from voluntary initiatives to regulations and from the local to the international scale. Within IPP, the tendency is clearly to work with voluntary approaches, although mandatory measures might also be required. The determining factor is the effectiveness of the tool to achieve the desired result with regard to sustainable development.

3. IPP Indicators

The UN's Department of Economic and Social Affairs has established a Theme Indicator Framework with indicators for SD. There is no product orientation in the framework, as these are classical environmental indicators.

The OECD has been working in the field of environmental indicators for more than 10 years. The work is divided into Core Indicators, Sectoral Indicators and indicators derived from environmental accounting. Indicators are structured by the PSR approach (pressure-state-response) which has formed the basis for the EEA's DPSIR approach. The OECD's indicators are much aggregated and not at all relative to products. In the two-yearly Environmental Outlook Reports the indicator framework is used as the basis for the structure, and the OECD has developed models for the prediction of the effects of specific policy measures on specific environmental indicators, e.g. CO₂, SO_x and NO_x. There are no IPP-related policy measures included in the models. At EU level, Eurostat, in co-operation with the EEA and other units, has developed different sets of environmental indicators:

- The structural indicators (SI), first presented in 2000 in order to monitor the Lisbon strategy (which sets economic, social and environmental objectives). In 2004, two lists of SI were presented: a short list, including one environmental indicator and a long list, including 7 environment-related indicators (and a total of 15 sub-indicators, which are listed in the current text).
- The environmental pressure indicators

- The integration indicators, which aim at monitoring the progress achieved in the Cardiff strategy. At present the following indicators are available: the transport-environmental (TERM) indicators, the agri-environmental indicators (IRENA project) and the energy-environmental indicators. Four other sectoral indicators (fishery, industry, economy and development) are under development.
- The Sustainable Development Indicators, which aim at monitoring progress in achieving the objectives of the SDS, which are currently under development.

Several countries (UK, Sweden, Finland, Denmark) have developed several indicators for relevance on IPP. In the Study on IPP indicators, the following selected existing indicator types were proposed of relevance to an IPP (literature IPP indicators)(22).

Table 1 List of selected existing indicator types proposed of relevance to an IPP

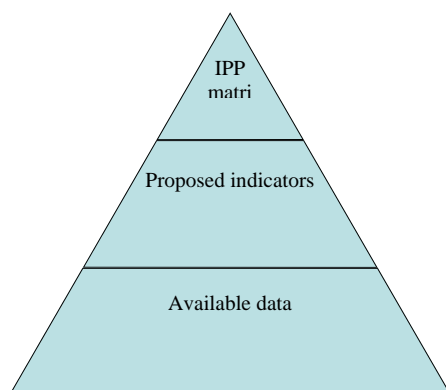

Indicator	Theme	DPSIR	Note
Number of eco-labeled products	Industry, production, consumption	R to R or partly R to D	Since the mid 1990s this indicator has been the only one with clear reference to greener products. Its steadiness makes it a cheap parameter, because the figure is published regularly by the eco-labelling bodies. The disadvantage is that it does not link to changes in impacts on the environment; maybe not even to changes in industry (D).
Number of products with environmental product declaration (EPD)	Industry, production,	R to R or partly R to D	This indicator is very similar to the number of eco-labelled products. A problem with this indicator, however is that EPD is a pure quantitative information and documentation system. There are no end-points in EPDs, so it is not possible to follow parameter's development over time, unless the specific product or a line of products is followed as an example.
Number of EMAS or ISO 14001 certified installation	Industry, other sectors	R to R or partly R to D	This indicator is a fair measure for the dissemination of environmental aspects in general in industry. Though a certificate in itself does not indicate the level of environmental impact, it is an indication of the interest from management in the company. The disadvantages are that it is not a measure of the environmental impact, nor is it product-oriented. As for eco-labels and EPDs, there is no link to changes in impacts on the environment.
Energy intensity or resources intensity for economic sectors	Energy, resources	D to P	These types of efficiency indicators provide benchmarking platforms for environmental issues within an economic sector. Underlying such indicators are normally very detailed and bulky data on the energy aspects of specific processes. They can be product-oriented, but are most often related to production units and aggregated from this level up. However, basic information like this normally provides valuable input to LCA case studies, and ground-level data may fairly easily be translated into product-related data
Transport efficiency	Transport, energy	D to P	See above for "energy intensity"
Recycling degree and resource flows	Waste, resources	R to R or partly R to D	Recycling degrees are typically aggregated for waste fractions, like newspapers and magazines or electronic scrap. The indicator is, however not easy to transform into changes in impacts, because recycling may imply extra energy consumption, chemicals etc. for the recycling processes, which in some cases generate greater impacts than disposal or incineration. Therefore, such indicators are mostly pure R-to-R indicators.
Environmental investments as direct investments or companies in e.g the Dow Jones Sustainability Index	Financial	R to R or partly R to D	The degree of environmental investments is very difficult to relate to environmental impacts, like for management systems. It is a pure response indicator, which only tells us how much money has been channeled into companies that meet simple criteria. The advantage of this indicator is that it involves the financial sector, which has not otherwise been very interested in environmental issues. Such indicators could be product-oriented if the criteria in the indexes were changed into product-oriented issues, like for example investments in specific cleaner technology, producing a certain amount of products or saving a certain amount of emissions. As for eco-labels, there is seldom any link to changes in impact on the environment, and such indicators are, therefore, mostly pure R to-R indicators
Emissions factors	Substances	D to P	The classical emission factors indicate the emissions we can expect from a specific industrial process. Thus, they link together D and P. There are numerous databases of emission factors today, of which the EPER is the most widely known in the EU. Emission factors are very specific and tell us only about one process and one substance at the time.

Indicator	Theme	DPSIR	Note
Biological indicators	Biological parameters	S to I	The classical biological indicators, like the presence of a species, the concentration of nitrate in a lake etc. provide a picture of the state in nature. If they are related directly to humans, like the concentration of a substance in groundwater for drinking, then they indicate the impact. Such indicators form the core of environmental monitoring, but have little relevance to IPP.
Environmental impact of consumption per citizen per year (energy, CO₂, or other parameters)	All	D,P,S and I	Such indicators are extremely aggregated and require large statistical tables, covering all industrial activities etc. They may also be seen as combinations of some of the other indicators. For an IPP such indicators give interesting pictures of the impacts from products, but none of the effects of implementing an IPP measure politically. Further, the conversion from the aggregated citizen unit to a product unit would be quite complicated. On the other hand, underlying such indicators are numerous data, which may comprise input to useful indicators for IPP.

4. Composite index for measuring level of introduction of an Integrated Product Policy in countries under certain circumstances

The so called composite Index for measuring level of introduction of an Integrated Product Policy was proposed using available data (bottom-up approach).

Statistical data, data from different other sources (National Strategy for sustainable development, National environmental indicators, National Strategy for complex energy development, National Industrial policy, OECD/IEA, [2008], IEA Online Database: Energy Balances of Non-OECD and OECD Countries and Energy Statistics of Non-OECD and OECD Countries reports etc, EEA reports on inventory of emissions, Reports on GHG emissions etc) were used put in the correlation with proposed IPP matrix [28, 29]

		EU	MK
1.	Consumption of primary energy/capita (toe/capita)	2,45	0,8
2.	Energy consumption in industry sector per GDP (10 ³ toe/1000 UDS\$)	45	145
3.	Intensity of energy consumption in traffic sector (ktoe/capita)	780	170
4.	CO ₂ eq emission per capita (2000)	0,5	7,16
5.	Carbon intensity per GDP, (tCO ₂ eq./mil. USD GDP)	443	700
6.	% of RES	20	15,3
7.	Number of companies with adopted ISO 14001	450	25
8.	% investments in environment	3,2	0,25
9.	Number of municipalities with adopted local development plans	150	55
10.	Emission of SO ₂ (k t)	99	90
11.	Emission на NO _x (k t)	60	35
12.	Emission на VOCs (kt)	51	25
13.	Emission of amonia (kt)	20	14

5. Results for the Republic of Macedonia

For the Republic of Macedonia, an environmental indicators as well as proposal for indicators on sustainable development have been developed (24-27)

Within the proposed indicators, 40 environmental indicators have been developed out of which 5 for energy, 2 for climate change, 4 for air pollution and ozone depletion. In the proposed indicators on sustainable development there are no product related indicators proposed.

Therefore, data from different sources have been used which are of relevance for the IPP. Areas were chosen based on the available studies for IPP (1-12). The weigh for each area was chosen as an equal (0,25). Scoring was proposed based on deviation from the set values of proposed variables. Margins of tolerance for scoring were proposed based of the deviation from the EU levels for proposed variables.

Subject	Weight	Variable	Score	Sub weight
Legislative and fiscal measures	0,25	% investments in environment from budget <0,5 0,51-2 >2	0/0,5/1	0,25
		Carbon Tax (y/n)	0/1	0,25
		Developed guidelines for public procurement (y/n)	0/1	0,25
		% of transposition of IPP aquies*		
Industry, production, consumption	0,25	Number of products with eco-label <10 10-30 >30	0/0,5/1	0,5
		Number of companies with introduced EMS <10 10-35 >35	0/0,5/1	0,5
Energy, resources, transport	0,25	Carbon intensity per GDP, (tCO ₂ eq./mil. USD GDP) <200 201-500 >500	0/0,5/1	0,25
		Intensity of energy consumption in traffic sector (ktoe/capita) <100 100-500 >500	0/0,5/1	0,25
		Energy consumption in industry sector per GDP (10 ³ toe/1000 UDS\$) <50 50-150 >150	0/0,5/1	0,25
		% of recyclable waste <10 10-50 >50	0/0,5/1	0,25

		Emission на VOCs (kt) <20 20-50 >50	0/0,5/1	0,25
		Emission of amonia (kt) <20 20-50 >50	0/0,5/1	0,25

*level (%) of transposition means % of transposition of directives listed bellow (13-20). Regulations have no transposition just implementation

6. Conclusions

For the countries under certain circumstances, a mixed approach which combine available data from different sources which are of relevance for the IPP combine with the set of indicator and areas based on the internationally available studies for IPP was used to propose a matrix for measuring level of introduction of an Integrated Product Policy. Into the matrix, % of transposition of IPP aquies* was proposed as a characteristic variable for the countries with candidate status for full membership into the EU. Following the differences into scoring through the years, the level of introduction of an IPP into the country can be monitor and assess. Proposals for changes in some policies can be also made.

³*CIRPS Sapienza University of Rome, Rome, Italy, grgvitali@gmail.com*

The focus of this work is the collaboration between Industry and Academia in the process of building of the Sustainability Science. The idea is that Industry can contribute to the achievement of a more sustainable world, by adopting processes that assures profits but respect interests and values of environment and society. This implies a common vision across the globe and a strong willingness to face challenges and complex issues related to sustainability. Sustainability Science has the ambitious aim of overcoming the theoretical discussion on sustainable development that clashes with the difficulty of achieving tangible results by involving actively in a process of real change the main actors: the civil society, the private sector and the policy-makers. The industrial sector can play a crucial role in this scenario, but to do so effectively and to accelerate the process, a close collaboration with Academia is not only needed, but represents a win-win solution for both, industry and academia but also for the entire society. In the work will be described the central features of Sustainability Science and why insert the I&A collaboration process in the framework of Sustainability Science, the previous and next steps of the I&A collaboration process towards sustainability, which instruments are useful to finalize the collaboration.

Keywords

I&A collaboration, Sustainability Science

1. Introduction

The global financial crisis, the climate change and the increasing of geo-politics conflicts are some of expressions of a development model not sustainable. It is clear the importance of a reverse course. Several definitions of sustainable development exist, one of most important is: "Sustainable development is realized when current society does not compromise with its development the possibility of development for future generations" [1]. Since '80s appeared clear the challenge of the 21st century, the transition toward a future sustainable world.

In a process toward a sustainability society is really crucial the involvement of different stakeholders and of different disciplines. In the process of change the dimensions are simultaneously social, technological, economic and political. Became necessary a trans-disciplinary approach with the aim to understand the linkages between the different dimensions. Sustainability Science with its feature of problem-solving and trans-disciplinary approach can help in understanding these linkages.

In this context policy-makers, academics, representatives of industries and civil society have to work together to find concrete solutions to risks to human well-being and security issues.

Industry may give a fundamental contribution in the process of building of Sustainability Science, changing the way to achieve profits with respects interests and values of environment and society.

CIRPS Sapienza University of Rome, in organizing ICSS 2010[1] and in particular the Industry Panel, started a tighter collaboration with industries in the framework of Sustainability Science and in this work will be described the process of collaboration.

2. Sustainability Science

Sustainability Science is a new science, emerged in last years as one of the most important avant-garde of international scientific research. Based on an integrated and trans-disciplinary approach, it is oriented to study and understand the complexity of the interactions between economy, society and nature in order to propose concrete solutions to complex problems locally and globally threatened the very survival of humanity. Sustainability Science can help in create methods and visions for analyzing the trade-offs and develop policy-making support tools to solve the concomitant risks to human well-being and security issues [2].

As pointed out Clark and Dickson [3], sustainability science is not yet a traditional discipline, but rather a vibrant arena that is bringing together scholarship and practice, global and local perspectives, and various disciplines. It aims to overcome the traditional mono-disciplinary approach, in order to allow us to see phenomena in their entirety and facilitates the identification of integrated solutions.

A characteristic of Sustainability Science, moreover, is its problem-solving perspective. Komiyama and Takeuchi [4] stated that a problem unique to sustainability science is the process of shifting from the stage of phenomena identification and analysis to that of problem-solving. To attain a goal we must seek a fundamental understanding of the system as well as solutions [5].

Sustainability science is a new field that seeks to understand the fundamental character of interactions between nature and society [6]. Such an understanding must include the interaction of global processes with the economical, political, ecological and social characteristics of particular places and sectors. Sustainability science is trying to explain means that relevant research will have to integrate the effects of key processes across the full range of scales from local to global. Combining different ways of knowing and learning permit different social actors to work in concert. The role of sustainability science is also the distribution of knowledge to society through communication among experts, decision-makers, academics, politics. The participation of diverse stakeholders in setting and implementing solutions is indispensable, because as science and technology advance, knowledge tend to be centralized, sustainability science tend to involve different expertises.

In this context is crucial the role of industry in order to pursue sustainable economic patterns, to create well being and to reduce environmental impact of the economic activity. Representatives of the industry sector may give an important contribution to the process of foundation of this new Science and to the creation of its definition. The adoption of production processes and dynamic socio-economic and environmental gains that ensure interests and values while respecting the environment and the society implies a shared global vision of sustainability.

2.1 I&A collaboration in the framework of Sustainability Science

2.1.1 I&A collaboration

Different approaches exist to analyze the Industry Academia collaboration. Lee [7] focus on sustainability of University-Industry research collaboration, analyzing the so called behavioural outcomes (e. g. degree of satisfaction), the reasons for academics and for firms to create a collaboration.

Most studies of industry-university collaboration have framed the analysis of such partnerships in terms of research project outcomes, defined here as a result that create opportunities for a company, such as a guidance for the direction of technology development. From a business standpoint, however, research outcome is of only incidental importance. What matters is not outcome but impact, how the new knowledge derived from the collaboration with university can contribute to the company's performance. With the focus on the impact of the collaboration on company products, processes or peoples, an important three year study of MIT [8] determined seven best practices for university-industry collaboration:

- Define the project's strategic context as part of the selection process;
- Select boundary-spanning project managers
- Share with university team the vision of how the collaboration can help the company;
- Invest in long-term relationships

- Establish strong communication linkage with the university team;
- Build broad awareness of the project within the company;
- Support the work internally both during the contract and after, until the research can be exploited.

To identify the best practices MIT analyzed 100 university projects sponsored by the companies, so the best practices can be applied for different kind of I&A collaboration.

Our approach was practical, asking to the two protagonists of this challenge to sit at the same table and to work on it, and structuring the I&A collaboration sharing the choices. We focus our attention to the question on why is important and necessary structuring a I&A collaboration in the field of Sustainability Science.

2.1.2 Sustainability Science and I&A collaboration

It is clear that to move on a sustainable world Industry will have to face several challenges like contributing to education enablement and economic empowerment, particularly of women; Developing radically more eco-efficient solutions, lifestyles and behaviour; Taking into account the cost of externalities following the life-cycle approach; Doubling of agricultural output without increasing the amount of land or water used; Strongly reduce carbon emissions worldwide through a shift to low-carbon economy; Delivering a four-to-tenfold improvement in the use of resources and materials.

To do so effectively and to accelerate the process, a close collaboration with scientist is not only needed, but represents a win win solution for both, industry and academia. This virtuous cycle will benefit and be supported by the three main innovative characteristics of Sustainability Science that firstly, addresses complexity with a trans-disciplinary approach, secondly, is problem-driven and it uses both, scientific and local knowledge, to resolve contextualized problems and thirdly, it promotes the active involvement of the different stakeholders - civil society, the private sector and policy makers - in a process of scientific co-production.

The I&A collaboration could be at different levels, on a specific project or several projects, on a process of building of a specific field. In this work we describe the I&A collaboration process to obtain a shared definition and structuring of Sustainability Science. Behind the idea that, to move toward a sustainable society and in the involvement of different stakeholders, Industry has a key role and can lead with academia the change of route considering an appointment that cannot be postponed.

2.2 I&A collaboration process description

To involve the private sector in the process of building of Sustainability Science, CIRPS Sapienza University of Rome, organized the panel "Industry and Academia for a transition towards sustainability" within ICSS 2010, starting a close collaboration with some important companies before and after the conference.

The central idea behind the Panel was to follow a fully cooperative way of working, by ensuring the involvement of all participants in the process of structuring of collaboration and in the definition of content to be discussed.

2.3 Before ICSS 2010

The modus operandi chosen was to cooperate with involvement industries before and after the conference to begin the collaboration.

Academia provided a background documentation which served as a first input to participants: the *Guidelines*, gave necessary information about objectives of the Panel and panelists role prior, during and after the conference; the *Working Points Concept Paper*, outlined central themes of the Panel discussion and guided the invited panelist to the preparation of their contributions for the session.

Single meetings with each company have been organized to discuss about the Panel objectives described in the guidelines, that are the following:

- *To share a definition of Sustainability Science: going beyond sustainable development*
- *To clarify what sustainability means from a business perspective*
- *To identify "what industry asks and offers" to Sustainability Science: exploring room for collaboration with academia*

- To edit a “*Paper of wills*” synthesizing achievements and challenges of the Panel and to pave the way forward: next steps towards New York meeting (USA, October 2010) and towards continuative collaboration
- To provide a “*toolkit*” for sustainability.

Moreover, Academia and Industry discussed also on five working points, previous identified, as the base of Panel discussion, that are:

- “*Sustainable profits*”: history cases of “sustainable business activities” as a part of industry strategy
- *Deployment of new technologies*: effective policies to promote sustainable business
- *How to measure sustainability*: indicators for assessing progress and development beyond GDP and ‘conventional’ business profits
- *Industry and Sustainability*: reaching a shared definition of Sustainability Science
- *How to enhance Industry & Academia collaboration*: making research findings useful to industry and industry needs feasible for the academic world.

With Industry feedback on the proposed working points, as outcomes, have been edited two documents; the Background document, and the Working points concept paper, both distributed at the conference.

The *Background document* described the objectives of the Panel and the modus operandi in the structuring the Industry-Academia collaboration (Figure 1).

In the *Working points concept paper* have been explicated the points of Panel discussion, with the aim to outline the central themes of the discussion, to guide the invited panelist to the preparation of their contributions, and to ensure a structured and productive discussion.

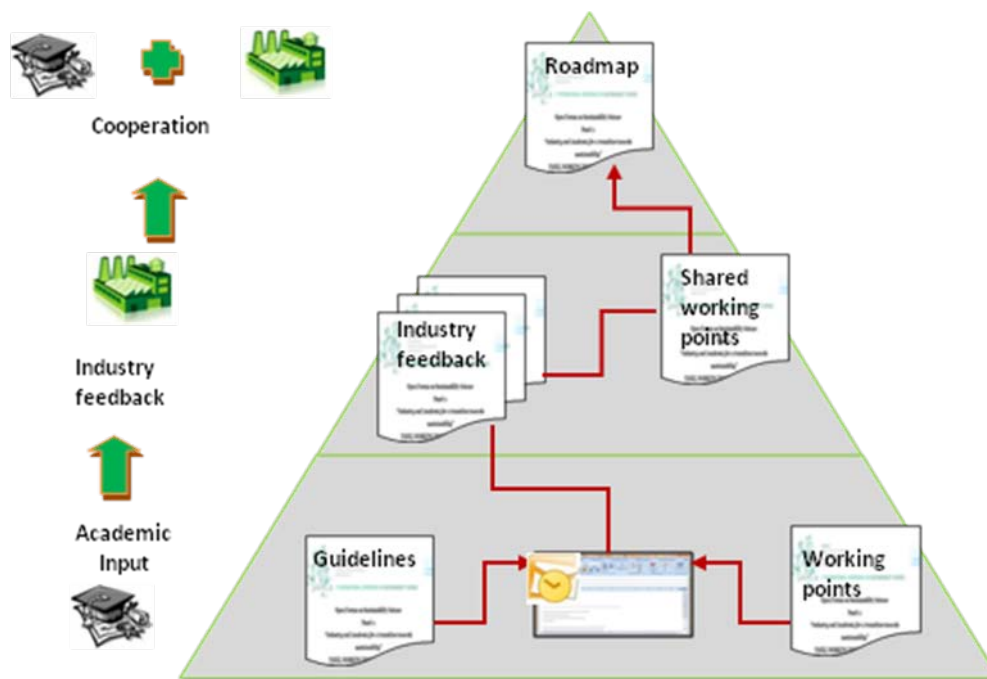

Figure 1 A synthetic description of the modus operandi

2.4 After ICSS 2010-New York Workshop

The final result of the process of collaboration and of the Panel discussion was a Roadmap to finalize the I&A cooperation, identifying the future steps and the key topics to be discussed in the possible future workshops and in ICSS 2012.

As a second step in the process of collaboration, after fourth month, CIRPS, co-organized a workshop *A Roadmap for Industry-Academia collaboration towards sustainability*[2], with the aim to involve not

only Italian companies in the I&A collaboration process. Three company and three universities, coming from Asia, Europe and America, met to continue the collaboration process at a global level within the International Network for Sustainability Science[3].

The workshop was animated with a broad debate with an audience coming from several countries. Two important points have been revealed to develop and to improve the I&A collaboration:

- The necessity to create a common platform to plan next steps
- The necessity of new approaches to involve more stakeholders.

3. Conclusion

Industry and academic collaboration takes place in different ways: it may granted by partnerships, promoted by foundations or public institutions, to origin from crucial technological discoveries and encouraged by clusters or spin-off. When this happen both gain and there is margin for transferring benefits to entire society. However, too often the work of researchers faces some limits (i.e budget or dissemination constraints), staying behind business needs.

A solution to this trade-off must be addressed in order to accelerate the achievement of sustainability and that's why we ask the two protagonist, Industry and Academia, to sit at the same table and to work on it. Brainstorming about the best ways to enhance the collaboration is the first necessary step. Strengths and weakness of collaboration experience reported from the panelist revealed the main issues to tackle. Consequently, the debate has to focus on concrete tools that may reduce the distance, filling the gap between the industry and academic needs.

On the basis of best practises identified by MIT and of our directly experience, we consider important to achieve a profitable collaboration:

- the knowledge exchanges between Industry and Academia
- the importance of a multiyear collaboration
- to establish strong communication linkages with university team (visits of researchers to the company, scheduled video or conference call)
- to build broad awareness of the project within the company with the involvement of professionals from different functional areas.

To do so we thought a *closed cycle collaboration process* (Figure 2), where Industry identifies problems, asks Academia to analyze and to find solutions for them, evaluates its feasibility from a corporate perspective and together with it establishes good practices of joint problem-solving.

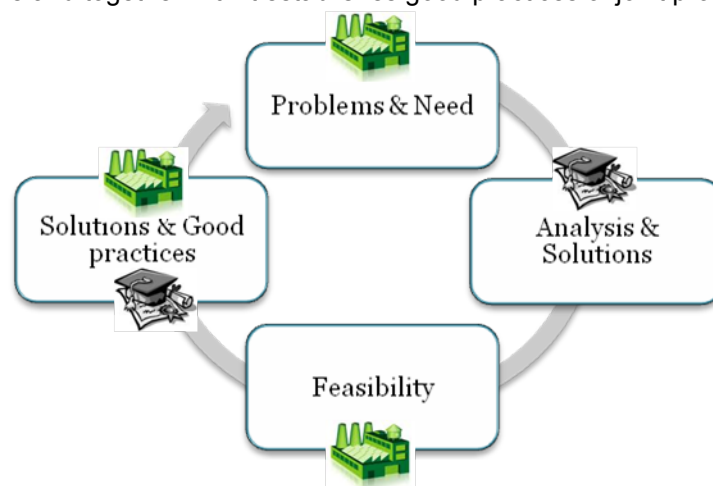

Figure 2 The *closed cycle collaboration process*.

After the New York Workshop and ICSS 2010 we identified the topics to be analyzed and deepen studied according with the Sustainability Science methodology (trans-disciplinary approach, problem-driven, active involvement of the different stakeholders, civil society, private sector and policy makers. A first list of key topics can be the following:

- Education for Sustainability

- Research activity
- Problem solving by topic for Sustainability
- Energy
- Transport and mobility
- Manufacturing
- Food
- Water
- Banking
- Sustainability Indexes
- Reporting

Identified the topics, to structure a closed *cycle collaboration process* it is necessary create working groups able to support with due contents the cooperation between I&A on each key topic and improve the knowledge and the analysis of the different aspects to be addressed.

Each workgroup must involve at least an academic institution and major international industries from relative fields. It will accelerate with a “by doing” method the necessary cooperation between Industry and Academia to seek and experiment solutions and alternative approaches to the different matters in order to meet the final objective of a full sustainability of human activities.

Impact of retail on the competitiveness of tourism destinations [1]

Nataša Pavlović¹, Nevena Ćurčić²

¹Tourist organization of Vojvodina, Novi Sad, Serbia, pavlovic.natasa@eunet.rs

²University of Novi Sad, Faculty of Natural Sciences, Serbia, galant@ptt.rs

Each tourist country is in some ways limited with the possibilities of providing basic services related to housing, nutrition, and part of the transport. Maximum capacity, which is expressed in the number of beds and seats (in the capacity of vehicles not in the form of foreign tourists who travel by own vehicles) are determined to a certain limit of the accommodation and catering facilities and they cannot be crossed, in order to achieve higher spending tourists in the destination. I.e. the accommodation and catering facilities were previously given, and when it reaches the maximum level of their coverage, there are limiting factors in the achievement of profit. On the other hand, extra services, which refers to the retail offer of various goods, tours, entertainment and leisure activities is unlimited. Offer in tourist destinations could largely be expanded in the retail and other sectors, which offer a wide range of opportunities for achieving a much higher level of tourist spending. At retail stores could be directly settled the various needs of tourists. This applies especially to sale of souvenirs, newspapers, photographs, books, textiles, cigarettes, flowers, fruits, sports goods, then perfumery shops, jewelry stores, etc. This paper aims to analyze the level of retail development in Vojvodina. The goal was to show the connection between retail and volume of tourist spending in destinations, as and the retail impact on increasing the competitiveness of tourist destinations.

Keywords

Competitiveness, impact, retail trade, tourism destination

1. Introduction

There is no doubt that tourism impacts on development of many sectors and in general it could not be expected its development without a corresponding with retail trade. Complementarities of trade and tourism development have become inevitable, as evidenced by numerous examples of the most developed tourist countries. On the one hand, there is great interest in travel to countries as far as possible to ensure exportation of goods and services through tourism business, because of the great advantages of such exports has, on the other hand the development of tourism in a particular tourist site or region would have been difficult and taken to without question the proper development and inclusion of trade in direct and indirect marketing of goods and services. Direct marketing of goods includes retail, wholesale and indirect sale, which supplies major customers in the tourist areas [1]. Retailing trade in small countries has decreased if it's not disappeared entirely. In recent years major changes have occurred in how and where tourists shop. Targeting more of tourist money is one of strategies that could help some communities in Serbia and its retailers as shopping and tourism often go hand in hand. Successful retailing is often rooted in a growth of innovative businesses both local residents and visitors [2].

Retailers that sell to tourists are unique because their potential customer base is often, much larger than traditional trade area of local residents. Many retailers appreciate the importance and potential of visitor market. Most, however, could benefit from further exploration of the links between the tourism market and retail businesses. These links can have significant implications for a retailer's operating and marketing decisions [3].

Each country is in some ways limited with the possibilities of providing basic services related to housing, nutrition, and part of the transport. Maximum capacity, which is expressed in the number of beds and seats (in the capacity of vehicles not in the form of foreign tourists who travel by own vehicles) are determined to a certain limit of accommodation and catering facilities and they cannot be crossed, in order to achieve higher spending tourists in the destination. I.e. the accommodation and catering facilities were previously given, and when it reaches the maximum level of their coverage, there are limiting factors in the achievement of profit. On the other hand, extra services, which refers to the retail offer of various goods, tours, entertainment and leisure activities is unlimited. Offer in tourist destinations could largely be expanded in the retail and other sectors, which offer a wide range of opportunities for achieving a much higher level of tourist spending. At retail stores could be directly settled the various needs of tourists. This applies especially to sale of souvenirs, newspapers, photographs, books, textiles, cigarettes, flowers, fruits, sports goods, then perfumery shops, jewelry stores, etc.

2. Tourism Impact on Retail Development in Developed Countries

The diversity and richness of Spain's tourism offer has been affected in the fact that in this country expenditures of tourists in accommodation and food, considered in relation to other expenditures, are relatively low. Particularly, there is a high share expenditure on the purchase of various types of products (especially souvenirs), entertainment and leisure, and various forms of extra services spending, especially on the well-equipped beaches, and the like. It is estimated that trade in Spain takes part in the total tourist consumption, with about 30%. On example of Palma de Majorca could be seen what kind of attention is paid to the development of retail in the tourist destination. Palma de Mallorca, actually Mallorca Island is one of the most popular tourist destinations in Europe and has about 270,000 beds, which can still be increased by another 100.000 beds. The tourist accommodation capacities very efficiently are supplied 111,000 of various retail stores and over 60,000 objects of so called mobile commerce. These objects are main suppliers of five specialized wholesale organizations, they are supplying whole retail network and catering [3] [4]. Hong Kong is, with Singapore and Dubai, well-known shopping destinations. A key factor in the development of tourism in Hong Kong was a performance increase in retail sales. Importance of integral development of tourism and retail trade is reflected in the fact that in 2006th retail revenues from tourism amounted to purchase \$ 6 billion, which represented 22% of the total value of retail sales. When the alleged spending of tourists, it should be noted that in Sydney purchase of foreign visitors is 15% of total retail sales. The author of The Strategy of Trade Development of the City of Belgrade emphasizes that it is not necessary to be a city shopping destination in order to speak about the importance of tourism for retail development [5]. This statement can be viewed from another perspective that without adequate retail "package" deals it is not possible further development of tourism. Thus, foreign visitors represent a quarter of all buyers in central London, which is a little more than the share of customers who come from the rest of the UK. It is estimated that the value of foreign visitors spending at retailers in London is between 1000 and 1700 pounds. It should be borne in mind that London is not a shopping destination because only 1% of foreign visitors come here for shopping. As for the German cities, the one in seven visitors says that shopping is a key activity on their travel. Shopping tourism accounts for only about 3.5% of the total retail stores in Germany. However, with the exception of Berlin and Munich, which is an attractive shopping a significant factor, other cities for now, mostly; do not play on that card. In this connection, it can be said that among the tourist destinations there are differences in the development of extra services. Research has shown that those countries where the share of catering to absorption of the overall tourism spending relatively less than the share of other activities (especially retail, leisure and recreation), and have a higher level of tourism development in general [3] [4].

3. Suitability of Retail Development in Tourist Destinations

Purchasing of goods and services by tourists in the tourist destination are achieved by exporting goods and services through this activity. This export has several advantages: it exports without tariff barriers, transport costs and the like. The data show that sales of various goods and services makes up 40% of foreign exchange earnings and total foreign tourism expenditure in some countries, which confirms their export orientation, which yields significant profits [6]. Particularly through the additional spending by tourists, which is a significant factor in retailing, each country tends to export more of its

products and services. The tourism developed countries, exports through tourism and stimulate it with specific measures. Thus, many countries encourage the purchase of foreign tourists with making the return of VAT (Value Added Tax), when living the country, immediately at the cross border or mailed to their home. They draws attention of tourist in special brochures in which everything is explained, and where are also retail stores that sell goods free of duties, marked especially noticeable tax-free stickers. These brochures are divided to tourists at border crossings, when entering the country, tourist info centers, agencies, airlines and others. In Serbia, unfortunately, travel and retail companies do not show much interest in such exports, thereby losing the opportunity to domestic goods are marketed and offered to foreign tourists, which best shows an example of the free shops, which were in late 80's opened and the mass not only at border crossings, but also in the interior of the country in hotels, shopping streets and malls. These facilities were supplied by foreign goods, while our domestic goods, unfortunately, was not represented in these stores, although in our produce items made of crystal, leather, gold, handicrafts and other products, which have the quality, design and prices correspond to world standards and would be interesting offer for the tourists. In recent years, especially the emergence of new retail stores (shopping malls, outlets, hypermarkets, department stores, etc..), the release of the tourist fees and encourage the export of this type was established and in some tourist destinations in Serbia [7].

4. The Role of Retailers in the Supply of Tourism Market

Retail has a key role in the supply, as local residents of tourist destination (like regular consumers), as well tourists, which, depending on the season, are visiting the destination. There is the role of retail expressly for it, as part of a tourism destination provides settlement needs more massive and heterogeneous tourist demand. The main task of retailing is, therefore, that its material-technical base and organizational staffing structure and mode of service delivery, adapt to the growing demand requirements of the local population and tourists, as a special customer. Adjustment of retail organizations, the demands of the tourist trade depends on the size of the tourist destinations of the local population and the number of tourists visits. On the basis of previously performed analysis of the market, in the tourist area, of an estimated potential market and trade goods in the content structure, and is based on planning and organizing retail network in the tourist destination. It is very important to the same analysis to determine the purchasing power of tourists in order to develop and therefore offer appropriate goods and services. What is a distribution network with its size, structure, spatial layout, external appearance and more features on the second largest adjusted frequency, socio-economic structure of the customer, route, and places to keep the tourists, this tourist destination is more developed and richer in terms of tourism and trade deals. It can be said that the development of trade and retail in a tourist destination, is a reflection and measure of its tourist development. Shopping of local and foreign tourists in Austria makes 23% of the total tourist spending, 21% in Paris, over 20% London, and in Singapore 50%. From tourism development and the purchase by tourists, a key benefit have the city's central commercial area, shops nearby and convention centers, shopping malls and lifestyle centers (shopping malls, open spaces, often as a simulation of the traditional shopping area, with wide promenades, street cafes, entertainment and sometimes the apartments and offices above shops), and airport shops [5]. The number, size and structure of retail outlets have to be aligned with the number of tourists and residents of certain tourist areas, otherwise it may lead to adverse consequences, such as making jams, overburdened staff, who, because of that tired more quickly and more easily can lead to conflicts and misunderstandings. How will the product be marketed to tourists through its retail network depends on several elements, namely [1]:

- Range, quality, size and price of the products and method of payment,
- Readiness of the economy or the service sector to export their products through tourism,
- Working time of shops,
- Structure of retail stores,
- Personnel and Human Resources,
- Technical equipment of buildings.

With the rapid development of tourism in the twentieth century souvenirs have become mass products for final consumption and tourist souvenir shops have suddenly started to "sprout" some famous tourist attractions [8]. Also, air travels becomes increasingly popular form of transport, airports and expand their services including retail, intended for tourist consumption. These trends could be more and more spread, but most important is to emphasize that the more the world's population participates in the tourism and travel; new places for shopping are beginning to develop. As already previously

stated, recreation and shopping tourists was caused by social and psychological factors that tourists choose to purchase, and which have a strong influence of location, environment and characteristics of retail stores. These facts, together with the growth and development point of purchase indicating the great importance of understanding the location in which to place tourist shopping. Therefore it is necessary to explain what the organizational forms are and retail space for shopping, which meets in a tourist destination [3] [9] [10].

5. Presence of Retail in A Different Types of Tourist Movements

In one tourist destination an offer of variety of goods for sale may be organized differently i.e. may be presented different forms of retailing. In the more developed tourist destinations present a streamlined and modern retail outlets such as supermarkets, hypermarkets, then ever-increasing number of specialist shops-boutiques, jewelry, filigree, and a variety of small shops catering trade and profession (such as drugstores, snack-bars) , kiosks and stalls at intersections, beaches and busy places. Often, in tourist resorts appears Retail Street with a number of different tastefully decorated shops and boutiques, craft shops, souvenir shops, art salons, flower shops, cafes, snack bars. There is then located, also exchange offices and banks, as tourists would come as soon as the necessary funds for the purchase.

Special attractions for tourists are old town on the tourist areas. These narrow streets and intimate squares, which form a high quality offer in tourist places, become meeting places, for exchange of opinions, information, presenting fashion achievements. They have a dual role-supply, and fun. With this, it is necessary to ensure that it will be shops with distinct aesthetic elements and entertainment, and that their construction and adaptation fit on the maximum to the specific architecture of tourist destination. In the hotels of higher category are present souvenir shops and luxury goods [11] [12]. In tourist areas, especially those types of apartment complex and resorts are very popular so called "Green Market", that offer fresh fruits and vegetables, fish and other agricultural products. In addition to being used to supply the local population and tourists in agricultural products, "Green Markets" are one type of tourist attractions. On the "green market" farmers successfully sell their products and a tourist destination completes its offer with fresh agricultural products. Big stores cannot have profitable operations in the tourist areas, where there are many villages with little population and many small beaches and other places where tourists go in the season. So it should be gone for a simpler and less visible retail outlets, such as smaller shops, stalls with seasonal goods, novelty shops, souvenirs ... It is advisable to go to various forms of mobile trade, such as kiosks of light material that can be moved if necessary. Demand for goods and a range of different types differs depending on the different types of tourist movement and therefore he must be taken into account when creating a range of retail offer. This is depending on whether it is about tourism in already-developed tourist destination-a classic tourist spot, or just transit tourism, conference tourism and shopping tourism, which is becoming increasingly popular in recent years. Under-developed tourist destination means the destination that is most visited by tourists and where the infrastructure and superstructure is adequately developed. In developed tourist destinations are clearly differentiated tourism products and are complemented with additional content. Most often these are the tourist spots in the coastal areas (especially the Mediterranean countries), the famous ski resorts, spas and cities as a special City Break offer. As for the "city break" or short breaks in cities, it should be noted that the main motives of tourists in the city is business, heritage, and culture. Analysis of the number of tourists in season and out of season in a tourist destination, taking into account the maximum record in meeting and satisfying the needs of tourists as consumers, could be planned the offer the widest goods. Travel trends in the World are increasingly focused on large urban centers [13] [14]. Concentration of demand in time and space is, especially related to large cities, which will, as tourist centers, have a positive development. In addition to the tourist attractions that tourists show interest (e.g. cultural, historical and artistic value of these areas), large cities are important for maintaining large sets of content with various cultural and sports events. These are centers for the organization of mass entertainment and they are rich in offering various products [15]. In tourist areas, in which is primarily represented hotel accommodation, tourist expenditure takes place primarily through board services, or quite often, through half board. With full board, space for Additional spending is somewhat narrowed by the fact that tourists all their needs, for beds and food will meet in a hotel. The half board room, which is much more pronounced recently, tourists themselves leave the possibility for optional dinner at their option, a la carte, in places where they most like, and which is typical, they are often changing places to meet many objects. The Additional spending is very important, because tourists in their nights out not only meet their need for food, but expressed a desire to experience and curiosity to discover new things, for which if they are

satisfied, would pay much more. Various goods in this case can cause a desire to buy to the consumers-tourists. This particularly refers to the postcards, souvenirs, jewelry, books, clothes, pictures, etc... Tourists, who have opted for private accommodation, are consumers in the retail supply of food stores and markets, because they often prepare themselves food. The most attractive recently and the most wanted classic form of staying in the tourist area are the apartment complexes so called "resorts". This form of stay is advantageous for the retail supply of various commodities, especially food. In these objects, the supply of various commodities is significant, because in such settlements. Additional spending often exceeds the basic rental price of apartments and therefore in any analysis is extremely important. Of course, there is a possibility of a significant increase in spending, because of the fact that the rent of apartments has fixed character, and its accompanying spending has no limit. When is planned the supply of consumers goods in a classic tourist destination, it should be taken extra care of mentality and habits of its visitors, so it could be prepared an adequate supply of goods [16]. Of course, the analysis of tourist clientele and evaluation of its purchasing power must be provided with market offer to meet all its needs and desires and thus achieve substantial additional consumption through the retail supply of various commodities.

6. Ways for Retail Development in Tourist Areas of Serbia

Retail companies and enterprises that operate in tourist areas of Serbia, and in conditions far from equilibrium, will have to adapt to volatile and turbulent conditions that occur in the tourism and commercial market. They should be except instability, as innovative condition and as condition of accepting the default change, and only in this way will have the opportunity and chance of success [17]. The success of retail businesses in tourist destinations, and general trading companies themselves, will result in increasing the efficiency of management, retail companies, and the ultimate goal of developing tourism and increasing profits in the enterprises themselves, and all key stakeholders that appear in one destination. Taking into account that the tourist scene of Serbia, as relatively new and is subjected to adjustment, will be the same case with the management of retail companies, which will be easier to deal with changes in the product range, market demands, technology and the like. Special emphasis will be on the operational management of retail companies because management is the one who is directly responsible, that the various inputs and transform in output, through external factors, and the managerial functions of planning, organizing, staffing, leading and controlling [18]. Retail companies will be in activities related to retail management "package" offer, use different types of business policy- marketing policy, procurement, personnel policies, etc... In each of them worked out more detailed policies. The task of management is to create harmony between them. Also retail management should be also responsible for promoting of complete retail management "package" deals, and it is necessary to successfully lead the policy of assortment of goods, quality policy, procurement policy, the policy of the mark, the price policy, the policy site, promotion policy and personnel policy.

Successful policy of assortment of goods in the tourist destinations of the Republic of Serbia relies on desires and needs of visitors, based on which will be planned to make a selection of articles from the overall retail offer, and that they suit their needs and requirements. The future development of retail in Serbia, and thus the development of tourism mean a better understanding of tourists as a segment of consumers, particularly bearing in mind the growing trend of visitors to tourist destinations in Serbia. Marketing strategies must be directed to the segment of tourists, which until now in Serbia was not the case. Also, successful retail managers need to know your customer well, in terms of demographic characteristics, habits and lifestyle [1]. The existence of luxury products, which are currently scarce, when the retail offer of tourist places in Serbia is concerned, primarily intended for foreign markets, must be a key determinant of successful guided assortment policy. Dimension range depends on the profiles of market segments, which are determined on the basis of motive into a tourist destination.

7. Conclusion

When the retailer in Serbia is observed, seen as an integral part of tourism, it can be said that not much attention was paid to creating a retail "package deals", which means that there is no awareness of its importance for the development and improvement of tourist destinations. This means that the planning of tourist destinations, are not even take into account the additional activities that tourists do, and therefore there is no knowledge of the participants in the tourist industry, what is the importance of retail to tourism development in Serbia. Because of this so far and haven't been achieved significant

results, based on tourist purchases, and the same is true for other additional activities of tourists. A good part of the tourist in a, for these reasons, their time spent on activities in which it does not spend money, and undoubtedly reflects the fact that the existing tourism offer is not adequate, that is not presented in an appropriate manner (information, labeling, brochures, etc.). An additional problem is that tourists who go shopping spending, about the same as those, that take more attention to other activities suggesting that those who intend to buy do not have enough places where they could spend their money. For this reason it is necessary to examine tourism demand of Serbia, in order to obtain a realistic picture of the state of retail in tourist destinations and directed retail "package deals" to the wishes and needs of tourists, all in order to develop tourism in the Republic of Serbia and achieve significant economic effects of tourism and its complementary services, such as retail trade.

Innovative marketing tools for growth - brand extensions and brand portfolio strategy

Kristijan Petkoski¹

¹*University American College Skopje, Macedonia, petkoski@uacs.edu.mk*

Brand extensions is seen by companies as a profitable growth strategy, and it has been a hot subject among marketing academics in the recent research. Previous research showed that the extension success depends on the perceived fit between the extension and the parent brand. If consumers perceive high fit, the extensions would be more favourably evaluated. The case of lower fit between extension and parent brand may be considered as a mismatch between the attributes of the extension and the schema that represents knowledge structure about the parent brand. The basis of this study is the impact of brand portfolio strategy and differentiation on consumer evaluation of incongruent extensions, or extensions perceived to have low fit with the parent brand. The main issue addressed in this research is: how choice of extension's brand portfolio strategy and differentiation strategy from its parent brand can compensate for the problems caused by lower perceived parent-extension fit?

The study was designed to test the interaction between three independent variables (perceived fit, brand portfolio strategy and differentiation) and their impact on one dependent variable (brand extension attitude). The study was a 2 (perceived fit: low vs. high) X 2 (brand extension portfolio strategy: subbrand vs. endorsed brand) X 2 (extension's personality differentiation: same vs. different) randomized between subject factorial design. The interaction of perceived fit, brand portfolio strategy and differentiation, which is the main prediction in the hypothesis, was significant ($F(1, 150) = 4.49, p = .036$), supporting the predicted increased sensitivity to brand portfolio strategy and differentiation strategy in the lower perceived fit condition. The results of the additional tests indicate that using subbrand strategy and same personality for the extension as the parent brand can help to create more favourable brand extension evaluation despite the lower perceived fit. Therefore, brand managers may overcome problems caused by lower perceived fit, and succeed with business expansion opportunities that might be found in lower fit categories.

Keywords

brand portfolio strategy, brand extension, differentiation, personality, perceived fit

1. Introduction

Launching brand extensions is seriously considered by companies as a profitable growth strategy, and it has been a hot subject among marketing academics in the recent research. There are many studies on both consumer evaluation of brand extension and the impact of the extension on the parent brand. Companies tend to launch brand extensions with short or long stretch, thus building wider brand portfolios. Dove has extended from soap bar to shower cream and shampoo, Bulgari has extended from jewellery to perfumes to hotels, Courvoisier has extended from cognac to perfume etc. Previous research showed that the extension success depends on the perceived fit between the extension and the parent brand. If consumers perceive high fit, the extensions would be more favourably evaluated. But, it is naturally to ask what happens when the fit is perceived as lower. Do consumers automatically create negative attitude and reject the extension? How do they react to the information when they are exposed to advertising material for an extension with lower fit with the parent brand?

The case of lower fit between extension and parent brand may be considered as a mismatch between the attributes of the extension and the schema that represents knowledge structure about the parent brand, and therefore this incongruity case may be analyzed through the perspective of the Lee and Schumann's theory [1]. They propose an integrative framework for better understanding of the effectiveness of incongruity when it is employed in advertising, which is based on and combines Petty and Cacioppo's Elaboration Likelihood Model (ELM) and Mandler's Schema Incongruity Theory [2]. Congruity (incongruity) is defined as a match (mismatch) between a stimulus element (e.g. product, brand, or endorser) and the existing schema that one holds about the advertising stimulus. A schema represents the knowledge or semantic network structure regarding an object, which serves as a frame of reference in forming judgments. Depending on motivation and ability, consumers may respond differently to incongruent messages: they may ignore it, put relatively low effort (peripheral processing), or put relatively high effort (central processing). An individual that has motivation and ability to process the incongruity will try to find resolution. Mandler [2] has suggested four types of processing strategies: assimilation, alternative schema, successful accommodation, and unsuccessful accommodation. The basis of this study is that brand portfolio strategy and differentiation influence consumer evaluation of incongruent extensions, or extensions perceived to have low fit with the parent brand.

A key issue brand managers should address when launching brand extension and expanding the brand portfolio is the brand naming strategy, or the brand portfolio strategy for the extension (branded house, subbrand, endorsed brand, and house of brands). Subbrands and endorsed brands give the possibility to stay in a relationship with the parent brand, but still gain some independence. Subbrands allow some distance from the parent brand, and endorsed higher distance. Many leading companies have decided to extend their already established brands, using them as parent brands, and are successfully developing and managing brand portfolios. However, when brand portfolios become complex, distinction between brands becomes more blurred and consumers become confused. Customers switch when brands are similar; as a result, brand extensions may often cannibalize their parent brands [3]. Consequently, the brand portfolio strategy, choosing a name for the extension that signals close connection to the parent brand, may not necessarily improve the extension evaluation.

A second issue that brand managers are concerned with is the decision on position of the extension in the portfolio and the relationship with its parent brand: how distant should the extension be from the parent brand, should it have similar identity or slightly different identity from the parent brand? Many studies address the importance of fit between the parent brand and the extension in order the extension to be favorably evaluated by consumers and not to have negative feedback on the parent brand. Some studies support the impact of moderating variables that can facilitate to create fit between the parent brand and the extension. Although many companies have succeeded to create fit, there are examples where they fail to create a distinctive extension. The basic logic is that besides fit, differentiation from the parent brand [3] is another key factor in order to successfully launch an extension. This leads to one of the main issues to be addressed in the research: how choice of extension's brand portfolio strategy and differentiation strategy from its parent brand compensate for the problems caused by lower perceived parent-extension fit? While fit means creating similarity, differentiation refers to creating dissimilarity between the parent brand and the extension. While fit puts the parent brand and the extension under same brand platform, differentiation gives them a unique role in the brand portfolio. The need for two opposing factors in order to have successful extension and enhance the parent brand creates a paradox. The main goal of this research is to explore this paradoxical situation when positioning extensions in the portfolio, and the impact on the extension evaluation.

Finally, this study explores the impact of personality as a differentiating factor on consumers' attitude. Kapferrer [4] suggests that, as we move from product related to more abstract associations, the extensions can be more distant from the parent brand. Consequently, personality can be considered as one of the key differentiators. For example, Nike produces a range of sport products and equipment and has several subbrands such as Nike Football, Nike Golf, or Nike Air, all with same rugged personality. In Sony portfolio's case there are subbrands which have different personalities: Sony Bravia is sophisticated and elegant, but Sony Playstation has more youthful and exciting personality. After introducing the "natural" process of launching extensions and the strategic issues that need to be considered by brand managers, it is logical to put a research question that will bring together perceived fit, brand portfolio strategy and differentiation and discuss their interaction: *Can choice of an extension's placement in the brand portfolio relative to the parent brand, and the extension's degree of differentiation from its parent brand compensate for the problems caused by lower perceived parent-extension fit?* This research should give an insight how differentiation and portfolio strategy can be wisely used to overcome problems lower fit extensions might face. In many cases, interesting

business opportunities might be found in lower fit categories, and the study can give directions for how to succeed despite lower fit.

2. Literature review

Brand extension is one of the most commonly used strategies for growth and requires less support than launching new brands. Past research has identified different factors that influence consumers' evaluation of brand extension and the parent brand. Volckner and Sattler [5] find that fit between the parent brand and the extension is the most important driver of brand extension success, but some moderating variables can directly affect fit. Some studies challenge the view that congruent extensions usually enjoy success, but incongruent do not, or that as previous research demonstrates, unless consumers see bases for fit, they usually disapprove the extension [6]. Some further research implies that elaborative processing can influence consumer perceptions of brand extension fit and thereby change consumer evaluations of incongruent extensions. Maoz and Tybout [7] hypothesize that the relation between the congruity of an extension with the parent brand and extension evaluation will be moderated by factors that affect the cognitive resources that respondents devote to evaluating the extension. The findings are compatible with Mandler's schema congruity theory, showing that increasing involvement motivates cognitive elaboration and leads to the resolution of moderate incongruity and increases task satisfaction.

Consumer extension evaluation may be influenced by 'brand portfolio characteristics'. Volckner and Sattler [5] state that, although extension products do not guarantee success on the basis of the brand name alone, parent-brand characteristics, such as consumers' parent-brand experience and conviction, have an important impact on extension success. Several other studies consider some of the portfolio characteristics, such as various products and different categories with which the brand is associated, as moderating variable on the impact of fit on extension evaluation [8]. Meyvis and Yaniszewski [9] found that broad brands tend to have more accessible benefit associations than narrow brands and can therefore, engage in more successful brand extensions than narrow brands, even though narrow brands are more similar to the extension category. DelVecchio [10] argues that the number of product affiliated with the brand and the quality variance are important characteristics in evaluation of brand reliability. Additionally, alternative branding strategies can be used to increase consumer evaluations of an extension [11, 12, 13]. Still, there is need for evidence how brand portfolio strategy (brand name strategy) influences extension evaluations.

Differentiation of the extension from the parent brand is the second important issue when making decisions where to place the extension in the portfolio. In cases of incongruent extension fit is perceived as lower and the extension and the parent brand are not very similar. This indicates that there is no need for differentiation, since similar abstract associations may help for creating fit between the extension and the parent brand and may improve the consumers' evaluation of the extension. On the other hand, when the brand portfolio strategy signals that the extension is more distant from the parent brand, than it is expected of the extension to be different and similar associations may evoke confusion. Differentiated extension in this case may clarify the relation between the parent brand and the extension and generate more positive extension evaluation.

3. Conceptual framework

Based on the managerial problem I have identified in the Introduction section, and gaps in theory reflecting extension evaluation issues, I propose a conceptual framework that integrates the variables I have identified. The main purpose of brand managers is to maximize the market performance with optimized brand portfolio through building strong brand extension equity by leveraging parent brand equity and creating distinctive identities for individual brands in the portfolio. As previously discussed, alternative strategy seems to differentiate the extension from the parent name, while at the same time providing brand equity benefits. Besides, this strategy appears to affect customer perceptions of brand extension's similarity to the existing parent brand. Still, it is interesting to discuss the differentiators that can create sufficient differentiation of the extension from the parent brand, and thus result in more favourable attitude towards the extension and the parent brand. This study puts a particular interest in exploring the impact of the extension's level of personality differentiation on consumers' attitude to the portfolio strategy for a brand extension (subbrand vs. endorsed brand). In case of lower perceived fit or incongruent extension, subbrand strategy indicates closer position to the parent brand and same personality may strengthen the perception of closer relation between the extension and the parent

brand. On the other hand endorsed brands have higher distance from the parent brand and different personality may help to explain the relationship to the parent brand and avoid confusion, but at the same time endorsing strategy may help to leverage parent brand's equity.

In sum, this study predicts a three-way interaction between perceived fit, brand portfolio strategy and differentiation. More specifically, there is interaction between brand portfolio strategy and differentiation in low fit condition, and the interaction will not be significant in high fit condition. In order to test this interaction (perceived fit x brand portfolio strategy x differentiation), a 2x2x2 experiment study was conducted.

4. Overview of design, participants and procedure

Testing the research question requires a design that allows manipulation of the level of the brand extension portfolio strategy and personality differentiation, and control of the perceived fit measure. The prediction is that there will be interaction effect between these three variables. Additionally, internal validity is priority of this research, and also previous research in this field is based on experimental studies. The most proper way to examine the effect of three-way interaction is an experimental study with between-subject factorial design. The need to control perceived fit, brand extension portfolio strategy and personality differentiation on two levels each leads to eight conditions and a 2 (perceived fit: low vs. high) X 2 (brand extension portfolio strategy: subbrand vs. endorsed brand) X 2 (extension's personality differentiation: same vs. different) experiment. Personality differentiation and brand portfolio strategy were controlled on two levels each. To avoid unwanted associations, participants responded to only one brand portfolio strategy, and one differentiation strategy, either extension with same or different personality than the parent brand. Additionally, to reduce effect of potential confounding variables, participants were randomly assigned into different groups. A total of 160 students from BI Norwegian School of Management Oslo were selected to participate, randomly assigned to one of the four conditions (A-D), with a total of 40 respondents in each condition. Brand portfolio strategy and differentiation were used as factors to create those four conditions, and based on the level of perceived fit which was the third factor participants were additionally divided into eight conditions (A1-D1, A2-D2). The study is demonstrated in table 1.

Table 1 Experiment design

		Low fit		High fit	
		Same Personality	Different Personality	Same Personality	Different Personality
Brand Portfolio Strategy	Subbrand	Condition A1	Condition B1	Condition A2	Condition B2
	Endorsed Brand	Condition C1	Condition D1	Condition C2	Condition D2

Perceived fit was not manipulated, but it was measured and participants were identified and grouped depending on the perception as high or low fit. Lee and Schumann [1] argue that perceiving levels of incongruity (or fit) could be a subjective process. Therefore, participants completed question related to perceived fit and were identified as high or low on that measure by a mean split (Mean = 4.1329).

The brand portfolio strategy was manipulated through the name and visual identity of the extensions. Two portfolio strategies for manipulation were selected: subbrand and endorsed brand. Subbrands include the parent name and additional name related to the extension. The parent name and logo are included into the extension's logo through the original Nike logotype and swoosh logo. Endorsed brands consist only the extension name and are visually connected to the parent brand only by the Nike swoosh logo, playing a minor identification role.

Figure 1 Brand extension logos

The personality differentiation manipulation is concerned with the question if the extension has the same personality as the parent brand or it has new personality and identity. Based on the Jennifer Aaker's [14] five dimensions of brand personality (sincerity, excitement, competence, sophistication and ruggedness), the personality of the parent brand was identified and used in the further manipulations in the experiment. The pre-test showed that Nike has rugged personality, and therefore the extensions were designed and communicated with either same (rugged) or new (sophisticated) personality selected from the five aforementioned dimensions. Sophistication was selected as a new personality since it had the smallest beta coefficient in the regression analysis in the pre-test ($\beta = .009$, $p = .959$ n.s.), meaning that sophistication has the least significant role in attitude formation of the brand Nike.

In order to develop the experiment stimuli, previous Nike advertisements were analyzed. The same personality was communicated in the same manner as the previous advertising. The name "Eleven" was written with a number only and the logo was designed in a more sporty style. The message that the energy drink gives you power to reach the top was communicated through a rough image of a guy that climbed the top of a mountain. The slogan "Aim higher" was positioned vertically using Arial font with bigger size. The copy of the ad was also written with Arial font, using more rugged words "The new energy drink that gives you strength and max power". The differentiated extension was communicated with more sophisticated personality, which differed from previous Nike ads. The name "Eleven" was written with letters and the logo was designed in a more elegant style, giving associations of a more sophisticated product. The message that the energy drink gives you power to reach the top was communicated through a witty image of a guy that reaches the top of a building – the elevator goes to floor number 205. There was no slogan, but the message was rather visually communicated. The copy of the ad was also written with Times New Roman font, using more subtle words "The new drink that elevates your mind".

After being exposed to manipulation, the participants responded about their attitude towards the extension, as well as attitude towards the parent brand, ad attitude, personality of the extension, and purchase intention. The parent brand attitude was measured both before the manipulation and after the manipulation to identify the change. Therefore, participants first were asked to point out on the 7-point numerical scale their attitude towards the brand Nike, and then to answer the same question regarding the extension. Subjects were asked to rate their overall impression of the brands (parent and extended) on three seven-point semantic differential scales: bad-good, negative-positive, unfavourable-favourable. Ad attitude was also measured on three seven-point semantic differential scales: dislike-like, bad-good, favourable-unfavourable. Furthermore, extension personality was measured on 15 seven-point scales provided by Jennifer Aaker [14], grouped in five personality traits.

5. Results

The factor analysis with maximum likelihood extraction method and varimax rotation confirms that the three brand extension attitude measures are highly interrelated and yielded a one-factor solution accounting for 84.1% of the variance. Therefore, the brand extension attitude measure was calculated by averaging the three measures, or adding the three items and dividing the sum by three. Table 2 shows the cell-means of brand extension attitude measured in the study.

Table 2 ANOVA results - Effect of perceived fit, brand portfolio strategy and personality differentiation on brand extension attitude

		Low fit		High fit	
		Same Personality	Different Personality	Same Personality	Different Personality
Brand Portfolio Strategy	Subbrand	3.97 (1.27) n = 12	3.40 (1.26) n = 19	4.29 (1.04) n = 28	4.67 (0.87) n = 21
	Endorsed Brand	3.33 (1.16) n = 20	3.73 (.95) n = 25	4.37 (.99) n = 19	4.21 (1.11) n = 14
Marginal means		3.61 ^a		4.39 ^a	

^a: Main effect of perceived fit sig. $p = .000$
Std. deviation in parentheses

A 2 (perceived fit) x 2 (brand portfolio strategy) x 2 (personality differentiation) between subject ANOVA on the brand extension attitude index gave the following results. A significant main effect of perceived fit ($F(1, 150) = 19.43, p = .000$) showed that respondents rated the brand extension more favorably in the high fit condition ($M_{\text{high fit}} = 4.39$), than in the low fit condition ($M_{\text{low fit}} = 3.61$). This effect correlates with the previous theory that fit is necessary to have extension acceptance. The interaction of perceived fit, brand portfolio strategy and differentiation, which is the main prediction in the hypothesis, was significant ($F(1, 150) = 4.49, p = .036$), supporting the predicted increased sensitivity to brand portfolio strategy and differentiation strategy in the lower perceived fit condition. In the case of high perceived fit, participants did not show such sensitivity which correlates with the prediction that brand portfolio strategy and differentiation have no strong impact on extension attitude and perceived fit has the main impact. Simple effect tests within the low fit condition showed no significance in brand extension attitude, although within the same personality condition the attitude is more positive for subbrands ($M_{\text{same, subbrand}} = 3.97$) than for endorsed brands ($M_{\text{same, endorsed}} = 3.33, F(1, 30) = 2.1, n.s.$), and within the different personality condition the attitude is more positive for endorsed brands ($M_{\text{different, endorsed}} = 3.73$) than for subbrands ($M_{\text{different, subbrand}} = 3.40, F(1, 42) = .98, n.s.$). The pattern in figure 2 shows change in brand extension attitude in low fit condition when the extension is launched as a differentiated subbrand, meaning that subbrand with same personality as the parent brand has a higher attitude than the differentiated subbrand. In the case of selecting endorsed brand portfolio strategy, the differentiated extension has slightly higher score on attitude index than the undifferentiated extension.

Figure 2 The interactive effect of brand portfolio strategy and differentiation on extension evaluation in low fit condition

Figure 3 The interactive effect of brand portfolio strategy and differentiation on extension evaluation in high fit condition

The pattern in figure 3 shows that respondents were more sensitive to the manipulation of brand portfolio strategy in the differentiated condition, and this sensitivity disappeared when the extension had same personality as the parent brand. Still, there is no significance of the results in the high fit

conditions since, as previously said, perceived fit has the highest impact on brand extension evaluation.

Furthermore, additional test was conducted to check if the mean value of brand extension attitude for A1 condition (low fit-subbrand-same personality) was significantly different from the other high fit conditions. One way ANOVA showed no significant difference between A1 condition and the other conditions in the high fit case. The results indicate that using subbrand strategy and same personality for the extension as the parent brand can help to create more favourable brand extension evaluation despite the lower perceived fit. This supports the initial proposition that wisely using brand portfolio strategy and differentiation strategy might compensate for lack of fit.

6. Conclusion

As introduced at the beginning of this research, launching brand extensions has become extremely important and profitable growth strategy. There are plenty of examples where companies have created wider brand portfolios, multiplying their profit. However, there are many examples when companies have heavily invested in extension support, but have failed to succeed on market. Previous research has shown that if consumers perceive high fit between the parent brand and an extension, the extensions would be more favourably evaluated. But, brand managers have interest to launch extensions in more distant categories and in that case fit is perceived as lower. It is of key importance for brand managers to make right strategic decisions before launching and positioning and extension. As predicted incongruent extensions evaluation will be moderated by factors that affect the cognitive resources and impact the perception of lower fit between a parent brand and an extension to a more favourable evaluation. The expected three-way interaction between perceived fit, brand portfolio strategy and differentiation was supported. Namely, the results of the study suggest that when fit between brand extension and parent brand is perceived as lower, brand portfolio strategy and differentiation have an important role in brand extension attitude formation. More specifically, wisely using brand portfolio strategy and differentiation strategy might compensate for lack of fit, for instance using subbrand strategy and same personality for the extension as the parent brand may lead to more favourable extension evaluation, despite the low perceived fit.

The aim of secondary vocational education is oriented toward sustainable academics performance that can contribute the development of the country. A mission is of great importance to the organizations as well as for vocational high schools since it promotes vision, values and its goal. It communicates not only to the employees but to the stakeholders and thus provides the basis for the priorities, strategic plans and work tasks of the organization. The paper focuses on the mission statements of Macedonian vocational high schools which they posted on their web sites. With the use of content analysis, the research has the aim to evident the presence of mission statement and whether those statements contain words that support entrepreneurial spirit, like: entrepreneurship, innovation, creativity, self employment. Aside from determine the focus of interest of vocational high schools and their readiness to develop entrepreneurial skills, the research results can contribute to promoting the quality of the mission statements of the vocational high schools.

Keywords

Content analysis, entrepreneurship, mission, vocational high school.

1. Introduction

The vocational education and training system is a very important for the economic development of the country. The basic aim is to educate well trained labor that will be productive, cohesive, motivated and capable of accommodating change and introducing new technologies. The authors agree that there is a need to establish link between vocational education and entrepreneurship. Vocational educators have recognized that starting a business is a natural outcome of vocational skills training, and they are moving ahead to encourage the entrepreneurial spirit in all kinds of young people education. During this period, secondary vocational education in Macedonia is undergoing changes as in terms of programs and the aspect of the intervention of the Government for compulsory secondary education. All this reflects the increasing need for continuous quality improvement of the education plans end programs. This situation requires a sophisticated set of objectives and reallocation of resources in these institutions. One of the goals is certainly to build school programs that will develop student's entrepreneurial skills. To achieve these goals vocational schools need to master the strategic management skills. An important aspect of strategic management is creating a solid mission statement.

2. Secondary vocational education in republic of Macedonia and entrepreneurship orientation

Macedonia education system can be classified into two broad divisions i.e., pre-higher and higher education system. The pre-higher education at Macedonia can be further classified into primary, secondary and high education system.

Secondary education in Republic of Macedonia comprises of the following : vocational education; high school education for disabled students ; classical high school education ; art high school education .

Vocational education and training is a part of the educational system, which provides individual development of the personality before acquisition of competencies, knowledge and skills necessary for involvement in the labor market or continuation of the education. It enables initial acquisition of first, second or third level of vocational qualifications. The vocational education and training is delivered through teaching plans and programs for the following types of vocational education:

- Vocational training for jobs with lower requirements which provides practical knowledge and skills for various labor areas. The vocational training programs can include students that obtained elementary education as well as those who have not obtained, but with an obligation, in parallel with the vocational training, to finish their elementary education. The vocational training, depending on the complexity of the occupation, can last up to two years. After the students have finished the vocational training, they acquire I level of vocational qualifications. The students that have graduated vocational training which lasted minimum one year, can continue their education into the second year of the appropriate vocational training for occupation. The students that have graduated in vocational training which lasted minimum one year, can continue their education into the second year of the appropriate vocational training for occupation.
- Vocational training for occupation is dedicated to meet the needs of the economy. Students that have obtained elementary education can enroll in the first year of vocational training for occupation. The vocational training for occupation lasts three years. The vocational training for occupation is delivered in a vocational education and training schools, while the practical training is delivered in the school and in the employers premises. After the students have finished the secondary vocational training for occupation, they acquire the II level of vocational qualifications.
- Technical education is education which mainly produces staff for employment in all fields of labor, but also for continuation of the education. Students that have finished elementary education, or have graduated in vocational training, can get enrolled in the first year of technical education. The duration of the technical education is four years. After graduating in technical education, the students acquire IIIrd level of vocational qualifications. The total number of education profiles is 42 into the frame of the 14 vocations. Students that have graduated technical education can continue their education into university institutions, if they acquire State Matura

Secondary vocational pupils are the number of secondary students enrolled in technical and vocational education programs. Republic of Macedonia has 27 mixed high schools with classical high school and vocational high school education and 38 only vocational educational schools. According to this the total number of vocational high schools is 65.

So far there is little interest in the two-year vocational training for work, the first, lowest level of professional qualification. Such programs are offered only in a small number of occupations: mechanical, construction, electro-technical and others. The three year vocational education programs, which are the second level of professional qualifications, recorded 9.99% of the students, a relatively small percentage compared to 39.3% students who attend high school and 50.8% students who are enrolled in four year programs in vocational schools.

Presently, the Macedonia vocational high education system is undergoing reformation. The system is getting much more simpler so that it can match itself with the educational systems of other European nations. The basic idea is to abolish occupations that are obsolete and archaic and to introduce new one that will satisfy labor market needs.

The recommendations from European Commission for Enterprise and Industry is that if Europe want to make a success of the Lisbon strategy for growth and employment, needs to stimulate entrepreneurial mindsets among young people, encourage innovative business start-ups, and foster a culture that is friendlier to entrepreneurship and to the growth of small and medium-sized businesses. The important role of education in promoting more entrepreneurial attitudes and behaviours, starting even at primary school.

Educational institutions have a responsibility to include in their curriculum techniques for helping students develop entrepreneurial skills. In order to be successful in this reform it is necessary to

develop partnership between business owners and vocational educators and to infuse entrepreneurial education in vocational education.

Entrepreneurship education should not be confused with general business or economic studies, as its goal is to promote creativity, innovation and self-employment.

According to analysis on the official education programs approved from the Ministry of Science for the secondary vocational schools, made for the purpose of this research, education for entrepreneurship can be found only in the subject named "business". This subject generally contains basic aspects of how to establish and run business. Components like creativity and innovation are missing. Students learn this subject in 3 and 4 year on secondary vocational education level. The exception is program in high school for the economy where students learn subject "business" starting first year.

3. Vocational high school and meaning of mission statement

Mission statements are created to represent organizational values and guide the actions of the vocational schools. With increased demands for school management and academic accountability, school leaders are under pressure to ensure and maintain high levels of academic performance, and respond to the needs of the environment.

According to Ireland and Hitt mission is important for all types of organizations because: effective mission defines the fundamental, unique purpose, distinguishes the organization from others that are in the same business, identify scope of business operations, in terms of products and markets. Mission statements serve to provide motivation, general direction, company image, color, set of attitudes that guide organizational actions. The mission has the soul of the company and it is inspiring the actions of the members.

The authors like Drucker, Pearce and David agree that the need for strategic planning appears to be a foregone conclusion to the changing demands of the environment. Mission statements represent the first step of strategic management to adapt to changing conditions of their environment.

The success of any business, including secondary vocational education is perceived in the supply of products and services that are competitive worldwide, not just locally. Global markets are becoming reality. Macedonian high schools need to change the value system and organizational culture to be able to meet the new demands of their environment. That is to shape the profiles of students who will respond to market demands, but will be able to follow the innovations in terms of technology and have the leadership skills to create businesses to run.

4. Scope and subject of the research

The survey is conducted in high vocational schools in Macedonia is the first of its kind and seeks to explain:

- Whether or not there is a mission and what is the focus of attention devoted to specific topics;
- Which words are contained in mission statements of vocational high schools with particular interest to: entrepreneurship, creativity, innovation, self-employment, small business.

In designing the *sample* survey, the official data was used - a document issued by the Ministry of Education and Science of the Republic of Macedonia (4.02.2011), with the current number of vocational schools in the country. According to the document, in the Republic of Macedonia officially registered 65 vocational schools.

The *unit of analysis* in research was the missions content of vocational high schools announced on their WEB pages. In cases where the mission is not released, was analyzed the contents of the parts: Address of the founder, for us, Objectives and History.

The *technique of research* was content analysis, because this technique allows discovering and describing the focus of individual, group, institutional or social attention. It also allows inferences to be made which can then be corroborated using other methods of data collection. Content analysis is also useful for examining trends and patterns in documents.

The survey was conducted in the period from 11:01. 2011th to 4.02.2011

The components of the content research were the following words: entrepreneurship, small business, innovation, creativity, self employment.

4.1. Results and discussion

The web search results suggest that only 12 from 65 schools have their mission statement published on their official web site:

- “D-r Jovan Kalauzi” – Bitola
- “Jovche Teslichkov” – Veles
- “Dimitrija Chuposki” Veles
- “Metodija Mitevski - Brico” Delchevo
- “Mitko Pendzukliski” – Kratovo
- “Car Samoil” – Resen
- “Georgi Dimitrov” – Skopje
- “D-r Panche Karagjozov” – Skopje
- “Lazar Tanev” – Skopje
- “Marija Kiri Sklodovska” – Skopje
- “Nikola Shtejn” - Tetovo

Some of the schools (total number: 18) have their official web site, and most of them (total number: 30) are integrated in the portal which is established by the Bureau for education development. The access to the portal doesn't have an open character, it requires user name and password to log in, and the information are generally not up-dated. Only 3 schools promote e-learning. E-learning is a new tool that helps students to study 24 hours a day. This means that the teaching content is available online and provides immediate feedback to help students to learn. At the same time helps teachers to produce web-based courses.

The content analysis of the mission statements, as it was required for the purpose of the specifically defined research objectives, was focused particularly on these following components:

- Entrepreneurship
- Innovation
- Creativity
- Self-employment

Therefore, the results from this type of research bring disappointment from entrepreneurship perspective, as there is no emphasis on development of that kind of behavior, skills and spirit in young people in Republic of Macedonia, as the components are not consisted in any of the mission statements, except in the mission of “Lazar Tanev”:

“The school's mission is directed to training young people to be responsible in social life respecting the principles of democracy, tolerance, constructiveness, patience, mutual understanding, *taking initiatives, being creative and being competent.*”

The conclusion implied by the content analysis conducted of the missions is that schools are still self-orientated, because the missions highlight as most important values the implementation of educational plans and programs, while missing outward orientation or sense of fulfillment of wider social goal and development of entrepreneurship spirit, as high level priority.

Although further research is needed to determine relationships between mission statements and the values which contribute to the development of entrepreneurship and students behavior that is actually manifested in a school, some practical implications may be drawn from this study. As such, vocational school leaders should support the collaborative development of school- specific mission statement. Furthermore, vocational high school principals need to share their personal vision with their staff that articulates the type of organization they desire to achieve. Also, mission statements should be readily identified on campus websites to enhance communication with parents and the community.

We believe, however, that having a shared mission statement is a starting point to re-culture schools. As we stated in the beginning of this study, mission statement represent organizational values and provide direction for the employees and it will contribute to development of the entrepreneurship spirit.

5. Conclusion

The development of entrepreneurial skills among students is an important aspect of vocational high education. Agreeing with Drucker that the entrepreneur is a person that maximizes opportunities, a person with this competency is also required as an employee and as founder of a small business, or agent of social change for further development of the country. There is no doubt that vocational schools have an important role in this process and the upcoming reforms. But no reform is possible without changing the organizational culture and mind set of employees. A mission has important role because it shows at least a little, the values that institution tries to uphold, also the meaning and direction of action. From conducted mission research it is clear that the function of strategic management in many vocational schools has been neglected. Here we can share the opinion of Kreber and Mhina that mission cannot be held as sure proof that institution will meet the goals and ideals that they publicly declared to meet. Nevertheless, analyzing the mission is important because the institution itself holds it important. This is way researching mission statement is a useful start to researching values that schools uphold. The current analysis showed that in vocational high schools lack awareness of building the entrepreneurial spirit. The essential elements and characteristics of entrepreneurship as innovation from which comes the power of entrepreneurship, learning to take the risk to self employment, creativity, are rarely represented or do not exist in mission statements. From the analysis can be seen the school attitude toward the information and communication technology. In most schools analyzed web pages are have not been updated since 2007. This research can be used as the basis for understanding the changing trends over time.

Innovation as the answer to the quest for regional progress

Amna Potočnik¹, Matjaž Mulej², Simona Šarotar Žižek³

¹ *Maribor Development Agency, Maribor, Slovenia, amna.potocnik@mra.si*

² *University of Maribor, Faculty of Economics and Business, and IRDO Institute for development of social responsibility, Maribor, Slovenia, mulej@uni-mb.si*

³ *University of Maribor, Faculty of Economics and Business, Maribor, Slovenia, zizek@uni-mb.si*

Neoclassical Economics and Economic-Geography had the largest impact on the Slovenian regional development since the seventies in the 20th century. Joining the EU had its impact on regional development planning, especially with the preparation and implementation of Regional development programs, the first for the period 2004-06 and the second for the period 2007-2013. 12 development regions were established at the NUTS III level. The current economic crises shows, that the European and therefore also national development policies are not sufficient to shrink the divergence between the regions. But if the profit is not the ultimate goal (and neither is the competitiveness), what should be put in the centre of humankind's care?

With the Dialectical Systems Theory we can show, that the regional development is complex and complicated in nature and the humankind is endangered by entropy against which we can bet only with induction of innovative changes (that are constant parts of development). Consequently: if we strive for progress (and not only development in this or that direction) in regional development, the processes, the mechanisms and the tools for generating new and useful (and only such!) should be set up. Regional innovation therefore is in the centre of sustainable development. Without doubts, an adequate institutional framework should be established that would encourage the progress and would take into account all levels: individual – community – region – state – EU. Therefore we suggest establishing of two models: the first one for strategic regional management and innovation and the second for the implementation of the cohesion policy on the regional level for the period 2014-2020 that could be used for Slovenian region Podravje as well as other regions.

Keywords

Cohesion Policy, Dialectical Systems Theory, Innovation management, Regional innovation, Regional development policy

1. Dialectical Systems Theory (DTS) and regional development

Mulej's DST [1] made the dialectical system concept (instead of a General System Theory [2] one) methodologically supported by becoming, formally, a dialectical system of three elements and three relations, in general. They are supposed to both influence humans as observers, thinkers, decision makers, and decision implementers, and to help them attain the requisite holism of their behaviour to enable the best possible results. Success is thus attained with no excessive effort and no crucial lack of insight and influence; this requires a well-managed process in which all crucial steps, interdependences and synergies are considered. In order to attain such a success, human attributes of both decision makers and decision implementers must support creativity and requisite holism with co-operation of complementary professionals. In this effort, it helps a lot, if application of theory can

take place in an informal style. This is why there are three relations and three elements in the DST as a dialectical system: all of them are both essential and sufficient; in other words, DST matches criteria of requisite holism. The three DTS applied to the regional development are shown below.

The law of requisite holism (it demands the author/s of the definition of a system representing the object under their consideration and/or control to clearly state what part of attributes of the object is included into their system; this is the mental picture of the object under consideration and/or control; one must do one's best to fight over-simplification by all available/crucial knowledge and skills as well as by ethics of interdependence).

Applied to regional development, the law of requisite holism shows, that the space-based policy [3] in which region is described as three spatial and one time component is not sufficient to capture region as nexus of individuals (which can be on the aggregated level described in terms of well-being that can be measured with objective as well subjective indicators). In the same context the RDPs as the strategic plans of regional development are complex in nature and even in mathematical terms. However, the sustainability which is still understood as the leading objective of regional development is still divided into environmental, economic as well societal development. The institutional aspects are usually left out. Even if we take into account all four strands, the same challenges (as the development issues are) are viewed from too narrow viewpoints. This problem is not solved with the so called horizontal measures such as innovativeness, gender mainstreaming etc. What should be done is to overcome the »silos« thinking and start to work in the trans-disciplinary teams if the new and creative outcomes should be found for all the challenges that regional inhabitants judge as important (weather from the cognitive or emotional viewpoint)? We should not neglect the fact that the convergence (in macro-economic terms, [4]) is not seen between the states as well as not between the regions (in case of Slovenia the regional divergence is constantly increasing despite the regional policy proclaiming to act in favour of less developed regions, [5]).

The law of entropy (it reflects the reality in which there is a permanent tendency toward destruction, which demands requisite holism and innovations permanently; the latter ones have conditioned survival since the times humankind has given up human's adaptation to nature).

In the context of the law of entropy we have to consider, think and rethink: shall we induce the changes; shall the changes be hindered; shall we try to attain the equilibrium. The mentioned possibilities are showing the possible re-action to the changes: in the first case we strengthen them, in the second we try to suppress them, and in the third we try to minimise their impact. Why do holism and innovativeness as human attributes matters? With both of them we can act against the entropy. Although the innovation should not be linked to small technically and technologically novelties elaborated without the formal duty, the innovations are still described and interpreted in those terms (although the EU definition [6] prescribes, that innovation is every novelty proven as beneficial in praxis (and only such) [1]).

In the context of development the innovativeness could be defined as constant intention of spirit/thoughts/intention that is striving for newness (usefulness is the measure set by the European innovation policy as criteria for justification of the public funds spent). If the intention for people to look out for newness is the smallest denominator of the being and human doing, then in the regional development we have to take into account all three components:

- Organisational (with the question: is the organisation that should be liable for regional development, innovative enough to play the role of regional impulse maker)?
- Processes (if anything, and what, is changing with the introduction of single measures aimed at enhancement of regional development programmes and even more important):
- How the different components of the society/individuals are included in the development or products/services (of which the RDP is part)?

Speaking in DTS terminology the innovation is described not as a sum but as synergy. Which of the mentioned factors below may be zero? *Innovation = (invention X entrepreneurship and entrepreneurial spirit X requisite holism X management X co-workers X innovation-friendly culture X customers X competitors X suppliers X natural environment X socio-economic environment and other outer, i.e. objective conditions X random factors, such as luck)*. Thus, we see a long and complex way from idea via invention to innovation/new benefit.

1.1 Differences between invention, potential innovation and innovation

Invention is every new idea that might lead to the benefits of the customers and authors/owners. Technologically-technical invention used in the production could be monopolised by the patent. The number of patents in official statistics is a frequent measure of inventiveness and unfortunately also of innovativeness of particular state or the region. Potential innovation describes the level of invention development when it has all attributes needed for practical usability but still does not provide benefits for the users and authors/owners. The technological-technical as well as marketing, investment, financial, production and other viewpoints should be taken into account.

Innovation has already its customers and proven – more than usefulness: proven benefit in practice. Not to be forgotten: only one of 3.000 ideas, one percent of the patented inventions and four out of one hundred official company innovation projects become radical innovation and seven percentages incremental innovation. Percentages concerning non-technological innovations are not available, but they are obviously even more complex, because they attack the given habits.

What novelty is useful and beneficial, the customers decide; in case of the development funds these are the contracting authorities or the private capitalist (in case of regional funds the authorised civil servants). Therefore their judgments about the novelty and their benefit from it are matter of subjective viewpoints (norms, culture, ethics, values etc.) as well as the knowing about the regional state of affairs. Still there is no distinction between the promising idea-suggestion-invention and innovation in public calls and the scores that are usually given to the applications are solely arbitrary (what is assessed as the more then potential cannot be assessed; more, it is neglected that the target group has to decide whether or not the novelty is (and not will be!) useful and beneficial to them. Therefore innovation is invention plus commercialisation [8].

How do these findings apply to regions in need of more innovation as processes and its outcome?

2. Agency for Regional Innovation

The first step the regions can make to reorient development (at least in Slovenia) is to change the nature and tasks of regional development agencies (12 development regions in total, but without legislative power). Therefore we propose the model that could be applied to all regions called ARI (Agency for Regional Innovation).

The national innovation systems were popular at the end of 20th century. Slovenia is very centralized (in political as well as in policy terms) and »feudalized«: the regional development (and cohesion policy) is under the Governmental Office for Local Self-Government and regional policy that is also in charge of accreditation of the 12 development agencies; for encouragement of entrepreneurship and competitiveness the Ministry of Economy has its own agency JAPTİ (with the VEM points on the local level), Ministry of Higher Education, Science and Technology has its own agency TIA, while the spatial planning is under Ministry of Environment that is not active on the regional level (on the lower level of municipality there are special spatial departments and offices in charge of municipal preparation of spatial plans).

From the description it is obvious that Slovenia has a heavily centralised organisation (all important functions and funds) and on other hand it is explicitly dispersed without holism. Regional development policy must become trans-disciplinary; it cannot be in charge only of the economic development, but also of spatial, environmental as well as societal dimensions not neglecting the institutional set up (of its working). Regional development agencies, in the coming years, have to be transformed into agencies for regional innovation (ARI).

The tasks of ARI shall become:

- Mediator and mutual connectors of innovation potentials in regional community. It shall become nexus of the network that includes inventors, innovators and others that are encouraging new and useful that may become beneficial for the region at stake and its partners. ARI shall act on local, regional, and international levels by networking domestic and foreign knowledge by searching for new answers to the local needs (and not only global or national problems).
- ARI shall introduce new and useful ideas for local/regional society that are going beyond technical and scientific inventions into non-technological ones.
- ARI shall use the innovative technologies, including the e-Science, virtual reality, simulation techniques so that it will not only inform but also introduce innovative changes into its e-regional community.
- ARI shall shape the innovation policy on local, regional as well as on other levels by unleashing the potentials of public sector and public services and sponsoring their cooperation with business

and future to-be businesses. The innovation metrics shall be aligned to the needs as well as the innovativeness of public services shall be shown, documented and validated etc.

- ARI shall promote social responsibility of local and regional companies to become the echo of customers, their requirements as well as expert's discussion about what the customers expect from the producers. ARI can contribute to the social responsibility by revealing the cognitive preconditions needed for innovation: from interdisciplinary creative cooperation, basic creativity, problems detecting and solving, interpersonal skills to management, on one hand, and the risk taking, provocation, initiative taking and facing with problems as typical innovators attributes on the other hand. ARI shall contribute to socially responsible public procurement by requesting the green and innovation policy from the suppliers or the service providers: only the most socially responsible, total quality developed to systemic quality supplier-networks shall be eligible.
- ARI shall become research and development institutions for its region. ARI shall prepare pilot projects that have impacts on regional level of economy and quality of life.
- ARI shall not be only a propaganda machine for the mayors but shall serve broader societal interests reaching beyond for local policy people to meet, prescribe and decide but for companies, NGOs, research and educational institutions to meet. Therefore it shall become the engine of innovative and socially responsible changes in regional community.

Thus, the core of ARI shall consist of regional innovation and its diffusion.

2.1 Regional innovation and diffusion – the core responsibility of ARI

Due to the emphasis given to the economic development within the regional development, the question is how the ARI can contribute to the regional innovation and diffusion processes (IIDP).

The following question should be answered beforehand: 1. How to encourage the regional creativity; 2. Which is the invention-innovation-diffusion process management's role: from the idea generation to the innovation diffusion; 3. How to design the regional market for invention, potential innovation and innovation and how to impact the speed and volume of diffusion; 4. How to place ARI on the innovation market. The possible answers to the questions are there in the Table 1 below.

Table 1 Regional organisation of IIDP support

Level of novelty	Institutional support on regional level – ARI	The elements of support
Invention/suggestions (promising and written new idea)	Establishment of regional business angels clubs (to be included in EBAN and national business angles networks) with prepared services. Establishment of regional innovation fund for promising inventions with the web-portal for the mutual cooperation	Search for business angels; preparation of contractual agreements; act on behalf of the inventors; preparation of contracts (financial arrangements); services for business angles (clubs meetings, trainings, evaluations etc.). Establishment of teams (connection with research and marketing institutions), legal, marketing, business, financial, tax counselling.
Potential innovation (=useful novelty)	Set up of regional seed capital fund	Networking of potential innovation owners with the entrepreneurs and fund raising for the start of the production.
Innovation (=proven benefit for users of the novelty)	Regional marketing platform	Marketing research, connection of results from previous phases with potential producers; Marketing actions; function of opinion leaders.

3. The model of innovativeness and strategic management of development region (NUTS III)

3.1 Preparation of institutional framework for regional strategic and innovation management

1. Regional Council (at the very moment the group of all mayors in one development region) nominates the Council for regional innovation and strategic management (CRIS) that shapes,

steers, monitors and oversees the economic, environmental, societal as well as institutional development of regional society grounded in the IIDP. CRIS is composed of 12 experts (multidisciplinary team with references), established for a 5 years term. It prepares yearly report to be approved by the Regional Council (that decides about the awards for the members according to their effectiveness and efficiency – the measures to be elaborated in advance and to cover all five years to prevent short-term criteria).

2. For the implementation of strategic innovation and management of development regions the ARI shall be established in each of them. The composition could follow the principles of public-private partnership.

3.2 The roles and tasks of ARI shall be

1. ARI is responsible for IIDP in the region;
2. ARI shapes the innovation policy on the regional level;
3. ARI is multidisciplinary organisation, above any local/global »think-tank«;
4. ARI acts on all 4 pillars of sustainable development (societal, economic, environmental and institutional) as well overcoming the division to four pillars (inter-connection and mutual interdependency of the researchers as well as research topics and their interactions);
5. ARI is directed toward the development phase of new and benefit promising (and the implementation of novelty in the case of social innovation and commercialisation in the case of business innovation): ideas, suggestions, inventions and well as innovation promotion;
6. ARI acts as the quite holistic interdependent platform for public and private organisations to induce novelty (also with challenging or highlighting the norms, ethics, codes, modes of doing and being) and is so the basis for rethinking so called tasks of strategic development in researching what is the content and what the ways of possible development.

3.2 Basic regional development documents

1. ARI is responsible for the preparation of single strategic documents as basis for innovation of development regions (long-term, mid-term as well as short term strategic plans as well as for the organisation of ex-ante, mid-term and ex-post evaluation). The strategic documents are approved by the Council for regional innovation and strategic management. The funds are guaranteed by the ARI founders.
2. ARI acts with the established professional management of IIDP and strategic regional development team that has sufficient capacity of inventive, motivated and entrepreneurial managers, responsible for the implementation of the strategic documents including the establishment and financing of regional development instruments. Financing is assured through the offered services. For the elaboration and preparation of services the organisation shall apply in the eligible calls for proposals or by use of PPP.
3. Regional innovation instruments are (inter alia):
 - Preparation of regional development platform (active participation of regional inhabitants and use of modern ICT for open innovation);
 - Preparation of regional development indicators and their monitoring as well as evaluation of impacts of single programmes/projects that are implemented on the regional level (by taking into account subjective as well objective criteria of wellbeing and social responsibility, including sustainable development);
 - Preparation of regional platform for IIDP (for cooperation of: intermediaries whose success can be measured with the success of their target groups; specialised organisation – funds, clubs etc., inventors and innovators and broader public including public media);
 - Preparation of regional club of business angels (that is able to act closely with the national and international networks of business angels) with developed services;
 - Preparation of regional fund for promising inventions with the portal (for open innovation);
 - Preparation of regional seed capital fund;
 - Preparation of regional marketing platform (including the elements of regional internationalisation).

The proposed model for innovation and strategic management in development region has in its core its tendency to solve the problem of entropy and quest for permanent development of innovative

changes in the community worked on. On the institutional level it makes sense to innovatively change the existing model, reduce the competences of the current institutes (such as Regional Council), avoid conflicts of interest, foremost shape the regional instruments for IIDP that will enable development and break-through on the global level. The starting point is preparation of long-term, middle-term and short term development strategies which are not bound only to the cohesion funds. More, for the efficiency of regional strategic management there is a need to increase the professionalization - of ARI as institutions as well as their members. Therefore we propose to shape new organisation, ARI and the Council for its supervision. ARI must, especially in the phase of generating new ideas and suggestions and inventions, become local/regional »think-tank« that will have knowledge and competences to be actively involved in societal innovative changes that will see and take part in challenges and searching for answers that will be implemented with new development instruments.

4. Model for preparation cohesion implementation on regional level 2014+

The law of hierarchy of succession and interdependence (later events depend on earlier events of the same process crucially; processes and events interact, when and because they are interdependent; interaction is a precondition of survival, too: without it processes stop) is applied here.

Applied to regional development, the law of hierarchy of succession and interdependence shows that the final outcomes are not bound only to the implementation part (work programmes as the fundamental proves) nor to the management or information process but foremost (although not exclusively) it depends on its starting points. So: which starts points shall be chosen to be in line with the contemporary circumstances? Because one cannot neglect the subjective starting points of the observers/researchers/experts who are preparing the RDP, the broader societal consensus shall be reached not only about objectives, priorities and tasks in the defined time space but also about the ethics, norms, values and culture shaping the society. Therefore the new model (in accord with the regional development) shall be set up.

Model for the preparation of implementation documents for the new cohesion period on the regional level 2014 – 2020 is proposed due to the deficiency of centralized model of cohesion funds and unclear and especially conflicting roles of regional (local) development institutions. Therefore the innovative changes should be made on national, regional, and local levels.

4.1 National level

1. Development forum shall be set up consisting of e.g. all 12 Slovenian development regions to discuss allocation policy based on regional proposals (starting points are the strengths and regional challenges seen in long-, mid-term and short term strategic plans).
2. Allocation of funds on regional level with the establishment of special development fund by the ARI.
3. Yearly development forum with the task to monitor regional development and the impacts of the cohesion policy.

4.2 Regional Level

4.2.1 Phase: project identification

This phase should enable the broadest collection of potential projects that are justified as needed as well as holistic and considering interdependence of local and other units. In this phase the criteria for project ideas selection should be prepared and define the minimum criteria (elements for the purposes, partnerships, project types – services/supply/works as well as set up the financial volume of projects) and based upon the criteria select the project ideas.

1. ARI prepares the web-based platform for idea generation (and e.g. market the 10 best and 10 flops); their senders have to be identified (either as the representatives of organizations or physical persons).
2. ARI announces the criteria for project idea selection by taking into account the answers to the following questions:
 - Does the project contribute to the well-being of inhabitants (material vs. subjective well-being)?

- Is the project innovative (from the management viewpoint, processes or services/products) and, if so, is it found such by the target group (challenges for stakeholders/target groups or problems faced by the target group)?
 - Are there solutions that have already been developed with the public funds and must be only transferred, adopted, and adapted (and would therefore for the target group still represent a beneficial novelty)?
 - Does the project at stake contribute to the social capital of the region (partnership, quantitative and qualitative criteria)?
 - Is the project socially responsible, e.g. sustainable in the nature (viewpoints of sustainable development: environmental, economic, social, and institutional)?
 - Are the equal opportunities and other horizontal policies of the EU/nation/region taken into account?
 - Does it, and if so how, the project contribute to the social responsibility as the ethics and strategy in the region?
3. Part of the allocated funds shall be reserved for so called strategic projects and part for those for which the societies in broadest terms can participate.
 4. ARI prepares the list of proposed project ideas and submits it to the Council for information only.
 5. ARI gets into contact with the project idea holders so that the next phase could begin.

4.2.2 Phase of project structuring

In this phase the feasibility studies have to be prepared according to the joint methodology; the different policy should be taken into account by project screening, the private interest shall be estimated, cost-benefit analysis should be prepared, and the preliminary appraisal of financial construction as well the implementation structure should be done. Only so called structured projects should become part of Regional Implementation Plan.

1. Projects structuring is done in interdependence and interaction of the project holders and the ARI.
2. ARI reports monthly about the status of the projects to the Council.

4.2.3 Phase of Project financing

Project financing: cost-benefit is only one element of this phase which shall answer the question, which projects shall be co-financed and in which sequences; at this point it should be decided: whether the project is feasible (with/without modifications) or not and if it is acceptable from the cost-benefit viewpoint; if it is so, the implementation structure should be defined by taking into account potential risks in order to enable feasibility, transparency, efficiency and effectiveness of the implementation. The legislation linked to public procurement should be respected.

1. ARI is responsible for financial transparency of the project and for the closing of financial project's construction.
2. ARI is in charge to inspect the appropriateness of the documents (legal documents).

4.2.4 Project implementation phase

1. For the project implementation the project partnership is responsible.
2. ARI shall offer technical assistance to the project holders if needed.

4.2.5 Phase of projects monitoring

The phase includes the monitoring of financial issues as well as attainment of objectives/results/verifiable indicators as well as other aspects needed for the project implementation (spatial plans processes etc.). The on-site monitoring should become a crucial monitoring tool.

1. ARI shall prepare the on-going monitoring system for project implementation.
2. Council approves the monthly reports on the programme level.

4.2.6 Evaluation phase

The evaluation of RDP implementation (as well as of single projects) should take place as ex-ante, mid-term, and ex-post phase.

5. Conclusions

In order to avoid entropy and status-quo of the current regional development policy we proposed two models: the first model presents the new role of the regional organisations that has to manage strategic regional processes as IIDP (labelled as Agency for Regional Innovation in contrast to the current Regional Development Agencies); and the second outlines the participation model for the regions in allocation policy from 2014 on. The latter is feasible, if the preconditions are met: the regions seen as the networking of their members (inhabitants and organisations in which they are actively involved).

Methodological challenges of measuring intangible capital in developing countries: the case of innovation activity

Janez Prašnikar¹, Tjaša Redek², Marija Drenkovska³

Economic growth was long considered to be largely dependent on capital accumulation, but recent research confirms that intangible capital has a strong impact on productivity and growth. The investigation of the role of intangible capital is still in early stages of development in emerging economies, primarily due to difficulties in obtaining suitable and reliable data on intangible capital in the official statistics. Consequently, the survey methodology is used to overcome the data problem.

The paper analyzes the methodologies used to measure intangible capital, focusing on innovation activity. We focus on existing survey methodologies, conducted by national statistical offices or some supranational organization and analyze their appropriateness for this stream of research. Often, intangible assets are insufficiently captured in questionnaires; therefore extensions are proposed, following existing literature and own experience. We propose a method, combining a cascade constructed questionnaire and official company data (financial statements). A study on a sample of Slovenian manufacturing companies was also conducted, revealing many methodological challenges, which are presented in the paper.

Keywords

Developing countries, Innovation, Measurement problems, R&D activity

1. Introduction

Intangible capital represents a crucial factor of growth in developed countries and, as such, it certainly needs to be among their main interest, especially to those countries that find themselves on the brink of developmental breakthrough to the developed group. But the research has so far only scarcely covered those, for example Prašnikar (2010), Fukao et al. (2007), and VanArk et al. (2009). One of the major problems is collection and quality of data.

Innovation property, a part of intangible capital, depends largely on R&D. We attempt to first define R&D in accordance with the characteristics of R&D in developing countries, which differs from R&D in developed countries. Also, the data show that the size and characteristics of R&D are different in technology-followers in comparison to leaders. Therefore it is necessary to capture the R&D and innovation activity in the developing countries in a different manner. As sources of data normally official statistical sources are used, which describe the phenomenon by either capturing the expenditure on R&D, employment in R&D, number of patents of the company etc., or by using standardized (internationally comparable) questionnaires. But, these questionnaires, given their attempt to be simplistic, standardized, and comparative, are less able to capture the problems arising in technology-followers. We propose a methodology for capturing R&D and the innovation activity in developing countries. Last, we present preliminary results obtained with the application of this

methodology in the Slovenian manufacturing sector, focusing primarily on methodological challenges. The development and testing of the questionnaire used in this survey was a year long process. The preliminary results that are based on a sample of manufacturing companies in Slovenia are interesting and in many cases confirm the aforementioned characteristics of R&D in the technology-followers.

2. Measuring innovation activity

2.1 What is being measured?

According to the Frascati Manual (OECD, 2002) research and experimental development (R&D) comprise the creative work undertaken on a systematic basis in order to increase the stock of knowledge to devise new applications and can be classified into basic research (experimental and theoretical research with the purpose of gaining new knowledge), applied research (obtaining new knowledge focused on certain practical goals and purposes) and experimental development (systematic application of existing knowledge to new products and services).

Determining which intangibles should be considered as capital is not straightforward. According to the System of National Accounts (1993), the value of research and development (R&D) should be determined in terms of the economic benefits it is expected to provide in the future. In principle, R&D that does not provide an economic benefit to its owner does not constitute a fixed asset and should be treated as an intermediate consumption (Daniels, 2007). One firm's activities can only truly be called innovative when they have the effect of increasing productivity.

One outcome of innovation and R&D is the creation of new products, which when protected by copyrights i.e. patents allow the holder to exploit them and set prices above equilibrium. The other possible outcome is the increase in productivity, when research activity focuses on the production process. A recent study on the top 1000 Global Innovators (in Jaruzelski et al, 2005) also indicates that no statistical relationship exists between the number of patents and company business results: it is more important to develop a robust business model and solid cross-functional capabilities than to increase their R&D budget. Patents matter only if the underlying invention will result in profits for the patent owner, and only then can we equate a patent with innovation.

2.2 Measuring innovation in developing countries: challenges and data sources

Innovation can either be a new product, a process or their significant technological change. It is not necessary that the innovation is new for the market as long as it is new for the company that launches it (Prasnikar & Kotnik, 2005). That is the rationale behind our expectations to observe different types i.e. different stages of innovativeness in technology-leader countries as compared to the technology-followers. Forbes and Wield (2000) suggest that, the innovation process in the technology-follower countries leads to new practises in R&D. Followers rely more on incremental innovation, rather than radical innovation. Also process innovation is equally or more important than product innovation, especially if the follower is developing cost advantages (Prasnikar & Kotnik, 2005). Shop-floor innovation is perceived as a major source of cost-saving, while organisational, cultural, and managerial innovations can help build the environment in which incremental innovation can continuously spread. Given the industrial development stage of the technology-follower country, the process innovation will often be more important than product innovation (Kline, 1991).

Forbes and Wield (2000) also claim that with exceptions, research has a rather limited role in technology-follower countries, because the firms conduct research to increase their absorptive capacity for research done outside the firm. They add that it is beneficial that these firms involve in formal R&D for number of reasons: complementing shop-floor innovation; intangible spin-off benefits for the whole organization; learning capability of R&D teams and the notion that moving up the value-chain to more attractive markets depends on a firm's ability to develop proprietary product-designs.

The problem of capturing the characteristics of R&D and innovation activity have been dealt with in different ways in empirical work, but a large number of articles (e.g. Wakelin, 2001, Griffith et al., 2000) uses the official data, such as statistical sources, either in terms of hard data (expenditure on R&D, employment, number of patents, new products, etc) or standardized survey (questionnaire) data, like Community Innovation Survey, OECD Innovation Survey and national innovation surveys.

Several problems can be encountered when using this data. Firstly, much of the data is being collected with company-based surveys. Second, although the number of indicators is rather large and able to provide a good description of the current state of R&D and innovation, the data is often

problematical when attempted to be used in an empirical research. For example, studies have shown either a positive or a non-existing relationship between innovation, R&D, productivity and growth on an aggregate level (e.g. Damijan & Kostevc, 2006). The discrepancy between what is being logically expected and the estimates can be attributed to the following factors: (1) aggregated data does not fully reveal and, in the same time, simplifies the actual process of transferring R&D into higher value added, productivity and growth; (2) given that the data often originates from questionnaire data aggregation, there are many missing elements (especially the more detailed ones), while in addition, that data often tends to be out-of-date; (3) for the purposes of policy decision making, the data also tends to be misleading, since it does not reveal the heterogeneity by size and sectors.

The Oslo manual (3rd edition, 2005) specifies the methodological guidelines for collecting and interpretation of firm level data on innovation. It (2005, p. 18-20) provides a detailed description on how to provide data on key four elements: the definition of innovation activities and expenditures, the factors influencing innovation, the types and the impact of innovation in the firm, and innovation linkages. The Oslo manual is also used for the Community Innovation Survey (CIS) which analyzes firm level innovation in the EU. We next briefly describe the 2004 questionnaire, used also in the 2006 survey. The questionnaire begins with the definition of the firm location and its target markets, then continues with a careful examination of the product innovation (type, how they were developed, revenue from new products), deals with process innovation (type, how developed), briefly deals with the problem of whether or not the company had any abandoned innovation. Section 5 of the questionnaire deals with the R&D characteristics, R&D expenditure and structure, and the outside financial assistance. Section 6 deals with the sources of input information for innovation (internal, market, institutional), and the cooperation in R&D activities. Section 7 analyzes the impact of different types of innovation (product- and process oriented effects, etc). Further the questionnaire deals with the factors hampering innovation and intellectual property rights, and finally addresses the marketing and the organizational innovation (CIS questionnaire, 2004). The questionnaire is highly detailed and analyzes many aspects of innovation and R&D, and being implemented in 30 countries, it provides a vast coverage of the innovation activity. As such it is an important and a valuable database for the study of innovation in Europe. Nevertheless, the questionnaire does not deal enough with the capabilities and the competences, which might be one of the key aspects of why the innovation in developing countries is less successful. Also, there is still room for improvement of some of its other aspects for the specific needs of the research in the developing countries.

3. The case of innovation in Slovenia

3.1 Description of the methodology

Since the combination of quantitative data and qualitative data is of key importance for measuring the innovative properties of firms, we upgraded the CIS questionnaire by adding aspects relevant for developing countries and by developing different techniques of collecting data due to both lack of public data and lack of reliable quantitative data in enterprises. The data collection is mainly based on a simple set of three 'yes/no' questions, which were carefully designed so that each additional 'yes' indicates that the company is at a higher level of development in a certain aspect. Such cascading technique allows us to create a measurement scale from 1 to 4 in empirical testing. The cascading questions are supplemented by standard questions that require a specific information (R&D expenditure, number of employees in R&D, etc.) and by a few Likert scale questions which are used to measure the competences and the capabilities of the company as well as its perception of itself in that aspect in comparison with the competitors. All these questions can be easily transformed to a cascade type of questions which will give researchers a possibility to use different multivariate methods, like factor analysis, when constructing composite measures of innovative activities of firms.

The questionnaire is divided into 9 sections: 1) target markets and characteristics of the industry (q. 1 and 10); 2) types of new products (q. 2-6, 16), 3) types of new processes (q. 6-8), 4) technology development as a source of innovative products (q. 9), 5) sources of information and innovation ideas (q. 10-12), 6) organization of R&D activity and expenditure on R&D (q. 13-15), 7) examination of competences (q. 17-19), 8) examination of capabilities (q. 20-22) and 9) a question on external aid funds for R&D. We describe each section of the questionnaire and explain the methodology of dealing with variables. Where the Likert scale is used, we emphasise it and explain the transformation.

First we briefly comment on the most general type of question used: a question composed of three sub-questions, all three being of a type 'answer with yes or no'. The yes/no approach mainly attempts to simplify the answering process, which also contributes to greater trust in the data obtained.

Questions are formulated as statements, carefully designed so that each subsequent sub-question represents a higher level of development in a certain area. Methodologically, our goal has been to create numerical variables from a series of sub-questions. The transformation is already initiated by assigning a value 1 for the answer 'no' in the first sub-question and a value 2 for the 'yes'-answer. If the answer in the next sub-question is 'no', then the value remains the same, for example it has a value of 2 if the first sub-question is answered 'yes'. If the answer is 'yes' also in the second sub-question, the value increases to 3. Similarly if the answer is 'yes' also to the third sub-question, the final value of the variable for a certain question, composed of three sub-questions, has an end value of 4. Building such cascades is a novelty approach in the analysis of innovation, suggested by a recent study on intangible capital (Miyagawa et al. 2010). In our opinion this approach is more suitable for the analysis of innovation in developing countries for several reasons. First, in many cases it is difficult to obtain hard data (numerical data), such as expenditure, employment in R&D etc., because there is a lot of uncertainty what the companies actually report as R&D costs and what data is missing. Also, in many cases, especially in smaller and medium companies, R&D is not organized as a special unit, which complicates the analysis further if trying to obtain hard data. Next, by putting a lot of effort into the design of the questionnaire, we can capture the nature of a certain aspect of R&D and innovation, and in the same time, by posing simple and clear questions (statements), we avoid any possible misunderstanding. Given that many companies in developing countries do not place a lot of attention to R&D, they might not be familiar with the terminology such as, for example competences and capabilities. But by actually describing of those concepts through statements, leaves little room for misunderstanding. Therefore, the reliability of data is higher. And finally, as an end result we obtain a numerical variable, which can be further on used in empirical research. Such cascading approach was used for the majority of the questions (2., 4., 6., 8., 9., 12.-15., 20.-22., 23).

Where companies are asked to compare themselves to competition, the questions are based on a Likert scale. Since most of the questions are measured on a scale of 1 to 4, we have also transformed the answers of the 1 to 5 Likert scale to a ladder of 1 to 4 by using the following transformation method: each part of the question 16. could be, for example, transformed to a cascade type by assigning values 1 and 2 (1 = substantially worse than main competitors and 2 = worse than main competitors), values 1 and 3 (3 = equally than main competitors) values 2 and 4 (4 = better than main competitors) value 3 and 5 (5 = we outperform our competitors) value 4. Examples of such questions are questions 16-19. Also, the questionnaire includes a few questions where companies need to state whether a specific type of innovation (q. 3), source of information (q. 10) is being either highly important, medium, or less important for them (or not used). Here we also used a transformation method to obtain a scale from 1 to – we assign 'not used' a value 1 and 'high' a number 4.

In continuation we briefly describe the questions. The main idea is that companies differ significantly both in terms of their origin (developed, developing country) and their target market (home based, exporter). Those that operate more abroad and seek to penetrate the more developed markets have been shown to be more productive and innovative (Damijan et al., 2006). The issue is especially relevant for developing countries. If the company operates in more demanding developed markets then this reflects its past successful development on one hand, and it also implies further motivation to be innovative in order to keep up with the competition in those markets which is fiercer and where the consumers are more demanding (Zheng Zhou et al., 2007). We thus examine the division of sales across different markets (national, export and location of exports). Following the idea that the firm's behaviour is conditioned chiefly by the competition in their primary market, when asking companies about their competition, we always relate the specific question to their most relevant market.

The next two sections deal with the characteristics of product and process innovation. Regarding product innovation, we examine the importance of product innovation for the company and its performance in terms of its competition (q2, q4 and q7). We examine the types of product innovation (q3) of the companies (repositioning, marginal product improvements, adding to existing product lines, globally new products, etc.) and how the companies developed these products (q6) (by copying, by own development, by cooperation). We also ask what percentage of the company's sales is generated by the new products. Similarly, we investigate the characteristics of the companies' process innovation: whether the company improved their business processes (q7, e.g. production, logistics, distribution, IT, etc.), how the process innovation was developed (q8) etc. Given that growth theory often stresses the idea of catch-up and technology transfer, we were careful to include these aspects as well. Also, the types of process- and product innovation can significantly differ in the developing as compared to the developed countries (Forbes, 2000), hence we have carefully designed the questions to capture the types of both those aspects, expecting less focus in companies on basic research and fundamentally new products and processes, and expecting more marginal improvements. One of the

key aspects is whether the industry the company operates in is characterized by rapid technological change (q9). This can significantly impact the general product and process innovation in the company. Companies can get information and ideas for innovation from many different sources. These can be divided into internal sources (suggestions from employees, own research activities etc.) and external (market, institutional etc). This is the focus of our next section (q10). We believe that the location of the partners in innovation activity and other business partners can also impact the firm innovation characteristics (q11). The theoretical link for developing country model is the potential for learning effect caused by cooperating or operating in developed markets (e.g. Forbes, 2000).

The organization of the R&D department is another element of innovation success. Questions (with sub-questions) 13-15 analyze how the R&D department in firms is organized, whether companies have one, what are its tasks (q13) and what percentage of revenue is spent on R&D (q14). From a strategic perspective, it is important to analyze the company's attitude towards R&D: does the company believe that R&D is an important source of competitive advantage or is R&D perceived just as an unnecessary cost (q15)? Especially the last question can give an insight into the innovativeness logic in developing countries – often, they innovate because they are forced to by the competition on the market and the drive for building a competitive edge is not primarily their own. Also, the organization of their R&D departments is less straightforward, depending on the size of the company, the target markets and the country's level of development (for organizational design of R&D see for example Ambec and Poitevin, 2001). Since the expenditure on R&D is generally lower in developing countries than in developed (Forbes, 2000), based on observation, a series of sub-questions led to the highest answer "we spend more than 3% of revenues on R&D".

The questions 16–22 analyze the company's self-perception and its competences and capabilities. The competences (q.17–19) refer to the possession of knowledge for problem solving. The term capabilities (q.20–22) describes the company's ability to apply the knowledge in order to solve a specific problem (see Rajkovič and Prašnikar, 2009). Both are extremely important to understand the nature, size and success of innovation in developing countries. Apart from not being necessarily strategically oriented into R&D, not possessing the skills to develop and market (use) new products (process improvements) can significantly hinder the innovation in developing countries. Therefore, we feel that this section provides some of the most important information for understanding the characteristics of innovation in developing countries. The section is based on a mixture of Likert scale questions and cascading questions. We are foremost interested in how the company performs relative to its competitors on the market, in terms of new products, time needed to develop them, and the level of innovativeness in these new products (q16). The next set of questions refers to competences (q17-19): technological, marketing, and complementary. While technological competencies refer to the technological characteristics of the company, the marketing competencies to the company's marketing capabilities and competencies, the complementary competences refer to the company's system of sharing and spreading the information and the knowledge in the company, team-work, and cooperation among the different departments etc. Last, we examine the company's capabilities (q20-22), which are the only questions in this section that use the cascading method of yes/no answers.

The questionnaire we briefly presented differs from existing standardized questionnaires in at least three major aspects. Since our focus are the developing countries, we first extend the questionnaire with the questions that allow us to analyze the differences between better and less well performing firms in relation to their competences, their capabilities, and their strategic orientation towards R&D. It is a crucial element for understanding the innovation gap within and between countries.

Second, the use of the cascading technique in the questionnaire we believe is an important improvement which was shown as necessary in the testing phase of the questionnaire, in 2010, since companies tend to have insufficient data, especially when it comes to hard data. The smaller, the more diversified or less advanced the company was in terms of innovation (or any other specific field of intangibles for that matter), the harder it was to obtain a reliable answer. The personal interviews in the testing phase using the questionnaire revealed how important it is not to pose questions that are too specific, long, complicated or detailed, because the answers might be completely different from what was asked. Therefore, through a series of improvements, we developed a questionnaire that captures the entire innovation and R&D story, but is based on statements that are for majority of companies easy to understand and easy to answer. We supplemented the descriptive data with some hard data (expenditure, etc.), but we have already learned from the experience with the Slovenian companies that hard data is much more complicated to obtain given the size, industry, development of the company. It is often the case that that data is unreliable (e.g. companies may classify their R&D expenditure differently) or simply companies do not bother with finding these data. We also believe that as the study is extended to other countries in the region, which are in some aspects less developed than Slovenia, the problems with obtaining data will be even more severe.

Third, the questionnaire allows us to distinguish between expenditure on R&D, innovation, employment in R&D, which further distinguishes the flow of funds into R&D and actual innovation capital. On one hand, we have the company's R&D data, on the other hand, we obtain a significant amount of information on how R&D is conducted, what are the results of R&D (new products, processes), that is, whether and how R&D is being capitalized. This opens a question of efficiency of the R&D, which again is an exceptionally interesting issue, primarily in the comparative analysis.

Fourth, by running a multivariate analysis, like factor analysis, we are able to construct composite measures for each property of innovative activity of firms. This will provide an indication of the factors and the components in each factor are of key importance in developing countries. This could be a very significant finding since the simple quantitative indicators in the developing countries are less likely to be available due to lack of data.

3.2 Preliminary results

Thus far, we have produced the descriptive statistics, which already provides some interesting results. In 2010 we conducted an analysis in a sample of 61 companies operating in 23 industries. On average the companies were active in 4 markets: domestic markets, European markets, Western Balkan markets, and others. The domestic markets came as the second most important markets with 39.7 % operating in it, just after the European markets (48.3 % of companies).

The focus of the analysis was identifying the main characteristics of the activities that drive innovation in these companies. The results showed that 88 % of the companies have introduced a significant number of new products in the past five years in their relevant market. Out of these, 59 % have introduced novel products in their domestic markets and 27.9 % introduced globally novel products. The most important types of innovation, as companies report, are the improved existing products, introduction of new product lines, the expansion of the existing product lines, and the repositioned products. About half of the companies (50.8 %) stated that, in their view, they are among the leading companies with regard to product innovation (or product imitation) in their industries and relevant markets. Almost 97 % stated that they rely on own innovation which in 33 % has been a result of in-house development and/or 56.7 % of the innovation activities were a result of joint efforts with other companies. The companies were also asked to provide data on the share of new products included in sales figures. The results indicate that out of the 50 companies that responded, that the sale of products that were both new to the companies and their relevant markets makes up a 7.2 % share of their total sales on average, and 12.4 % of their sales were obtained offering products that were new to the company, but were already existent on the market they operate in.

In regards to process innovation activities, three quarters of the surveyed companies reported that they have also improved their processes over the past five years. 74 % of them said that they have made improvements in their production processes, 55.7 % have improved their logistics and distribution, and 68.9 % have improved the supporting services such as IT, sales, accounting, etc. Similarly to product innovation, the majority of companies (89.5 %) relied on either in-house process improvements or improvements from joint cooperation.

Another focal point of the 2010 survey was to identify the source of ideas and information on the companies' innovative activities. The majority (61 %) reported that suppliers, clients, and external sources of knowledge contribute to their innovation. Out of the respondents, close to 90 % have their own R&D departments, although the roles of the R&D departments in those companies differ (mostly being systematic support and problem solving (82.2 %) and in only 38.6 % of the cases having the ability to design in-house processes).

Furthermore, the research also examined the idea that the comparative performance of the companies depends on their comparative capabilities and the competences of the companies in their innovative activities. The questions are based on a Likert 1-5 scale and were for descriptive statistics not yet transformed. The results show that regarding the number of new and updated products, the majority of companies (46.7 %) rank themselves on par with competitors, whilst 38.4 % of them believe that they are better than the competition. Also large a portion of companies (84.4 %) believes to be either on par or better than their competitors when it comes to the time needed to adjust new products to market conditions. Interestingly so, when asked about the time needed to develop completely new products, the majority of companies (58.3 %) believes to be worse or, at most, on par with their competition and almost half of the companies are convinced that they contribute little to setting new trends in the market. The companies admit that their technological competences are at most on par with competitors or lower (72.4 %) and are slightly more confident when it comes to marketing competencies (70 %) The companies were asked to rank their capabilities and the results show that they have a rather high confidence in that aspect. When it comes to technological capabilities, 60 % of

the companies believe to have better technological capabilities than the average and have stated that dynamically renew their capabilities. Similar results hold for marketing capabilities, but with a slightly lower percentage (50 %).

R&D activity is one of the aspects often mentioned in government and EU strategies as a key element of growth (e.g. Lisbon Strategy). The results show that only 3.1 % of companies received assistance for R&D activities from local municipalities, 43.1 % received assistance from the state, and 27.6 % received assistance from the EU. Additional assistance from the authorities would help stimulate R&D activities.

The results that we briefly presented are for now preliminary results based on a relatively small sample of companies. Nonetheless, the results are very important already as they reveal the main characteristics of innovation, their importance for companies and competences and capabilities of companies in a comparative way, where comparison is made with companies in their relevant (biggest) market. Therefore, these results are also an important indication of their future potential.

4. Conclusions and challenges for future research

Investigating the link between aspects such as: R&D, innovation, growth, productivity, value added, and the like is extremely important for the developing countries. It is merely the growth based on company's own resources itself that can push the economy over the brink and into the company if the developed group. But there are many challenges when investigating R&D and innovation in developing countries. Firstly, the aggregated data on the different aspects of innovation activity in developing countries is not available. Second, the survey is often an unsuitable method for an in-depth analysis due to many aspects that are not covered by the (typically implemented) standardized questionnaires. Also, the quality of data is questionable due to the problems mentioned above.

We use an innovative cascading questionnaire that is straightforward and based on simple yes/no statements, adjusted for developing countries in order to avoid as many problems as possible. The research was initiated a year ago and the sample is still being extended. The first results are, despite the relatively small sample size, satisfactory as they indicate that the relationships between R&D and productivity are as expected. We expect that once the sample size is increased, the problems with the statistical significance will disappear.

The way in which we intend to extend the research is that we will firstly extend the sample of companies from the manufacturing sector in order to obtain more reliable results. We will also examine the link between innovation and company performance in the manufacturing sector, mainly expressed in productivity, by merging the database on innovation with the database of financial statements, which is prepared by the authorities (AJPES database). The test estimates indicate that the more innovative companies are more productive, but due to small sample size and many needed controls, statistical significance is only around 0.2. The methodology applied will allow us to easily create new composite variables capturing the characteristics of the innovative activity. Quantitative research methods will be used in order to extract as much information as possible from the dataset. That reduces the need to include various aspects of innovation into the productivity analysis, which could lead to the loss of degrees of freedom. Secondly, we wish to also extend the research to other sectors. We follow the idea of five sector economy (primary, secondary, tertiary, quaternary and quinary, where quaternary and quinary refer to the intellectual services and highest governmental decision-making powers, respectively). Our intention is that we include, besides the manufacturing, also the service sector. Some research for the financial services has already been done, but that always requires adapting the questionnaire to the needs of specific sector that is being researched and testing it. Lastly, our goal is to extend this research to the countries in the region. Again, the questionnaire needs to be adapted to the development and structural characteristics of these countries, as it was done for Slovenia. Interesting comparative results are expected.

Overall, the research of the role of the intangible capital, not just its innovation part, is extremely important for future development in this scientific area. Although the extensive model of growth that is based on export-led production can be a source of short and medium term success, it does not succeed in providing a solid foundation on its own for further growth, thus making the countries' economic position especially fragile to external demand conditions.

Entrepreneurship Challenges in Kosovo: Innovation, Research and Education

Gazmend Qorraj¹, Fatmir Stublla²

¹Institute for European Integration – IIE, Prishtina, Kosovo, gazmend.qorraj@iie-ks.eu

²Institute for European Integration – IIE, Prishtina, Kosovo, fatmir.stublla@gmail.com

Innovation has a potential role in strengthening social development and social cohesion. Innovative approaches to entrepreneurship can contribute to the sustainability of social systems and the development of economy.

According to the Lisbon Strategy of the European Union the interlinkage between education, research and innovation could increase the global and knowledge based economy. In this paper will be analyzed the role of education and innovation on entrepreneurship development in Kosovo.

The research question in this paper is: does in Kosovo exist this interlinkage between education, research innovation and entrepreneurship. Do Kosovo entrepreneurs have an adequate level of education?

There will be applied different statistical estimates based on questionnaires in order to provide empirical data about the role of education, and innovation on entrepreneurship activities in Kosovo.

Keywords:

Education, entrepreneurship, innovation, research

1. Introduction

Managing the transition towards a knowledge-based economy is the key challenge for the EU (European Union) as well as for the transition countries. The success of this transition will ensure a competitive and dynamic economy with more and better jobs and a higher level of social cohesion.

According to EU Commission [6], more than 60% of companies responding to the consultation consider that schools do not provide the competences needed by entrepreneurs and their staff. This result highlights the societal need to always provide young people with essential skills, such as reading, writing, natural sciences, management, technical, ICT (information and communications technology) and language skills and enable them to be creative. SMEs (small and medium enterprise) suffer in particular from the lack of skilled labour in the field of new technologies.

1.1 What about transition countries such as Kosovo?

Kosovo entrepreneurs have been pushed to undertake self-employment activities even though they had limited managerial experience and a limited educational background as required for entrepreneurship activities. In comparison, according to Bartlett and Prašnikar [2] most entrepreneurs in Slovenia were not pushed into setting up a business under the pressure of unemployment. They held experience in management positions and the most important objective of most entrepreneurs was to achieve personal independence. Compared to Kosovo, entrepreneurs in Slovenia appear to be growth-oriented.

Regarding Kosovo, two issues should be taken into consideration. First, new generations wanting to move from school to the labour market find the transition very difficult because of the lack of practical skills offered by school programmes. Second, a gap in human development was created in the 1989-1999 period.

During these years most of the work force was fired and as a result a layer and experience enterprise

managers are missing. Due to this gap, they do not have enough experience to adapt to the new market requirements. Given the above factors, there is currently shortage of people with adequate relevant experience or human capital who could embark on and intensify entrepreneurship activities in Kosovo. This is despite the very large number of new firms established in the post – 1999 period, but there is also very large number of failures.

2. Methodology

The empirical analysis of entrepreneurship and self-employment behavior is based on a questionnaire survey. On 2007 it was surveyed a random sample of about 300 entrepreneurs within Kosovo in seven regions. The sample is taken from the list of available official business registers in Kosovo in order to have proper statistical estimates.

Furthermore on 2010 in order to investigate the interlinkage between education, research and innovation, for increasing the global knowledge based economy, 100 entrepreneurs are interviewed.

In this paper are represented a descriptive statistics, that explore the entrepreneurs approach towards universities and other scientific institutions.

3. Education, research and innovation

There is evidence that education improves individuals' future earning and overall success [1]. On one hand, more educated people are better informed about business opportunities and might select occupations in which entrepreneurship is more common. On the other hand, the skills needed for entrepreneurship different from those provided by formal education. They are generally regarded as relatively original persons who may have learned their business skills without too much formal education.

There is some evidence suggesting that for highly educated people wage-based work tends to be a more attractive choice compared to self-employment. According to Lucas [11], highly educated people earn more as employees than they would if self-employed.

Also, if education is seen as a screening device then entrepreneurs have fewer incentives to acquire formal education. However, empirically most studies have found positive effects of education on self-employment. In general, the higher education of self-employed people should improve the growth opportunities of their firms because higher education improves the ability to comprehend market prospects, better exploit market demand, enhances the awareness of risk and improves adaptability in changing circumstances.

Pekkalas and Kangasharju [13] analysed the success of the self-employed and their firms in a period of economic downturn (1990-1992) in Finland and reported that in an economic downturn a higher level of education raises the probability of survival.

The impact of education on self-employment depends on the industry in which someone is self-employed. Bates [3] found significant and positive effects of education on the probability of commencing self-employment in skilled services, significant negative effects on the probability of commencing self-employment in construction and insignificant effects on the probability of commencing self-employment in wholesale and manufacturing activities.

In 2002, Lazear [10] proposed a jack-of-all-trades model of entrepreneurship, suggesting that individuals with a wide variety of skills are more likely to become entrepreneurs, while those who specialize are likely to pursue wage-based work.

A UNDP (The United Nations Development Programme) survey for Kosovo in 2005 [15] reported that the education system in Kosovo does not offer proper knowledge and skills to young generations in order to prepare them in line with market economy requirements. They proposed that vocational education and training could help young generations adapt to the labour market. Based on this UNDP report, currently there are low expectations that education will be a significant factor in supporting entrepreneurship.

4. What about innovation

For the innovation, many authors have provided different definitions and each of them has its own nuance. During the last 40 years, according to Cumming [7], the definition of the term innovation

changed. During the 1960s and 1970s, innovation was defined as the development of a new idea or a process to change.

According to Yukl [16] when the changes appear is necessary to adjust the ways in which employees will find it easier to cope with the changes. First, there is a need to explain that adjustment is necessary, this way people are asked about their previous experience and how they were adopted, another way is to organize some sort of trainings in order to make easier for them to adopt changes.

According to March [12] there are many ways that develop performance of companies such as analysis, learning, imitation, those are elements that reinforce any attempt to develop further organizational performance. When there is a chaos managers should structure the organization into the much-loved condition (change) and go back to status quo. It is about to remove the previous state of mind and implement a new one [8].

For organization environmental and learning, the leads of big companies have to know as much as possible about the benefit of core knowledge. Very often the way of leading the companies are connection the companies, not creating the new ones. By using this strategy of connecting the small companies it is good chance to raise their opportunity of standard. The connections of companies are more chases for incising the effect of quality in supplies and workforce is well, therefore from those are coming the culture and learning in organization [9]. For organization environmental and learning, the leads of big companies have to know as much as possible about the benefit of core knowledge. Very often the way of leading the companies are connection the companies, not creating the new ones.

By using this strategy of connecting the small companies it is good chance to raise their opportunity of standard. The connections of companies are more chases for incising the effect of quality in supplies and workforce is well, therefore from those are coming the culture and learning in organization [9]. At the time of selecting the strategic choice as model, decision - making is first evaluated to the organizational possibly position in their atmosphere.

A main part of this involve selection outside factors, and trends of time, marketplace indicators and opportunity such as imposed on the society by the suppliers, indicated to organization. In this perspective, an amount of objectives are achieved of which the association can be winning. Moreover, is not likely to ignore the external indicators as the situation itself, in the organization developed, constitutes the structure of the choices of vary can be performed [5]. Organization regulations and changes can be initiated in the order for better managing situations, therefore, those changes are used as a tool to improve the system of governance and regulations in the created situation [5].

Therefore, governmental regulations as external attitudes for companies are not evolution issue, as Child [5] argues all the regulations and laws are as revolution in the organization, and then the adapting and changes can happen in all levels of human resources.

However, community considers that the modernization or changes can have some advantages; they will be able to try and learn more on it in order to decrease their hesitation. At what time they cover sufficient information, they will create their choice on whether to adopt or reject the innovation and changes [14]. Lots of companies' reward incentives to possible clients to enlarge the apparent relation benefit, in categorize to change their behavior and make them adapt to the innovation. Then people can without difficulty try out the innovation and changes, what makes them adopt it more easily soon after on [14].

Knowledge is ordering of information, we gain knowledge of the world through our experience of it, so potentially everyone's knowledge of it differs. The attempt to make sense of the environment in the world is not an attempt to discover reality and truth, but an attempt of maintaining the stability so that we can continue to function and believe that we understand the situation as it is or as it can be after the situation is changed [8].

Many aspects of a change can feel threatening to people and thereby increase the ambiguity to accept the wished future state. However many changes lead to something better and the same people that made the resistance can be happy that the change occurred.

5. Results

The results of the empirical analysis respectively descriptive statistics are represented as follow:

When we asked our respondents: what is your level of education, 68.7 % of them answered that they have only low level of education, respectively secondary school while 31.3% of them superior education respectively bachelor degree.

The second important issue was to understand if Kosovo entrepreneurs cooperate with Universities (public or private) in order to use the scientific or professional aspects with regard to human resources.

Around 32.8% of respondents answered positively while 67.2% answered negatively meaning that they do not cooperate with universities.

Third important point of this analysis was the question: if the Kosovo entrepreneurs are satisfied with professional level of their young employees coming from universities. Most of the entrepreneurs around 86.6% answered that they are not satisfied with the professional level of young graduates while only 13.4% answered positively.

The last important issue was to investigate if university graduates could develop new strategies and accelerate growth oriented approach for the companies in Kosovo. Around 40.3% concluded that there is a possibility to interlink new knowledge's with entrepreneurial ventures while 59.7% of the respondents answered that there is no any value added coming from young graduates of Universities.

6. Conclusions

Kosovo suffer from very high unemployment, particularly where the official rate of unemployment is around 40% of the work force, with the rate of economic growth too slow to reduce unemployment, especially youth. The evidence in Kosovo shows that graduate students are not prepared to fulfill professional criteria's asked by employers therefore due to low level of education there is not an interlink between education, research, innovation and entrepreneurship activities.

The main recommendations of this paper are:

- By learning practical issues young graduates will be prepared and attracted to undertake actions towards self employment or being able to meet requirements from the employers.
- Promoting entrepreneurship and self-employment by improving the quality of human capital (education and training) are regarded as key elements.
- There is a need to fulfill the gap created by the lack of upgrading of university study programmes and curricula, especially in entrepreneurship and self employment.
- Developing relevant programmes based on the needs of the labor improving the quality of human capital by training.
- Connecting education, research and entrepreneurship activities by inducing research activities with universities which could be explored also by general public, institutions, policy makers and private sector.

Promotion of the entrepreneurial culture is one of the very important goals of Lisbon Strategy and is crucial for generations of new jobs and economic growth in Europe. European Commission proposed whole list of recommendations to promote the entrepreneurship in high education, with special emphasis to transversal approach meaning that entrepreneurship should be accessible to all students, at all faculties and not only to those of economics or business studies. “Entrepreneurial University” is the one with employees at all levels committed, and students of all faculties encouraged to think and act as entrepreneurs. That is the only way to create society driven by knowledge, with small companies dominating and being highly competitive.

The paper reviews the process of creating the Entrepreneurial University having in mind the following presumptions: (i) The entrepreneurship is predominant factor for growth and competitiveness; (ii) Education, and in particular high education, could impact student’s intention to become an entrepreneur; (iii) Various policies and programmes could be developed to increase someone’s affection towards entrepreneurial activity, and towards the results of that activity.

A case study of the University Arkansas will be presented in developing entrepreneurial culture at the university, as well as attempts of creating entrepreneurial university in Montenegro with recommendations including both policies and practical level of action for Montenegrin case, also applicable to other countries in the region.

Keywords

Competitiveness, Entrepreneurial University, Entrepreneurship Education, Higher Education

1. Introduction

Promotion of the entrepreneurial culture is one of the very important goals of the European Union’s Lisbon Strategy. Also, entrepreneurial culture is crucial for generations of new jobs and economic growth in Europe. Having regarded to above mentioned, the European Commission pays special attention to the development of life-long learning at all levels of education [1]. Furthermore, entrepreneurship has been recognized as one of eight key competences for a life-long learning. The European Commission proposed a whole list of recommendations to promote the entrepreneurship in high education, with special emphasis to transversal approach meaning that entrepreneurship should be accessible to all students, at all faculties and not only to those of economics or business studies. Innovated Lisbon Strategy has particularly pointed to the need of the European Union member states to better anticipate skills that need to be developed in order to education process could follow development of the economy. Thus, the Education Council in 2007 adopted the Resolution “New Skills for New Jobs”, [2]. Particularity of the Resolution lies in highlighting the lacking skills, weaknesses and new skills demands. The revised strategic framework for the European cooperation in education and training, yielded four strategic challenges that should be tackled in the period until 2020 and one of them is related to strengthening innovations and creativity, including entrepreneurship at all levels of education. These challenges are a contribution of education and training to Lisbon Strategy implementation and innovated social agenda and need to be included in common policies and

measures within entire system, including primary and secondary schools, higher education, vocational education and adult education.

Following the example of the European Union member states, as well as the countries applying for the membership that strive after, or at least they should strive, to accept the paradigm of entrepreneurial learning at all levels of education system. Following the logics of the European Charter for Small Enterprises, a few countries from South East Europe region has started small but strategic actions. However, the indicators referring to human resource development and entrepreneurial learning (dimension 1 and dimension 4 of the European Charter for Small Enterprises) show that the achieved progress was negligible. By accepting the European Charter for Small Enterprises, South East Europe countries have committed themselves to promote entrepreneurial learning in all sectors and to develop the connection between universities and enterprises and the economy. Certainly, one of the solutions is to universities become more entrepreneurship-oriented, in the first line, in its management, and in creation of their own strategy and education providing, in order to adjust to new market trends with more distinctive approach to entrepreneurial learning.

In the period 2006-2009, the European Training Foundation has developed a whole set of indicators related to entrepreneurial learning, including the promotion of entrepreneurship at the tertiary level of education. In short, these indicators show that the Europe lacks entrepreneurial studies primarily in the non-business institutions and disciplines: entrepreneurship is still not sufficiently integrated into different subjects of the curriculum. With increasing expectations in terms of university contribution to the competitiveness of local and regional economy, the European Commission recommends penetration of entrepreneurship education with other disciplines in order to make students able to develop a higher potential after graduation.

In this light, higher education institutions in South East Europe countries, including Montenegro, should have a strategy or action plan for teaching and research of entrepreneurship and the creation of new businesses and spin-offs. In other words, this implies forming of so-called "Entrepreneurial University" which also represents the major change in the culture of higher education institutions, through: study programs that must be more multidisciplinary oriented; teaching and learning methods (through team work and encouraging student's initiative); research strategies; employment policies (teachers employment practice, incentives and rewarding, training); and cooperation with the economy. Several universities in Southeastern Europe has already introduced activities in the field of entrepreneurship development, however, it is still not clear which institutional model and the approach will actually lead to the creation and sustainability of "Entrepreneurial University". The question is what should be done to position the university in a way to adapt to the challenges of the XXI century and how to create an entrepreneurial university, which will best meet the demands of time to come? It is relevant to mention the initiative of the South East European Centre for Entrepreneurial Learning (SEECCEL) which aims at developing the curriculum for entrepreneurial university in the region. It turned out that the main problem (both in the European Union and South East Europe countries) is the lack of personal commitment, interest and the lack of support of decision makers in these institutions. In this sense, the "Entrepreneurial University" is the one in which employees at all levels are committed, and students of all disciplines are encouraged to think and act in an entrepreneurial manner. Only in this way we can develop a society driven by knowledge, which is dominated by small companies, and that is highly competitive.

2. Entrepreneurship as key competence

As a key competence for lifelong learning, entrepreneurship refers to individual's ability to turn idea into action [3], which includes creativity, innovation and taking of the risk, as well as the ability to plan and manage projects in order to meet set goals. The essence of this competence is ability to recognize the context in which an individual acts and proactively respond to given opportunities. A small number of individuals are born entrepreneurs, but studies show that education and training can significantly contribute to the development of entrepreneurial views, knowledge and skills. Competence entrepreneurship implies [3]:

- Knowledge of available opportunities in order to identify those that match personal, professional and /or business activities of a person.
- Skills, including: ability for cooperative and flexible work as a part of the team; be able to identify personal strengths and weaknesses; ability of proactive reacting and positive reaction to changes; ability to assess and take the risk when necessary and justified.

- Views, including disposition to take the initiative; positive attitude towards changes and innovations; the willingness to identify areas where a person can demonstrate the full range of entrepreneurial skills - for example at home, at work and in the community.

3. Entrepreneurship education

Recognizing the importance of lifelong learning for entrepreneurial development of a knowledge society based on human capital, education, research and innovation, Montenegro has a lifelong entrepreneurial learning strategy for 2008-2013. By this, the need for constant development and improvement in order to monitor the daily technological changes, growing competition and globalization has been recognized. The question is how to adjust educational system to fit the needs of modern society and more distinctive influence of globalization in XXI century. As it has been recognized in this strategic document, the solution is to build key competences - multi-functional, portable packages of knowledge, skills, and attitudes that are necessary for every individual to personal fulfillment and development, inclusion and employment. In narrower sense, entrepreneurship education refers to acquiring knowledge on how to start a one's own business and economic literacy; in broader sense, it focuses on development of personal characteristics and skills considered to be a prerequisite for successful acting of individual as an entrepreneur. Entrepreneurial competence takes into account both definitions of entrepreneurial learning, but the focus of learning is different depending on the level and types of education. Education system should enable children in early stage of education process to develop their creativity and curiosity, while university students can learn practical and theoretical matters necessary for establishing a new business.

Strategy for lifelong entrepreneurial learning 2008-2013 contains an analysis of the current situation of entrepreneurial learning in Montenegro, from the regulatory framework through the practice of entrepreneurial learning at all levels of education, from primary to tertiary, including the breakdown of informal education that focuses on strengthening the entrepreneurial skills. We can conclude that all three universities that currently exist in Montenegro have programs aimed at developing entrepreneurial skills, and entrepreneurship is often a compulsory subject. All of the above and thousands of students who passed the training, largely contributed to the creation of entrepreneurial culture and entrepreneurial thinking in Montenegro. However, the analysis showed that there are many challenges to overcome, among which stand out (for details see [4], page 17) the following: lack of understanding of the concept of entrepreneurial learning, prejudice about entrepreneurial learning, low awareness and promotion of entrepreneurial learning, insufficient cooperation economy (enterprises) with facilities for education and training, etc.

4. Creation of Entrepreneurial University

Attention and importance given to entrepreneurship is growing. Data on the importance of small and medium-sized enterprises for creation of gross domestic product and creation of new jobs, put entrepreneur in the centre of interest of policy makers, and by that higher education as well. The higher education is expected to take a leading role in creating institutions and entrepreneurial culture that will, finally, contribute to strengthening the competitiveness of national economy. Initial assumptions are the following:

- Entrepreneurship is a major factor of growth and competitiveness,
- Education, especially higher education can influence on development of student's desire to become an entrepreneur,
- Policies and programs that will increase the affinity towards entrepreneurial activity and the results these activities will have can be developed.

Hence, the pressure on higher education institutions to become more entrepreneurship oriented, in the first line, through commercialization of researches in order to contribute to competitiveness of the economy at international market, and local economic and social development is growing worldwide. A special role of higher education has been recognized in preparation of students for the world of insecurity and complexity which is reflected in: frequent change of profession and job, global mobility, adapting to different cultures, greater opportunities for self-employment, and higher level of responsibility in family and social life. In other words, a university degree no longer offers the security of lifelong employment, but is only a ticket to the labor market. The question is how to train students for lifelong market competition? In general, entrepreneurship development policies at the level of

higher education can be divided into two groups: those that connect the higher education sector with other stakeholders, and those that are more focused on the education of students in the context of entrepreneurship.

Experience of United States and Europe show that at first policy group, the use of technologies is the most important. To this regard, it is necessary to stimulate multidisciplinary research and enhance cooperation of researchers with outside stakeholders (outside the university) which further contributes to the development of patents and spin-off companies. This will enable the commercialization of ideas developed at the university through the scientific and technology parks, research centers and incubators. In the second group of policies, the emphasis is put on educating students in order to prepare for self-employment and to start their own business. Studies show that such educated future "entrepreneurs" rarely decide to start their own businesses immediately after graduation, but they usually do that between 26 and 34 [5]. Also, while this study significantly influence the intention to engage in entrepreneurial waters, students can later gave up from turning their intention into action, which often happens.

There are numerous examples of creation of the Entrepreneurial University, but is still not clear which is the best model for it. Maybe it is the best to first determine the commitment to really create an entrepreneurial university, and then start the activities based on best practices in the world (especially in the United States where, it seems, this concept took hold more in relation to Europe). We are already aware that universities play important role in many economies, by having economic impact through their basic activity - education then through research and development and through many other effects they have. However, universities have the ability to create the culture and program to make entrepreneurship a common value. The best example is the Massachusetts Institute of Technology, which confirms that the universities that are intensively engaged in research and technology, especially through the creation of spin-off companies, significantly affect the economy of their country. Recently published research results [6]. indicate that if active companies founded by Massachusetts Institute of Technology alumni, students formed an independent nation, their revenues would make that nation be at least the seventeenth largest economy in the world. Less conservative extrapolation show that 25,800 active companies founded by former Massachusetts Institute of Technology students employ around 3.3 million people, achieve annual sales of 2 trillion dollars, and generate the same total production of the eleventh largest economy in the world!

5. What needs to be done?

The existing experience shows that the creation of Entrepreneurial University requires the following:

- Internal university organization based on entrepreneurship principles, headed by leaders entrepreneurs, then staff and teaching personnel who understand and act in favor of entrepreneurship,
- External funding, in the first line through connecting with external stakeholders (economy, local community, government),
- Interdisciplinary approach, which means that traditional entrepreneurship paradigm is shifted from narrow focus on business and
- lectures dedicated to development of entrepreneurial values, not only business models.

In terms of organization, entrepreneurial universities are themselves a reflection of entrepreneurial initiative and entrepreneurial ways of management meaning that they are flexible, strategically placed in relation to the local community and they monitor the opportunities that arise. In other words, entrepreneurship is becoming a cornerstone of university strategy. The ultimate goal is to create a "culture of enterprise"; that is open to change and explore opportunities for innovation and development [7].

Creating Entrepreneurial University primarily takes time. This is simply because traditionalists and traditional programs are highly likely to put up resistance. That is why it is important that university leaders are entrepreneurs or leaders with entrepreneurial skills and views. Besides leaders, the process of creating Entrepreneurial University requires attracting teaching and other staff with similar entrepreneurial thinking and who recognize a wider university role in society. Experience of other countries (especially United States) shows that leaders and teaching staff gathered in this way with entrepreneurial culture have the need for additional support, which primarily refers to external funding, outside regular university revenues. This does not only and primarily refer to philanthropic activities, but to connecting university with key stakeholders that will be actively involved in creation of Entrepreneurial University. Creation of Entrepreneurial University requires broader, multidisciplinary

approach that will not observe entrepreneurship through narrow focus on business, but on something we call intellectual entrepreneurship [8].

Instead of traditional lectures characteristic for business studies mostly related to creation of new companies, business growth, business planning and traditional management functions, Entrepreneurial University is aimed to something different. Namely, the focus is put on development of entrepreneurial characteristics and values at students, development of emotional intelligence, insight into real life of entrepreneur and etc. The accent is on recognizing opportunities for development and innovation, especially in linking different disciplines in solving social problems. In order to introduce Entrepreneurial University, first of all, it is necessary to have a clear concept, and then “champions” or “change agents” within university that will accept to develop the ideas of Entrepreneurial University. A clear concept implies that, instead of traditional, pure business model, the focus is put on approach that highlights the ability to recognize an opportunity, contribution to society, development of interdisciplinarity and involvement of local community. Regarding the human resource development of Entrepreneurial University it is particularly interesting to emphasize the importance and impact of foundations (such as Kauffman Foundation and Coleman Foundation) which provided financial support to teaching staff who decide to develop programs and materials for their department, and for the purpose of entrepreneurship promotion.

6. Case Study: University Arkansas – creation of entrepreneurial culture at university

University of Arkansas, founded in 1871, was the type of university whose focus was on teaching and educating students with research in the field of agriculture. Research function of the University has evolved throughout the century, however, only in the last twenty years more attention has been devoted to creating new companies and technology transfer in the economic base of the economy. As resources are always limited, the decision to use the same model or to create new companies or to create an infrastructure that will enable the creation and establishment of many new companies was crucial. Decision was made to create infrastructure that will enable creation of new companies, in cooperation with both Government and private sector, which made University Arkansas to become the centre of entrepreneurial activity of the state (for more information look at [9]).

In the change and creation of entrepreneurial culture the key items were: the establishment of technological business incubators; establishment of centers for coordinating research activities; inclusion of entrepreneurship into the curriculum; establishment of connections with business. Establishment of technological business incubator *Genesis* within University, only three miles away from the main campus, in abandoned factory, enabled small companies, which were created based on research work done at the University, to endure the first period of “incubation” until they are ready enough for market competition. Entrepreneurs who based their ideas on new technologies, *Genezis* provided shared premises and office services. Above all, *Genezis* provided the opportunity of using professional network of managers, marketing and financial advisors, as well as technical expertise provided by the University.

The next step was establishment of independent research coordination centers, who gathered multidisciplinary teams. Named High Density Electronics Center, , this group of mutually linked but independent research coordination centers has become the only laboratory in the United States that brought about several patents, who already found their use value at the market, while others are in the process of registration and commercialization. In parallel with advancement in research, the University hired professionals whose task was to develop education programs in specific areas (emp. nanotechnology). A new program must contain elements of entrepreneurship in part to encourage students to commercialize the research results at the market. Already in 1999, the post-graduate studies in the field of Microelectronics Photonics – microEP came to life. The successes achieved by the program were always awarded by additional state grants and aimed at further investment into development and research. Master studies in this area were soon supplemented with PhD studies. Despite significant technical and scientific achievements, the key for success were:

- Dedicated leaders among main lecturers in campus,
- Campus administration guided efforts to link the available funds at the local, national and federal level towards achieving common goal,
- The fact that the University’s business incubator and research capacities were sharing space,
- Coordinated strategy to start the research outside the existing research infrastructure,

- Harmonization among research, education and entrepreneurship in project proposals in preparation,
- New, interesting, educational programs that attracted students throughout the country and worldwide who were ready to take the risk,
- Employment of new experts who brought the perspective of industry into the curriculum,
- Cooperation with partners outside campus.

The analysis of the curriculum, which took place at the University of Arkansas, revealed what was common to many studies. It was identified the need for interdisciplinary studies, the need for business trainings for technologists, identified mostly negative impact of bad business decisions made by technologists, need to respond to rapid changes in technology-based businesses, lack of team work in college and the lack of educational partnerships between technology and business studies. This was the reason for forming a new educational program called *Technology Entrepreneurship*, which is just one of the programs developed in order to meet the needs arising, and to overcome the problems in development. The aim was to: increase understanding of creation and evolution of entrepreneurial companies based on high technologies, identify basic decisions faced by an entrepreneur concerning the choice of technology, market analysis, finance and general management operations; identify mature research efforts of University to commercialize them in partnership with the Technology Transfer Office and the professor who runs the research. The final step was to create the links between the University and business community, which is still in progress. This was done through establishment of new incubator, so-called Innovative Incubator, whose task was to:

- Receives and evaluates proposals for needed research for Arkansas business,
- Matches these needs with University Arkansas system capacities,
- Providing students in campus who will work on required researches and pay them for it,
- Provides vouchers for business clients, who want to use the campus research capacities.

The successful idea from innovative Incubator goes to Genезis where it gets the basic support necessary for start-up companies until they are ready to operate on their own at the market.

8. Entrepreneurial University in Montenegro – from a dream to reality?

Montenegro does not have an Entrepreneurial University yet. Based on the analysis of economic policies on contribution of small and medium-sized enterprises in creation of gross domestic product and employment, it is clear that entrepreneurship gains increasing attention. The importance of entrepreneurship both at local and national level is seen in on-going efforts to eliminate business barriers. While these efforts achieve limited results, the strategic commitment to support entrepreneurship is clear, as well as recognizing entrepreneurship as key competence for lifelong learning.

All three universities to lesser or greater extent turn their attention to entrepreneurship as a subject, and by that, to the development of entrepreneurial skills in students. At University of Donja Gorica, Entrepreneurship is optional subject at the first year of studies, but the entire studies and the work with students in all subjects are organized in a way to develop entrepreneurial skills. The focus is put on “awakening of entrepreneurial nerve” at students, developing ability to see opportunity in problems, ability to take the initiative, analyze the data, to think creatively, have the optimistic approach towards life and world, develop independency and individuality, creation and maintaining social networks, developing ideas, orientation towards success, team work, etc. Among optional subjects are those offering multidisciplinary knowledge (Economy of Media, Architecture and Business, Wine and Economics etc.). Within the subject Entrepreneurship, an entrepreneurial platform €€\$ is organized when students have the opportunity to listen to our guests from the practice, most successful entrepreneurs from Montenegro and abroad. Also, during the studies, students have paid internships in private companies and system institutions, in order to acquire practical in addition to theoretical knowledge. In order to strengthen team work skill the students work in groups of 10, with mandatory communication with the group mentor who is associate from the practice. Except faculties for economics and management studies, the students at faculties of other orientations have no opportunity to develop characteristics and values of entrepreneur.

Regardless of individual efforts, in general, we can say that the concept of entrepreneurship and entrepreneurial universities in Montenegro was not recognized. This is largely a consequence of

society attitude towards entrepreneurs whose success is often contentious, although it is not an excuse for higher education institutions that should create and determine the development of society. There is very limited link between universities and the business community. Current cooperation often comes down to visiting lecturers from economy, and organizing practice for students, while the connection of research universities and business activities is negligible. In Montenegro there are two incubators, while the third is in process of establishment. Although there is some communication and cooperation with universities, none of the incubators is primarily related to any of the three universities, or any university unit.

9. Conclusion and Recommendations

Creating entrepreneurial culture within the university is a complex task that requires considerable effort of dedicated individuals. These individuals are located in the industrial sector, in academia circles, in relevant ministries, and they are very loosely coordinated with each other in their activities. However, all have the same passion to create new and greater opportunities for the country's economy and its citizens.

If we agree that the Entrepreneurial University is a core that can significantly contribute to strengthening the competitiveness of the economy on the international level, that it contributes to community development and helps students to be more prepared to participate in the labor market or to develop their ability of self-employment, then it is necessary to take measures that will contribute to creation and development of Entrepreneurial university as follows:

In the period until 2015:

- promote entrepreneurship in a broader sense as a way of living and thinking, rather than through standard business skills,
- education of university leader on the importance of entrepreneurship,
- including entrepreneurship into the curriculum of non-economic disciplines in higher education,
- the development of programs that will complement the students technical knowledge with business and entrepreneurial skills, and vice versa, supplementing economy students knowledge with basics of technological process,
- create research centers in accordance with the priorities of the Montenegrin economy, which will monitor the development of these sectors and connection with world research centers in this area for the sake of cooperation on joint projects,
- providing support for financing student's research papers, either from the State Budget or from the European Union funds.

in the period until 2025:

- Establish strong connection and communication mechanisms between universities and economy in such way that universities conduct researches upon business request and with their financial support.
- Montenegro has at least one technology incubator that will allow the commercialization of the results of university professors and students at the market.

Assessment of Ozone Injury

*Snežana Rajković¹, Miroslava Marković¹, Ljubinko Rakonjac¹,
Radovan Nevenić¹*

¹*Institute for Forestry, Belgrade, Serbia, srajkovic1@gmail.com*

The essential basis for choosing ozone (O₃) induced visible injury is that many plant species respond to ambient levels of ozone pollution with distinct visible foliar symptoms that can be diagnosed in the field. The results attributed to LEVEL II Serbia – Kopaonik sites will be documented in maps covering Europe, characterizing areas of increased ozone risk for European forest ecosystems. The evidence we have today strongly suggests that ozone occurs at concentrations that cause visible foliar injury to a wide range of sensitive plants. The assessment of ozone visible injury serves therefore as a means to estimate the potential risk for European ecosystems that are exposed to elevated ambient ozone concentrations and has to be considered in the context of ICP Forests aiming among others to document the presence of environmental drivers that may affect forest condition across Europe. Many plant species respond to elevated ambient levels of tropospheric ozone (O₃) with distinct specific foliar symptoms. These symptoms can be diagnosed only after adequate training. Harmonization of procedures is essential to ensure spatial and temporal data comparability. For the injury data being accepted for the international database and evaluations, National Focal Centers and their scientific partners that are participating in the UN/ECE ICP Forests program must follow the methods and apply the manual described herein. The assessment for visible ozone injury on main tree species is conducted on the leaves from the same branches where foliar analysis is carried out. The samples for foliar injury are collected every second year from the upper sun exposed crown. Ozone visible injury on conifer species is expressed at the upper parts of the crown, in the upper side of branches and needles.

Keywords

Assessment, experiment, injury, ozon.

1. Introduction

Vegetation is a major component of forest ecosystems. The composition, diversity, and structure of vegetation are important factors for assessing biological diversity of forest ecosystems. Vegetation is the source of primary production, plays a direct role in water and nutrient cycling, and interacts strongly with other biotic components (insects, game, etc.) being a determinant habitat for many species. Vegetation has also been identified as a specific target for the calculation of critical loads/levels.

The development of ozone-induced injury is inter- and intra-species specific, and depends apart from local ambient ozone concentrations on other environmental such as biotic and climatic factors. Due to the complex nature of the diagnosis and the given restrictions of the investment, results from the tree and vegetation assessment should be considered as semi quantitative. Ozone pollution leaves no elemental residue that can be detected by analytical techniques, as do fluorides [1] and sulfur dioxide [2]. Therefore, ozone-induced visible injury on needles and leaves is the only easily detectable evidence in the field as a result of oxidative stress, leading to a cascade of adverse physiological and morphological effects. These “ozone response variables,” made at the needle, whorl, branch, tree, or stand level, and aggregated in analysis, can be an effective way to quantify ozone effects on pines [3]. Ozone response variables include microscopic and macroscopic injury to the foliage (primary effect), and injury to branches and roots (secondary effects) that can be quantified within defined levels of

accuracy and precision. These “ozone response variables,” made at the needle, whorl, branch, tree, or stand level, and aggregated in analysis, can be an effective way to quantify ozone effects on pines [3]. Ozone response variables include microscopic and macroscopic injury to the foliage (primary effect), and injury to branches and roots (secondary effects) that can be quantified within defined levels of accuracy and precision.

Until now, experiments have concentrated on explaining the mechanisms leading to injury observed in experimental studies, rather than to identify and characterize the symptoms observed in the field on a regional scale.

The evidence we have today strongly suggests that ozone occurs at concentrations - cumulative exposures greater than 60 ppb; [4] that cause visible foliar injury to a wide range of sensitive plants. Gaseous pollutants pass through the stomata of conifer foliage and cause direct damage to the photosynthetically active mesophyll cells, often producing a diagnostic visible injury pattern [5]. Next, degeneration of essential biological processes in the needles occur that may eventually lead to reduced crown vigor, increased susceptibility to other pathogens, and tree death [6].

Controlled exposures and field observations of ozone effects on western conifer species have confirmed that a distinct visible symptom known as chlorotic mottle typically occurs on needle surfaces [7,8]. Chlorotic mottle begins as the walls of mesophyll cells below the epidermis degrade, causing the loss of cellular contents and the subsequent degradation of chlorophyll within the cell [5,9,10]. Microscopically this condition appears as amorphous staining of cellular contents, plasmolysis of cell contents, and cell death. The degradation of chlorophyll beneath the epidermis appears on the needle surface as amorphous chlorotic blotches with diffuse borders that occur in irregular patterns, giving a yellow “mottled” appearance; hence the terminology “chlorotic mottle”. This foliar injury symptom is visibly distinct from foliar symptoms induced by other air pollutants.

Chlorotic mottle frequently appears in the one-third of the needle surface nearest the tip on 1-year-old or older needles, and progresses basipetally until the entire needle is affected [7,8].

This pattern is observed mainly in southern California. In the Sierra Nevada the mottle tends to occur randomly along the entire needle length [11,12]. The current-year’s needles will show small amounts of chlorotic mottle only when summer ozone exposure levels are higher than usual and/or adequate soil moisture contributes to higher stomatal conductance and more ozone flux to needles, or both. This condition is usually the exception and not the rule for the response of current year needles to ozone exposures in the Sierra Nevada. Tip necrosis or necrotic bands can result from acute ozone exposures in fumigation experiments, but chronic field exposures typically induce only chlorotic mottling.

The assessment of ozone visible injury serves therefore as a means to estimate the potential risk for European ecosystems that are exposed to elevated ambient ozone concentrations and has to be considered in the context of ICP Forests aiming among others to document the presence of environmental drivers that may affect forest condition across Europe.

The main objective of assessing ozone visible injury on a selected number of Level II plots is to assess the effect of tropospheric ozone at the sites where ozone monitoring is performed, and to contribute to an ozone risk assessment for European forest ecosystems.

Specific aims are set as follows: Quantification of ozone injury occurrence on a selected number of Level II plots in Serbia – Kopaonik. Detection of temporal trends on a selected number of Level II plots in Europe (significant changes within 10 years with a 95% significance level for individual plots).

2. Measurements

Symptoms of ozone injury on red fir, ranging from effects on needles to effects on portions of ecosystems, were differentiated from symptoms induced by other natural biotic and abiotic stressors occurring in the same area. Identified in laboratory and field studies, quantification and monitoring of these symptoms were used to provide reliable information on the effects of air pollution on forest trees and ecosystems. Monitoring symptoms of ozone injury were used to determine status, changes, and trends in effects ranging from needle injury to tree growth.

2.1. Variables measured and reporting units

For the in-plot assessment, the following variables are measured:

- Symptomatic leaves or needles, reported as frequency classes (% score of symptomatic leaves for each sampled branch per IM plot)

For the off-plot (LESS and LESS-plus) the following variables are measured:

- Lists of symptomatic and asymptomatic species per quadrat (LESS). 'Empty' quadrats such as a gap, skidder trail, rock, etc., where no woody species are growing are also recorded.
- A list of symptomatic species within a radius of 500 m from the ozone sampling device (LESSplus).

2.2. Symptom identification

Towards the end of the growing season, foliar symptoms may progress to leaf yellowing or premature senescence, followed by earlier leaf loss. Severely injured leaves may develop necrosis that can also be seen on.

2.3. Symptom identification for conifer species

Ozone visible injury can be identified and distinguished from symptoms caused by other biotic/abiotic factors by the following criteria:

1. Visible symptoms are typically expressed as tiny purple-red, yellow or black spots (described as stipple) or sometimes as a general even discoloration, reddening or bronzing.
2. Look for ozone visible injury on fully developed, light-exposed leaves.
3. Symptoms are more severe on mid-aged and older leaves than on younger leaves. Older leaves are the first ones that develop symptoms followed by an accelerated senescence (age effect).
4. Shaded portions of two overlapping leaves do not show any visible injury (shade effect).
5. Ozone visible injury normally does not go through the leaf-tissue (exception, see point 6). Both, stippling and even discoloration, occur only between the veins (interveinal) and do not affect the veins the lower leaf surface towards the end of the growing season.
7. Plants growing on more humid sites are more likely to develop ozone visible ozone injury compared to plants grown on drier sites (higher O₃ uptake).

2.3.1 Conifer trees (main tree species and others) within the Intensive Monitoring Plots

Once the branches are collected, the different needle age classes are identified. Only current year needles (C) and current + 1 year needles (C+1) are assessed. Needles have to be placed close to each other (making a "plane", at least 30 needles if available) and examined in full sunlight. The chlorotic mottling will be scored for each needle age class in percentage of total surface affected. The resulting percentages per branch and needle age are then transformed to the corresponding score (classes), according to Table 1.

Score	Frequency class (%)	Definition
0	No injury	None of the leaves are injured
1	1 – 5 %	1 – 5% of the leaves per branch show ozone symptoms
2	6 - 50 %	6 – 50% of the leaves per branch show ozone symptoms
3	51 - 100 %	51 – 100% of the leaves per branch show ozone symptoms

Table 1. Scoring and scoring definition for visible ozone injury as it is expressed on the respective needle years for the collected branches of conifer species

3. Results and Discussion

Estimates of ozone damage was done in the manner provided for the Manual on methods and criteria for harmonized sampling, assessment, monitoring and analysis of results of impact of air pollution on forests adopted by the International cooperative program for assessing and monitoring the impact of air pollution on forests [14]. Visible damage to the assimilation organs of conifer expressed ozone in the upper parts of the crown, the top of the twigs and needles.

Minimum of 3 branches per tree and five trees per plot are assessed. The evaluation is very different for deciduous trees and coniferous trees and trees from which they reap the samples in Kopaonik are dominant spruce trees. The trees are on the ground marked the permanent markings on the bark,

numbered 1-195, at 3 under plot. The numbers of trees to assess damage caused by ozone are 9, 20, 54, 76, 108.

Needles in the laboratory for evaluation prepared by placing the flasks with 2.5% solution of glutaraldehyde ON (SN2) 3SNO. Microscopic changes were found chlorotic-most common symptom induced by ozone damage.

The samples were assigned to these five trees with three branches - the three clusters (1-3, 3-5 ... 15) in the form LTF2004. The number of needles per sample is 30.

Other required parameters are listed in table-form LTF2004. (Type number, dates of sampling, analysis, method of detection and other observations). Needles are grouped by category (percentage share - a result with symptoms from each branch were taken to five trees on the experimental plot).

Table 2 LTF2004- Determination of ozone injury on conifer

Point No	Tree No	Cod of species	Latin name	Material of cluster	Date of taking samples	Date of analyses	Injury of conifer	Status of examples
2	9	118	<i>P.abies</i>	1-3	131010	191110	0,0,1	NR
2	20	118	<i>P.abies</i>	4-6	131010	191110	0,1,0	NR
2	54	118	<i>P.abies</i>	7-9	131010	191110	1,0,0	NR
2	76	118	<i>P.abies</i>	10-12	131010	191110	0,0,0	NR
2	108	118P	<i>P.abies</i>	13-15	131010	191110	1,0,0	NR

Foliar injuries resulting from biotic agents may appear on needle surfaces, confounding diagnosis of ozone injury. Chlorotic and necrotic spots or blotches caused by sucking insects, such as aphids and pine needle scale, may sometimes closely resemble ozone chlorotic mottle (Figure 1). The most common confounding pests are fungi [15], and chewing (needle weevil) or sucking (scale or aphids) insects [6,11]. Chlorotic mottle can be differentiated from injuries brought about by these diseases and insects by in-hand observation of the color and pattern of the symptoms on the needles. Careful observation may reveal the presence of fungus fruiting bodies. Close inspection of chlorotic islands of tissue (aided by a hand lens) often reveals a distinct necrotic point at the center of the discolored area, where the insect penetrated the epidermis with its piercing mouth parts.

Figure 1 Healthy ponderosa pine needles are shown on the right one– third of the photo compared to chlorotic mottle caused by ozone injury that gradually increases in intensity on the left [16].

In many conifer species, foliage longevity can be measured by counting nodes on branches back from the branch tip to the oldest whorl, with each node separating a annual whorl of needles or needle fascicles corresponding to one year of growth. Reduction in needle longevity is recognized as an indicator of air pollution stress for these species when other factors leading to accelerated abscission of needles are taken into account. Foliage longevity is related to other factors, most particularly the elevation at which a tree grows [17], which is an indication of the length of the growing season at a particular site. Interpretation of data on foliage longevity must consider other confounding factors, for example, persistent infections of needle cast fungi can lead to tree crowns that are extensively defoliated. The bole and other crown variables that are associated with growth and overall tree vigor

can respond to elevated ozone exposures. Branch mortality in the lowest portion of the crown has been observed in southern California [18], leading to a decrease in vertical crown length, as measured by percent live crown [19]. Before lower branch mortality occurs, a decline in vigor in the lower crown may be observed as a reduction in needle length [20], and the production of fewer numbers of needle fascicles [21,22]. A reduction in the vertical and radial growth of stems has been documented for ozone-stressed trees in southern California and southern Sierras [23,24,25]. Cone and seed production can also be reduced by ozone stress in ponderosa pines [6]. Oleoresin exudation pressure, yield, and rate of flow were all substantially reduced in oxidant-injured ponderosa pines in southern California, while the crystallization rate was observed to increase [26]. The moisture content of phloem and sapwood were found to be reduced, as well as a reduction in phloem thickness. These phenomena have been associated with susceptibility to cambium damage from the heat of fire and successful attack by bark beetles (Cobb and others 1968, Graban and Duriscoe 1992). [26, 27].

4. Conclusion

- In Europe, ambient ozone levels are high enough to cause visible injury in native species. Assessment of visible injury is a feasible way to detect the impacts of this pollutant in forest plants and to identify potential risk areas. Ozone-induced visible injury has been incorporated in monitoring programmes, and it is surveyed at a pan-European scale under the protocols of ICP-Forests and FutMon (Life+) project.
- Conifers are presented on categories in percentage. Results with symptoms are shown from each branches from 5 trees from experimental plate. The peaces of conifers were estimated for 5 trees from 3 clasters (1-3, 3-5...15).
- Chlorotic mottle caused by ozone injury were on the toop of the tree, in first part of the conifer.
- Minimum 3 brances by tree and 5 trees by parcelles are controled. Evaluation is different to leaves and conifers, and the experiment were made on red fir. In locality Kopaonik- Rtanj.

5. Acknowledgements

The study was carried out within the Project TP- 31070: "The development of technological methods in forestry in order to attain optimal forest cover", financed by the Ministry of Science and Technological Development, Serbia.

Knowledge Networks of Universities and other Research Institutions in South and East Bulgaria

Stela Raleva¹

¹*Department of Economics, University of National and World Economy, Sofia, Bulgaria, stelarl@yahoo.com*

The paper analyses the networks of knowledge supply institutions in South and East Bulgaria using data gathered through a range of interactions with 20 universities and other research institutions in South and East Bulgaria and as well as through a focus group. The paper is structured as follows: The first section focuses on knowledge assets and the analysis of their importance and effectiveness. The second section summarizes the results concerned with knowledge transfer. The third section highlights the main barriers, faced in the processes of knowledge transfer and the future support that is needed to improve the knowledge supply and transfer. Based on the data obtained, the following conclusions could be outlined:

- Knowledge supply and transfer is dominated by training activities and training programs, and training is the most important knowledge type and intellectual asset. The universities are focusing mainly on education in almost all fields of the science, and they do not pay sufficient attention to research activities;
- The traditional research institutions carry out significant research in the area of fundamental sciences, whereas the applied research is of a secondary importance. In the area of external relations, reputation is considered to be of a high importance for knowledge suppliers, whereas the responsiveness to beneficiary demands, and relationships with beneficiaries and other providers are considered to be less significant;
- The main knowledge recipients are universities and other higher education institutes, whereas the private sector firms are rated to be of less importance. The research institutions closely interact with major business and professional institutions, however the interaction is happening mainly on the institutional level;
- A lack of public support is the main barrier to knowledge transfer for knowledge suppliers, whereas the main barriers for the firms are a lack of financing and access to skilled labour.

Keywords

Innovations, R&D, Knowledge

1. Introduction

Knowledge is well recognized as a key ingredient underlying the competitiveness of regions, states, sectors and individual firms. The knowledge-base of the economy can be defined as the capacity and capability to create and innovate new ideas, thoughts, processes and products, and to translate these into economic value and wealth [1].

The paper presented the results of benchmarking regional knowledge supply and transfer in the region of South and East Bulgaria. This region includes four out of the six planning regions (NUTS 2 level) in Bulgaria – South-West region, South-Central region, South-East region, and North-East region. It covers an area of about 74.2 % of the country's territory, homes 79% of the total Bulgarian population, and provides 83.8% of the country's GDP level.

Regarding the R&D investments, the region manifests its main characteristics - the high centralisation and concentration of resources in the capital of the country. In relation to knowledge supply and

creation, the region covers 93% of the staff involved in such activities in Bulgaria. Within the region the South-West planning region concentrates more than 80% of the R&D personnel and researchers, and hosts approximately half (21 out of 43) of the universities.

The analysis of knowledge networks of universities and other research institutions summarizes the results from structured interviews with representatives of 20 key knowledge supply institutions in the region and from a focus group, which was organized as a networking event [2].

The interaction with knowledge supply actors was aimed at: a) exploring types of knowledge that is generated by these institutions; understanding how knowledge is currently transferred from the research to the SME community; identifying and understanding how knowledge creating institutions and intermediaries can be involved and in the future enhance knowledge transfer and infusion activities; gaining an understanding of the issues that the research community is facing when they are trying to engage with the SME community in regard to knowledge transfer and supply.

The main goal of the paper is to analyze the kinds of knowledge that universities and other research institutions create, the R&D that they currently undertake, and the existing modes of transfer and barriers hindering such transfer. The interviewed firms were expected to access the role of different innovation related factors, using a 1 – 9 scale, where 1 is the minimum, and 9 is the maximum grade. They were also expected to rate the importance and effectiveness of the various factors, where the importance is related to the necessity of a particular factor, while the effectiveness is connected with its efficient usage for the competitiveness of the knowledge supply institution.

The paper is structured as follows: The first section focuses on knowledge assets and the analysis of their importance and effectiveness. The second section summarizes the results concerned with knowledge transfer. The third section highlights the main barriers, faced in the knowledge transfer and the future support that is needed to improve the knowledge supply and transfer [3].

2. Knowledge assets

This section contains a description of knowledge assets that interviewed institutions possess and an analysis of their importance and effectiveness. Knowledge assets are classified in 13 groups: employment law; health and safety advices; finance, accounting and auditing; development of new markets, new products, new processes, and new services; new technologies; recruitment or skilled labour; training; procurement of inputs; IT development; general business support.

Table 1 Types of knowledge supplied to external sources (%)

Types of knowledge	Very often supplied	Quite often supplied	Not often supplied	Never supplied
Employment law	5	15	35	45
Health and safety advice	0	20	25	55
Finance, accounting & auditing	25	25	25	25
New Market development	10	20	30	40
New Product development	10	20	30	40
New Process development	10	10	35	45
New Service development	10	20	30	40
New Technology	5	10	45	40
Recruitment or Skilled Labour	40	5	10	45
Training	75	25	0	0
Procurement of inputs	0	10	45	45
IT development/support	30	30	20	20
General business support	30	45	25	0

The results presented in Table 2 shows that the most important intellectual assets supplied are training programmes, websites and market knowledge with average scores of 8.07, 7.56 and 6.75 respectively. At the same time, the importance of typical intellectual assets as patents and copyrights is ranked as the lowest (2.63 and 3.44). Processes manuals and IT facilities appear to be of an equal importance for the knowledge supply organizations with an average score of 5.38. Six of seven intellectual assets are rated more important than effective. The only exception is IT facilitiesq where the percentage difference between the importance and effectiveness is only -4.65%. The biggest percentage differences between importance and effectiveness are related to copyrights held and

patents. The percentage difference for training programs is only 3.35%, which means that their significance for the organization is almost the same as the efficiency of their use.

Table 2 Intellectual assets

Types of intellectual assets	Importance	Effectiveness	Percentage Difference
Patents filed	2.63	2.37	9.89
Copyrights held	3.44	3.06	11.05
Market knowledge	6.75	6.25	7.41
Process manuals	5.38	5.00	7.06
Training programmes	8.07	7.8	3.35
Website	7.56	7.0	7.41
IT facilities	5.38	5.63	-4.65

Figure 1 suggests that business and administration (e.g. logistics), and computer science and information systems are considered to be the most significant disciplines for knowledge creation with average scores of 7.25 and 6.13 respectively. The rest of disciplines are not rated highly, and the lowest score 1.75 is given to architecture, building & planning. Almost all of the respondents under the section 'other disciplines' added different fields of social sciences, with an average score of 4.43, which is higher than in other disciplines, such as engineering technology and other fields of natural sciences. This can be explained by the fact that the majority of the interviewed universities and most of the Bulgarian universities as a whole supply knowledge in the field of social sciences.

Figure 1 Importance of academic disciplines

In terms of sources of knowledge, the highest rated source within and outside the region are "universities or other higher education institutes" with an average score of 7.4 (see Figure 2). These knowledge sources are distributed almost equally within and outside the region. All other sources of knowledge, except the "other", have a medium frequency of usage with average scores of 4.7 and 4.3 within and outside the region. Firms and organizations from private sector and professional networks are definitely more important sources of knowledge within the region rather than outside the region. Not surprisingly international organizations are the only high important source of knowledge outside the region with an average score of 5.00. The basic locations of the outside sources are grouped into two main groups. The first group consists of the district centers located outside the MIRIAD region such as Veliko Tarnovo, Rousse, Plevan, Swishtov, Vratza, Vidin, and Montana. The second group includes locations outside the country and especially the EU countries.

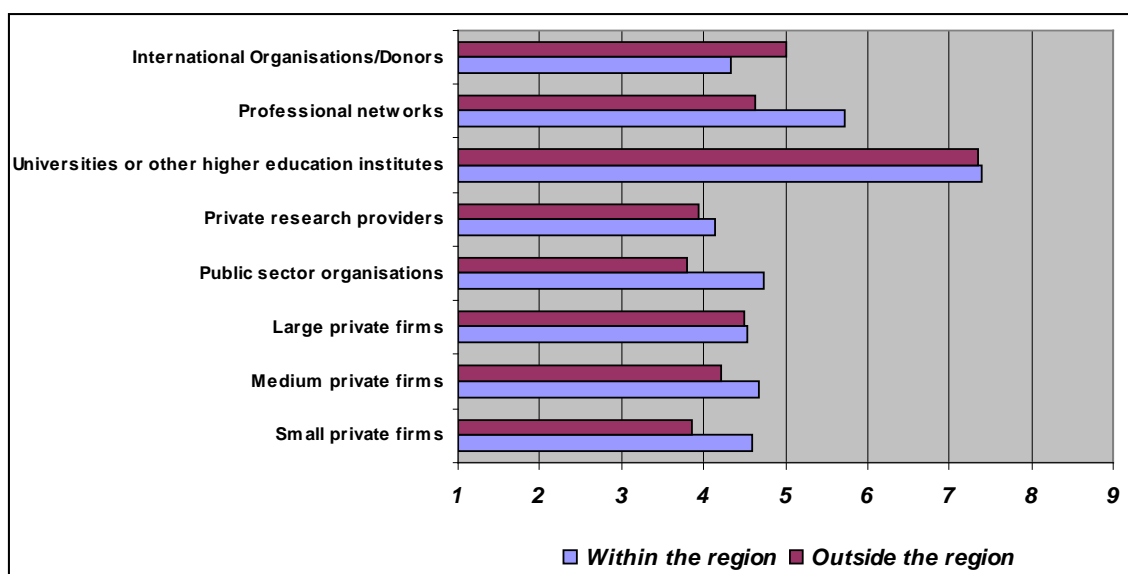

Figure 2 Sources of knowledge

3. Knowledge transfer

This section contains empirical analysis of the practices and routines, and the main kinds of external relations of the knowledge transfer organizations. The focus is on their importance and effectiveness for the competitiveness of the respondents.

Table 3 Practices and routines

Types of practices and routines	Importance	Effectiveness	Percentage difference
Process manuals	5.64	5.07	10.11
Training materials	8.07	7.64	5.33
Customer project materials	4.36	4.07	6.65
Library	7.57	7.14	5.68
e-library subscription	5.00	4.71	5.80
Forums for solving problems	6.57	6.5	1.07
Communication with beneficiaries	6.64	6.00	9.64
Communication with other service providers	5.14	5.07	1.36

Table 3 suggests that training materials are the most important and the most effective practices and routines, affecting the organizations' capabilities to transfer knowledge to business. The average values of 8.07 and 7.64 are high which documents that this significance occurs both in relative and in absolute terms. The second ranked item is library, whereas the lowest score is given to the customer project materials. The importance of all "practices and routines" is higher than their effectiveness, i.e. knowledge transfer organizations are not able to use them as efficiently as it is necessary in order to be competitive. The difference between importance and effectiveness of 10.11% for the process manuals is the highest, whereas the difference for solving problems forums is only 1%.

When considering the external relations of the knowledge transfer organizations, the following major characteristics could be outlined: In comparison to other external relations, the reputation of knowledge transfer organizations appears to be the decisive factor in terms of importance and effectiveness with average scores of 8.43 and 7.57. The next three positions were obtained by information on an organization's roles, presentation of their services, and the level of client satisfaction. Interestingly the relatively low scores were obtained in the area of relationships and collaborations with business and other providers, which suggest that they are less significant in the knowledge transfer process.

Similarly to the previous table, all forms of external relations are rated as more important than being effective, and again these forms are more important for the knowledge creation organisation than they are being efficient in regard to the knowledge transfer (See Table 4). The percentage difference between the levels of importance and effectiveness varies from 3.96% (satisfaction of clients) to 10.2% (reputation of the organization).

Table 4 External relations

	Importance	Effectiveness	Percentage difference
Reputation of your organisation	8.43	7.57	10.2
Presentation of your services	7.36	6.93	5.84
Knowledge of your organisation's role(s)	7.79	7.14	8.34
Satisfaction of client/customer/partner	7.07	6.79	3.96
Responsiveness to beneficiary demands	6.71	6.36	5.22
Relationships with your beneficiaries	5.71	5.36	6.13
Relationships with other providers	5.86	5.29	9.73
Collaboration with business to innovate	6.00	5.50	8.33
Collaboration with other providers to innovate	4.86	4.57	5.97

Figure 3 Importance of academic disciplines for knowledge transfer

Regarding the importance of scientific disciplines in relation to knowledge transfer, Figure 3 shows that they are ranked in very similar way as the results on Figure 1. The obtained scores for a majority of disciplines are in this case higher, which denotes that they are of higher significance and contribute to knowledge transfer. The data on Figure 3 confirms the inference, drawing from knowledge supply analysis, that the scientific disciplines are not rated highly, except business and administration, and computer sciences.

Figure 4 presents the results concerning knowledge transfer to the different stakeholders. It highlights the fact that the recipients of primary importance are universities and other higher education institutes, public sector organisations, private sector organisations, and professional networks. The scores for all types of private firms are much lower, and this fact can be interpreted as an unfavourable in respect to the innovation capabilities and competitiveness of the firms.

Figure 4 Main knowledge recipients

The knowledge transfer recipients are located mostly inside the region. Thus, the average scores for the agents outside are very low in absolute and in relative terms, due to the broad definition of the Bulgarian region for the project purposes, which has more than ¾ of all Bulgarian universities and other research centres. Similarly to the previous results, the main outside knowledge transfer destinations are the district centres of the excluded planning regions, as well as the EU countries.

Table 5 Interactions with other stakeholders (%)

Partners to knowledge transfer organizations	Yes	No
Chamber of Commerce	57.1	42.9
Trade or Business Association	78.6	21.4
Business Club	64.3	35.7
International research organisations	100.0	0.0
Professional organisations	92.9	7.1
Subject focused organisations	85.7	14.3
Funding organisations	85.7	14.3

Table 5 provides information for various partners to knowledge transfer organizations. All the listed partner organizations appear to be of a high importance. 100% of the respondents interact with international research institutions, 92.9% with professional organizations, and 85.7% with the subject focused and funding organizations. These data can be perceived as evidence that a relatively big part of interactions relates to fundamental research, having little to do with the applications to SMEs.

The most important interaction for the knowledge transfer seems to be an improving of the university-business relations, whereas the effect on developing a trust between research providers and companies is rated relatively low. The obtained results suggest that interaction at institutional level is rather high but the real collaboration with the firms is actually not happening.

4. Barriers and future support

There are two types of barriers to knowledge transfer: barriers concerning knowledge transfer to firms, and barriers to acquiring or creating knowledge in the organisations which need to maintain or improve

their competitiveness. This fact raises the problem concerning the areas of policy interventions that could help companies to acquire and develop knowledge needed for improving their performance.

Figure 5 suggests that over 50% of barriers to knowledge transfer are rated below 5 and consequently they are not classified as significant. The most important barrier faced by knowledge transfer organizations is a lack of support from the public sector, followed closely by a lack of finance/budget to reach many firms and a lack of demand from local firms with scores of 6.06 and 5.63 respectively. It should be pointed out that none of the barriers (except the item "other") is ranked below 4, which means that these barriers are not significant. These data are indicative and suggests that the public sector interventions are necessary in regards to the knowledge supply process. In this case it is necessary to take into consideration the fact that a majority of the research institutions are still state-owned and subsidised, and therefore rely on the public support more than on knowledge transfer activities initiating by themselves.

In terms of barriers faced by firms, Figure 6 shows that the two most important barriers are the access to suitable finance and the access to skilled labour with average scores of 6.94 and 6.56 respectively. The relatively high scores of the access to suitable finance and the access to skilled labour highlight the financial problems of most of Bulgarian firms, which suffer from the adverse demographic trends and the "brain drain" processes.

Figure 5 Barriers to knowledge transfer

The priority for future policy should be a focus on creating better networks that link companies with universities and other R&D performing organisations. The high percentage (70%) suggests that it should form the core policy. The other areas that seem to be of a high importance are the improvements to the physical infrastructure (55%), and creating more access to training and workforce development opportunities (50%). From the obtained data it becomes apparent that the universities and other research centres do not think that making finances available to firms or providing more support to companies to improve their supply-chains should form the core future policy.

Figure 6 Barriers to knowledge creation faced by firms

5. Conclusions

Based on the conducted analysis of the knowledge supply and transfer in the region of South and East Bulgaria, the following conclusions could be outlined:

- Knowledge supply and transfer is dominated by training activities and training programs, and training is the most important knowledge type and intellectual asset. The universities are focusing mainly on education in almost all fields of the science, and they do not pay sufficient attention to research activities;
- The traditional research institutions carry out significant research in the area of fundamental sciences, whereas the applied research is of a secondary importance. In the area of external relations, reputation is considered to be of a high importance for knowledge suppliers, whereas the responsiveness to beneficiary demands, and relationships with beneficiaries and other providers are considered to be less significant;
- The main knowledge recipients are universities and other higher education institutes, whereas the private sector firms are rated to be of less importance. The research institutions closely interact with major business and professional institutions, however the interaction is happening mainly on the institutional level;
- A lack of public support is the main barrier to knowledge transfer for knowledge suppliers, whereas the main barriers for the firms are a lack of financing and access to skilled labour.

Venture Capital in Macedonia - Does it really exist?

Veland Ramadani¹, Shqipe Gerguri²

¹*Faculty of Business and Economy, South-East European University, Tetovo, Macedonia, v.ramadani@seeu.edu.mk*

²*Faculty of Business and Economy, South-East European University, Tetovo, Macedonia, s.gerguri@seeu.edu.mk*

Due to inexperienced management, lack of specialization, lack of undifferentiated production program, lack of reference of successful story, unwillingness of entrepreneur to share the ownership etc., many researches confirm that financing represents a serious difficulty for small and medium sizes enterprises. Financing is a very critical issue for the survival and development of small and medium sized enterprises. Venture capital represents a very interesting solution for the new and existing small and medium sized enterprises which have interesting and attractive ideas and projects, but are short of finances. The specific importance that lies on venture capital and its impact on small and medium sized enterprises is the fact that they provide much more than money for them.

This paper offers analyses the current situation in Republic of Macedonia related to the development of venture capital - what is done and what should be done? It also gives data on the features of investments made by venture capital funds, established by Small Enterprise Assistance Funds - SEAF from USA (SEAF Macedonia, Small Investment Fund and SEAF Fund for Southern Balkans) as the only funds which provide venture capital in Macedonia. The data are related to the number of investments made in Macedonia, preferred sectors for investments, amounts of invested capital, factors that affected these investments, received benefits of businesses from invested venture capital, level of success achieved from investments etc. Up until now these funds have invested in 17 small and medium sized enterprises in our country.

Keywords

Business angel, exit strategies, investment criteria, venture capital, venture capital fund.

1. Introduction

The idea of investing capital in risky businesses and seeking sources of capital is not new. In the XV century explorers - adventurers to sail around the world looking for a big wealth in exotic locations was needed to find financial resources from someone. Using their connections with the king or queen they came to the appropriate financial means for realization of their goals. It can be stated that the first venture capitalist was the Spanish Queen Isabella, who invested in its well-known entrepreneur Christopher Colombo for various researches and searching for new places. [1, p2-5] In the nineteenth century a large number of wealthy individuals and families financially helped researchers of new technologies. Immediately after The World War II, in 1946 was formed the first venture capital fund, American Research Development Corporation, which initially invested in new companies with great growth potential, mainly composed by soldiers returning from the war, and later it invested in other businesses types as well. [2, p32] It is assumed that the term "venture capital", for the first time is mentioned by Jean Carter Witter in 1939 in an open forum at Convention of Associations of Investment banks of United States of America, and since then venture capital began to be considered as a particular source of financing small and medium enterprises. [3, p2] The term "venture capital" derives from the nature and characteristics of investment projects in which the capital is invested. Because the bulk of investment projects are characterized by a high degree of risk and the capital invested in them is qualified as "risky."

Venture capital is often invested in small enterprises which deal with scientific studies and application of modern technology, in which investments are characterized with a high risk. If they realize a successful penetration in the market, then they will achieve a high level of profitability, in compared with other enterprises. In the seventies as risk investments were considered companies that were engaged in production and development of computers.

As features of small and medium enterprises, which are distinguished by a high degree of investment risk, are: the availability of a strong potential of growth and development, orientation to the rapid growth and great development of the product for a short time period; appearance on the market with completely new products or products that have been modified.

But it should be noted that not all businesses are attractive for investment by venture capitalists. According to many studies in different countries of the world, venture capitalists analyze 100 to 200 projects before they invest their financial means, which have been planned.

2. Definition and types of venture capital

Venture capital represents the financial funds, usually in the form of equity capital and know-how management, which are invested by individuals and institutions in small and medium enterprises, which are not listed on the stock exchange and have high growth potential. Venture capital represents long-term investment in the form of equity capital, or similar to it, in small and medium enterprises - new and existing, which includes not only financial resources but also managerial advices. [4, p166] Venture capital can be presented in two basic forms, business angels, as informal venture capital funds and formal venture capital funds, which will be addressed in the following pages.

Business angels are private investors, wealthy (often millionaires) who invest in small and medium enterprises, which are not listed on the stock exchange, mainly in the early stages of their development in order to help young entrepreneurs in the achievement of their objectives, and in the realization of profits for themselves. Business angels as an informal source of capital, they represent important force in the financing and the management support to newly created enterprises.

In literature and practice we can see certain types of business angels. Main division is as follows: active, latent and virgin angels. [5, 6] Active angels are people who have experience in investment and continue to seek investment. Latent angels are passive investors who have invested in the past, but have not invested in the past three years. Virgin angels are people who want and seek to invest, but have not yet made their first investment

The origins of modern formal venture capital is related with the formation of the American Research and Development Corporation (ARDC) in 1946, which was mentioned beforehand, at the initiative of General Georges F. Doriot, who is also known as "the father of the formal venture capital", together with Ralph Flanders and Karl Compton, in order to support investments in the weapon industry, and soldiers returning from World War II to form and lead their own businesses.[2, p32] ARDC, as the first formal venture capital fund, the most successful investment marked in 1957 when it invested \$ 61,400 in Digital Equipment Corporation (DEC), which in its first appearance on the stock exchange in 1968, was valued at \$ 355 million. DEC began with "a table and two people", while in 1971 numbered 7000 employees. ARDC Fund continued to invest up until 1971, when the founder George F. Doriot was retired. In 1972, Doriot merged ARDC with another fund - Textron. ARDC had so far invested in more than 150 enterprises. According to the ARDC system, other venture capital funds were formed.[7, p13-4] The formal venture capital represents the capital mobilized by pension funds, insurance companies, corporations, financial institutions, academic institutions, individuals and others from the venture capital firm, which manages the same and invest in small and medium enterprises that are not listed on the stock exchange within a limited period in order to realize a profit for themselves, investors and entrepreneurs.

There are several types of formal venture capital. On the basis of who provides the capital, we can distinguish state venture capital (government, is usually the sole investor), financial venture capital (investors are banks and other financial institutions), corporate venture capital (non-financial corporations are investors) and venture capital partnership (partnership between so called institutional investors and venture capital firms).

Formal venture capitalists invest large sums of capital in the enterprise, which are already developed, respectively, have exceeded the risky stages of their life cycle. In this way, formal venture capitalists support only when entrepreneurs are convinced that the business to some extent has proven to be successful, this mostly can be seen through the positive sales figures and profits. They simply are "part" of a particular investment in a period of 3-5 years.

There are several types of companies that work with venture capital. They are divided in Independent captive, and semi-captive. [8-11] Independent companies are those which raise capital for investments from other sources (pension funds, insurance companies, corporations, wealthy individuals and families, etc.) and invest in small and medium enterprises. Captive companies are those that raise capital for investment by the parent company, which is the dominant financier of the investment fund, which is created by the company for venture capital. The captive company is a subsidiary or department of a bank, financial institution, insurance company or industrial company. These firms are formed to seek new ideas and projects for investment, which are related to the sector in which the parent company operates. Banks create these firms/sectors to distinguish their commercial activity from the investment one. Semi-captive companies are almost the same with the previous, with the difference here that aside the parent company, largely as financiers a third party appears. Venture capital companies, in most cases are structured as partnerships or limited liability company, as in Figure 1. [12, p.500]

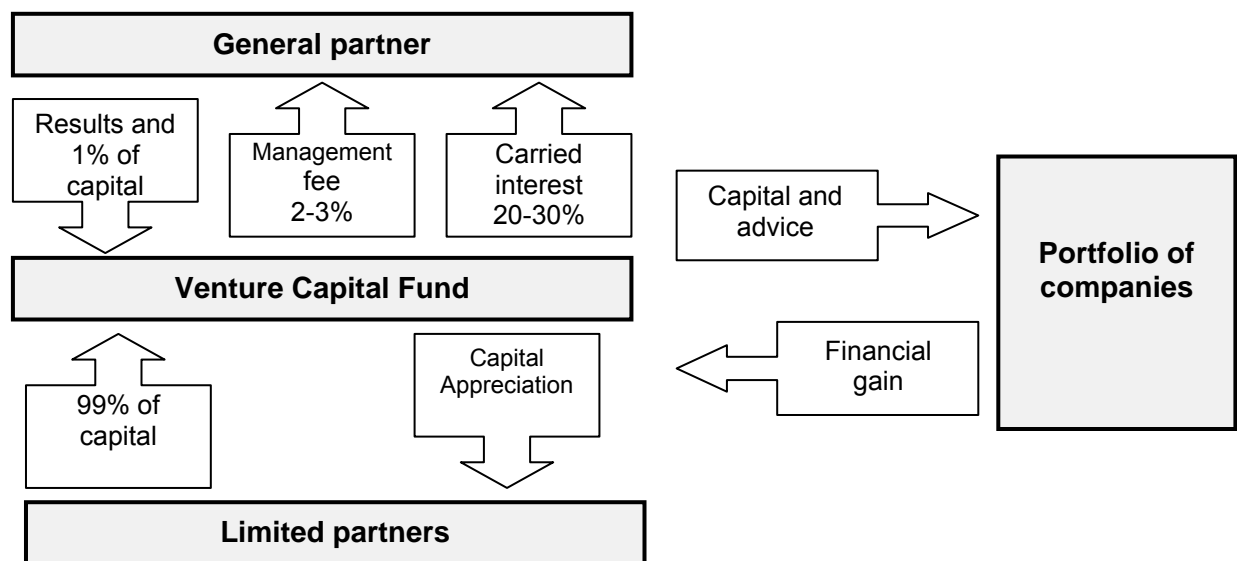

Figure 1 Venture Capital Partnership

Venture capital companies for their efforts and investments made are compensated in two ways, through a management fee and carried interest. Venture capital companies receive annual compensation, which amounts to about 2-3% of the gathered and dedicated capital for investment. This management compensation usually serves for payment of workers engaged in the investment process, office rent, phone, electricity, travel expenses and marketing costs. Carried interest is around 20% of profits from investments made. It is distributed to venture capital companies, after the investors (limited partners) have returned their invested means.

At the new era, venture capital marks developments even in some countries in transition. Causes for this capital development are different, for example, 1) necessity that investment project with a high degree of risk to be financed in a more flexible way rather than financing through bank loans, which are characterized by fixed costs and fixed date credit returns and 2) development of small and medium enterprises as a source of innovation, new jobs creators and their role in the holistic development of the state.

3. Macedonia and venture capital - conditions, problems and perspectives

The financial system in Macedonia is shallow and unbranched system and is characterized by limited access of SMEs to financing sources needed for their growth and development.

Venture capital as an important source of financing is almost completely absent in the Republic of Macedonia. Consequently, our small and medium enterprises are deprived from "one of the most favorable and most quality financing sources for their development" [13, p215] In our country, recently the interest for formal venture capital started to take place, while business angels still remained "unknown term".

In 2007 the Government launched an initiative to open three venture capital funds (with the participation of state capital) in order to determine is there a willingness of the private sector to invest together with the government in promising, risky investment projects. Some activities around this initiative took place during 2007, but ended unsuccessfully. [14] In Macedonia there is a legal framework for the establishment of venture capital funds. The establishment and operation of these funds is regulated under the Law on Investment Funds (from 2000, which suffered amendments in 2007 and 2009), which enables the formation of private funds, whose operation is similar with the operation of venture capital funds. Private funds are established to raising funds through a private offering, which are then invested according to the aims of the fund. According to Article 41 b of the Law on Investment Funds: [15, p2] 1) A private fund is established in temporary basis that can not be shorter than eight years 2) The size of the fund is at least 500.000 € converted in denars. Under the fund's size means a committed capital from all investors during the entire time of existence of the fund, 3) Minimum taken concerted commitment of investment of each investor in the private fund can not be less than 50.000 € converted in denars which the investor is obliged to pay on a call of the company for managing private funds in accordance with the provisions of the prospectus, 4) The maximum number of private investors in the fund is 20 investors; 5) Private fund is established and it is managed by a company for managing private funds; 6) To establish a private fund, the company for managing private funds adopt a statute and prospectus of the fund; 7)The private fund can borrow without any limit.

The only funds which invest in the form of venture capital and operate in our country are funds established by the U.S. Fund for Small Businesses - SEAF (Small Enterprise Assistance Funds - SEAF). SEAF is a global investment company based in Washington, where its work focuses on providing capital for business development in fast growing markets as well as those who lack traditional sources of capital. These funds are: SEAF Macedonia Small Investment Fund (SIF) and SEAF Fund for South Balkans. [16]

SEAF Macedonia was established in 1998. SEAF Macedonia is a small venture capital fund with total capital of \$ 13 million. The founders and investors of SEAF Macedonia are: The European Bank for Reconstruction and Development (EBRD) - which has invested \$ 4 million, the International Finance Corporation (IFC) - 2,5 million \$, the German Investment Company (DEG) - 2,5 million \$ and The U.S. government's Agency for International Development (USAID) - \$ 4 million.

The mission of SEAF Macedonia is making wise investments in small and medium businesses. Investments in these companies are carried out in combination with management training and technical support in order to improve their business performance and achieve their development goals. The Fund actively supports its portfolio companies in implementing appropriate improvements in the techniques and practices of management, particularly those related to financial control, cost accounting, quality control and marketing (see Table 1).

Table 1 Types of support offered by SEAF Macedonia

Type of support	No. of firms
Regular management support	14
Financial consalting	14
Marketing consalting	14
Recruitment and personnel development	5
Assistance in legal matters	11
Access to other sources of funding	11
Organization development	6
Product development	8
Entrance to the international market	5
Other	1

Information obtained from our research related to SEAF funds investments say that they mostly are focused in the sector of production (42.86%), followed by trade sector (28.57%), media (21.43%) and internet traffic (7.14%). In terms of invested amounts, for the most part, respectively 35.71%, they moved within 100,001 to 500,000 \$. The most part of the investments were made in the early stage of development of enterprises, in 78.57% of total investments. Only one investment is made in seed phase, while none in the start-up phase of development. In late stage are made 14.29% of the

investments. In enterprises where SEAF invested his funds, the percentage of the share of ownership that was taken from SEAF, in 42.86% of cases are moving from 20-40% (the share of ownership does not exceed 49%, with the exception of On.Net, where SEAF had taken 64% of ownership). SEAF used these strategy to exit from its investments: management by out (42,86%), exit through strategic partner (14,29%), selling to third party (14,29%) and others (28,56%). Until now, only from three investments SEAF has not exited yet. According to SEAF, from previous investments made, in terms of success, they are categorized as follows: 42.86% moderately successful, 28.56% very successful, 14.29% slightly successful and 14.29% finished with failure (realized loss).

SEAF Macedonia has invested in 14 enterprises in Macedonia: Login Systems (authorized distributor of the largest IT companies in the world, such us Microsoft, Cisco Systems, Hewlett-Packard, Navision Solution Center and provider of solutions and services from business-information sphere in Macedonia and the region), Fonko (dealing with air conditioning, but produce and wine and men's shirts), Mako Market (one of the leading suppliers of consumer goods in Macedonia to the most wholesalers and retail enterprises in Macedonia as Vero, Tinex, Skopje Pazar, Tediko and others), Gica (production of animal feed), Tinex (one of the leading supermarket chains), Krug (publisher of one of the most sold daily newspaper "Dnevnik"), On.net (one of the most popular ISP in Macedonia), Pilko (the largest Macedonian producer of fresh chicken) Datapons (one of the leading printing houses in the country), Medium Export (one of the largest exporters of red pepper and lamb meat), Nasto (producer of dairy products, the most famous cheese like "Gauda" and "Ajdamer"), Magnolia (children's apparel manufacturer) Ivoprom (production of spices) and Planet Press (publisher of the journal "Tea Moderna", "Tin shema" and "Tea krstozbor"). SEAF no longer invest in Macedonia.

Key factors which attracted SEAF to invest in these companies are shown in table 2.

Table 2 Factors for attracting venture capital from SEAF

factor	Percentage	No. of firms
Entrepreneur / management team of the company	100,00	14
Solid history of the operation of the company	78,57	11
The development phase of the company	42,86	6
Product Innovation	42,86	6
Technical Innovation	35,71	5

Small Investment Fund - SIF was established in July 2007 and until now has made three investment in Macedonia, such as: Oktober (company for producing toilet paper), INet (system integrator and distributor of various products of information and communication technology) and Urban Invest (the largest producer of concrete paving elements and mosaic products).

SEAF Fund for South Balkans was established in 2006. The headquarters of the fund is in Belgrade, Serbia. This is a regional fund and operates in Serbia, Montenegro and Macedonia. SEAF Fund for South Balkans has not invested in any company in Macedonia. Currently is preparing three investments in our small and medium enterprises, but because the principle of "business secret" the names of companies and amounts of investments were not disclosed.

Considering the presented information we can conclude that SEAF funds did not have a significant impact on the financing of small and medium enterprises. In fact, very few companies in Macedonia were able to use venture capital as a source of funding, respectively only 17 companies of about 70,000 active companies. However, the role of SEAF funds is immense because they laid the foundation of the functioning of venture capital in our country.

4. Measures to encourage the development of venture capital in Republic of Macedonia

Measures which were taken in developed countries and those in transition countries were different. As a measure that was most exploited in the analyzed countries was the establishment of state funds of venture capital – from which after a certain period, the state retreated and were transformed into a private commercial venture capital funds. Significant role in the development of venture capital have played and the European Bank for Reconstruction and Development (EBRD) and International

Finance Corporation (IFC), which initiated the formation of many venture capital funds and networks of business angels. In certain states to encourage investment by venture capital have been introduced and numerous tax incentives by the state, particularly in income tax.

Considering the experiences of countries in which venture capital is present and developed as a source of financing for small and medium enterprises, we suggest the following measures which should be taken to promote the role and importance of venture capital in the Republic of Macedonia:

- Raising awareness about the benefits of venture capital for small and medium enterprises. Considering that in our country venture capital is not enough known concept, it is needed to organize seminars, workshops, conferences, etc., introducing the curricular content in the programs of faculties of economics and business administration, publication of professional and scientific papers, where in the explicit way will be explained all the good and bad sides arising from this method of financing.
- Increasing the number of investment opportunities. This can be achieved with the development of entrepreneurship and small business in the country, i.e. by creating more business incubators, business centers, science parks and so on, where we could develop and present interesting business ideas. We should consider that venture capitalists prefer to invest in interesting entrepreneurial businesses with high growth potential.
- Establishment of state funds for venture capital. Starting from the experiences of countries in transition in which has been developed this way of financing, the first venture capital funds/companies should be established by the government itself, which may appear as a single investor (which is not very desirable), or in cooperation with international institutions and agencies such as the European Bank for Reconstruction and Development (EBRD), International financial corporation (IFC), the American Aid Agency (USAID) and others, which confirmed that they are willing to invest risk capital (for example, they supported the establishment of SEAF funds).
- Formation of a hybrid venture capital funds. Besides the formation of pure state funds, good practice is the formation of so-called hybrid funds, where despite the government, as investors may appear institutional and private investors, such as corporations, banks, pension funds and wealthy individuals. This measure was successfully implemented in Hungary [17].
- Establish networks of business angels. Networks of business angels can be formed with government (central or local) and private initiative. These networks will provide connectivity to prospective investors with entrepreneurs, which can have a good business idea but have lack of funds.
- Providing a supportive fiscal policy. Almost all countries in which venture capital operates and is quite developed, as an incentive to include institutions and wealthy people in this type of investment is tax relief or full exemption from the government. Our country applies a flat tax, which is 10%. As a good measure to encourage venture capital investment could be if the potential investors in the year in which they investment to be completely exempt from income and profit tax, while the profit tax be reduced to 50% in first 3 years from the moment when the investment is made.
- Further development of the Macedonian Stock Exchange. Venture capitalists invest in companies that are not listed on the stock exchange. In the meantime, these companies are growing, becoming known to the market, and to the additional funds coming through the stock market. Venture capitalists are willing to sell their shares of ownership, in these companies. If there is no effective stock market and they can not sell their shares to gain profits from investing, they would not be willing to invest in new businesses. In this context, is very important the establishment and development of the OTC market (over the counter market), which is characterized by much more liberal entry conditions for enterprises, which would enable the listing of successful small and medium enterprises. These are practices of developed countries such as USA, Great Britain, France, Sweden and others. It should also be offered a special service that would pick up buying and selling share prices from various dealers that would be presented to potential investors. Then, investors will complete the transaction through special computer software, without the help of a broker. For example, NASDAQ, Reuters, Telerate and Bloomberg work on these principles[18].
- Reduction or elimination of investment restrictions of pension funds in risky deals. According to the Law on Mandatory Fully Funded Pension Insurance, pension funds are not allowed to make investments that are typical for venture capital. Under Article 108 of this law, the assets of pension funds can not be invested in stocks, bonds and other securities which are not listed on official stock market or are publicly traded, instruments that can not legally be available, material goods which are rarely traded on organized markets and whose assessment is uncertain except in securities which are issued based on mortgage and indirect investment through investment funds.

Under the same law, Article 106 and 107, pension funds can invest: maximum 30% of the assets of pension funds in securities issued by foreign governments and central banks of EU countries and OECD countries; maximum 80% of the assets of pension funds in securities guaranteed by the Government or the National Bank of the Republic of Macedonia; maximum 60% of the assets of pension funds in bank deposits, certificates of deposit, commercial bills, bonds and securities based on mortgage of domestic banks; maximum 40% of the assets of pension funds in bonds and commercial bills of domestic corporations other than banks; maximum of 30% of the assets of pension funds in shares of domestic corporations (shareholding companies) and maximum 5% of the assets of pension funds in share documents and stocks of Macedonian investment funds.[19] But pension funds in our country are not quite developed and have no practical experience in investing in the stock market or small businesses. They also lack managerial staff to do these kind of investments. Hence, the implementation of this measure is too risky. It could be implemented in the future, in a further phase of development of venture capital.

- Training of talented students from different fields about the functioning modes of venture capital. The students who have shown excellent results during their studies, from various fields, government and other institutions and organizations may provide scholarships for training and further formation outside the country, specifically in those countries that are characterized by a developed venture capital, such as United States., Great Britain, Ireland, Sweden, France and others. Once they complete their training, they will return to the country with the obtained experiences and knowledge related to the functioning of venture capital.
- Support and promotion of venture capital from other sources of funding. Commercial banks, savings and other various funds should promote and support the venture capital, as a specific and particularly important source of capital because they give great help in the creation of new enterprises. These enterprises, once they stand on "healthy legs" in the subsequent phases of development will require funding from these sources in the form of loans, allowing the realization of income in the form of interest payments, commissions, etc. Also, commercial banks and other financial institutions can establish a separate department/sector for venture capital, where interesting businesses will be financed, and where they will gain additional profits and other benefits.

5. Conclusions

Venture capital in the Republic of Macedonia is not yet developed. The only funds that invest and operate in the form of venture capital in our country are funds established by the U.S. Fund for Small Businesses - SEAF (Small Enterprise Assistance Funds-SEAF). SEAF is a global investment company based in Washington, where his work focuses on providing capital for business development in fast growing markets as well as those who lack traditional sources of capital. These funds are: SEAF Macedonia, Small Investment Fund (SIF) and SEAF Fund for South Balkans. Barriers for the development of venture capital in our country, and in countries in transition in general, mainly are related to: underdeveloped capital markets (stock markets), a small number of domestic and foreign investors, higher risk for investment, untrained and inexperienced management, corruption, bad regulation, unfavorable tax treatment for this type of investment, bureaucratic and administrative obstacles and so on. Measures of initiation and development of venture capital that were undertaken in developed countries and those in countries in transition were different. As a measure that was most exploited, particularly in countries in transition was the establishment of state funds of venture capital, from which after a certain period, the state retreated and they were transformed into a private commercial venture capital funds. So the first venture capital funds/companies should be established by the Government of the Republic of Macedonia, which may appear as a single investor or in cooperation with international institutions and agencies such as the European Bank for Reconstruction and Development (EBRD), International financial Corporation (IFC), the American Aid Agency (USAID) and others. Besides the formation of pure state funds, good practice is the formation of so-called hybrid funds, where despite the government, as investors may appear institutional and private investors, such as corporations, banks, pension funds and wealthy individuals. This measure was successfully implemented in Hungary as a country in transition. Almost in all countries where venture capital operates and is quite developed as an incentive to include institutions and wealthy people in this type of investment is tax relief or full exempt from the government. Besides these, other measures that should be taken to promote the role and importance of venture capital in the Republic of Macedonia and the development of it, we suggest the following: to continue improving the general business climate, raising awareness about the benefits of venture capital for small and medium

enterprises, increasing a number of investment opportunities by creating a greater number of business incubators, business centers and so on, forming networks of business angels, further development of the Macedonian Stock Securities and establishing and development of the OTC market (over the counter market), allowing pension funds to invest in risky deals, training of talented students from various areas about the operation of venture capital, promotion and support of venture capital from other sources of funding.

Trainings have their importance and their managing today is a need without which could never be imagined the development of the human society. They are divided according to criteria which are oriented to the development of society.

General management training which will be implemented in practice has its importance for the implementation in daily life in order to increase professional and general development of the overall society.

Keywords:

Management, training, project, idea, purpose, innovation,

1. Introduction

Training Management and management of knowledge and innovation are very important because they all should be available for projects to go well for different companies in all fields and human activities. The goal of training is to provide coaches with experience, modern environment, including interactive and modern methods. Trainings are different and their focus is oriented as per their filed. Training for managers in education has focused on the distribution of experience previously created with the development of training programs for management education in different countries with experience. The program aims to build national capacity and development of materials related to running the schools. The main goal has to do with the training of trainers program for school principals, development of programs and development of teaching materials. The aim of this training is the distribution of experiences among participants, capacity building training and creating training modules. Training of human resources management, include concepts of human resource management, development and evaluation performances based on a combination of international best practices, and recognizing local circumstances. Training for project management, financial management, customer service, training in leadership and training in information technology. All training should be managed in order to be successful and achieve the desired results.

2. Management training in various activities

Trainings is different from their management following results that affect the quality of life in raising activities and events. As we introduce the knowledge and “know how” to apply each time the function will be put on innovations that are new to the development of human society and overall development of socio-economic development. Profile management of education should be noted that the training itself, with a range of features, including leadership and manager duties to the institution in order to succeed in the development of performance and results. In this case are involved the basic skills and facilities. During the training should take into account the organization of cooperation. Also giving and receiving feedback, including an understanding of the management situation, together with the evaluation meetings, analyzing all the circumstances and assessment of behavior in a large scale

term. All you can take to complete and deciding where to put their implementation plan. In these cases, management training has several goals:

- To communicate in collaboration with staff and effectively to ensure understanding and commitment at work.
- To clearly describe the differences between leadership and manager.
- To demonstrate the ability to describe and assigned staff duties effectively in a way that invites participation.
- Develop a variety of schemes for decision making.
- To conduct staff meetings productive
- Describe the mentality to deal with conflicts of interest in the workplace.

3. Human Resource Management Training

Has its role and importance, as it helps in improving the learning outcomes of the concept of human resource management, including planning, recruitment, selection and remuneration of labor and training, including development and evaluation of performance. During the training has to rely on a combination of best practices in various countries, without ignoring the local circumstances in the country and the region. Human resources must always be under development in order to prepare the staff motivated.

Training for this department is offered for you to have a staff of motivated, happy and valued. Training in human resource management should include: employee benefits, relationship with employees, employee motivation, compensation, selection and recruitment, performance management and career planning assessment.

4. Project Management Training

Project management is an important area where the person responsible for implementing the project due to be prepared and organized to complete the due date and the projected results for time management and work overload. In order to effectively manage projects should consist of the activities of project management, project scope, time and cost management, human resources and communications.

5. Training in sales management

It begins with what the customer is always right there. Sale of goods is important and that can not survive without any of the companies and firms if they do not sell products or services. Customer needs and requirements change every day and more and even sales techniques should be parallel to meet those needs and requirements. The combination of what information needs of clients and wants the good presentation of products or services to ensure successful sales and profits for the company.

Training to better manage customer needs to provide answers to questions provided such as:

- What are the needs and demands of customers?
- How will they react to a particular product or service?
- How long does the process of buying a product or service?
- How should the sales person to react in a situation of denial?
- How can I understand the sales person when it comes time to close deals?
- When should I ask the sales person to close?
- How to close the deal?

6. Management training in customer service

We have case management training has to do with the "customer is always right." For many years dominated by the philosophy of good customer service more customers. Today is a philosophy that has changed little in terms of quality and quantity. Well-known international companies and more successful than requiring customers loyal customers who come once and never return. That is why many companies are focused on consumers, and that is training to be successful. Staff training in this area will result in more satisfied and loyal customers in these cases t training program will include: How to deal with customers:

- Communication Skills;
- Listening skills and problem solving;
- Resolving disputes and conflicts;
- Overcoming barriers in difficult situations;
- Cultural diversity;
- All these will give their influence in management training.

7. Management training in leadership

Construction is due and tough. He was expecting a tough challenge. Being a leader is not easy, because not everyone can be, the reason is that you should know and follow techniques that will ensure successful management and operation of your staff. With a dog that leadership has to do with various companies and institutions then has its own specifics. We must be clear what the Leader is? And what someone should have to be a leader? In order for training to succeed, it should be clear:

- Types of leadership;
- Leadership in change and transition;
- Leadership competencies;
- Dealing with difficult situations;
- Developing individual and group performance;
- Presentation of productivity and profitability;
- Time management and office.

8. Management training in financial management

Training and development are important for continued success. Financial management has its role and importance in accordance with the development and performance of each company. To be a successful management must have the following basic parameters:

- Evaluation of financial performance;
- Planning and forecasting;
- Monitoring and reporting;
- Financial Management;
- Human capital;
- Strategic planning;
- Investments;

9. Conclusions

Training Management and knowledge management and innovation are important in performance on the basis of development. The development of today's society requires innovation and new conditions for the development of all human activities in order to follow modern trends in the economic sectors, manufacturing and services. All activities as the best managed better training to achieve results that will be effective for society. Training is seen as a necessity of time. We are working on some do not include all of these roles and their importance for the development of society. Development prospects will be good with training, which means that knowledge management and innovation, where developed. Training and development are the success and continued progress in development. Success in this depends on the specifications and performance and use of standards.

The estimation of competences for veterans included in civilian life-second career

Zivko Ramov¹, Elizabeta Popova Ramova²

¹Military academy, „General Mihail Apostolski“ Skopje, University Goce Delcev, Stip, Macedonia, zivkoramov62@yahoo.com

²University, „St. Kliment Ohridski“ Bitola, Macedonia

The new time of transition imposed changes in the army. In our army there is a need for transformation, modernization and reorganization of the units. In this transformation appears more personal, who should be prequalified for civilian occupations. The organizational setup of the program includes the prequalification assessment of whether the accuracy for the selection of the second occupation is. The aim of the research is to access the factor which most affects the accuracy of selection of the second occupation and assessment of the first term results from applicability of the program. The results of the prequalification estimation of person for its second occupation, have the largest meaning in the personal values that can be accomplished with the prequalification like economical and social safety. General conclusion is that in our country as a candidate for the NATO Alliance, the reforms have been made for the care of military personnel by the termination of military service, but there are general social and organizational differences between R. of Macedonia and the USA. Individual personal conclusion is: the excess of personnel in our army has the possibility of a second career choice through a free program, which is demonstrated practical applicative, but it is not solving the employment.

Key words

Management of human resource, comeback of veterans in civil life

1. Introduction

Human management in the defense. The human management today represents very significant factor for the efficient and effective accomplishment of the defensive tasks. The human management in the defense became an important factor in the realization of the national defensive interests^{1,2,3,4}. Today, it has to successfully solve the issues in the reduction, that is reduction of the number of the members of the army, privates, civilians, to protect the qualitative staff, to maintain the readiness for execution of the tasks in the defense and to care for each private with great attention and with feeling of commonness^{5,6,7}.

The system for obtaining staff for the necessities of the army has been built in order to secure staff that will be corresponding both by quality and quantity of the active and the reserve army⁸. The obtaining of people for service in the army will be made due to the confirmed quality standards which must be fulfilled by each individual. For the privates and the officers there is secured logical path in their career, which covers long-term professional training and practice and achievable oriented development⁹. To the military people (officers, non commissioned officers, and professional privates), according to the Law for service in ARM (The Army of the Republic of Macedonia)¹⁰ can stop the working contract in the army on many bases and that is: the end of the working relation, due to age limit, certain level of disability or extinction of the working post, then in many armies in the world and in our as well there has been developed a program for adjustment and redirection of the military officers for civilian life in order to achieve employment again and to have economic benefit.

The process of returning of the military officers to civilian life has always been actual, since there had always been wars, officers and privates. After the end of the wars, after the end of the military period

as a paid private he had to return to the civil life where there were different rules and behavior attitudes. It is in our interest to get knowledge for the following issues:

1. What is the condition and the way of the returning of the military officers in the civil life?
2. How is that solved in many countries in the world and in our country?

We have searched for many countries. The knowledge shows that the former people who served in the army by any status are named veterans. A veteran is a person who at any time served to the army as a professional or a reservist. Their number is not small in the world.

1.1 Existing model of management in the process for returning of the military officers in the second career in the Republic of Serbia

In the Republic of Serbia there is an organized program for returning of the military officers in civil life named "PRISMA" which has been introduced by law in 2010. The activity and the program have been organized and managed by the department for tradition, standards and veteran at MO. In the program beside the Ministry¹¹ of Defense are included the Ministries of Education, Economy, Finances, Ministry of Foreign Economy, nongovernmental organizations and the Chamber of Economy. The activities are regulated by law which includes regulations for election of end of work in the army, decision for the residential issues, as well as the help at the prequalification for other employment and mediation in the employment¹². In this program military officers and civilians are included who on any base are found as a surplus of staff.

1.2 Existing model of management in the process of returning of the military officers in second career in the Russian federation

Knowledge says that the organizational setting as a special unit or a department for veterans does not exist at the Ministry of defense. Certain knowledge we gained from the part for the legal regulations when recruiting officers for service in the army. In this part the conditions are defined as well the obligations of the officers and the obligation of the army towards the military officers¹³. In 2005 The Ministry of Defense of the Russian Federation introduced changes in the management of the military officers because the requests of the modern fight could not satisfy the current organizational setting of the management with the military staff and as a result of that the law allowed 90% of young men to avoid the military service from one side and from the demographic structure of the population that is shortage of people at the age which is corresponding to the military service from the other side in 2005 appeared as a demographic trench. The demographic trench is a shortage of military officers in the service of the army which continued to grow until 2010. From those reasons, a need appeared for big changes in the recruiting of the military force and the program for the same. The program is developed and conducted by the Ministry of Defense, Economic Development and Commerce, The Ministry of Finance and the other ministries and agencies authorized by law for maintenance of the military force. The contract for service in the army is on 12 months with possibility the mobilization with the recruiting to be conducted according to the necessities. When the contract is ended the people who had a contract join the military reserve and by necessity they conclude a contract again. This allows fast mobilization by necessity and it is avoid continuous financing on longer period which has financial importance for the state.

1.3 Existing model of management in the process of returning of the military officers in the second career in The Great Britain

In the frames of the Defense of Great Britain is the Ministry of Defense. Veteran in Great Britain is each person who served to the military forces regardless to the length of service (private, officers, reservists). In the Ministry¹⁴ of defense there are many services which give corresponding help to the veterans that is: the department for information, the department of military pensions, the department for medals, departments for veteran voluntary activities, department for health protection of the veterans and the departments for celebration of the veteran days. The work in this ministry has been regulated by law since 1947.

1.4 The existing model of management in the processing of returning of the military offices in second career in the Republic of Turkey

In the Ministry of Defense there is no department for veterans issues and for the conduction of the legal regulation the national Association of Veterans takes care¹⁵. The Association obtains financial aid by the state agencies, the local administration, the state enterprises and they are economically connected to institutions according to the law 5253 and the article 10 of the Turkish constitution¹⁸. The Association counts 19000 members and takes care for the memories of the former military staff who participated in the wars home or abroad in wars for the independence from the occupational authorities^{16,17}. The army, the Turkish Academy, the military aircraft, the rehabilitation centers and other medical institutions cooperate with the Ministry of Defense.

1.5 Existing model of management in the process of returning of the military officers in the second career in the Kingdom of Canada

In the kingdom Canada there is a special ministry with a Ministry of veteran issues¹⁸. A status of veteran is obtained by each person who participated in the army of Canada, the privileges have the families for obtain payments and pensions. In the frames of this ministry several organizational departments exist: the department of mental health, the services by the veteran hospital St. Ana, the bureau of pension and disability, the department for information the department for rewards and medals.

1.6 Existing model of management in the process of returning of the military officers in the second career in the United States of America

The most extended data for the management of the process of returning of the military officers in civil life we got for the United State of America¹⁹. The first organized forms of protection of the participants in war date from 1636. In 19th century an aid program benefiting and pensions for the veterans was reached. The Congress of USA in 1917 reached new system of benefiting for veterans directly after the including of USA in the military actions of the First World War. The benefiting included a program for payment in a case of disability by war, insurance for the veteran and professional rehabilitation for veterans. In 1920 for the first time it has been registered the existence of organized institutions for a veteran that is: Bureau for veteran, Bureau for pensions and internal affairs and the National home for disabled soldiers. The organized leading of the administration for veterans was founded in 1930. The veterans' department in its frames has medical institutions clinic and program for administration of the benefiting for the veterans and their families, the administration for disability in work, pension education, residential credits, life insurance, professional rehabilitation, payments for survived, medical benefiting and funeral benefiting. The Department for Veteran Issues in USA constantly changes its work according to the legal regulation for the work and the actual happening or military activity. The last change of the law was in July 2010²⁰. At the Department¹⁹ for veteran issues there are in function many programs for returning of the military people in the second career. The veteran centers secure free adjustment services for the veterans who served at any military activity. There existed individual and group counseling centers, a family counseling centers and etc.

1.7 Existing model of management of the process for returning of the military officers in the second career in the Republic of China

The data primarily refer to the transitional changes in the army in the Republic of China. Institutionally the law is effective for service in the army from 2004-2008²¹. The organizational units for veterans at MO do not exist. The transitional changes in the army of the Republic of China are in the section of the information system, the planning of the economic development, reforms of the security system, development of modern logistic system, development of the international cooperation with the other armies in the world. The reforms in the defensive system of Republic of China are applied in the human resources management section and in the projection activity drawn by the Government of the Republic of China and in the following period until 2020 prequalification of the soldiers from the reserve forces in the workers in the industry that will work for the army has been planned. Part of the

reforms in the defensive forces have already been conducted at the police forces. The police forces have been reduced from 10 to 8 millions.

1.8 Existing model of management of the process of returning of the military officers in the second career in Republic of Macedonia

The basis for gaining knowledge for the way of conduction of the returning of the military officers in the civil life in R. Macedonia are the acts of the Ministry of Defense²², the legal regulation and the program for returning of the military officers in civil life "LEPEZA"²³. The serving and the end of the working relation in the army are regulated by law²⁴,. In MO there is a Section of the staff management that will conduct the program through the department of transition. The program will be in three educational centers that have for a purpose to make an evaluation of the qualifications of the military officers for inclusion in civil professions. There has been no cooperation with other institutions and the employment bureau until 2010. The employment was individual and in 2011 the program was developed with larger institutional care for return employment.

2. Definition of the Research

In the current conditions of functioning of the defensive system in the Republic of Macedonia, faced with the process of transition and the tendency for admission at the North Atlantic Alliance defensive system, the offices and the professional soldiers take the largest burden by the necessities for reorganization of the defensive structures

The acceptance of an offered model of management in the process of returning of the veterans in civil life by the program "LEPEZA" in Republic of Macedonia should give the predicted results for integration of the military officers and the surplus of the staff without feeling of a refusal by the society. This program is doctrinally discussed by the higher structures in the country and abroad and should give its contribution in our country in the solution of this problem.

3. Qualitative Analyses in the Research

3.1 The organizational setting of the care for the veterans in the societies with different social system

From the researched material regarding the tradition and the care for the society for the veterans, it could be confirmed the following: the oldest social care by the analyzed countries exists in USA (1636), then The Great Britain 1947.¹⁴ In the Kingdom of Canada there is a special care for the veterans by the Ministry defined for veteran affairs and the ministry for veteran affairs.¹⁸ In the Republic of Turkey modern care for the veterans with protection as a special category in the society has existed since 1965.,^{15,16}. The veterans in the Turkish army have special treatment of respect towards the society. In modern Russian federation and at the Ministry of Defense there is no department for veteran issues and the serving of the military term is a national duty and it is not paid. In Republic of Serbia¹¹, the Ministry of Defense has a national counsel which coordinates the work for care of the military officers that will appear as a surplus.

In the Law for serving in ARM the conditions have been correctly defined for contract for working relation in the army and its end²² which after the end of validity of the contract for work on any of the listed bases, the ARM has no further obligation for the military officers. In the Ministry of Defense there is a Section for staff management and it has the department for transition which fulfils the program "LEPEZA"

3.2 The legal regulation for the working obligations in the army and the end of the same

In the USA there is the law which has been efficient for serving in the army since July 2010, but the legal regulations come since the time of the president Lincoln, who named the returned officers from war veterans and he gave special social status described in the previous text.

In Great Britain and the Kingdom of Canada the serving in the army and the rights of the veterans have been regulated by law since 1947.^{19,20}

In the Republic of Turkey in the constitution there is a law number 5253 with article 10 and number 2847 by which the rights of the veterans and the treatment in the society have been regulated.^{14,15}

In the Russian Federation there is a law which has been efficient since 2003 which in the period from 2004-2007 regulates the way of recruiting of paid privates, their payment and duration of the contract.¹¹ In the Russian Federation there is the shortest period for work contract in period of 12 months.

In the Republic of China there is the law which has been efficient since 2000 with many changes which has a purpose to supply China until 2020 with modern technically equipped and functional army. The legal regulations for serving in the army. In the Republic of China were not available at the web sites by the Ministry of defense²¹.

In the Republic of Serbia there is a law which is efficient for serving in the army and the article 107-242^{11,12}. According to this law the program for returning of the military officers in civil life called "PRISMA" has been implemented.

In the Republic of Macedonia the law for serving in the army in the article 84 the relations for the end of the working relation with the army have been regulated ²⁴. The same law has no explanation of the status of veterans, because such category is not defined.

3.3 Reasons for end of the military service

The knowledge says that the end of serving in the army can be caused due to: regular retirement, premature retirement due to losing of the post or disability, end of the contract unfulfilling of the obligations from the contract by the military officers.

At the same time, there is no guaranteed working relation and in the society where there is health and pension insurance payment the person receives it until the working contract is forceful, but not after that. In USA as there is no obligatory health and pension insurance, the military officers after the end of the military service are treated on the burden of the state for any disease gained in the army. In all armies in the world there is constant employment and firing of the military staff.

3.4 The organizational programs for returning of the military officers in civil life

In the USA, the Great Britain, the Kingdom of Canada and the republic of Turkey, the returning of the military officers in civil life is imposed by the necessity of transformation of the military structures in modern number of small and efficient army. The programs have been organized and finances by the budget of the state. In the Russian Federation and in the republic of China on the web sites of the Ministry of Defense there are not available data for the organized programs for returning of the military officers in civil life.

3.5 Achievement of the military protection and the pension insurance after the end of the working obligations towards the army

If the military officer gained the right of age pension in the societies with regulated health and pension benefit the same receives pension personal or family. Such is the case with the Republic of Macedonia and Republic of Serbia. If it is a case of premature pension according to the working training and the age the person can or can not gain a pension.

If they were not insured after the end of the obligation the payment of salaries stops. For injuries, damages and incapability during Military mission, they gain health protection through the Section of health in the veteran service, by previously health evaluation. For special benefits and contributions they receive pension by the army.

3.6 Possibilities that are offered by the society for returning into civil life and the second career

In the USA, the Kingdom of Canada and the Great Britain there is a similar system of organizational and offering possibilities for the second career^{25,26,27,28,29}. Through programs for introduction in civil life, the veteran can choose to achieve his personal small business, to open factory which will

work for the necessities of the army and will employ veterans, to be included in serving activities of the army with prequalification such as care of sick, transport of food, medicines for the necessities of the hospitals of the veteran association. They are included in different non military logistic organization which cooperate with the army.

In the Russian Federation after the end of the working relation of 12 months the person is treated as reserve soldier and he can by necessity be reemployed or he can have some other civil profession.

In Republic of China the reservists are pre-qualified to work in the industry with advanced technology which works for the necessities of the army

3.7 The process of transformation of the armies

The process of transformation of the army is not appearance only in our country, it is not an appearance only in underdeveloped countries and countries that formerly belonged to the socialist state management or still belongs such as China but also the developed countries. 36 37

Many from the former activities which have been going on in the frames of the military forces, primarily the technical and the logistic support are in the function of civil institutions which work for the defensive forces.

For the standards and the legal regulation when performing service for the military forces by the civil institutions are also reached laws by which their activity is controlled.

In these conditions of transformation MCR should take its place, as care for the military staff after the end of using of the services of the individual veteran who was in military service by contract.

4. Conclusions

By the observations of the situation in the Republic of Macedonia as well as with the comparison of the named state for return of the military officers in civil life we came to the following conclusions:

1. In the Republic of Macedonia at the Ministry of Defense a program has been started for return of the military officers in civil life named "LEPEZA".
2. The realization of the program "LEPEZA" is a result from the necessary need with the appearance of the new organization of the army, the appearance of surplus of staff, the professionalism of the army and the tendencies towards NATO standards.
3. The program for returning of the military officers in civil life in republic of Macedonia is in certain degree started earlier regarding republic of Serbia although the both states were former dafter the falling apart of Yugoslavia
4. The program for returning of the military officers in civil life helps the individuals in the evaluation when choosing second career but does not solve the employment as it is case in USA.
5. There are individual differences in the society in the Republic of Macedonia and USA which result from the differences in the health and the pension insurance and the accomplishment of the benefits.

The education for physical therapy, Where are we today, possibilities and perspectives

Elizabeta Popova Ramova¹, Anastasika Poposka²,

¹Department for physical therapy and nurse education „St. Kliment Ohridski" University, Bitola, Macedonia. betiramova62@yahoo.com

²Medical faculty „SS. Khiril and Methodius" University, Skopje, Macedonia. ninomiki@t-home.mk

The process of education is changing globally and locally. The earaches in education must be in way which educative model accepts and what is needed and is aktuel for society. We have impresion that our staff is well educated and can find place in job market all over the world. In this case education is economic. We try to solve deficite of physiotherapists in Republic of Macedonia with opening of Studies with 3 and 4 years at four public universities. Aim of our investigation was to determinate the level of education compared with other countries in the world. Material and method: We have made one interview with 12 university professors, from 15 different countries from the world (Italy, Germany, USA, UK, India, China, Ghana, Romania, Indonesia, Canada, Belgium, Macedonia, Albania, Ethiopia, Haiti, Madagascar, Brazil) on 9 questions, with maximum point of 9, and minimum 0. The level of education was graded as low (0-2) points, middle (3-5) points, high middle (6-7) and high (8-9) points. Results: Our investigation is showing a high middle level of education in Macedonia (7). Discussion and conclusion: Educational system is involved according Bologna standard, ECTS in Macedonia, We have not physiotherapist with doctoral level of education for practical education of students. The interuniversity collaboration for theoretical support is possible with internet techniques like Skype, in same land and from outside, but for better quality of practice is needed interuniversity exchange of students.

1. Introduction

The process of education is changing globally and locally. The earaches in education must be in way which educative model accepts and what is needed and is aktuel for society [1]. We have impresion that our staff is well educated and can find place in job market all over the world. In this case education is economic. We try to solve deficite of physiotherapists in Republic of Macedonia with opening of Studies with 3 and 4 years at four public universities. Ministry of Health and Ministry of Science and Education in our country are trying to make education on level of European standards. This was considered an important issue, in part because of the imminent accession of Macedonia to the EU, and they launched a reform process [2,3,4].

There is still great diversity in how the education of health professionals is organized, not only among EU member states, but also among non-members, develop and an develop countries. It is not easy to define standards of high develop countries for countries with low health standards and economy. The second problem are consequences of individual follow and adapt them in own society [5].

The need for defining rigorous standards and standardizing them across the EU is apparent, due to the dramatic changes in physical and rehabilitation medicine practice over the last decades, as well as the changing position and role of rehabilitation staff in the health care structures.

Traditionally, physical therapists have provided treatment on the basis of the medical diagnosis and supervision of physician's instructions. Thus physical therapists have served the physician, not the patient. While assisting the physician in this curative role is an important function of physiotherapist, it is not his or her primary role. For the physiotherapist today, the principal responsibility is to identify and address patients needs, disabilities, develop a plan for rehabilitation, provide rehabilitation, and assess the outcomes. Obviously, this is a complex intellectual process and requires a wide range of knowledge and skills.

During the past century, physiotherapist responsibilities have proliferated from one fairly limited set of skills that any physiotherapist was expected to have into every preventive and curative intervention. Today, physiotherapists are involving in primary care for patients in early stage of rehabilitation.

In this frame of reference, authorities responsible for the education of health professionals have had develop new operating principles in order to create a new paradigm. The task is a considerable one: all health professionals should be educated to deliver patient-centered treatment as members of an interdisciplinary team, with an emphasis on evidence-based practice, quality improvement, and intensive use of health-related information technology.

Recent development of a system of peer review to assess educational standards has provided an opportunity to build an international community of professionals and formulate Educational Standards for physical therapy and rehabilitation [6].

The key changes in educations for physiotherapist involve:

- identification of common elements that underpin all health practice,
- the development of clinical competency and practice-based learning paradigms, with increase emphasis on health-related subjects in educational curricula.
- a focus on essential practical skills, with emphasis on clinical practice.
- recognition of physiotherapist education with an academic degree as well as professional registration.

In most Western European countries programs for physiotherapist education are linked to higher education institutions, like in Macedonia. However, fewer than half of these programs award a baccalaureate degree and most physiotherapists still graduate without an academic degree. Such reality indicates deficit in implementation [7].

Over the last decade, the World Health Organization (WHO) has provided a number of tools to support and facilitate the design of new models of university-based nursing education. It is not same situation with physiotherapists. In addition, the WHO provide guidance on quality control and education evaluation; preparation of nursing teachers and mentors; and criteria for the schools of nursing. We must be informed and involve in all strategies of WHO not only for nurses but also for physiotherapist education [8].

Aim of our investigation was to determinate the level of education for physiotherapist compared with other countries in the world.

Material and method. We have made one interview with 12 university professors, from 15 different countries from the world (Italy, Germany, USA, UK, India, China, Ghana, Romania, Indonesia, Canada, Belgium, Macedonia, Albania, Ethiopia, Haiti, Madagascar, and Brazil). The interview was made on 06-09.06.2009 in Kayseri, Turkey, on the 1st World conference on Medical Rehabilitation in Rural and Developing Regions. Our presentation with theme. Education for physical therapy in Macedonia,, was the first step to represent us and to open discussion about it. The interview was made on the end of the conference with questionnaire. The questionnaire was consisting of 9 questions, with maximum point of 9, and minimum 0. The level of education was graded as low (0-2) points, middle (3-5) points, high middle (6-7) and high (8-9) points. The collection of data was analyzed according the country, level of education, name, science level of educator and country of educator.

The questionnaire is showing in table 1. The qualification of educators and country are showing in table 2.

Table1 The questionnaire

No.	Question: Do you have	YES	NO
1	Middle school for physiotherapist		
2	High Professional School		
3	University degree (3years)		
3.1.	Theoretical education	Conference master	
3.2	Theoretical education	Doctoral degree	
3.3.	Practical education	Conference master	

No.	Question: Do you have	YES	NO
3.4	Practical education Doctoral degree		
4	Technical support (equipment, labor)		
5	University degree(4 years)		
6	Doctoral studies		
TOTAL			

The level of education was graded as low (0-2) points, middle (3-5) points, high middle (6-7) and high (8-9) points.

The results of our interview are showing on table 2.

Table 2 Results from interview

No	Country	Name of educator	of Science degree	Level of education	of Total point
1.	R.Macedonia	E.Popova Ramova	Conference master	1./2./3./3.1/3.2/4/5.	7
2.	Italy	G.Pestelli	PhD	1/2/3/3.1/3.2/4/	6
3.	Romania	A.Nika	PhD	1/2/3/3.1/3.2/4/5	7
4.	United Kindom	Chamberian MS	PhD	1/2/3/3.1/3.2/3.4/4/5/6.	9
5.	USA	Haig AJ	PhD	1/2/3/3.1/3.2/3.4/4/5/6.	9
6	Albania	G.Pestelli(Italy)	PhD	1/2/3/3.1/3.2/	5
7	Etiopia	G.Pestelli(Italy)	PhD	/	0
8	Madagaskar	Chamberian MS(UK)	PhD	/	0
9	Haiti	Canfield J(USA) Vice President, International Society of Educators in Physiotherapy	PhD	/	0
10	Ghana	GGNyante	PhD	1/2/3/3.1/	4
11	Brazil	DA Jorge	Physioterapist on doctoral study	1/2/3/3.1/3.2/4/5/	7
12	China	J Li	PhD	1/2/3/3.1/3.2/4/5	7
13.	Germany	Atabas E	doctor	1/2/3/3.1/3.2/3.4/4/5/6.	9
14	New Zeland	Sekerak R	doctor	1/2/3/3.1/3.2/3.4/4/5/6.	9
15	Belgium	Draulans N	PhD	1/2/3/3.1/3.2/3.4/	9

The five countries (33,3%) have high level of education and all are from develop regions, high middle are 5 (33.3%) from countries in transition 4, and 1 from EU, 1(7%) is middle from Africa, and 4 (27%), with low educational level are 3 (20%).

2. Discussion: Influence of Bologna Process

The principal aim of the Bologna process is to bring about the convergence of higher education across the European Union by 2010. Thus, it will lead to the unification of professional and higher physiotherapist education and facilitate mobility of graduate physiotherapist across the European Community. In addition, the process has provided the impetus to raise the educational status of physiotherapist from diploma to graduate level across Europe. Reciprocal recognition of EU

physiotherapist qualifications will increase mobility and employment opportunities, alleviate shortage in some countries by redistributing the surplus in others, and allow more efficient use of physiotherapist workforce. The Bologna process will also offer more opportunities for undergraduate and post graduate study and research across Europe and for international collaboration research, in order to advance rehabilitation knowledge and scholarship [5,9].

3. Physiotherapist education in Macedonia: an abbreviation history

Education for physiotherapist in middle medical school was started in Macedonia 20 years ago. Education for physiotherapist with high medical school was possible in ex republics of Yugoslav federation, but not in Macedonia. Macedonian young students had studied in Belgrade, Zagreb and Rijeka. The university level with basic and post graduate level was starting four years ago.

We have deficit of physiotherapist with university level of education, and many people have studying in Bulgaria. In the market of job was deficit of physiotherapist too. The government of Macedonia together with Ministry of Sciences and Education decided to open departments for physiotherapist education at four government universities. The models of curriculum were made by models from European countries adapted by our possibilities.

Those educational models are based on Bologna process, and ECTS system, with more opportunities for undergraduate and post graduate study compatible with European standards and for international collaboration research. The curricula of those educations are consisting of basic subjects, clinical subjects, sociological subjects and professional subjects. All of those curricula are presenting on their university web sides and they shall development in the future. Every university educational institution has a foundation: the curriculum. It is the main frame on which the institution is built, which represent the expression of educational ideas in practice, and refers to the totality of the educational program for student who will enter a practice-based profession [10,11,12].

Macedonia has high middle level of education, according Bologna process and ECTS. It is very significant, for one country that is not still in European Union. Our biggest problem in education of physiotherapist with university degree is it that no exist a doctoral studies yet. We have a vision to dissolve it with sending the best students in forger countries from EU. It can be helpful for increase a quality of practical education [13,14,15].

4. Education of generalist, specialist, or advanced practitioners

Traditional school of physiotherapist exist in France, Germany, Austria, and Luxemburg. High professional School University exists in Holland, Belgium, UK, Spain, and Norway. University at 2 levels is existing in UK, Ireland, Sweden and Germany [16].

We have University 2 level education for Physiotherapist (bachelor and master) in Macedonia.

As a prerequisite for design of a high-quality curriculum, an assessment must be made of the knowledge, skills, and attributes that country needs from health professionals [17].

The prerequisite of successful implementation of radical changes in structure, content, and context depends on capabilities in structure, content, and context depends on the capabilities of them changed with translating plans into practice [18,19].

We shall up the level of health care by our patients in field of rehabilitation with employed new generation of university educate physiotherapist in our health system. Medical workers with not adequate education are working in many physical therapy departments, employed in time of physiotherapist deficit. The new plane of management of human resource, must be planning and controlling from the Ministry of Health, if we liked to have a model of health system compatibility with EU standards, because not only equipment is important, but also the people who are educate to work with new methodology of practice and technology.

We like educational institution had made the first step. We are working on a unified platform of higher education system, it is assumed, will support a policy of licensure reciprocity, which is intended to facilitate the mobility of physiotherapist across Europe and World.

We think that the future collaboration between countries must be first in straight line to change experience in education and researches in EU, and second to help on rural countries in developing the management plans and actions for rehabilitation.

At the 1st World Conference on Medical Rehabilitation in rural and developing Regions was representing many experiences, for help of those poor and rural countries. Those activities were organized by government and not government organizations from UK, USA, Italy and other develop

countries. We were participants of this conference and we think that WHO, must manage all activities (planning, organizing and control finance) to educate people who shall help in their own countries, for their own people. Many of disability peoples are poor and vulnerable-no jobs, no education, and low incomes. The program of Italian Volunteers in Ethiopia is example of good management plane, because it gave jobs to unemployed Ethiopian people and it served to improve the rehabilitation of Ethiopians with disability [20]. The same was made in Madagascar from UK [21], Haiti from USA [22], and Sri Lanka from Canada [23].

5. Conclusions

We can say the next conclusion after explanation of physiotherapist education in Macedonia compared with EU and World:

1. Republic of Macedonia has university 2 level education, by Bologna, and ECTS standard.
2. The new generations of university degree educate physiotherapist must be involve in our medical system, if we lake to have European standard for treatment in rehabilitation.
3. Our Future Vision is to change students and researchers to up physical therapy on higher level for doctoral studies for physiotherapist.
4. Our physiotherapists are compatible to employ in market of job in EU, but we need them to help us for our population of sick people.
5. There are many disability people, who wait for help in rural countries. Macedonia during organizational process from WHO, can be involve in their help.

Why international R&D Cooperation performs better than national?

*Karin Rehatschek*¹

¹*Industrial Liaison Department, Montanuniversitaet Leoben, Leoben, Austria,
karin.rehatschek@unileoben.ac.at*

The global perspective on world-class research performance with the challenge of rapid adaptation to technological & environmental changes leads to a higher demand for cross-border and inter-institutional research-cooperation. This means that opportunities & challenges within our dynamic world have never been greater than now. Therefore R&D (Research & Development) cooperation projects require an integrative system approach embracing several spheres, like market considerations, production processes, usage of raw materials & technologies, quality and risk analysis, implications on environment/health issues; etc.

Beside that cross-European R&D cooperation projects and associated multidisciplinary and inter-institutional working teams are necessary in order to deal with the inherent complexity of research topics, technologies and corresponding environments considering the underlying objective to boost organisational performance and efficiency.

Major success factors of such R&D cooperation projects (for example Integrated Projects within FP7) are that the best researchers and the most qualified institutions/companies cooperate in relation to a specific research topic on a cross-national level. In this connection cross-cultural knowledge sharing activities and a mutual learning process are taking place.

Other success factors of fruitful international R&D cooperation projects are: a project consortium consisting of experts from different research areas as well as adequate involvement of commercial and end-user partners to ensure the proper exploitation of the project results; the whole cooperation is based on mutual trust; all partners within the R&D project have a real benefit and incentive to contribute to the project work; and a balanced IPR approach.

The above mentioned R&D cooperation requirements will continue into the future, and those organisations which can best cope with it, will benefit the most.

Keywords

Cross-border & inter-institutional research projects; interdisciplinary project teams; R&D cooperation projects.

1. Introduction

The global perspective on world-class research performance with the challenge of rapid adaptation to technological & environmental changes leads to a higher demand for cross-border and inter-institutional research-cooperation. This means that opportunities & challenges within our dynamic world have never been greater than now. Therefore R&D (Research & Development) cooperation projects require an integrative system approach embracing several spheres, like market considerations, production processes, usage of raw materials & technologies, quality and risk analysis, implications on environment/health issues; etc.

Beside that cross-European R&D cooperation projects and associated multidisciplinary and inter-institutional working teams are necessary in order to deal with the inherent complexity of research topics, technologies and corresponding environments considering the underlying objective to boost organisational performance and efficiency.

However, especially cross-border & inter-institutional research projects involve a dynamic complexity which result from a number of facts like different cultural backgrounds & philosophies (on an organisational and on a national level), different motivations (scientific publications versus achieving a market advantage through non-disclosure-policy), etc. Unfortunately, this kind of R&D projects can not be seen as a self-organising success story [1] but require an efficient, clear and well-structured project management approach which considers a variety of different aspects like scientific, technological, organisational, legal and commercial project goals.

This paper is based on practical examples/case studies and proven principles, which will act as instruction:

- to fulfil some general research cooperation requirements, and
- to plan balanced human interaction processes

in order to facilitate innovative breakthroughs and best practices in a cross-country and inter-institutional environment.

With regard to international R&D cooperation projects this paper concentrates on EC funded projects performed in the area of “Information and Communication Technology” under the European Research Framework programme. The paper is based on the experience of more than 40 projects (within 10 of them the Author acted as Project Manager and/or Project Coordinator) which were carried out within the 4th, 5th, 6th and 7th Framework Programme – whereas only 2 of them are described in detail in this paper.

2. Some basic assumptions for the comparison of international R&D cooperation projects with national ones

Even we have already stated that in most cases international R&D cooperation projects are more complex than national ones and need more rigorous project management structures and procedures – we assume in the following sections that the working atmosphere in the international R&D cooperation project is fruitful and the cooperation between the different project partners is functioning well.

This means that successful R&D cooperation projects, independently if they are operating on a national or international level, require excellent teamwork. So for example within a project one or more inter-institutional team(s) has (have) to be set-up in order to pool knowledge and experience. In this connection each team has to learn to cooperate within itself and has to initiate positive learning and knowledge-sharing experiences [2].

Beside that an excellent and professional management of the R&D project plays a fundamental role for the success of the project and helps to set-up a trustful relationship within the project consortium. In this relation a clear distribution of responsibilities as well as an efficient communication policy is of special importance. Additionally a comprehensive project assessment system as well as an appropriate risk management system complete that approach and guarantee the achievement of project goals within the timeframe of the project.

Other success factors of fruitful international R&D cooperation projects are:

- a project consortium of high quality, consisting of experts from different research areas as well as adequate involvement of commercial and end-user partners to ensure the proper exploitation of the project results;
- encouraging enthusiasm in relation to the overall and joint project goal;
- all partners within the R&D project have a real benefit and incentive to contribute to the project work; and
- a balanced IPR (Intellectual Property Rights) approach.

3. Prerequisites and advantages of international R&D cooperation projects

EC funded research cooperation projects are in fact cross-cultural knowledge sharing activities and in this connection also a kind of cross-institutional negotiation process in which the project consortium aims to agree on the following issues:

- who is going to share resources with whom of the other consortium partners;
- the degree of access to the before mentioned resources, and
- the degree of a possible compensation in order to obtain that access.

Such regulations are normally part of the work plan (Description of Work) as well as of a contract called "Consortium Agreement" which is concluded within the project consortium. In most cases a signed Consortium Agreement is obligatory before the EC Contract can be signed. However, it is quite obvious in regard with these regulations that all partners get a particular incentive to give their best in order to achieve the planned project goals and that the rights and obligations out of this contractual regulations are balanced between the different consortium members.

In comparison with industrial R&D departments Universities are more likely to deliver interesting and provocative out-of-the-box concepts/solutions, which might be of great interest for the development teams in companies in order to plan their next product releases (including testing of the market acceptance of new products). So for example, whereas company employees have a stronger focus on development issues with the underlying goal to bring forward their own product development (as this process is closely linked to the product life-cycle), the researchers of Universities or other public research entities are concentrating on targets like exploring new concepts and developing completely new approaches [3].

Prerequisites of projects operating on an international level are that project members of transcultural and interdisciplinary project teams have to appreciate to cooperate with people who are different. At the same time the project goals of such international R&D cooperation projects have to be very attractive so that the most talented people world-wide would like to participate within such projects.

4. Two case studies

In the following two different successful EC-funded projects including their particular project structure and their corresponding results are described. Both projects were running under the European Research Framework Programme/Information and Communication Technologies. However, these two projects are characterised by completely different research contents, project partners, management structures and processes.

Both projects consisted of multidisciplinary project teams who worked in an integrated way towards achieving a joint project goal across several partner organisations, countries and cultures.

4.1 Case Study 1: EC funded project DIAMANT (FP5/IST-1999-12078 – Duration: 2000 – 2002)

DIAMANT -Digital Film Manipulation System [4] is a project aimed at developing a digital film manipulation system and was the fundamental basis for a product called DIAMANT Suite [5] which allows the semi-automatic digital restoration of films.

The initiative for this project was launched by the research organisation JOANNEUM RESEARCH in Austria together with another Austrian company called HS-ART Digital Service GmbH. Other participants of the project DIAMANT were Filmmuseum (Netherlands), Technikum Joanneum (Austria), University of Southampton (Great Britain), Dolphine Interconnect Solutions AS (Norway), Laboratoires Neyrac Films (France) and Media Consult Buscher GmbH (Germany). The total budget of the project DIAMANT was 2,3 Mio. Euro with a total funding of 1,3 Mio. Euro.

In connection with this project it is also necessary to mention that background knowledge from some previous EC funded projects also contributed to the overall success of that particular project.

However, for the success of the project it was crucial that the film restoration knowledge from all participating project partners were exchanged and that a synergistic action of learning took place within the Consortium as a whole.

As the existing and above mentioned solution for digital film restoration is just serving a niche market within the global film industry market – such a project wouldn't have never been carried out successfully within one single European country alone. The project DIAMANT pooled together knowledge, values and experience from different experts located in different countries and which were dealing either with film, hardware/software components and/or the overall film market in general.

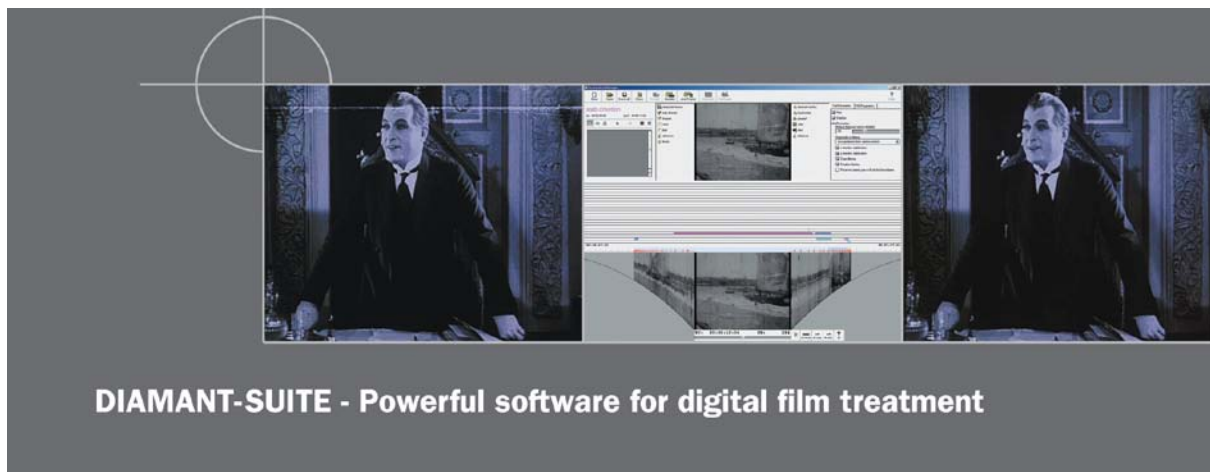

Figure 1 System for digital film restoration

After the DIAMANT project was successfully finished, the Austrian company HS-Art Digital Systems won several awards in connection with its innovative product DIAMANT Suite. As financial reward for the successful pre-development of the product DIAMANT Suite - those DIAMANT partners who contributed to the system development received a part of the annual turnover in relation to the exploitation of the product DIAMANT Suite. Whereas the user partners Filmmuseum and Laboratoires Neyrac Films received special favourable conditions as they wanted to use the DIAMANT Suite in their own institutional environment.

4.2 Case Study 2: EC funded project CLINICIP (FP6-IST-506965 - Duration: 2004 – 2007)

The CLINICIP (Closed Loop Insulin Infusion for Critically Ill Patients) project [6] had a particular focus on the health status monitoring of critically ill patients and was accepted as an Integrated Project in the e-Health sector of the 6th EU Framework Programme. Within that project clinicians and scientists joined forces regarding the development of an intelligent glucose monitoring and control system for critically ill patients. The most important aims of the CLINICIP system were to help to improve the survival chances in the intensive care units and to increase efficiency and safety in clinical practice.

Figure 2 Glycaemic control on an automated basis

Within CLINICIP 13 partners from 7 different countries contributed to the successful implementation of the project. The overall budget of the project was 11,2 Mio Euro with a community contribution of 7,5 Mio. Euro.

A key distinction of the CLINICIP project was that it was a clinically driven project. In the most other cases within the e-Health sector projects are going to be initiated by technicians and not by a clear clinical demand. This means that the project had a well established origin from medical sciences and clearly defined the need for such a system.

Close collaboration of medicine and engineering was necessary in order to realize the CLINICIP system containing several prototypes which were developed during the project duration (see Figure 3). So for example it took approximately half a year until engineers and physicians used the same wording for the same issues and could understand each other without any misinterpretations. Especially important for the project was also the consideration of the different legal and ethical frameworks within the 4 medical hospitals (Medical University of Graz (Austria), Royal Brompton Hospital in London (UK), Univerzita Karlova in Prague (Czech Republic), Katholieke Universiteit Leuven (Belgium)) which participated within the project. The exchange of a lot of explicit but also of tacit knowledge was necessary between the different project partners but also quite a number of impressive and fruitful discussions between the different professional groups in order to achieve a competence-based advantage in the prototype developments. Beside that a mix of experience, values, contextual knowledge and expert insight built a suitable project framework in which the evaluation and the incorporation of new experience and information was possible. Also within this project a cross-national and multi-disciplinary approach was necessary in order to achieve real breakthrough project results.

Figure 3 Prototypes developed during the project

5. Reasons, why European R&D projects perform better than national ones

The R&D cooperation projects funded by the European Commission are seen as key strategic instrument in order to deal with R&D opportunities and challenges on a cross-national level. In the most cases this kind of projects embraces the best researchers, the most qualified institutions and companies in relation to a particular research topic. However, other important strategic goals of these R&D funding programmes are to reduce the imbalance of the scientific & technical capabilities of the different European countries and to improve the general competitiveness of the European industry [7]. Beside considering the special complexity of a project which is carried out on a European level, it has also to be mentioned that normally higher project budgets are available and different national situations have to be considered. In most cases these circumstances and regular extensive project reviews have a positive impact on the future commercial application of the project results.

6. Conclusion

As already mentioned in the sections before:

- increasing global competition in the world class research area as well as on the commercial consumer markets,
- shortening of product life cycles caused by rapid technological developments, and
- extreme knowledge growth,

leads to the increasing pressure that different actors (companies, research institutions, etc.) collaborate in international R&D cooperation projects (for example Large Projects within FP7 [8]).

According to Boutellier, Gassmann and von Zedtwitz [9] the necessity that organizations & companies are concentrating on their own core competencies and get access to complementary resources & knowledge through collaboration with other (national and/or international) partners will become even more important within the future. The form of future cooperation might be a flexible learning and business network in which the different parties with their complementary resources cooperate just temporarily on the basis of common interests.

In this connection EC funded research cooperation projects can be seen as an ambiguous system that offer interesting opportunities for mutual learning and introducing unconventional solutions. They might reveal new and unconventional opportunities that were not visible before.

The above mentioned R&D cooperation requirements will continue into the future, and those organisations which can best cope with it, will benefit the most.

Twenty first century has influenced companies of all kinds. Many of them turn to project organization of their business, or decide to outsource. In cruel market conditions and raising competition, it is necessary to keep up step with contemporary technology and modern business practices from domain of project management and monitoring of all aspects of enterprise business. If it is about internal organization or outsourcing, Redmine, issue based project management system, offers possibility to organize and monitor greater number of teams and projects simultaneously. This paper describes the methodology of project management and enterprise by using issues (cards), and gives concrete examples where these organizations are applied and results from using Redmine project management system.

Keywords

Project management, Redmine, Agile project management, Open source web applications

1. Introduction

Agile project management lets software project managers and employees alike adapt to changing circumstances, rather than try to impose rigid formal controls, as in traditional linear development methods. Internet offers variety of tools for project management. There are both standalone PC or MAC applications and, web-applications. Some of them are available for rent and other are open-source, community based web-applications to download and install on server. Such open-source, community driven web-application is Redmine. In this paper, we are going to discuss web-based approach to project management, using Redmine, and a way how it is implemented and used in service providing public company.

2. Theoretical backgrounds

We like to say that project management is older than pyramids. As soon as humans started to build homes, cities and villages, organizational questions were raised. As projects became more complex and more people involved in project realization (like building a pyramid), resource management and project management became more important. Today, in 21st century, thousands of new projects are started, worked on, or finished each day.

Managing projects was never easier, electronic tools such as PDA's, iPads, notebooks and personal computers offer variety of software resources for storing data about projects, organizing timelines etc...

2.1. Electronic project management

Electronic project management is a generic term which describes usage of computers and handheld computing devices as a tool for managing one or more projects [1]. In the following part of the paper we will give an overview of some common techniques for electronic project management, their benefits and setbacks, and overview of some modern concepts which help electronic project management using open source internet tools to show its best potential in modern changing environment.

2.2. Traditional computer based project management

This type of project management considers using computer instead of paper-based planner. Meaning, you cannot get any statistics from it, you cannot see progress of other people unless you entered data by yourself. You can lose files on your hard drive; your notebook can be stolen, etc... This "Traditional computer based project management", means managing projects with email, using Excel for to-do lists, storing project's documentation on desktop folder, etc... Such project management suffers from baby-steps problems, which modern, web-based project management overcomes. Problems like data loss, non-accurate project status, document or source code versioning and location based data-access issues from which "Traditional computer based project management" suffers do not exist if some form of web-based project management is used. In next few chapters we are going to give an overview of usable web applications, and give an example of web-based PM software implementation at service providing company.

Sometimes software products for electronic project management tend to be a „project management Swiss-army knife". Biggest setback of such product is "shooting a fly with cannon" problem. Often, for successful project management, only simple issue management and document sharing is required. Otherwise, managing a project in such software might require too much effort.

2.3. Agile project management, using web-based tools

Nowadays, every application which can be made as web application should be made as such, because of maintenance, upgrades, etc... Thus, Microsoft, for its Project offers web-based interface as well, in most of its product configurations. Standard desktop instance of MS Project is especially useful for construction companies. However web-based interfaces like ones for MS Project server, offer engineers of construction company to use PDA's, laptops, cell phones and handheld computers to interact with their projects onsite.

Figure 1 Various PDA/phone devices used for web based project management

Software or Marketing companies however do not require such rigid form of resource control, as construction projects does. Thus, various Agile methodologies, like XP, CAS and SCRUM are developed [2].

2.4. Overview of standard web-based tool features

Scope of this paper prevents us from describing each of features that web-based project management tools usually have. More various features and aspects can be found at [4],[5].Table 1 is a research-based overview of features [13].

Results of this research show that open-source software product called “Redmine” has all the features that we were looking for, thus, 3rd chapter of this paper will discuss experiences of Redmine implementation and usage at service providing company.

2.5. Modern hosting environment for web-based project management

Another important aspect of web-based project management is cloud computing. It is a modern term, describing a concept where person, as a user of some kind of software product, does not know or even care, where and how is that software physically stored. To be more specific, term is used to describe computation, software, data access, and storage services that do not require end-user knowledge of the physical location and configuration of the system that delivers the services. Parallels to this concept can be drawn with the electricity grid where end-users consume power resources without any necessary understanding of the component devices in the grid required to provide the Service. Web based project management, also uses this concepts for it's operations, and there are ready-made virtual machine images that can be downloaded and added to your virtual servers farm. The analyzed service providing company, has successfully adopted concepts of cloud computing and virtualization for it's internal, and it's clients needs. Thus, web-based PM tool (Redmine) is hosted as virtual machine in cloud.

2.6. Redmine as Enterprise information portal

Redmine itself or through its plug-ins provides all features of enterprise information portals [6]. Figure 2 gives overview of modules/building blocks of such company's portal.

Figure 2 Standard features of Enterprise information portals [6]

Some of those features come packed with Redmine, and some of them are available through 3rd party plug-ins, such as Document management and workflow plug-in for eDocumentus (Document management and Workflow software product implemented at our case study service providing company).

3. Redmine implementation and usage experiences at service providing company

The City of Novi Sad has a rich informatics tradition. Owing to the wisdom of the City authority, by the end of the '60s, the City-Regional Computing Centre was formed. Significant resources were committed to equipping the computing centre and providing a high-qualified personnel support. At the beginning of the '80s, the development of the City Information System experiences a new swing through the purchase of new, modern equipment, an appropriate operating system and software for databases maintaining. At that time, a developed unified billing system for utility-residential services was already in place, with processing coupled with databases and public records of the General Information System of the City. At the turn of the century, a migration to PC technology was carried out. As time went by, both hardware and software have experienced transformations and development. Nowadays, we boast modern equipment, latest operating and database maintaining systems, exploitation of the Internet and cutting-edge architecture of the Information Systems and telecommunications. Today, we have over 110km of optical infrastructure throughout the city, and 2 data-centers with modern network and server infrastructure.

Situation at the company featured various software and hardware platforms and solutions, due to position in city's government and time that it exists. Such various platforms, solutions and projects, where some of them were not even developed by the company, but due to circumstances become its problem were hard to maintain. As time goes by, source codes get lost, security credentials, and project documentation in paper or electronic form. To overcome those problems, company decided to use web-based open source project management application called "Redmine", freely available at www.redmine.org. The Redmine virtual machine was chosen, also freely available to download and use from Turnkey Linux.

3.1 Why choose Redmine?

Since the developers used variety of development tools and software platforms, they needed a solution that could integrate various source code types via source control management. Such SCM (Source Control Management) system is SVN (Subversion numbering) [6].

Figure 3 Security aspects of SCM/SVN [8]

Various tools like CVS and Teamsystem were used, it was decided to seek for a project management tool that could integrate more than one SCM system, and possibly support newer SCM as they become more popular. Redmine supports most of popular open source VCS (Version Control Systems).

Source control management becomes increasingly valuable as time goes by. In case study company, there were cases of total source code loss due to human overload problems. So if company's profile is like the one's in this study, which means producing over 15 different software products per year, SCM becomes exponentially important, even without its collaboration features.

Another reason for choosing Redmine is a structure of human resources. Structure of this service company varies from electrotechnic engineers and computer science engineers to law and accounting workers. Judging by this, most of them are not very familiar with project management. So they should use systems like e-mail, which they are already accustomed with. Since Redmine features two-way e-mail integration, this was very important aspect of the evaluation.

Internationalization and localization is also one important reason for choosing Redmine at service providing company. As public company, it is trying to use domestic literals (Serbian Cyrillic) anywhere it can. Redmine does have Serbian translation and Cyrillic support, done by Vladimir Medarović.

3.2 Implementing and using Redmine

Company's Redmine is hosted internally on vmware ESX system Turnkey Linux Redmine stack, virtual appliance. It's a plug & play Redmine installation to download and use in your cloud environment. However company's Redmine is heavily customized and configured per it's needs. First baby-steps that company took with Redmine were with web-based birth certificate ordering application. Today, this application is still in function, and still tracked as active project with Redmine.

User groups. Since the company is of medium size, around 180 workers, assigning users to groups is really important aspect of Redmine's usage. Groups let company replicate it's organizational structure to Redmine's user structure in elegant way.

Collaboration via user roles and permissions. This role-based permissions lets users see what Redmine administrator intend them to see. For example, company owner will have role named Company Owner, he will be able to see project status, but will not be able to interact with it directly.

First level of collaboration at case study company:

- Design Engineer -> Programmer
- CEO -> Overview of Project activities
- Testing clerk -> Members of development team
- New team member -> Training
- System maintenance -> Information
- Design Engineer -> Programmer

This is accomplished through flexible role based access control, based on per-role permissions (Figure 4).

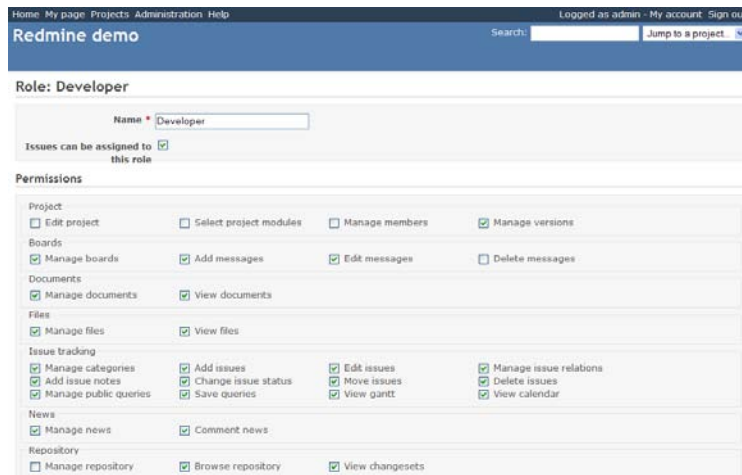

Figure 4 Redmine role editing

Programmer gets task details on e-mail (those details are also available when user logs-in to Redmine). Programmer can reply to task details directly from e-mail client, or via web interface. If some of supported SCMs is used, task can be closed via SCM.

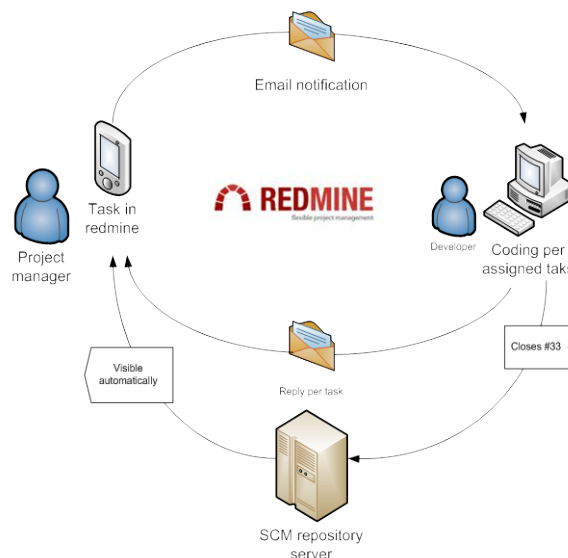

Figure 5 Project manager and developer communicating via Redmine

Aspects of use for management and reporting. Executive offices can quickly get various reports about project's status and overall activity on projects - various gantt-charts, pdf tables, etc. can be generated with Redmine's standard reporting capabilities.[9]

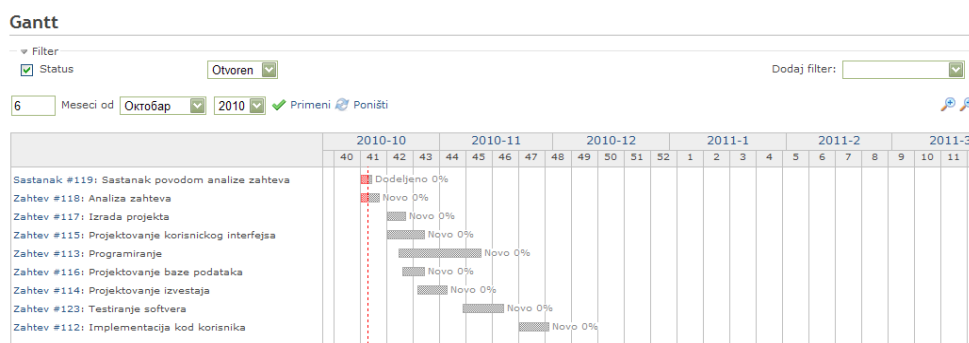

Figure 6 Typical gantt chart for management use.

There are also filtering capabilities, and custom queries, which can be saved for quick access, available in right menu bar. Important accomplishment is detailed tracking between connection of assigned task and software's source-code done via revision control.

Reminder summary e-mails. Important accomplishment is detailed tracking between connection of assigned task and customer's request being worked on. This feature enables worker to have 1 new e-mail each morning he comes to his workplace and opens his e-mail client. This mail gives a summary of tasks that are waiting to be done in next 7 days, or tasks past due date. This has a psychological effect, that worked does not have to think or ask boss, or look anywhere for his notes and tasks, he simply clicks on task in his e-mail message and starts working on it. It saves time and makes workers feel better about their place in company.

Usage of documentation module. Documentation is particularly important, for storing server and various other credentials. For example, if a worker leaves the company. In presented case study Redmine is also used as Enterprise knowledge environment, so all product documentation is stored in it [6].

Issue extensibility. Custom issue types are created for each project, with some common issues featured across projects. Using this capabilities, lets company use Redmine for any type of case or order management [10].

Workflows. Another very important and modern feature is workflow. At our case-study company, workflow is defined for bugs and features, so developer can not close bug until it is tested and reviewed by project manager or design engineer [11].

Key aspects of important internal organizational company rules regarding Redmine. To successfully adopt Redmine into the organization several key aspects of internal organization need to be adopted. Aspects like project oriented organization, and set of rules supporting it. One such rule is that no e-mail from Redmine should stay unread, and no task can be ignored. Also electronic media (email, documents, and Redmine) should be made official communication channels in organization. Anything that can be assigned or written to Redmine should be done that way. No punishments should be applied to ones who do not obey those rules, but they should be addressed and explained the benefits of Redmine usage, each time they skip it in daily work. At case study company, such rules have not been adopted yet, but as time goes by, the company is converging to it, simply because it has issues related to who said what, too many e-mails regarding one task, no visible connection between task and e-mail regarding it, etc.

Figure 7 Organizational aspects of agile project management

Productivity practices. One extremely good practice, regarding productivity is setting up e-mail folders and filters. If person is involved in one or more Redmine installations, he/she should setup a folder in e-mail client for each installation and filter which automatically places messages to assigned folders. Such virtual organization helps navigate through messages quickly if user heavily depends on e-mail. Redmine provides us with employee monitoring capabilities [7].

Human aspects of Redmine implementation. At first, people were skeptical and accustomed to old ways (telephone, sticker notes, excel charts, e-mail and word documents). But features described above which enables Redmine to integrate with e-mail, incorporate word documents to searchable forms, made people gradually switch to this kind of project organization. Main turn point at Redmine usage is when management became aware of need for some kind of project tracking, since company's amount of development work increased, and started to use Redmine by themselves [12].

4. Conclusions

This paper discussed the open source web based project management applications and Redmine implementation at one service providing public company.

To successfully implement Redmine or any other web based project management application at any company, determination is required.

Hardware and software infrastructure (standalone, virtual or hosted Redmine server) and web browser are essential. SCM and Email are optional.

To successfully implement Redmine, organization must have following requirements:

- clearly defined work scopes,
- clearly defined who assigns the tasks,
- clearly defined who gets tasks and
- clearly defined who submits errors.

If the previous requirements are met Redmine will make the following work easier:

- Simultaneous managing of multiple projects,
- Accurate determination of worker's daily workload,
- Project documentation management,
- Source code management and
- Collaboration on work tasks.

Competitive market positioning and successful operation of SMEs in contemporary conditions is increasingly determined by the application of innovation. Hence, the establishment of a system for ongoing development of innovation through mobilization of internal resources and potentials and/or their associated innovation networks is essential to enhance the SMEs competitiveness. Empirical research indicates that SMEs are becoming more dependent on external networks of knowledge primarily because of limited financial and human resources to realize their own research activities.

Innovation networks include cooperation and interaction between the subjects of innovation system. These networks enable entrepreneurs and SMEs to overcome the limitations arising from scarce research resources on the one hand, and utilization innovations from external institutions and entities, on the other side. Hence, this paper is primarily focused on considering the possibilities for increasing the linkage of SMEs with innovation networks as an important prerequisite for fostering their competitiveness.

Keywords

Competitiveness, innovation networks, SME

1. Small businesses and competitiveness

Although frequently used, the concept of competitiveness may possibly be elusive and subject to many debates. As to enterprises, the meaning of competitiveness and competitive strategy is being relatively clear, since it usually refers to the capacity of the firms to compete for markets, resources and revenues assessed by indicators such as relative market share, growth, profitability or innovation. Nevertheless, the concept is to be a subject to a worth mentioning debate if expanded from enterprises to economies. That is to say, the possibility to perform nations as compete with each other on the world market and become more or less competitive is considered as to be a "dangerous obsession". [1]

Partially to response, the competitiveness is being assessed as a multilevel concept thus national competitiveness is closely related to the enterprise one. At national level, competitiveness is usually defined as a nation's ability to produce goods and services that meet the tests of international markets while simultaneously maintaining and expanding real incomes of its people over the long term. [2] Put differently, the capability to compete in international market is thought to be a function of macroeconomic conditions and policies, factor endowment (land, labour and capital), as well as microeconomic factors, counting for a quality of business environment, sophistication of firm's operations and the state of cluster development. From this point of view, national competitiveness is ultimately considered to reflect productivity. That is to say, competitiveness is dependant not only on macroeconomic adjustment or natural endowments but also on the national economy's ability and

more specifically the enterprise capacity to achieve higher productivity levels by using these assets (human resources, capital and physical assets) more efficiently.

Macroeconomic fundamentals are therefore necessary but not sufficient to reinforce the nation's competitiveness, if there is a weak enterprise sector. Or, as Porter says, "for sound policies at the macro level to translate into an increasingly productive economy, than parallel microeconomic improvements must take place". [3] Hence, competitiveness is being an ultimate firm - level concept that brings up the relative enterprise performance in particular markets. In other words, enterprise competitiveness is the ability to sustain a superior market position by providing quality products on time and at competitive prices with the flexibility to respond quickly to changes in demand, as well as successful product differentiation management by building up innovative capacity and an effective marketing system. [4]

Generally, the main distinction between enterprise and national competitiveness is that the firm will cease to exist if it stays uncompetitive for a long time unlike the nation that never goes out of business regardless of how badly it is managed or how uncompetitive it might be. That is to say, the loss of a national competitiveness may well be reflected in a possible aggravation of welfare conditions instead of the market elimination. Competitiveness is therefore based on permanent increases in value added which requires the companies to shift from comparative advantage (low cost labor) to competitive advantage i.e. the capability to compete on quality and cost, flexibility and delivery. This, in turn, depends on business environment and sophistication of the firms' operations. To sum up, one may possibly notice that a number of factors at different levels affect the competitive performance of enterprises, such as: resources (people, skills, physical capital and technology), capability to respond effectively to competitors, market power, flexibility to act in response of changing circumstances, capacity to create new market slots, business environment, policy and regulatory setting and the supporting services provided either by public or private organizations.

Globalization and liberalization of markets enhance competitive pressures and force firms to create mechanisms that will ensure their successful performance. Competitive strive for better positioning in the global market imposes an immanent need to the companies for development of internal mechanisms that will encourage technological awareness through systematic monitoring of technological advancements and implementation of innovative solutions in business processes. Adoption and application of new technologies as well as development of innovative activities are particularly relevant for survival and progress of small businesses.

Taking into consideration the economic development of the countries, as well as the access to global markets alike, the SMEs crucial success factors to increased international competitiveness are to be found in their innovation capacities, capability to properly implement information technology and networks, but more generally the ability to innovate and transform knowledge into competitive products and services.[5]

Specifically, smaller firms need to observe market signals constantly and to adapt effectively to competitive changes. Analysis shows that competition is the main driving force of innovative activities of small businesses. Small businesses operate in a competitive and changing market environment, which creates continuous pressure for reduction of costs and prices, and enables better customer supply. Consequently, their performance is directly determined by the ability and willingness for permanent changes and improvements of the business. Because of their size and customer proximity, SMEs can easily identify opportunities, anticipate customer needs and quickly respond to changed market conditions. Such flexibility and adaptability to market changes creates more opportunities for innovation. Moreover, practice shows that their innovation efforts are determined by the influence of other factors. There is widespread evidence about the impact of innovation and technology on SME growth and competitiveness. Thus, the fastest growing SMEs in Asia Pacific region are distinguished by the huge technology assimilation. In this context, the high growth rates noticed in some countries such as Taiwan have been actually achieved by SMEs activities heading for the technological innovations that have led them to production and export of high value added goods and services. These SMEs in particular have still preserved their remarkable capacity to innovate and permanently create the leading edge technologies besides their flexibility and ability to resist the external challenges such as the global competition and market conditions [6].

2. Innovative activities of SMEs

Despite the fact that SMEs account for a very small part of total national innovation activities, they have been considered as one of the "driving forces" of modern economies. The general assumption is

whether SMEs have significant impact on innovation system in view of the fact that they are more flexible and more adaptable to the customer's needs and introducing the new products and services. Innovation is a key factor for competitiveness of enterprises and there is strong relationship between competitiveness and innovation. Since competitiveness of the enterprises may be defined as the manner in which companies are trying to create and develop a unique comparative advantage [7], the innovation processes encourage development by successful introduction of the new goods, new services, new technologies, new ideas, new methods, opening of new markets, new ways of organizing the business or new sources of supply. Since the "innovations are resulting in qualitatively new products or processes, which differ significantly from the former state" [8] they are significant source of distinctive competitive advantage.

Companies consider innovations as a major engine of enhancing their performances and strengthening their competitive position in the market. Most companies and SMEs as well, connect innovation only with the development of innovative products. However creating new products is only one category of innovation. There are several types of innovation such as: innovation of process, innovation of product/service, and innovation of strategy. Innovation specialists in addition, argued that there are two basic types of innovation: incremental innovation and radical innovation.

Incremental innovation exploits existing products, processes or technologies by improving on what currently existed. This type of innovation is negatively correlated to breakthrough innovation and nowadays most of innovations are incremental. Incremental innovation is the improvement in component performance that builds upon the established technological concept.

Radical innovations pull up existing markets by providing something completely new. This kind of innovation dramatically changes social or business practices and involve new fundamental technological approach [9].

Harvard Business School professor Clayton M. Christensen [10] described new type of innovation named disruptive innovation. Disruptive innovation describes a process by which a product or service takes root initially in simple applications at the bottom of a market and then relentlessly moves 'up market', eventually displacing established competitors.

Providing innovative products with improved convenience may help firms reinforce their competitive position in home as well as global markets. This necessitates innovation efforts to bring new and/or better goods into the marketplace while developing organizational and manufacturing processes that enable more efficient and cost-effective production, distribution and after-sales services [11], [12].

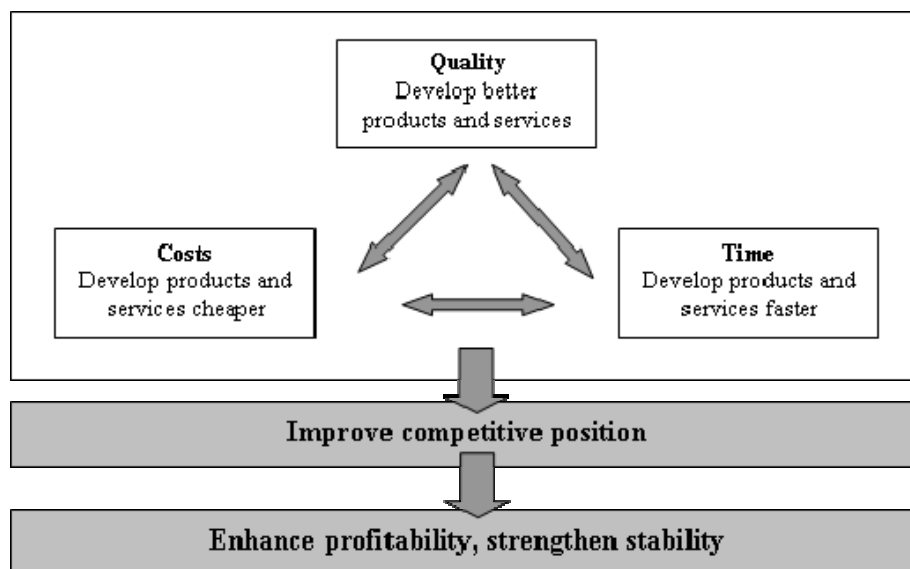

Figure 1 "BCF model for innovation in SMEs

One of the main challenge for the SMEs, if they want to became more competitive and to enhance profitability and reinforce stability, is to innovate products, services or processes making them better, cheaper and faster. Tiwari and Buse suggest BCF (BCF referred to better, cheaper and faster) model for innovation in SMEs. [13] (Figure 1).

3. Innovation networks

Small businesses innovate both reactively and proactively. They innovate reactively in response to customer, market and competitive pressures. But they are also proactive innovators, scanning for and acting on new business opportunities [14].

Due to limited financial and human resources SMEs are less able to invest in R&D and to produce innovative outputs. Hence the ability to exploit external knowledge is a critical component of developing innovative capability and competitive advantage.[15].

Literature review clearly indicates that “innovation activities, including the diffusion and adoption of new technology, do not occur in isolation. The actions of innovating firms are determined by the wider socio-economic context within which they exist. A firm exists within more or less complex networks of suppliers and customers, sources of labour and skill, finance, and so on. These networks may include inter-firm relations, but they also comprise public sector institutions such as research institutes and universities.” [16]

Innovation networks are defined as groups of businesses, research organizations, universities and government working together to achieve shared R&D goals [17]. Many countries such as the United States, Australia and the United Kingdom have recognized the importance of these networks in developing innovation capacity and international competitiveness [18]. Democratic and open networks based on a shared innovative culture enabled by regular direct interaction provide an effective environment for a collective learning process. Such organisational framework allows diversity of knowledge, competencies and backgrounds with regard to a maximum range of reachable synergies. In order to ensure cohesive and efficient functioning of the network, a high level of coordination between network participants is necessary to be achieved [19]. Coordination may involve a level of formalization and clear definition of deliverables.

Therefore, in order to encourage innovation and provide competitive advantage SME may be involved in multiple innovation networks (innovation networks with suppliers and customers as well as with knowledge institutions). It is generally recognized that networking enables small firms to establish formal and informal co-operation, which may include exchange of knowledge through business cooperation or a more articulated web of relations which involves different actors. Many studies confirm that a key role in such complex networks is played by universities, research centres, local institutions, which provide external support in many stages of the production as well as in innovating activities [20]. Setting up network synergy allows creating new business opportunities for SMEs and gaining strategic competitive advantages. Networking is significant source of competitiveness. Networks enable companies involved to work together in development and transfer of knowledge. Recent researches indicate that inter firms networks of collaboration are positively correlated with the firm's growth while institutional collaboration emerges as a key source for innovation.

Innovative impulses provided by customers, suppliers and competitors have equal relevance as the innovative inputs from scientific institutions. However, the effects of networks may be different for different types of innovation. Basically the SMEs efforts are focused on product and process innovations as an important source for increased productivity, competitiveness and growth. The experience shows that customers give a significant innovative impetus to SMEs to create or adapt products according to their needs [21]. Process innovation, on the other hand, is more likely to depend on interactions with the suppliers who provide new elements to the production process and/or the organization of the firms. Innovations regarding the improvement of existing products and processes are important for maintaining competitiveness but in conditions of stronger competitive pressures, they are not enough. At present “competitive conditions are imposing necessity for more radical innovation that will allow differentiation as a precondition for the survival of companies” [22].

Innovation networks can be initiated by SMEs or other participants in the network. The governments usually play a “facilitating role in the formation of networks but leaves decisions on network objectives, composition, structure and activities to the member firms. Governments can play an important role in facilitating network development through the provision of funding that encourages organisations to collaborate.” [23] General and specific policies are being applied by governments for encouraging innovation. Universal policies are mainly focused on promoting education and developing a strong research community. On the other hand, specific programmes are designed to encourage innovation and R&D comprising tax incentives; subsidies for start-up businesses; creation of high technology incubators etc.

Evidently, innovation networks, whether science-based or business related, create broad opportunities for SMEs to promote innovativeness as a basic prerequisite for enhancement of their competitiveness.

4. Conclusions

Competitiveness is generally accessed as a multilevel concept as national competitiveness is being closely connected to enterprise one. That is to say, competitiveness is not to be a subject merely on macroeconomic adjustment or natural endowments but also on the national economy's capacity and more precisely the enterprise ability to raise productivity by using assets (human resources, capital and physical assets) more efficiently. Macroeconomic fundamentals are necessary but not sufficient to underpin the nation's competitiveness, if there is a weak enterprise sector. Consequently, competitiveness is ultimately a firm - level concept conducting the relative enterprise performance in a certain product market.

The SMEs competitiveness and growth depends on a number of factors emphasizing primarily the relevance of innovation and the ability to absorb new knowledge. Consequently, small and medium firms have an important role in the development and spread of innovation. Innovation activities of SMEs generally arise from two sources: a) innovation generated by SMEs based on their own research and experience resulting with improvement and advancement of the business process and existing products or introduction of completely new products and processes; and b) innovations resulting from systematically structured and organized research and development activity being implemented in collaboration with other business entities or in cooperation with research institutions (universities, centers, institutes).

Due to the limited research resources SMEs are forced to enhance innovation cooperation through innovation networks. Successful innovation networks allow SMEs to gain access to new markets technologies and external knowledge.

The paper presents an overview and investigation of business modelling frameworks. It is based on current research in the field of business modelling innovation. The paper is also based on the experience from the author's participation in a number of business plan competitions in 2010 across Europe. It observes and analyzes common steps in the business modelling process with the goal of extracting best practices. We also identify and present a number of requirements on business modelling tools. The long term goal of this research is to develop a generic business modelling methodology for young fast-growing start-ups particularly in the IT field.

Keywords

entrepreneurship, business model innovations, business modelling frameworks

1. Motivation and goal setting

According to Prof. Howard Stevenson, business modelling is an integrate part of the entrepreneurship process, succeeding the opportunity recognition and preceding the marketing and finance elements in the process of resource acquisition [1]. As such business modelling can be seen as a starting point towards commercialization, in contrary to new technology currently perceived as the trigger for innovation. Recent research suggests that most of the start-ups do not use business plan if any structured business modelling tools. Start-ups who do use such tools, in the contrary, seem to stick to their business plans even in cases it is obviously leading to wrong decisions. A good business model can not only leverage profits, but it also is a requirement to capture value from the innovation at all [2]. Therefore, the outcome of the commercialization of one technology depends on the business model it is based on [3]. In other words value is created not only by the technology itself, but also through the business model.

Choosing the right business model is one of the challenges with which new companies are confronted. Scientific research suggests that a sound business model is a key success factor for start-ups in the current dynamic economy. Venture capitalists can be divided in two groups regarding their position to this statement – the one that support it, like Randy Komisar, partner at Kleiner Perkins Caufield & Byers [4], and the one denying the first priority of the business model at the beginning of a venture, like the founding partner of garage technology ventures and former chief evangelist of Apple Guy Kawasaki [5]. True or not, 70% of companies in 2009 were engaging in business model innovation, and 98% were modifying their business models to some extent [6]. This empirical evidence for the importance of the business model is one of the reasons for the current study of its nature. Another reason for this research is that most business modelling frameworks fail to provide the dynamic tool, necessary in the ICT industry, especially in today's uncertain and volatile market environment. For this reason, our goal is to propose a framework that serves the needs of young ICT companies in the very beginning of their existence in an unsteady and complex environment. In order to develop such framework we will first define the term business model and review existing business modelling frameworks. We will then investigate current research on business model innovation and extract the requirements for a framework in the ICT industry. We will also define the basic elements of a business model of an IT start-up, which can be co-ordinated in a graphic instrument that can be used by entrepreneurs in the ICT industry to model their business ideas into real businesses.

The paper starts with a common definition of a business model and discusses its statistical importance on the success of young ventures. We represent different success factors discussed in contemporary research. Next, we give an overview of the entrepreneurial process and the business plan as a tool for

setting it in boundaries. We analyze the practical use of business planning tools in the start-up phase in a number of representative companies across Europe. In this process we identify reasons for failure of early business modelling, lessons learned and tools to overcome it. The paper finishes with recommendations for a practical and easy-to-use methodology which can be applied by young fast-growing IT start-ups to model their business in the early-stage phase. The theory-based conceptual framework aims at the identification of inefficiencies in the business planning process. It also can be used as a red line for encouraging entrepreneurs to experiment with their business model and stay open for changes in today's dynamic business environment.

2. The business model nature

The business model has gained importance after the bubble burst in 2001. With the internet and the complex environment of the globalization the term business model evolved to an individual science sector, investigating the question why some companies succeed and others don't. There are contradictive opinions not only about the importance of the business model, but also about its nature. Whereas some almost exclusively define it from a clearly financial perspective, e.g. How does one business make money, others accentuate on its competitiveness, e.g. What is the value proposition. Teece even sees business models as conceptual rather than financial models [7]. This paper will review popular definitions and pursue by choosing the one particularly suited for the start-up case.

2.1 Definition of a business model

Joan Magretta, a management writer, defined a business model as "the story that explains how an enterprise works" [8]. Although there is no clear definition of the term business model, we can round it up as follows: A business model is the way a company creates value for profit. For this reason Chesbrough believes that business models usually contain two basic pivots – the value proposition and a revenue mechanism [9]. The value proposition consists of the value created for a specific market segment that would pay for it. The revenue mechanism describes the value chain in which the value is delivered to the customer, as well as profit and cost factors that derive from its specific implementation. McGrath also formulates those two basic components slightly differently: the unit of business, which constitutes what customers pay for, and the process or operational advantages. Business plan and pitch competition judges usually ask for a sustainable competitive advantage, when discussing the business model. This is what a start-up can make better, cheaper, faster, or cooler than the competition, and most importantly cannot be copied by others. Although we believe that every company has some sort of explicit or implicit business model, some research suggests that a business model concept is a superior way of analyzing opportunities to traditional concepts like positioning within a market segment [10][11].

2.2 Business model vs. strategy

Some may argue that the business model is then equal to the firm's strategy. However, they differ in a couple of elements. The business model should be kept dynamic, whereas the strategy usually is part of the a long-term plan of the firm. The business model is based on capabilities, whereas strategy is usually promoted on a resource-based view of the firm [12]. Rita McGrath summarizes those differences in the following four criteria.

- Business modelling implements an outside-in rather than an inside-out focus.
- Business models cannot be entirely designed in advance, whereas strategy formulation is key to success.
- Business modelling should consider the changing basis of competition
- Business models therefore require a discovery-driven rather than a planning oriented approach.

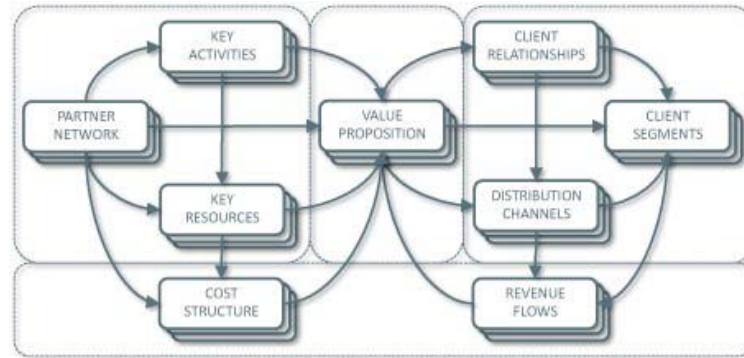

Figure 1 The business model canvas [14]

2.3 Business modelling frameworks

There are a number of business modelling tools [13]. Below we have selected two of the most popular ones in order to illustrate some main patterns. The business model canvas by Alexander Osterwalder in Figure 1 is a mapping tool which consists of nine elements: value proposition, client segments, distribution channels, client relationships, key activities, key resources, partner network, cost structure and revenue flows. This ontology, as the author calls it, has proven its simplicity, ease-of-use and affectivity, since it has spread widely throughout the start-up community.

Figure 2 represents the virtuous cycles method for mapping business models. It has been developed by Ramon Casadesus-Masanell, an associate professor at Harvard Business School, and Joan Ricart, a professor at IESE Business School in Barcelona, out of the assumption that a business model comprises choices and consequences. By designing self-feeding cycles of choices and consequences, successful companies can assure their competitive advantage. This model, even if more eloquent, is however a little bit more complex, which is possibly the reason for its relatively narrow spreading in the start-up scene.

3. Business model innovation

3.1 Key aspects of business model innovation

The widely accepted key aspects of business model innovation are novelty, lock-in complementarities and efficiency [16]. Business model innovation can only prevail in an environment with dedicated experimentation processes, leadership commitment and authority [3]. There are several principles and parameters supporting effective experimentation, like fidelity, cost of conducting tests, cost of failure, time for feedback, amount of information learned [17]. The more difficult factor of leadership and authority is a question of organizational culture. In today's dynamic market environment companies are found to be dealing not simply with one innovation S curve, but with a total of 3 hidden S curves for competition, capabilities and talent [18]. While there is evidence that companies consciously are trying to deal with the first and the second one, many fail at the hidden talent S curve, because it requires change at the top.

3.2 Barriers to business model innovation

Main barriers to business model innovation are obstruction, like in the case of conflicts with the dominant business model, or with the supporting assets configuration, and confusion, like in the case when it is not clear what the business model should be at all[3]. As a market is changing successful companies succeed to adapt their business model to its new requirements. Those who fail are not necessarily bad at fixing failures, but are often too late in their attempts to do so [18]. The reason is, that adaptation requires a priori experiments with the business model, especially in industries where current business models are obviously outdated. Investigating the barriers for such experiments it

turns out that the main conflict lies between the current business model and the new one[2]. In the case of disruptive innovation that barriers are especially high. There is also a cognitive barrier to business model experimentation, also known as dominant logic [19], which postulates the information flow into and out of the company's decision making process. It means simply that companies are filtering out information that conflicts with their logic, and are in contrary looking for information that supports it. Dominant logic is necessary in the daily business but can harm on a strategic level.

3.3 How to innovate the business model

A CEO has 3 main tasks (1) manage the present, (2) selectively forget the past, and (3) create the future [20]. Following this path, we can extract a generic approach to business modelling innovation. First, in order to overcome the barriers towards business model innovation, companies should retain a constant commitment to experiments with it [3][12]. Secondly, given this commitment a business model innovation could then start by mapping the prevailing business model with a mapping tool, like the 9 elements mapping approach of Alexander Osterwalder [13] or through the Virtuous Cycles method[6]. Mapping the "old" would then help changing it, by identifying key areas of changes or challenges. Unfortunately, innovation is not done by mapping the business model alone. Creating the future, at last, can be accomplished by redesigning the mapped business model, or in some cases entirely replacing it by a new one.

3.4 A case study for business model innovation: GymZap

3.4.1 Customer problem

Sports instructors are faced with inherent limits of the scalability of their services as sports facilities can only accommodate a certain amount of customers. Furthermore, commercial fitness studios, where instructors typically offer their services, rarely offer very large halls. These factors, as well as the participants' specific requirements with respect to the time and location of a sports session, significantly limit the revenue potential of a freelance sports instructor. One way to overcome this scalability limitation is the production of home exercise videos. This approach, however, requires a significant financial investment, which makes it most attractive to celebrities and less accessible to others.

3.4.2 User problem

On the other hand, the lion's share of the population tends to dread going to the gym for one or the other reason. Fitting sports into the family and career planning is a complicated task for mothers on maternity leave, frequent travellers, elderly or disabled people, and especially for the exercise shy ones. Gyms and sport associations are one way to stay motivated in the daily routine. But for many people, they are no option. Finding an affordable and available alternative often results in home exercising. Unfortunately getting in shape on one's own or by the means of an aerobics DVD often fails. No interaction with the trainers on the video and missing personal identification with their iron bodies and perfect movements mostly bores, decreases effectiveness and discourages by and until the New Year's resolutions for losing weight and getting sports on the agenda are soon forgotten once again. Home exercisers confess that without appointment they lack discipline. Keeping up with sport requires knowledge and motivation, which are usually unavailable at home.

3.4.3 Solution and value proposition

GymZap connects professional instructors and home exercisers. We provide the infrastructure necessary to enable fitness professionals to offer their classes live additionally through the Internet against payment. Home exercisers can access those through a web interface. Users engage in the platform either by broadcasting their own workout or by participating in available ones, such as indoor sports, dancing, martial arts, general fitness or relaxation classes, or new services like a 5 minute face workout or back exercising. Our solution creates a win-win situation for all involved parties. By using

GymZap, instructors can scale their service to reach more people without any investment and make money out of new services. Young instructors can gain experience and popularity. Fitness studios and health care insurance companies provide a low cost value-added service to their existing subscribers by enabling them to attend sessions remotely. This improves customer loyalty and most of all customer health. Online they can reach new customers unable or unwilling to make it to the gym, who are likely to convert to offline subscribers once they get in shape. Our users benefit from the advantages of live trainings independently of their location and gain access to a great variety of classes unavailable locally. They can find a suitable training spontaneously whenever they have time for exercising, e.g. when the baby sleeps or in the break. They save travel time and organizational resources, but still can influence the tempo, discuss with the trainer or other users, or change the training any time. They don't get bored with unchanging exercises and can improve their fitness level due to professional guidance.

3.4.4 GymZap: Innovation

Despite the rising number of live broadcasting services online, during our market analysis we could not identify any other platform providing live broadcasting infrastructure dedicated to the needs of instructors and home exercises. The key elements of our value proposition to the end users are real-time, flexibility, availability, communication, and diversity. Our platform is silhouetted against traditional home exercising alternatives, like videos and books, by the integrating user-generated content with professional trainings, which allows for personal identification, spontaneity and diversity. We deliver the two key success factors for exercises, knowledge and motivation, through our service by providing the user with an individual sports network. Our users gain access to the experience of like-minded sportsman, and to a variety of sports which keeps them on track. GymZap is the first provider of live exercise videos online. Unlike other home exercise alternatives, GymZap sessions are live so that users can benefit from real-time professional guidance independently of their location. Users can ask their questions, influence the tempo, discuss with other users. A direct communication with the instructor is guaranteed. They don't get bored with repeating exercises. Unlike organized sport classes, they save travel time, and have an on-demand access to a great variety of sports, so that they can also participate in very short trainings.

3.4.5 GymZap: Business model

GymZap started as an online fitness company. The team was nominated and awarded at a number of international and regional business planning and pitch competitions in 2010. GymZap is an online platform which connects home exercisers and fitness instructors. GymZap was primarily addressing a two sided market serving end users as well as business customers. End users included everyone who is practicing sports at home or while travelling. Those could be mothers on maternity leave, business travellers, the overweight, and many others, comprising 20% of Europeans. The initial business model of the company was based on the proven freemium model: User-generated content was provided for free to other users, and professional sessions were offered as paid-services on the pay-as-you-go principle. End users was supposed to use GymZap as participants in free or paid exercise sessions, or alternatively, as broadcasters of their own sessions. The customers were, in the first place, freelance sports instructors, who would like to expand their customer base by offering live exercise sessions through the Internet. Those would freely offer their services online, they would set the price for the sessions, the content, the frequency and everything else themselves, paying only a commission on sales for using GymZap as a marketing channel. The idea was a success, especially among end users.

3.4.6 GymZap: Changing the business model

Analyzing the business model in detail it turned out that it neither proposed barriers to copycats, nor did it prove to be sustainable in the long-term. Offering group fitness session in real-life is connected with the social context, the studio assets, the smell, the location of the facilities according to the living place. In the online world all those were replaced by the price. This would result in a heavy price competition leading to a lose-lose-lose-situation for anyone involved. Session prices would fall until the cheapest ones wouldn't serve their purpose anymore. This would make end users in contempt and

probably reduce their usage. The company itself was supposed to profit by sales commissions. If prices fell margin and revenues would also decline. Realizing those factors, the founders decided to re-model the business. The goals were:

- To create lock-in effects or other major barriers to entry
- To ensure at least mid-term sustainability of revenue growth
- To really connect home exercisers with live fitness sessions online, without challenging the quality

4. Business modelling tool for ICT start-ups

4.1 Characteristics of ICT start-ups

To design a business modelling tool for ICT start-ups one should take in account the specifics of their businesses. First of all, they usually “trade” with intangible goods, which influences the need of a warehouse. Secondly, the cost of goods sold is almost entirely determined by marketing and human resource spending, whereas the marginal manufacturing cost is negligible. This results in a relatively high proportion of variable cost, and low fix cost factors. This not only facilitates rapid growth, but also significantly reduces investment amount and respectively capital costs.

4.2 Classification of generic business models in ICT

To classify the business models in a generic way, ICT start-ups can follow one of the patterns below:

- Independent software vendors (ISV) – software manufacturer, who can sell software in different ways, directly or through a distribution channel
- Value added reseller (VAR) – companies reselling software licenses from ISV to consumers or business, and offering additional services, like consulting, installation, customization, maintenance and so on
- Distributors – Intermediaries in the software distribution process, usually between ISV and VAR
- Original equipment manufacturers (OEM) – companies buying whole-sale licenses from vendors, who modify and repackage them to create a separate self-branded product. The latter can be redistributed in either way.
- System integrators (SI) – Companies realizing solutions on the basis of products of a couple of vendors for business customers
- Software-as-a-Service (SaaS) providers – software provided as a service through the internet

4.3 Requirements for a business modelling tool for ICT

A business modelling tool for ICT start-ups should take those characteristics in account. Those are represented in Figure 3 on a conceptual level. This combines the generic business models of ICT start-ups with the uncertainty of the development stage and the ICT industry characteristics. Thereby we extracted six requirements to a business modelling tool for ICT start-ups. First of all, it should be easy to adapt, because business models are likely to change very often especially in the beginning. In the case of GymZap we wrote 13 different business plan version in the first 6 months only. A graphical tool should reduce the effort of adopt new business models, or simply test them on paper. A business modelling tool should also be pluralistic, meaning that it should allow for more than one scenario, market segment, revenue stream etc. It should be modular, in order to allow for changes in the value creation chain. For efficiency reasons it should have a graphic representation. Furthermore, it should combine mechanisms for creating competitive advantages against copycats and newcomers. Last but not least, the outcomes should be easy to communicate, since start-ups need to pitch their business and send in business plans and presentations on almost a daily basis.

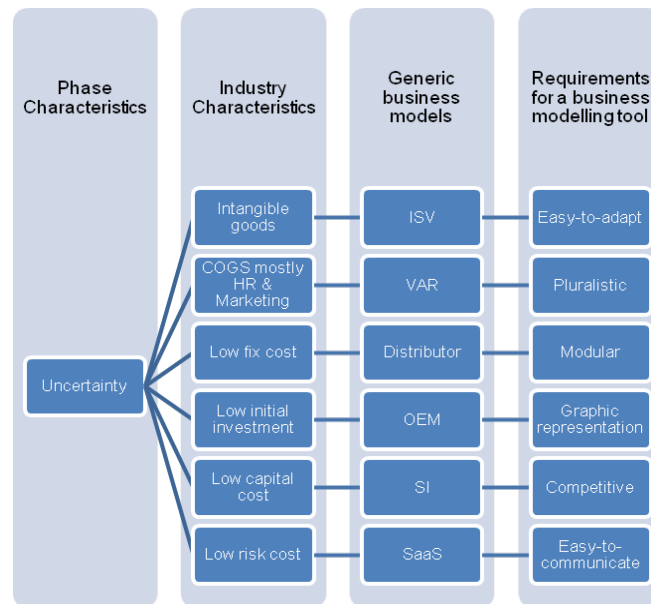

Figure 2 Requirements for a business modelling tool for ICT start-ups

5. Conclusion

Business models are an element of the value creation when it comes to the commercialization of an innovative technology. Therefore they are at least as important as the technology innovation and should be handled by companies consciously. Since new ventures exist in highly unpredictable market and company environment the business model is a subject to change and deliberate experiments far beyond one of the tests prove successful. To proceed with business model innovation companies should start by mapping their prevailing business model with some mapping tool in order to identify change potential and risk factors. Following that, weaknesses of the prevailing model should be identified and redesigned. In some cases it is necessary to entirely replace the model by a new one. A tool for business modelling for ICT start-ups should be easy to adapt, have a pluralistic view on market segments, revenue streams, cost factors etc, be modular, possess a graphic representation, offer tools for elaboration of competitive advantages and be easy to communicate to stakeholders. Following the generic business models of ICT start-ups presented in this paper, the business modelling tool should help answer specific questions like “What type of licensing is in use?”, “How volatile is human resource cost?” etc. Such a tool needs significant empiric evidence and is an object of consequent work. All in all, business model innovation is virtually indispensable in the current market conditions for sustainable success. Business leaders need to grasp and live its principles by implementing continuous experiment practices on a business model level. This requires leadership and authority, as well as diffusion throughout the company.

JA-YE Graduate Student Company Strategy

Petko Ruskov¹, Milena Stoycheva², Caroline Jenner³;

¹Sofia University "St. Kliment Ohridski", Bulgaria, petkor@fmi.uni-sofia.bg

²CEO Junior Achievement, Bulgaria, milena@jabulgaria.org

³CEO Junior Achievement-Young Enterprise Europe, caroline@ja-ye.org

The paper presents authors experience and learned lessons in the field of Graduate Student Company (GSC) education from years of experience at master's degree level. It analyses information about the status and good practices in the Graduate Programme and how countries in Europe implement the Graduate Programme and what their best practices are. The application of Junior Achievement – Young Enterprise entrepreneurial education model and strategy has been developed in the creation of student's entrepreneurial mindset.

The goal of the paper is also to share and discuss the latest findings and future creative effective strategies about practical entrepreneurial education.

Keywords

Graduate Student Company, strategies, practical entrepreneurial education

1. Introduction and problem statement

We study, live and work in a new reality, i.e. a reality of global competition, knowledge economy, successful cooperation between business and education. [1, 2, 3]. In this global competitive business environment, the educating young people and equipping them with entrepreneurial competences, especially those with technological and engineering background, becomes critically important for their realization. To our mind, improving and increasing the potential for innovation and entrepreneurial competence will be a major factor to ensure competitiveness on the market of the graduating students. Innovation and entrepreneurship which are based on technology, the mobility of intellectual and financial capital, are some of the basic factors for successful realisation [20, 21].

While most of the stakeholders keep promising that education reforms are coming, government and big agencies change slowly. Innovators have two choices in such circumstances - Figure 1.

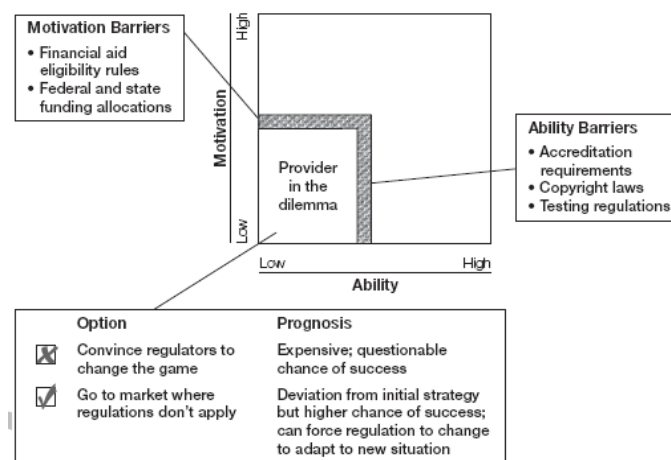

Figure 1 Strategies for dealing with nonmarket forces (Clayton M. Christensen, Scott D. Anthony, and Erik A. Roth, *Seeing What's Next* [1])

Clayton Christensen wrote “Many think of innovation as antithetical to education. But important innovations are reshaping the delivery of education. In 2004, for-profit competitors offering distance learning via the Internet, corporate universities, and some community colleges were growing robustly. All of these developments bear the hallmarks of disruption. Online learning offered by for-profit providers such as the University of Phoenix and Concord Law School create opportunities for thousands of previously non-consuming adult learners to obtain degrees in their spare time” [1].

The authors of the present paper perceive the work that has been done so far in creating a subject within the elective courses curriculum in the masters and bachelors degree programs that focuses on and develops entrepreneurial competences for students from technology and engineering specialties, an example and good practice in bringing disruptive innovation to education. The high interest in the course shown by the students, its applicability and the support demonstrated by different stakeholders for its further expansion and development, strengthen the argument and open opportunities for bigger investment in this educational method.

2. Methodology and research design

This study is based on a research project (started in 2005) that is coordinated by the Junior Achievement Bulgaria [5, 6] and Master of Sciences “e-Business and e-Governance” and “Technology Entrepreneurship” Programs at Sofia University [13, 14, 17, 18]. The methodology of this study rests on the following pillars:

- Practical Education [5, 15]
- Disruptive innovation [1,12]
- Value Co-Creation [2, 9]
- Profit patterns [19, 11]

This combination of interpretive methodologies is deemed appropriate as we are studying and applying a complex phenomenon. This kind of methodology offers context-rich descriptions of strategic pattern and implementation aspects of disruptive innovations in student education.

Our methodology includes research and analysis of best practices on national and international level and innovation in the field of learning by doing, taking into consideration the local ecosystem [4, 5]. On the other hand our joint work in a network with many Bulgarian and European universities, participation and conducting of forums and competitions, gives us the opportunity to expand the reach of the entrepreneurial education and ensure its sustainable development [16, 18].

3. Student education processes and experience

Education in the subject “Graduate Student Company” is innovative and interdisciplinary (technology and business), combining the theoretical and practical education, and has been developed in cooperation with leading European and American companies and universities. While developing the subject, we have used best practices and introduced innovations, reflecting the Bulgarian business environment. It gives the students the necessary competences for real participation in innovative business processes and entrepreneurial companies. The main purpose of the subject is to prepare students from bachelor’s ad master’s degree programs who will discover and validate critical needs in the consumers:

- to evaluate opportunities, develop concepts and find resources to solve the problems of the consumers
- to develop business plans and prototypes of innovative projects and start-up companies in the sphere of IT/IC, healthcare and clean technologies ;
- to think critically, analytically, creatively and innovatively
- to develop entrepreneurial way of thinking and successful entrepreneurial competencies.

The education in the subject “Graduate Student Company” is used also to increase the motivation and impact of the education, introducing different active styles of delivery, as well as acquiring skills for life-long learning. While developing the program, the best practices of Junior Achievement, as well as the definitions and stages of technology entrepreneurship program of UC Berkeley и Intel Corporation [15] have been used – Figure 2.

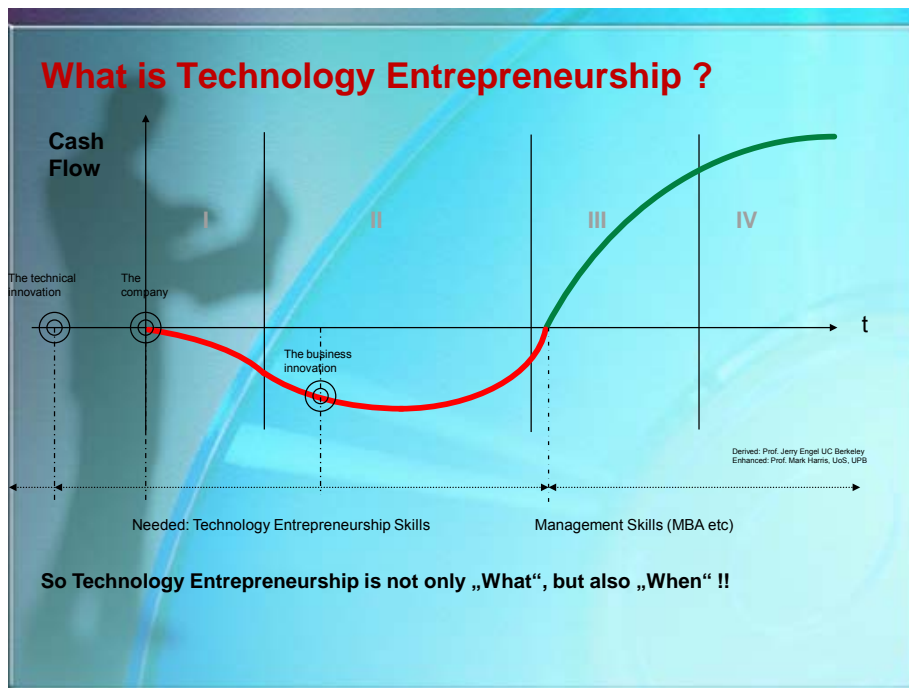

Figure 2 Technology entrepreneurship phases

The values that lead us in pursuing the mission of the program are as follows:

- education directed at the students;
- constant improvement of processes;
- collaboration among all parties involved in the work on the program;
- innovative and creative thinking;
- variety and alternativeness of ideas;

The number of students that have undergone the study and the number of companies established by them in different universities in Bulgaria is shown in Table 1. The interest in the subject by universities in different spheres of study as well as the progress achieved is impressive.

Table 1 Student companies in Bulgaria

Year	2005	2006	2007	2008	2009	2010	2011
Number of Universities	1	1	1	5	9	13	15
Number of Students	25	39	45	51	108	305	500
Number of Student Companies	1	2	2	6	11	28	35

We follow the job base thinking to identify the opportunities for GSC [12]. Based on the 10 years of experience, annual meetings, competitions, and discussion at a pan European level, worldwide forums and roundtables, we have summarized in Table 2, some of the most important findings in the field of disruptive innovation in education related to the learning by doing method of teaching and experience.

Table 2 Job to be done list

Job to be done	Importance	Frequency	Frustration	Score	Rank (1 – high 5 – low)
1, To create competitive new ventures	Strong	Yearly	Low	60%	2
2, To stimulate entrepreneurial mindset	Very strong	Long term	Very high	100%	1

Job to be done	Importance	Frequency	Frustration	Score	Rank (1 – high 5 – low)
3, To generate sources of innovation	Strong	Yearly	Medium	50%	4
4, To contribute to the entrepreneurial ecosystem	High	Medium term	High	40%	3
5, To develop a more entrepreneurial culture	High	Long term	High	80%	5

Our experience shows positive results related to the higher motivation and activity of the students, more tolerance to risk when making decisions and executing activities.

Classification of GSC processes - operating, management, and support processes is shown on Figure 3.

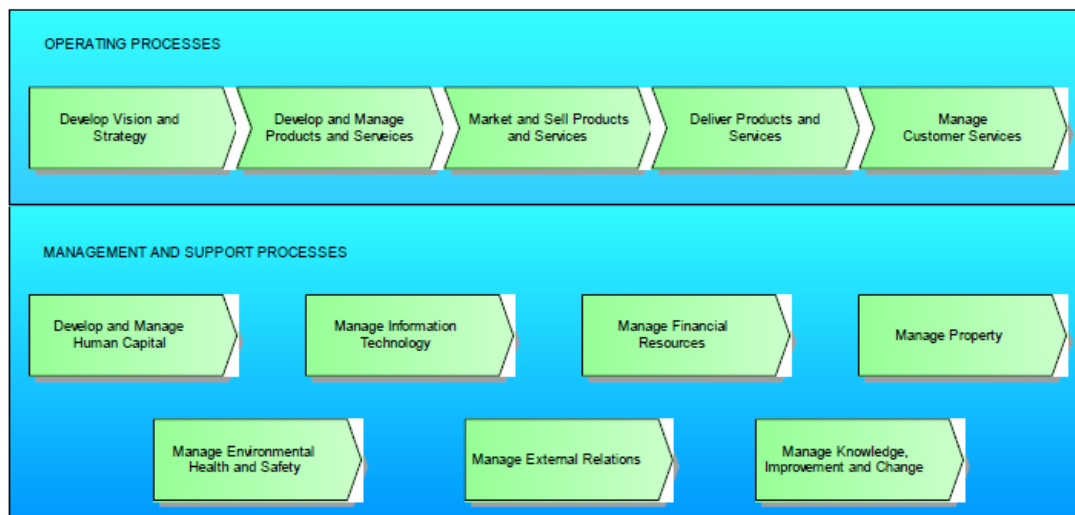

Figure 3 GSC operating, management and support processes

The execution of thus presented processes gives the opportunity to students who participate in the education to go through the whole life-cycle of a company – from the stage of idea generation to establishment, running, and closing all processes and procedures and archiving documentation [11, 12].

4 JA-YE students' companies' strategy

Understanding the processes by all participants as well as the development, discussion and execution of the strategy for the development of the student company is an important key stage. We have started with creation of a resume of disruptive ideas – Table 3.

Table 3 Disruptive ideas resume

Our strategic intent is to:	Essence of an idea
The target customers are:	<p>Users: scientific and engineering students, start-up owners; people changing careers, etc.</p> <p>Providers: universities, associations, academies, other NGOs, etc.</p> <p>Payers: government, associations, companies, VCs and angel investors, etc.</p>

Our strategic intent is to:	Essence of an idea
Our sources of revenue will be:	Government, VCs, angel investors, companies, corporations
We will minimize competitors by	Existing network of human capital and practice, flexible processes, more cost effective training
We will create it by:	Volunteer business expertise and competence, distributed knowledge, value co-creation
We will deliver it via:	All Stakeholder's networks
We will market it by:	By student networks and organizations, stakeholder's networks, higher yield of results in starting-up,

The development of the strategic plan, its communication to all stakeholders and its execution is another opportunity for analysis, planning, modelling, execution and improvement of the work while studying. To this purpose we are using the System of Balanced Scorecard (Balanced scorecard) [6, 7]. It encompasses four areas – knowledge about and development of the organization, its internal processes, customers and finances. The different stages and sequence in the development of the strategy are shown on Figure 5.

Figure 4 BSC strategy phases

Organizational chart of the Graduate Student Companies in Europe (JA-YE Europe) is shown on Figure 5. The strategic goals for every stage of the balanced scorecard system have been defined as shown on figure 7.

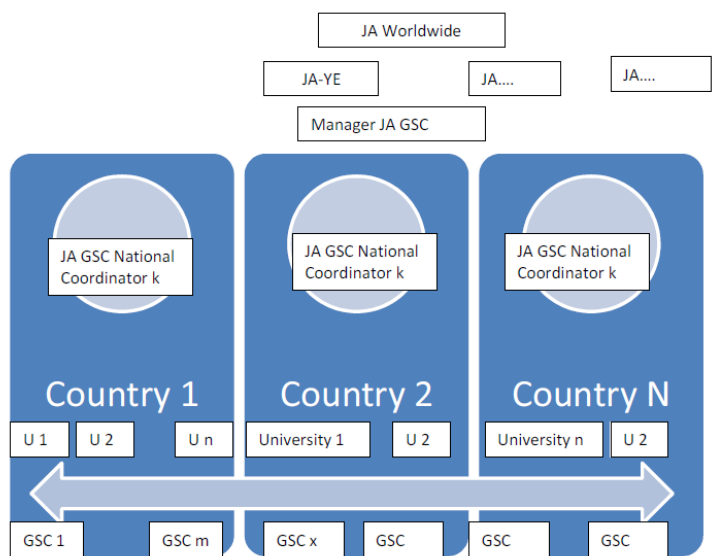

Figure 5 JA-YE Organizational Chart

We have modelled also and created the strategic goal of an appropriate structure for innovation for GSC education – Table 4.

Table 4 An appropriate structure for innovation for GSC education

	Potential	structures
Stimulate	GSC	Stakeholders
Shepherd	JA - YE	JA-YE European Council
Spearhead	GSC Incubators	JA-YE European Competition
Stringent	GSC National Coordination	GSC Development team

We conducted a SWOT analysis and defined strategic goals for every one of the Balanced Scorecard fields – Figure 6.

JA-YE GSC Strategy

Leading goals	Learning & Growth <ul style="list-style-type: none"> • Talented, open minded and highly competent staff • Leadership • Mobile and Communicative • Visionary and Risk Taking • Transparent Organization • Open standard ICT infrastructure 	Internal Processes <ul style="list-style-type: none"> • Innovation • Teamwork • Synergy • Carrier growth/path • In real environment • Creating added value • Incubating business start up
	Stakeholders <ul style="list-style-type: none"> • Improve the ecosystem • University-Business collaboration • Creating opportunities for policy making • Long term positioning and impact in the society • Family support 	Finance <ul style="list-style-type: none"> • Business sponsorship • Financial efficiency in real environment • ROI • Real Business Start Up
Lagging goals		

Figure 6 JA-YE GSC Strategy

The work on the modelling and implementation of the Balanced Scorecard system is being further developed.

5. Conclusions

Based on the presented results and the feedback provided by the different stakeholders we can reach the following conclusions:

- The education based on the presented methodology and processes has a strong competitive advantage when teaching entrepreneurship, especially in specialties orientated at engineering and technology faculties;
- The Graduate Student Company attracts the most innovative and motivated students and the educational process is very attractive and can be recognised as best practice;
- The Graduate Student Company has the potential to position itself as an open and disruptive innovation model for active practical education of students from different levels/degrees of education.

Exploring the collaboration between industry and academia in South-Eastern Europe within the scope of the I-SEEMob project

Dimitrios Sanopoulos¹, Vesna Babaja², Neven Duic³

¹Centre of Research and Technology Hellas, Themi Thessaloniki, Greece, sanopoul@certh.gr

²Agency for Mobility and EU Programmes, Zagreb, Croatia, vesna.babaja@mobilnost.hr

³Faculty of Mechanical Engineering and Naval Architecture, University of Zagreb, Croatia, neven.duic@fsb.hr

Collaboration between industry and academia, as one of the cornerstones of innovation, is becoming one of the central points of European research policies. Increasing knowledge transfer between academia and industry is a key goal of the European Commission's innovation plan and it is thus important to understand the level of communication between these two sectors, their motivation for mutual collaboration and the barriers that exist to such collaboration. This paper examines the level of inter- sectoral collaboration in eight countries of South-Eastern Europe from both points of view – academia's and industries. The paper further explores both stakeholders' motivation for collaboration, satisfaction with existing connections and the barriers they both perceive as impeding to better collaboration. In order to contribute to the development of researchers' careers, the paper also addresses the additional skills that researchers need to acquire in order to be more attractive to the private sector.

1. Introduction

Co-operation between industry and science is considered one of the most important elements of the innovation system due to its expected positive effect on a company's innovative potential. Since launching the European Research Area (ERA) initiative in 2000, the European Commission has concentrated on the need to create a more favourable environment for transnational and inter-sectoral mobility of researchers as an inherent element of the greater agenda to establish a European knowledge-based society. According to the Green Paper on the 'European Research Area: New Perspectives', one of the features the ERA should have is "*an adequate flow of competent researchers with high-levels of mobility between institutions, disciplines, sectors and industries*" [1]. Nowadays more than ever, the EU puts a special emphasis on the collaboration of research with industry. The Europe 2020 Strategy, adopted by the Council of the European Union in June 2010, puts forward three priorities: Smart growth: developing an economy based on knowledge and innovation; Sustainable growth: promoting a more resource efficient, greener and more competitive economy; and Inclusive growth: fostering a high-employment economy delivering social and territorial cohesion [2]. In order to initiate progress on the headline targets, the European Commission put forward seven flagship initiatives. Among the first to be launched was the Innovation Union, to improve framework conditions for research and innovation so as to ensure that innovative ideas can be turned into products and services that create growth and jobs. Concretely, the Innovation Union proposed, among other, that the "*cooperation between the worlds of science and the world of business must be enhanced, obstacles removed and incentives put in place*" [3].

Since most existing studies on cooperation between science and industry were conducted in developed economies, the results of the I-SEEMob project, examining this issue in eight South-Eastern European (SEE) countries, will be significant for the region.

2. About the I-SEEMob project

In accordance with the ERA objectives and priorities, the main goal of the I-SEEMob project is to contribute to the enhancement of the career development of R&D personnel in the ERA by examining the existing legal and research policy gaps hampering the inter-sectoral mobility of R&D personnel in the South-Eastern European countries participating in the consortium and, accordingly, provide recommendations and guidelines to the respective governments so as to raise the remaining obstacles and promote inter-sectoral mobility and the career development of researchers. The activities foreseen to be carried out are the following: a mapping exercise on the current state of industrial representation on R&D sector in SEE and its respective needs; a legislation gap analysis which will examine the legislative framework for career development of researchers in SEE; development of policy guidelines for the formulation of common research policies for enhancing the inter-sectoral mobility of researchers and, finally, establishment of a set of networking initiatives with other relevant national and European networks.

The consortium consists of nine governmental and public research organisations from eight countries: Greece, Bulgaria, Turkey, Romania, FYR of Macedonia, Serbia, Bosnia & Herzegovina and Croatia (see Table 1).

Organisation Full Name	Organisation Acronym	Country
General Secretariat for Research and Technology	GSRT	Greece
Centre for Research and Technology Hellas	CERTH	Greece
The Scientific and Technological Research Council of Turkey	TUBITAK	Turkey
Sofia University "St. Kliment Ohridski"	SU-NIS	Bulgaria
University of Nis, Mechanical Engineering Faculty	MEF	Serbia
Agency for Mobility and EU Programmes	AMEUP	Croatia
Macedonian Academy of Sciences and Arts	MASA	FYR of Macedonia
Unitatea Executiva pentru Finantarea Invatamantului Superior si a Cercetarii Stiintifice Universitare	UEFISCSU	Romania
Ministry of Civil Affairs	MoCA	Bosnia and Herzegovina

Table 1 Organisations of the I-SEEMob consortium

Although these South-Eastern European countries are challenged by similar issues, every country has an individual approach to Science and Technology policy-making regarding inter-sectoral mobility which the I-SEEMob project wishes to examine and provide recommendations pointing out their strengths and weaknesses. The most significant achievement of the I-SEEMob project will be the development of a set of policy recommendations to the national governments for improving and supporting the inter-sectoral mobility of R&D personnel and, thus, enhancing their career development.

The synthesis report that will be developed after the conclusion of the national reports will include the common inter-sectoral mobility challenges faced in today's South-Eastern Europe and provide policy recommendations to national and European research policy making bodies for their solution.

3. Methodology

The first phase of the I-SEEMob project encompassed a mapping exercise in the eight previously listed countries of industrial subjects which conduct R&D activities. For each country a priority industrial sector (or sectors) was chosen (see Table 2). These subjects were then approached in order to pinpoint a contact person in charge of those R&D activities who would take part in a survey on the needs of their company regarding R&D personnel and inter-sectoral cooperation. In total, 569 contacts in industrial subjects were identified and subsequently contacted (see Table 2).

Country	Chosen priority sectors	Number of identified contacts
GR	1. Information technologies- Telecommunications 2. Food industry 3. Pharmacy 4. Chemical industry 5. Metallurgy	122 contacts
TR	1. Biotechnology 2. Electronics 3. Materials 4. ICT	49 contacts
BG	all industrial sectors	30 contacts
RS	1. ICT 2. Energy Industry 3. Biotechnology 4. Materials 5. Civil Engineering Industry (constructions)	130 contacts
HR	all industrial sectors	85 contacts
MK	1. Biotechnology 2. Pharmacy 3. Metallurgy 4. Energy Industry 5. IT 6. Construction	54 contacts
RO	1. IT 2. Agriculture 3. Biotechnology 4. Healthcare & pharmaceutical 5. Security & defence industry	51 contacts
BA	all industrial sectors	48 contacts

Table 2 National priority sectors for the mapping exercise and identified contacts

Using these contacts, as well as the already existing contacts in the academia sector of each partner in the consortium, a survey was conducted, focusing on (a) the needs of industry for additional skills and competencies researchers should acquire to make them more attractive as employees and cooperation partners to the industry sector and (b) both sectors' opinion on remaining barriers to inter-sectoral mobility. Two questionnaires were developed to survey the two sectors, one for industry subjects and one for academia representatives.

The survey is still ongoing, but the preliminary results already show some trends and opinions on inter-sectoral mobility in South-Eastern European countries. The preliminary results were based on the following number of responses (Table 4):

Country	Responses from industry	Responses from academia
RO	25	13
HR	16	195
RS	11	49
MK	11	22

Country	Responses from industry	Responses from academia
BG	8	0
GR	7	0
BH	5	2
TR	3	0

Table 3 Number of responses by March 1st 2011

The respondents covered industry subjects of all sizes, 78% of which confirmed that they run a specialized R&D department. In almost two-thirds (64%) of those companies which have an R&D department, the company employs less than 10 researchers.

From academia the responses came from various fields, and mostly from public organisations – public universities and public research institutes. The respondents' positions in their respective organisations are diversified, ranging from assistants to full professors.

4. Results

4.1 Level of cooperation and satisfaction with the achieved cooperation

The results show that a majority of surveyed companies cooperates with other organisations for their R&D activities, mostly with other companies and universities. On the other hand, the academia respondents in all involved countries believe that their organisation cooperates with the private sector only to a small or moderate degree. The academics gave an even smaller value when asked about their opinion on inter-sectoral cooperation in their country in general. Conversely, they believe that they are more interested in inter-sectoral cooperation than industry subjects – on a scale from 1 to 5 (1 being the worst), they give their own interest a grade of 3,73, and they grade the perceived industry's interest with a 2,34.

Figure 1 Level of cooperation; industry's view

Figure 2 Level of cooperation; academics' view

When asked about their satisfaction with the already achieved inter-sectoral cooperation, the industry gave a relatively high grade of 3.63 to the quality of the cooperation and 3.15 to the commercial value of the cooperation. The academics on the other hand gave a lower grade of 2.62 to the already achieved cooperation between their organisation and an industry subject. However, the 43% of the respondents in academia who have had a personal experience in inter-sectoral mobility report high levels of satisfaction with the experience – 50% were “very satisfied”, with a further 22% “satisfied”.

4.2 Difficulties and how to overcome them

Both questionnaires contain the question on the perceived barriers to cooperation, asking the respondents from both sectors to grade them from 1 to 5 (1 being the lowest). These preliminary results show that the academics perceive the barriers as stronger than their counterparts in industry.

Figure 3 The estimated barriers to cooperation from the academics' point of view

Figure 4 The estimated barriers to cooperation from the industry's point of view

When representatives from both sectors were asked from where the initiative for better collaboration should come, they were given three choices: industry, academic community or third party (such as a liaison office, mediating agency etc.) and asked to rank those choices from 1 to 3 ("1" being their first choice). The cumulative answers for this question were very similar in both industry and academia, with both giving first choice to industry for taking the initiative to establish a better inter-sectoral collaboration.

Figure 5 Opinions of both sectors on who should take the initiative for a better cooperation

4.3 Researchers' skills

Respondents from both sectors were further questioned on their opinion of their national education system and how it prepares researchers for work on the market, and specifically in the private sector. The questions examined the level to which young researchers possess particular skills necessary for work in industry (innovative thinking, computer literacy, technology transfer skills, team work, presentation and communication skills, knowledge of IPR, managerial and entrepreneurial skills), as well as the general level of knowledge received at universities (whether it is up-to-date, adequate for the market, as good as knowledge received in foreign institutions). The respondents from both sectors were asked to assign grades from 1 to 5 (1 being the lowest)

The industry's opinion of the received skills was higher than academia's, with the acquirement of four skills getting a grade higher than 3, and none lower than 2. The academia graded only the reception of two skills with a grade higher than 3, and most of the others around 2,2 – with the acquirement of knowledge of IPR graded with 1,68.

The general opinion of the quality of education received in national universities shows lower grades from both sectors, especially when asked about the adequate preparation of university graduates for work on the market.

5. Conclusions

The results shown here are preliminary, with more questionnaire responses coming in every day. The final results will be achieved with a multivariate statistical analysis, exploring in more depth the correlations between the variables.

These preliminary results however point to a more sceptical attitude of the academic community towards inter-sectoral cooperation – whilst they are interested in cooperation, they perceive more barriers than their counterparts in the private sector.

The study also shows several gaps in the education of young researchers and their preparation for work in or with the private sectors.

These indicators can serve towards concerted regional and national efforts in order to create and foster a better environment for inter-sectoral cooperation.

Europe 2020 Strategic Document was adopted on 17 June 2010 the European Council meeting in Luxembourg. It is a document that should be not only "organic" as successor of such a strategic document - the Lisbon Strategy 2010 (inaugurated in March 2000), but essentially and qualitatively much more - you need to truly revitalize the strategic commitment of the Member States of the Union its global economic competitiveness, performance and relevance be based and built on the foundation of the concept of knowledge economy.

Research - empirical knowledge unambiguously confirmed in the EU that higher rates of growth of rival global economies are basically due to their higher level of competitiveness in global markets, and that higher level of competition is essentially the most direct product of a thorough and highly successful installation and developing economies such as economies of knowledge.

Europe 2020 document is (only) defined as "Strategy for smart, sustainable and inclusive growth," and very similar to the Lisbon Strategy 2010, is based on three basic groups of priorities:

1st Smart growth - through knowledge - based economy and innovation;

2nd Sustainable growth - through the "green" economy, based on more resources to be environmentally friendly - sustainable climate and, 3rd Inclusive growth – achieving high employment, followed by social and regional cohesion.

Keywords

Concept of knowledge economy, Europe 2020, Lisbon 2010, Scientific research and innovation, Smart growth.

1. Introduction

Strategy Europe 2020 as the successor of the Lisbon Strategy in 2010 cannot be based on the same tenets of which was grounded and the Lisbon strategy, as it cannot and does not share the same goals. Europe 2020 and the Strategy and the Lisbon Strategy in 2010 have the same generic nature and background - as fundamentally important strategic documents founded to build and ensure stable and sustainable high growth economy EU level developed globally competitive economies. The emphasis that this growth should be competitive with the growth of developed economies globally competitive, which primarily refers to the economies of the U.S. and Japan (despite all the current problems that they face), he clearly and obviously implies a very significant refinement which must in this place to emphasize elementary. Namely, "cosmic" rate of growth of rapidly growing economies such as those of group BRIC (Brazil, Russia, India and China) or those of the G-5 (Brazil, India, China, Mexico and South Africa), or some other rapidly growing economies really are not members of some more formally established and transparent (narrower) groups of countries, but, meanwhile, are members of the G-20 - the first hint of Turkey, not simply reference the rates of growth the developed

economies. Clearly the enormously high rates of growth of rapidly growing economies (eg, those almost two-digit growth rates) are possible within the social - economic conditions of developing and implementing economic - development policies that are characterized by low initial level of (no) development.

Despite such social - economic conditionality within the socio - economic backgrounds developed, most realistic looking and judging, it is impossible for the developed economies, or social - economically developed societies, to achieve those growth rates that are characteristic of rapidly growing economies - they are such (rapidly growing) economies due to poor or socially - economic low, initial level of the base on which the calculated rates of growth. His remark is essential and permanent need to have in mind when the comparative and competitive context are talking about growth rates - growth rates of developed economies versus rates of growth in underdeveloped economies (emerging economies). In this paper when talking about growth rates of the EU economy (or economies of EU countries) or never explicated, nor imply "naked" comparison between the calculated growth rates of developed economies versus developing economies (rapidly growing economies) . Therefore at the very beginning of this introduction stated that the growth rates of the EU economy has real economic - sense and scientific justification competitively to compare growth rates globally - competitive economies, which, quite normal and understandable, we primarily the economies of the United States and Japan. So, the strategy Europe 2020, taking, developing the postulates, tasks and goals of the Lisbon Strategy 2010, to enable rehabilitation and resuscitation rates of growth of the European economy that it will be competitive in terms of growth rates of competing (developed global) economies.

2. Global competitiveness of the German economy - anticipation of meaning and justification of Europe Strategy 2020

Strategy Europe 2020 is produced within the European Commission ("government" of the EU) was officially submitted as a proposal to the European Council (comprising the heads of states or governments of the Member States of the Union) on March 3, 2010, and by Council was adopted at a summit in Luxembourg on June 17, 2010.

Strategy Europe 2020 contains the defined objectives of the Union in the area of social - economic relations, which would need to be implemented in the coming ten years - so by 2020. These goals largely essentially identical with the goals specified in the Lisbon Strategy 2010, which is quite normal when we know the undeniable fact that the strategy Europe 2020 should be a kind of resuscitation and revitalization of the Lisbon strategy 2010th I really do not have to specifically indicate that the overlapping objectives defined in two successive strategies has its genesis in an obvious fact, which causes very great dissatisfaction, even resignation to the Union - the goals of the Lisbon Strategy[1] is not implemented (in the period 2000 - 2010) at the required level and quality required dictate that real social - economic situation in EU countries, and current global (world) social - economic conditions and trends. This statement is a separate specific gravity obtained by the impact of the global (Stagg - deflation - recession plus deflation) financial - economic crisis and by the impact of the crisis on the eurozone[2].

Speaking at the most basic level could be particularly noted that the first of the two mentioned crises (that of global financial - economic crisis) does not hit with equal weight the economies of EU countries, some economies from the crisis came faster and some slower, extremely obviously is in this sense that, for example, the German economy, which was not seriously threatened by the crisis short of it came out pretty revitalized and has extremely serious and respectable growth rates of GDP, of course, on the basis of its export force, as a free single market of the Union, also, more importantly, and social - economic quality and far-reaching effects on the global market. The superiority of the German export economy, primarily set on the basis of proven quality of its products is upgraded in the early years of this century through reform of the German labor market - Hartz reform (Peter Hartz, who was head of the team that conceived and operational reform), conceived, conceptualized and modeled in four reform - successive steps (as it must be emphasized that the essence of the reforms contained in the fourth step - because the reform is best known as Hartz IV reform), which neo-liberal and consistently liberalized deregulating the German labor market, that he more flexible. Previous rigidity of labor markets in EU Member States, i.e. the complexity of the procedures for starting and termination of employment, together with the enormously high guaranteed employment rights (a phrase "enormously high" in this place we use to mean that it refers the ratio of capital to the obstacles to achieving quality possible competitive market position), especially at the end of the 90 s of the last century and the beginning of this century, it is actually one of the most important elements of T. us.

Americanization of the European Left are imposed on the European left ideological - political scene as one of the top (neoliberal) reformist priorities. Priority primarily determined by the necessity to achieve the maximum possible quality and high level of market competitiveness, and above all in terms of the price - it is the market price-cost necessity, along with, as one of the most important factors, the price of um, can be downloaded to, most realistic and objectively looking at, the lowest possible level[3]. By the way mentioned, a kind of paradox lies in the fact that reform was an expression of political will, determination and action of the coalition government whose main pillar was the German Social Democratic Party. So left government, but reformed left (social democratic) government, reformed in terms of t. us. Americanization of the European Left, ie the government ie. us. New Center (Social Democratic Party in Germany, at a time when its president was Gerhard Schroeder) or t. us. third time, or T. us. New laborizam (Labour Party in Britain at the time when its president was Tony Blair)[4]. The reform essentially means that the European left parties accepted, with some leveling, especially with regard to dienziite of key parameters, basically - neoliberal, social - economic policies, they own policies (and, of course, with their ideological matrix) to the long line of neo-liberal tenets, abandoning the classical left (socialist, social democratic, Labour) piles tenets of the socio-economic policies.

The quality and competitiveness of the German economy, ie its exports, essentially laid the foundations of the German economy of knowledge (the organic unity of the scientific - research and knowledge of economics or the scientific - research and economic / business communities in Germany) are eventually the right answer question regarding the "secret" of success on the German economy through stag-deflation cycle of global financial - economic crisis not to suffer serious damage, quickly get out of it and realizes high post-crisis growth rates of GDP.

In the context of the theme of this analysis - the organic unity of the concept of the knowledge economy (defined first in Lisbon 2010, and then taken, developed and developing strategy in Europe 2020) and the global competitiveness of the EU economy / economies of member states EU, reserve the right to elaborate on the case of the German economy because it is exactly the best example of successful design, conceptualization and modeling and practical application of the concept of knowledge economy and its absolute validity and importance as social - economic framework that determines very high level of global market competition (at a national or regional economy) and has such a level of GDP growth. Undeniable fact, especially in the context of the theme of this paper is that the objectives defined in the Lisbon strategy, and then basically taken, developed and developed in Europe Strategy 2020, are not actually related to the German economy in general and the German social - economic relations (conditions, trends, processes), because these goals have largely been a reality when it comes to the German economy and German society in general, as the economies and societies more advanced European economies, especially the Scandinavian ones. The goals identified and contained, first in Lisbon and then in Europe Strategy 2020 targets are actually related and should meet economies and societies of less developed economies and societies of member countries of the Union. Export competitiveness and strength of the German economy has also a very important feature which refer to a kind of liberation and security of the fiscal policy of the German government, understood in the sense that there is a need / necessity of entering a larger budget deficit. Namely, the global financial - economic crisis proved too obvious and confirmed that the global neoliberal capitalism is deficient and failure in terms of its financial - economic crisis. The crisis is not overcome indigenous market. Laws of neo-liberal market ("steel" and "invisible"), or the autonomy of markets, are exposed and are certified as incompetent and irrelevant in critical conditions. Because inevitably imposed necessity of heteronomy counter crisis intervention. The only institution that could do it was the state or its interventionism. This interventionism, this must be strongly emphasized, contrary to the postulates of the maximum freedom of "steel" market rules - (rational) Maximum liberalized and deregulated markets, immediately apply the outset of the crisis, even then the administration of George W . Bush (Secretary of the Treasury, or finance minister, in those moments was Henry Paulson), ideological administration - was the outstanding political opposite - that neoliberal. Counter crisis state interventionism, obviously that was proposed and favored by the president of the Federal Reserve (ie the U.S. central bank) Ben Bernanke - and the fact that just like the neo-liberal ideology was eligible to be nominated by President Bush for his position as chairman of the Federal Reserve. We want this way, and that the most basic possible level, to say, to document and argument that global financial - economic crisis very clearly demonstrated deficiency and counter insufficientnost crisis of neo-liberal market, and the necessity of counter-crisis intervention the neoliberal state[5]. It is a state interventionism essential set of postulates of the theory of John Maynard Keynes, at which practically the only counter Crisis / counter recession / counter stag deflation (specifically when it comes to the global nature of financial - economic crisis, a phrase first stag deflation has used Nouriel Roubini) macroeconomic policy is the policy of state interventionism,

which through activation of counter-crisis monetary and fiscal policy (their leisure) must necessarily (if it wants to overcome the crisis recession) to raise the level of aggregate consumption, which in turn continues to be appropriate to raise the level of aggregate demand, both elemental and fundamental prerequisite for revitalizing the economy crisis facing a crisis situation, with knowingly accepting parallel, of course - however, as the lesser evil in the given socio - economic and financial circumstances, quite patronizing the growth of the budget deficit and the loss in value (depreciation) of currency. Just as an illustration of this depreciation: Federal Reserve (with Chairman Ben Bernanke) got her off its reference interest rate of only 0.25%, Bank of England (with Governor Mervyn King) removed the reference rate at 0.5%, while the European Central Bank (President Jean - Claude Trichet) removed reference rate of 1%. By the way, the recognition by the neo-liberals (and neo-liberal theorists among the academic community, and neo-liberal ideological profiled politicians) that the neo-liberal market does not have an autonomous capacity and counter crisis mechanism and that inevitably must be activated counter crisis capacity and mechanism of state interventionism was extremely relevant and valid facts and arguments for sentence - paraphrased: "The global financial - economic crisis and its efforts to counter any crisis violation (and theorists and politicians) did supporters of the theory of Keynes". Simultaneously, the necessity of acceptance and practical application of the concept of counter Keynes for solving global crises financial - economic crisis forced the neo-liberals, at least as inevitably require some kind of counter-crisis management, to accept the deeply hated responsibilities and powers of the capitalist state interventionism, ie (state) capitalist "big government"[6]. Returning to the problem of the German experience with global financial - economic crisis, and look at this problem defined especially in light of global competitive power of the German economy, primarily have a very strong conclusion that generally speaking the German Bundesliga government and the bank did not have to enter the adventure of a large budget deficit, simply because of the global export strength / power of the German economy. Exactly because of that force, precisely because of that power, the government and the bank did not have to raise the level of domestic aggregate consumption, aggregate demand, ie, using / relaxation of fiscal and monetary policy, at least not on the level and extent as that forced the U.S. government and Federal Reserve. Not that the German government in crisis global stag deflation conditions are reached for the application of instruments of a package of state interventionism of Keynes, but their sizes were not so much to produce larger budget deficit. Government, for example, subsidize automobile industry (in the crisis was particularly problematic Concern Opel, but his government helping to terms with one course - informal, protective clause: even the smallest part of the assistance does not redirect to a total crisis ailing U.S. concern Chrysler, which was the majority shareholder in Opel), of course because it is an industry that is highly export, increased trade surplus, a large number of employees, self binds a number of other industries and trades and so on. Global competitive strength / power of the German economy (in fact, the German economy of knowledge) is the fundamental reason for the fairly comfortable position in which the country found. Namely, the crisis conditions stag deflation German government and central bank were downgraded in a necessary situation through extremely high level of instrumentation (ie, relaxation) of fiscal and monetary policy to raise the level of aggregate domestic consumption, ie the level of domestic aggregate demand , thereby entering the risks of growing budget deficit. The fact, however, that Germany has no more budget deficit and enable very hard to perform in relation to the actual definition of common policies of the Member States of the euro area, ie to seek and successfully impose gradual entry into the framework / conditions posed by the Stability Pact and growth of the eurozone. In this context, as an anecdote (but too serious anecdote) may be recalled the reaction of the Deputy Prime Minister of Greece Θεόδωρος Πάγκαλος (Theodoros Pangalos), who in moments of "draconian" German conditioning for the assistance that Greece has demanded the Union extremely resignation and "hysterically" nervous (in his well known style) will be called to look at and properly analyze (who actually uses that, exploited, manipulated... ") level of the German level of surplus versus deficit Greek in mutual trade. In this context, quite elementary, to notice that the height of the German trade surplus, ie, low budget deficit, the German government at the last summit of the G-20 (in Seoul in November 2010) put in the position of leader one of two diametrically opposing macroeconomic poles. Namely, there is Germany (with Wolfgang Schäuble as Minister of Finance) loudly, clearly and expressly advocated strongly for abandonment of a package of instruments of state interventionism of Keynes, ie to reduce the budget deficits that cause relaxation of fiscal policies, thus entering into direct conflict with the U.S. administration (with Timothy Geithner as Treasury Secretary) and her insistence indications regarding the dangers processes of post crisis recovery of the economy if we abandon the "doping" the arsenal of policies of state interventionism of the Keynes. So, to emphasize once again, by using the case of Germany, ie the strength / power of the global competitiveness of the German economy, concluding in a certain way, we want to illustrate and to emphasize several important features essential to the positive effects, especially in Business -

Financial crisis - economic circumstances produced by the high level of global competitive strength / power of a national (or regional - in the context of this theme is no essential difference) economy, a fundamental set, developed and upgraded as a knowledge economy.

3. The economic - sociological holizam of the Strategy Europe 2020 - goals, initiatives and components

Immediately and inevitably there is a something that is of utmost importance when you need to determine the nature and mission or objectives of the strategy Europe 2020th[7] It is extremely obvious that the strategy in Europe 2020 overcame a holistic, or economic - sociological approach rather than an approach that would closely economically. The definition of growth in this document Europe 2020 is definitions that transcends narrow framework of economic growth, for example, defined as a specific growth rate of GDP[8].

Growth strategy is defined as: 1. smart - with substantial growth under such growth means founded and built the foundation of the concept of knowledge economy, the second sustainable - growth that will not cause environmental damage, but quite the opposite - growth that will be environmentally sustainable, and, third inclusive - growth that will contribute to the qualitative increase in the number of employees and growth that will be a function of regional and social cohesion - in fact, cohesion policy and the EU Cohesion Fund occupy very important place in the range of policies of the Union.

The bottom line, with full rights can be brought successfully to argue and defend the claim that in fact the need for social cohesion is the ultimate goal and ultimate interest to be achieved through a multitude of separate objectives defined in the document Europe 2020[9]. The required level of social cohesion may never otherwise be achieved except through the mechanism of social inclusion, or by reducing the level of negative impact on all relevant social reality existing differences, competition and conflict.

We think we can talk for a few most significant that is the most important and most essential goals, and a few with the same meaning and importance of such initiatives, contained in the strategic document Europe 2020th.

These objectives could the next "tight" way to recognize and define: increasing the rate of employees aged 20-64 years from the current 69% to at least 75%; realization of the goal of investing 3% of GDP research and development, reducing emissions that cause greenhouse gases by at least 20% compared with the level of 1990 or 30% if conditions are favorable move in that direction, raising the share of energy from renewable sources in the whole of energy consumption of 20% and achieve 20% increase in energy efficiency, reducing early school leaving to 10% compared to the current 15% and raising the level of the population aged 30-34 years who have completed tertiary education 31% of at least 40% reduction in the number of Europeans living below national poverty line of 25% and extraction of 20 million people out of poverty.

Also, despite the most essential goals of the Strategy Europe 2020, and closely related to them, can identify a few most essential and most significant initiatives contained in it: Union innovative - improving the framework conditions and moves in the area of finance research and innovation ; youth movement - changing the characteristics of education systems and strengthen the international attractiveness of higher education in Europe, European digital agenda - further accelerating the broad - the Internet and explain the benefits of utilizing digital single market for households and firms; Europe with efficient resource - helping economic growth through exploitation of available resources, decarbonization of the economy, increase the use of renewable resources, modernization of the transport sector and promote energy efficiency, industrial policy for an era of globalization - raising to a higher level of business environment, especially for small and medium enterprises; agenda for new skills and work - modernizing the labor market to facilitate labor mobility and to develop skills throughout life; European platform against poverty - through achieving social and regional cohesion.

All this is in fact contained in the name of the strategy - in her very precisely defining direct and flagrant as a strategy for smart, sustainable and inclusive growth. Through the implementation of the strategy should ensure the achievement of growth is essentially based on three components contained in it, that he should be founded on three pillars: the economy of knowledge / smart economics, "green" economy / sustainable economy, reducing the rate of unemployment, together with the achievement of fundamental socio - economic and regional cohesion and achieve higher levels of social inclusion in the Union.

4. Conclusion

Strategy Europe 2020, as "a strategy for smart, sustainable and inclusive growth" in reality should be relevant and worthy response to the European Union, cardinal and crucial challenge of the situation, trends and developments in the global economy. In fact, it should not only be the basis on which to build growth in the European economy and its global competitiveness, but has far wider coverage and social function - they should, ultimately, dramatically raise the quality of social inclusion and social cohesion of European societies.

Strategy Europe 2020 must necessarily be seen and understood in relation to the Lisbon strategy 2010th. In essence, the strategy intends Europe 2020 is an attempt to revitalization the Lisbon Strategy 2010th. Indeed, more than obvious conclusion, and it is aware of her share and the highest representatives of the Union, that, speaking at the level of the Union, it is quite unsatisfactory level of implementation of the majority of the commitments and objectives contained in the Lisbon strategy especially those essential-sublimated through the upgrading of European economies as a knowledge economy.

Indeed, in some EU countries, primarily about economic / social - economically more developed countries - for example, Germany and Scandinavian countries, key and essential goals of the Lisbon strategy a reality. Indeed, one could say, without any greater danger would be unjust and would be wrong to say it is a reality that is independent of the Lisbon strategy. For the fact is that in these more developed countries of the EU objectives and goals of the Lisbon strategy was designed, conceived and practically - politically defined and implemented by their political elites even before the official Lisbon 2010th

Strategy Europe 2020, as an heiress of the Lisbon Strategy 2010 actually like her specifically economic - sociological development, a concrete materialization in the form of a strategic document, the vision of Europe's political elite of the society (not just strict / close economic) growth European societies, as well as their competitive potentials and capacities in the modern world of globalization and universalization.

Some aspects regarding IP stimulation and awareness in the field of technology transfer, key position in regional development (Part I)

Dan Săvescu¹, Mihaela-Georgia Sima², Simona-Clara Bârsan³

¹Faculty of Product Design and Environment, Transilvania University of Braşov, Romania, dsavescu@unitbv.ro

²Bucharest Chamber of Commerce and Industry, Technology Transfer Centre, Romania, georgiasima@yahoo.com

³Institute of Research in Analytical Instrumentation, Technology Transfer Centre, ICIA CENTI Cluj-Napoca, Romania, simonaclara_barsan@yahoo.com

The paper presents some aspects regarding IP in Romanian universities and research institutes, establishing a stimulation and awareness methodology of the innovative spirit at level of researchers such as: teaching professors, students, start-uppers, PhD and master students, young people, and others, so as to protect their research results. This principle was promoted at the WIPO reunion in The Hague in 2008, also in Iaşi, Romania, (2009) and Bucharest (2010). The purpose of these reunions was to establish a road-map in order to introduce IP knowledge in universities, steps to realise high performance innovative products, with protected IP rights. All these performing products can be realised within entities like technological and business incubators or technology transfer centres that exist in Romania.

Keywords

Networking, innovation and R&D, Intellectual Property, technology transfer

1. Introduction

The numerous challenges of the new century call for new approaches. One such challenge is in information technology, notably in the worldwide spread of the Internet use, and all the issues it raises in copyright and related rights, as well as in fair practice in industrial property, most urgently in the use of domain names. Another challenge is in the field of biotechnology, which has seen momentous breakthroughs in genetic engineering, generating questions that are not only of biological and technical order, but also human and ethical ones. The use of traditional knowledge and genetic resources is also evolving in ways that particularly affect the developing countries: it should bring rewards to the societies that produce it, as well as to its users.

Intellectual property in itself has always been an integral part of general economic, social and cultural development worldwide, but these new challenges emphasize all the more how globally interlinked national and regional intellectual property systems have become. Fresh approaches to meet the challenges have become correspondingly global, with concerted action at national, regional and international levels, to enable developing countries to participate in and benefit from technological advances.

Inventiveness and creativity are features which have favored the differentiation of mankind in the course of evolution from all other living species. The capacity to put these features to productive use continues to be of fundamental importance within the social and economic structures of human society. Indeed, the survival of any enterprise, organization, or even nation, may be said to essentially depend on its capacity to keep pace with development and progress.

2. Theoretical notions

Innovation is the creative process (generating ideas) followed by making the changes generated by it. Product or system innovation must be protected. The State Office for Inventions and Trademarks is the special body of the central public administration, subordinated to the Government, with sole authority to ensure protection of industrial property, which makes and submits to the government the development strategy of industrial property protection in Romania and also implements the Government policy in this area. The legal basis which entitles these above mentioned attributes is the Government Decree no 573/1998.

Intellectual property (IP) refers to mind creations: inventions, literary and artistic works, as well as symbols, names, images and designs used in commerce.

IP is divided into two categories: *a) Industrial property*, which includes inventions (patents), trademarks, industrial designs, and geographic indications of source; *b) Copyright*, that includes literary and artistic works such as novels, poems and plays, films, musical works, artistic works (drawings, paintings, photographs and sculptures) and architectural designs. Rights related to copyright include those of performing artists in their performances, producers of phonograms in their recordings and those of broadcasters in their radio and television programs.

IP has long been recognized and used by the industrialized countries and is being used by an ever increasing number of developing countries as an important tool of technological and economic development. Many developing countries are aware that it is in their best interest, on the one hand, to establish national industrial property systems where they do not exist and, on the other hand, to strengthen and upgrade the existing systems which, inherited from their historical past, are no longer adequately responding to new needs and priorities [1].

Countries have laws to protect industrial property for two main reasons, related to each other. The first one is to give statutory expression to the moral and economic rights of creators in their creations, and the other is to promote, as a deliberate act of government policy, creativity, dissemination and application of its result and, at the same time, to encourage fair trading, thus contributing to economic and social development. The materialization of IP protection is represented by *industrial property rights*, which allow the creator or owner of a patent or a brand to benefit from his work or investment. The industrial property rights are outlined in Article 27 of the Universal Declaration of Human Rights, which states that everyone should enjoy the protection of moral and material interests resulted from any scientific, literary or artistic production of which is the author. They reward the effort and creativity that are driving human progress.

IP protection is regulated mainly by the following laws: Law no 64/1991 on patents, GO no 41/1998 on property taxes in industry and their use approved by Law No.383/2002.

Advantages: a number of fee reductions for the legal protection of IP objects, according to the average gross monthly income on the last 12 months of the person (either applicant or holder) or depending on the turnover of the trader; profit or income through effective implementation in the country by the proprietor/by the licensees of inventions patented in Romania, including the manufacture of the product or, if necessary, application process is exempt from tax in the first 5 years after the first application, calculated from the beginning of the application and included in the patent validity. The patent holder, respectively individuals and / or legal persons are the ones that exploit the invention, by the above provisions benefits. The income obtained by the holder of the patent from the disposal is tax exempt.

IP rights offer opportunities for the creators of innovations to penetrate new markets with minimum risks and to amortize the investments made in the research that led to the innovations in the first place. In a practical sense, these innovations become the spearhead of some of the most advanced technologies.

Patent confers exclusive rights on an invention which may be a product or a process that offers a new way of doing something or to create a brand new technical solution so as to solve a problem. It ensures the protection of the invention holder, granted for a limited period, which generally is 20 years. *A patent holder has the right* to decide who can and who cannot use the patented invention for the whole duration of protection. He may, on the basis of a license, allow third parties to use the invention based on conditions mutually agreed. He may also sell the right on the invention to a third party who thereby becomes the patent holder.

No industrial property system, no matter how well its basic laws are drafted and efficiently implemented, can make an effective contribution to economic and technological development unless the system is known to, and used by, those for whose benefit it was established. An industrial property system is established to serve the needs of traders, manufacturers, industrialists, researchers, businessmen and consumers. The list of potential users and beneficiaries is inexhaustible and the

benefits to be derived from an effective use of industrial property cut across the sectoral lines within an economy.

An essential task is to promote industrial property among owners and users, as well as among potential owners and users, from the public and private sector, and, at the same time, the awareness of industrial property nature and how its main components can be developed and successfully exploited in commerce and industry, so as to enable the industrial property system to serve better the national interest and development goals.

An *efficient patent system* contributes to the stimulation of innovation in three main ways [2].

First, the existence of the patent system, with the possibility of obtaining the exclusive right for an invention to work for a limited period of time, constitutes an important incentive for the inventive and innovative activity.

Secondly, the limited period of time during which the patent owner is entitled to prevent others from using his invention creates an environment which facilitates the efficient development and utilization of patented inventions. It protects the inventor against uncontrolled competition from those who have not taken the initial financial risk. It thus creates conditions in which the risk capital can be safely advanced for the transformation of an invention into an innovation [2]. The inventor will be at ease to further develop the invention into a final, commercially polished, product or process that could be marketed and produce a benefit.

Thirdly, the patent system provides the framework for the collection, classification and dissemination of the richest store of technological information existing worldwide today. In other words, it contributes to the dissemination of new knowledge since the right of the inventor to prevent others from using his invention for a limited period is not freely granted. In return for the grant of a patent, the inventor must disclose to society the details of his invention. Thus, the information contained in a patent is available for research and experimental purposes (although not, for commercial use) by anyone, during the term of the patent grant. At patent deadline, the information falls into the public domain and is freely available for full commercial use by all [3, 4]. The patent system thereby contributes to the evolution of the technological base of industry.

Innovation is often influenced by the environment in which innovators work. The factors that generate a favorable overall environment for inventions and innovation are: the state of science and technology; the legal, fiscal and general financial systems; the scientific and entrepreneurial culture; the technological and manufacturing infrastructure; human resources and their level of knowledge and education.

The specific factors that influence innovation are represented by the relationships between universities, financial institutions, governmental offices and industry networks among others. Furthermore, the administrative and financial regulations governing the creation of new companies play an important role.

Since these factors can be influenced by national policies, the establishment of support services or a structure for invention and innovation should be considered as a governmental priority. At the same time, the national innovation support structures and programs for services should be viewed as a unified whole, with the main objective of increasing the capacity of society to generate inventions and innovations, including technology transfer, both at national and transnational level.

Technology transfer is the introduction or acquisition in the economic circuit of the technology and specific machines, equipment and facilities resulted from research, in view of new or improved processes, products or services, required by the market that induces an innovative behaviour, including the disseminate information, to explain, to transfer knowledge, to provide consulting and communicate with people who are not experts on the issue of basic research, applied and precompetitive research so as to increase the chances of applying such results, provided there was a results owner [5].

This is carried out by the network of innovation and technology transfer entities (*ReNITT*).

The infrastructure of Innovation and Technology Transfer was created and is functionally assessed and accredited by the National Authority for Scientific Research under GD no 406 / 2003 and aims to support economic and social development, foster innovation and technology transfer, attract investment to capitalize results of research and innovation, as well as human resources from the national research and development system.

Its role is to support SMEs and the interface between them, as beneficiaries and producers of innovation, "inventors" (natural or legal persons) represented by universities, research institutes and companies with research and development activity. Innovation and invention support structures and services have to develop their own type of management, with planning and policies depending on the circumstances prevailing in each country [3].

Competitiveness is a complex concept which, at a general level, expresses the ability of persons, companies, economies, regions to maintain competition on the internal and / or especially international scale, and to get, in terms of a specific business environment, economic benefits, resulted in constant increases of productivity and standard of living. As a result, one can speak about SMEs' *profitability*. Research has shown that SMEs can and should contribute considerably to employment creation and trade, which ultimately promote economic growth. It has also been shown that, given the opportunity, SMEs are innovative and competitive. However, SMEs need to be encouraged to take full advantage of the existing intellectual property protection system in order to compete more successfully in the global economy. This is a snapshot of economic activity, both at micro, and macro levels, and the extent to which companies are in the competition and are competitive. Functioning as a binding element and a balance between the potential, resources and costs, research-development networks support SMEs in their efforts [1,3,5].

2.1 Technology Transfer Centre

As part of a research and development network, a *Technology Transfer Centre* is the entity whose business is to foster innovation and technology transfer for the purpose of placing into the economic circuit the obtained results, transformed into products, processes and new or improved services. Other results of technology transfer: the modernization of production, including manufacturing costs and lower economic resources, organization and management, production and services under the ISO quality standards, investment in industries of the future: IT / Hi-Tech; services / consultancy.

2.2 Technological and Business Incubator

According to a definition of the European Committee, a Technological and Business Incubator is a place where, in a limited space, new created companies are concentrated. The incubators' objective is to increase, for these companies, the chances to grow up and survive time. This objective can be accomplished due to the supplying of modular spaces with common services (copiers, communication services and computers) and to an enrolment for specific services (production spaces having modern technology). The accent is stressed on local development and creation of new jobs, the technological orientation coming afterwards.

The Business Incubator represents a property initiative which assures a small office and/or manufacturing units for new or young companies. It usually assures a flexible work space for accessible prices, common services and direct affairs consulting, as well as access to specialized assistance (such as support in R&D and risk capital).

Business Incubators and Contractor Supporting Services help people become independent due to their own small business. The Contractors are persons who recognize opportunities. Once an opportunity is identified, the contractor's action line will be drawn. In other words, Business Incubators promote an environment where the new business can develop.

Business Incubators transform an idea into an opportunity. Once the idea is moving, the contractor's way is open and it is time to look for the working instruments. These instruments include business analyses, management, marketing and technological support. They also include business software, communication skills and presentation means [6].

The Incubation and Technological Transfer Program aim is to stimulate the sub-products (spin-off) and applications which develop the newest technologies in different research fields, all these in the actual context of R&D activities. One major objective is represented by the assurance that SMEs having no technologies now have opportunities to easily use advanced technologies. Another objective is to support the technologies' renewing and to help technology developers to learn from other sectors. Beside the offered spaces, the assistance includes presentations of affairs inside a network dealing with business and technical consulting that promotes legislation in the field, marketing, engineering, design, relationships with financial institutions, access to universities' resources and new business opportunities in cooperation with other incubator's clients.

In order to become one of the selected potentially valuable businesses, assisted within an incubator, a company is submitted to a rigorous analysis. Its stages are: the analysis of the economic potential to be incubated; the selection of the incubated company, depending on potential, interests, activity field; incubation with a coherent and steady program of support / collaboration activities; making the product in prototype phase; accreditation and technology transfer; consultation and logistic support; transfer from incubation to independent activity.

2.3 IP in Universities

Although different by their nature of activity, universities should not be seen as a self-centered system, but always take into account the labor market as a reference system compulsory to establish those landmarks necessary for self-definition in society. It should focus on the society's dynamic, graduates' development, the condition of secondary schools. Basically, the role of the university in society is to create culture. Moreover, for a contemporary approach, its role is also to provide welfare.

IP culture is an organizational value system resulting from an environment oriented to observing and protecting industrial / intellectual property. It consists of all the behavioral and professional reactions related to observing the right to intellectual property, reactions supported both by a law system and by a system of unwritten rules, structured over the time in institutions and society. As a result to a study performed in the most important universities, the academic environment does not consider IP culture very substantial in the Romanian universities. Some reactions are very rough and they can sometimes be conditioned by an exaggerated self-critical attitude of those interviewed. Anyway, the general conclusion is that, at this point, one cannot talk about authentic quality culture in the Romanian universities [2].

A possible manner to develop IP culture in universities is to identify those already existing successful practices and to generalize them. Taking into account that the university is very responsive to outside intrusions, it is highly advised that the IP techniques, methods, procedures, and methodologies that proved themselves efficient should be undertaken and, as much as possible, generalized at national level [7, 8]. The current state of Romania shows that there are many similar university reactions regarding the IP issue.

In this respect, universities should adopt IP policies according to the dominant activity profile. Therefore, the priority of technical universities should be to achieve and enhance their own inventions (the technical side should prevail), economical universities should promote evaluation and transfer procedures (the economic side should prevail), law universities should foster aspects related to defending and observing intellectual property (the legislative side should prevail) a. s. o. It would be wrong for universities to be offered a single orientation framework by the specific national organisms.

Concerning the IP issue in universities, it should be noted that [7]:

1. Generally, the Romanian universities have not managed to create an efficient and coherent way of thinking and acting regarding IP and, especially, regarding IP achievement and enhancement. There are no distinct and practiced university policies in the IP field.
2. Despite the important potential and the significant overweight on a national level, the contributions of the university researches to national production of inventions, brands, and industrial models are not so relevant.
3. The inventions achieved by university specialists have a higher confirmation rate than the national average and approaches especially top technical fields. This could be taken into account as a real starting point for improving the criteria of performances that are specific to top universities in the world evaluation.
4. In most universities, there are no adequate forms of training, informing and assistance in the IP field. Everyone seems to ignore the fact that universities (especially the technical ones) have significant human and operational potential that could produce inventions liable to be enhanced, could offer specialized evaluators and could help operational centers to enhance industrial property.

The main coordinates of a university policy in the field should envisage the following operational systems:

- A system for assuring industrial property culture (education, good practice, operative information);
- An assessment system (procedures, methods, specialists);
- A capitalization system (regulations, service patents);
- An evaluation system (cessions, licenses, know-how).

2.4 Why should we?

Because innovation has a strong impact on economic growth.

1. Impact upon productivity
 - R&D activities determine labour productivity growth, by introducing new technologies (products, processes).

- The impact of a new technology upon productivity depends on the complementary investments supposed by the organizational changes (structure, procedures, management modifications).
 - The impact upon growth also depends on the investment degree, at societal level, in training human resources.
2. R&D investment type
 - The most important effect on the economic growth by private companies, preferred as a result of some public initiatives.
 - Public investments in R&D have a positive effect on private investments, because they reduce the uncertainty degree and raise the recovery degree, expected as a result of the R&D investments made by the private companies.
 3. Impact. In the last 15-20 years, the scientific effort of the R&D activities (both private and public) in the industrial production have been oriented towards large impact “technological breakthroughs” (but of whose results are less frequent).
 - The impact has significantly increased, especially in the new industries area.
 4. Waiting time
 - The impact upon economic growth, as a result of increasing the industrial R&D investments made, becomes visible after approximately 3-5 years and this period is reducing rapidly.
 - The impact of the R&D public investments is visible only after 7-8 years, this period extending towards 20 years.
 - The complementarity with positive effects between the two types of investments (private and public) depends very much on the institutional characteristics and the linking mechanisms between the decisional factors of the two mentioned fields [9].

Table 1 Differences between public and private R&D units:

	PUBLIC	PRIVATE
PRIMARY GOAL	Knowledge production and circulation	Knowledge use in production
Operational principles	Scientific freedom Priority rule Large scale dissemination	Industrial secret Hierarchical control
Typical results	Publications Scientific works Presentations in conferences	Prototypes Execution documentation Encoded application software
Waiting time	Long time No pressure time	Short and medium time Significant time pressure
Performance criteria	Precompetitive research Demonstrators	Aplicability Productibility (repetability) Measurability
Satisfaction followed	Free knowledge Scientific community Community value	Economic value

2.4 What should we?

Peter F. Drucker found 7 stimulation sources of innovation [9]:

- Internal: Unforeseen events; Contradictions; Change of work process; Change of industrial structures and of market.
- External: Demographic changes; Changing the way of seeing the world; New knowledge emergence.

Main objectives:

1. setting up a network between the State Office for Inventions and Trademarks (OSIM), National Council for Scientific Research in Higher Education (CNCSIS) and Romanian universities, in order to allow and facilitate an inter-institutional information exchange and a practical framework able to stimulate research, ways of IP protection (using IP specific elements) and thorough use of research results;
2. setting up Technology Transfer Offices attached to certain universities; the TTOs will receive logistic support from OSIM and will have as main functions:

- to achieve an optimal bidirectional technology transfer between universities and the industrial and business environment at national and international level;
 - to develop strategies in order to stimulate and protect technical creation in universities and to enhance research results by means of patents;
 - to offer access to technological information in patent literature and to information on the legal status of protecting the technical creation; dissemination of such information;
 - to increase the awareness of the importance and role of industrial property protection within the Romanian academic environment;
 - to appoint representatives authorized by TTOs so as to display procedures to OSIM concerning the protection of the original technical creations developed by universities.
3. extending the teaching of an IP course module (optional) in technical and economic universities in Romania. OSIM will grant assistance for this action by offering:
 - specialized materials elaborated by OSIM specialized staff;
 - other relevant materials in the European and world-wide specialized literature;
 - training of specialized lecturers;
 - teaching courses or specific elements of courses by OSIM lecturers;
 - a project for developing an industrial property education system based on the concept of e-learning.
 4. ensuring access to European and international programs in the field of industrial property protection the rights for original creations made in universities;
 5. jointly organizing seminars, symposia and round tables on current and resonant topics concerning industrial property protection in technical fields, such as:
 - information technology and business environment;
 - biotechnologies;
 - nanotechnologies;
 - pharmaceutical products;
 - European patents, Community mark and design etc.
 6. including in the Draft Law on employees' inventions (which is currently being elaborated as a legislative initiative of OSIM) a special chapter concerning inventions made in the academic environment;
 7. setting up, within CNCSIS, an office of about 3 persons, that should coordinate, at national level, the patenting activity within universities;
 8. improving the current regulations with the purpose of increasing the importance of patents in awarding scientific degrees to university research staff and professors that are applicants and/or owners of those patents;
 9. providing, within the framework of the programs coordinated by CNCSIS, specific funds meant to support the patenting with OSIM, or, in case of special valuable inventions, for getting European patents with the European Patent Office or international patents.

CNCSIS and OSIM will elaborate annual collaboration programs meant to contribute to the stimulation of creativity and innovation in universities, to support the patenting process and to enhance the scientific research results, through specific transfers of technology and knowledge to the economic and business environment.

3. Conclusions

Innovative ideas used in new products and services, are essential to business success, increase the ability of businesses to obtain profits and to discover new opportunities so as to adapt to the rapid change, characteristic to globalization. If one would maintain current technological endowment of most SMEs, their risk of becoming uncompetitive quite soon is imminent. A real solution is provided by technology transfer centres, which by the nature of their activity, as they work with intellectual capital, allow SMEs to access both research results and funding sources for the implementation of new technologies /innovations.

The existence of business incubators inside universities, research institutes and R&D platforms, definitely stimulates the entrepreneurial initiative, improves the innovative spirit and contributes to regional technological development and economic growth.

The benefits resulted from the cooperation of SMEs with research centres, through the technology transfer entities, are very high. The effects are noticeable in the concrete economic results achieved by SMEs in the position that they manage to enforce or maintain on the market (the market share, quality of products /services) the positive effects generated in the chain at the level of national economy (raising the living standard of the population, increased exports).

The contribution to increasing awareness and interest towards the development of RDI activities by the economic agents and at legislative level, optimizing the technology transfer / industry ratio, promoting a culture about the importance of technology transfer, increasing the added value of production (technological and non - technological elements of innovation: organizational innovation, innovative marketing), promoting a knowledge-based dynamic market: regional innovation systems, clusters of innovative enterprises, participation in international networks so as to promote innovation, creating virtual collaborative systems and mechanisms, an integrated information system (web site, portal, database, e-newsletters), obtaining patents and registering trademarks, in direct collaboration with OSIM, encouraging public-private partnerships in order to attract capital to technological companies and start-up companies. All of these represent only some issues that recommend a Technology Transfer Centre or a Business incubator as a reliable partner both for the creators of innovation and its users.

The simple presentation of the worldwide valuable facts regarding Intellectual Property (IP) and technology transfer is not enough, so the authors have decided to exemplify the facts. The article presents examples standing for the implementation of the IP stimulation methodology at University of Brasov level; how a Technological and Business Incubator, such as “Products and Technologies for Sustainable Energy”, can actually sustain the SMEs from within; explains what two technology transfer centers, one from Bucharest and the other from Cluj-Napoca, Romania, have done for the surrounding economic environment.

The authors are willing to convince the others of the importance of innovation, IP protection, technological development through technology transfer and money production, all coming out from exploiting IP rights.

Keywords

Innovation and R&D, Intellectual Property, technology transfer, efficiency

1. Introduction

The present economy of Romania has been passing through the same crises as well as other countries have or already did, reason enough for SMEs to adopt measures to enrich resistance to potential waves due to new arrangements of the involved actors - clients, suppliers, competitors, the state and government institutions [1]. There are several solutions offered by specialists in the field, but for the present paper, the authors have chosen to analyze the viability of innovation stimulation theory, applied at company level, instead of macro level. If proven as functional at micro level, one could expect, in certain conditions, to generate a structure on which an economic viable program can be made, in order to re-launch the Romanian economy.

2. Case Study – IP Connections: University- ITA – CTT- Economy

2.1 CTT-CCIB

In the Chamber of Commerce and Industry of Bucharest there is a Technology Transfer Centre (CTT-CCIB) that was accredited by the Ministry of Education and Research – National Authority for Scientific Research (NASR), by Presidential Decision No. 9434/06.12.2007, as an entity member of ReNITT. It has the mission of supporting absorption of innovation in the economy and the purpose to provide services to promote technology transfer [2].

Its general objectives are: promoting technology transfer to increase competitiveness of products and services in light industry, furniture industry, electrical and electronics industry, the construction machinery and equipment, information and communication technology in the city of Bucharest.

Long-term objectives:

- CTT- CCIB integration into the national information and communication regarding demand and supply of technology transfer; provide technology transfer through knowledge transfer and staff training;
- development of partnerships between international European organizations, R&D units and SMEs in Romania;
- attracting more SMEs to benefit from technology transfer; increase public information on science and technology; training / human resources innovative improvements;
- increase the number of SMEs applying innovative technologies;
- increase the potential for technology absorption of the economic agents.

Short and medium term objectives:

- facilitating cooperation in research between R&D units, universities and industrial partners (in particular SMEs);
- training and development of culture of innovation in SMEs through seminars, courses, contact scholarships;
- involving SMEs in programs financed by the Romanian Government and international organizations through information and advice;
- promotion of science and technology specific activities through scientific events, promotional materials, trade fairs and exhibitions;
- organization of events to promote companies: "Ranking of R&D activity companies in Bucharest Municipality";
- improving the role of CTT- CCIB within the national information and communication system on technology transfer demand and supply;
- development of international partnerships between European organizations, R&D units and Romanian SMEs.

Target groups: SMEs, other companies, research units, institutions of higher education in the field; industry specialists who will be trained for the application of R&D results; specialists who want technological, economic training so as to establish a SME; SMEs and other economic agents, research units, higher education institutions in Romania and other countries of the European area that are interested to capitalize R&D results through technology transfer.

CTT- CCIB has been authorized to provide the following services:

- Technological information services, technology audit, technology forecasting and wakefulness;
- Support services and consulting for the operation of intellectual property rights;
- Support services and advice on legislation at national, European and international level;
- Support services to obtain funds through national and international programs;
- Identify partners from academic and research institutions;
- Provide access to specialized databases;
- Information on the national, regional and local priorities;
- Services for the organization of conferences, scientific events and specialized exhibitions;
- Information services on intellectual property.

In order to achieve the objectives of CTT-CCIB the following activities and services are planned during the period 2008-2011:

Technology Transfer (www.ccib.ro/ctt):

- Creating an interactive stock exchange of demand and supply of technology in the fields of light industry, furniture industry, electrical and electronics industry, industry of machinery and equipment construction, information and communication technology, by creating a database that includes the demands of SMEs for technological products and another one covering the supply of technology products available;
- Creating a database with providers of support services for SMEs (information services, consulting services, assistance, training);
- Brokering contacts between companies, research establishments and universities to strengthen / develop their cooperation;
- Developing partnerships between R&D units, universities and industrial agents, especially SMEs;
- Support the development of innovative activity in SMEs;

- Providing assistance and consulting services on industrial property rights;
- Collaboration with other technology transfer entities to allow the access, as quickly as possible, of users to the innovation supply;
- Advanced training through workshops, roundtables, seminars etc.
- Dissemination of information:
- Provision of technological information through printed material, electronic material (CDs, email, website);
- Information - documentation in the technology fields: light industry, furniture, electrical and electronics, construction of machinery and equipment, communications and information technology;
- Organization of scientific events and exhibits;
- Promote R&D programs, supporting development of capacity to absorb and disseminate the RDI results in the economic environment.
- International Collaborations:
- Facilitate contacts between foreign investors, R&D units and SMEs;
- Organization of scientific events, bringing together researchers and potential foreign investors for research projects
- Facilitate contacts between companies, research institutions, foreign organizations;
- Identification / search of partners for European projects;

Services provided by CTT-CCIB for SMEs' business development and other economic agents:

- Providing general information about companies in the fields of activity: light industry, furniture, electrical and electronics, construction of machinery and equipment, information technology and communications;
- Organizing business meetings, presentations of companies, products and services;
- Assistance provided to SMEs to identify partners, domestic or external;
- Organizing campaigns for information / awareness on the opportunities of access to finance for SMEs;
- Supporting the internationalization of SMEs' business through their participation in trade missions organized by CCIB and international fairs and exhibitions.

2.2 ICIA-CENTI

Another example of a Technology Transfer Center is given by CENTI, that is a department inside the Research Institute for Analytical Instrumentation Cluj-Napoca, ICIA, one of the three subsidiaries of the National Institute of R&D for Optoelectronics INOE2000 Bucharest.

CENTI was set up in 2004, at the initiative of the Romanian Education and Research Ministry (MECI). Due to its employees and external consultants, who have continuously developed their skills and experience, CENTI is able to provide professional consultancy in the following accredited activity fields:

1. environment;
2. medical instrumentation;
3. food;
4. non-conventional energies (bioenergy, biomass and alternative fuels).

CENTI has developed a very sustained and diversified activity, such as:

- market and feasibility studies, business plans for SMEs;
- professional consultancy for the SMEs that have been willing to modernize and retechnologize their activity;
- on-request identification of partners belonging to the academic field (universities, research institutes) as providers of applicable research results;
- technology transfer from research institutes to SMEs.

In 2006-2007, CENTI managed 2 important national technology transfer projects, which aimed to the transfer of the national research results belonging to an important Romanian research institute to different associations of SMEs that wanted to develop their activities.

- dissemination of the information regarding the national, regional and local priorities, by organizing several roundtables and workshops;

- organizer and co-organizer of several national and international workshops, conferences and summer schools.
- on-request access of SMEs to the specialized databases of CENTI.
- support regarding the participation of Romanian companies in economic missions and brokerage events.
- identification of financial resources and writing project proposals for SMEs.

As an example, CENTI has identified funding resources at the Romanian Administration of Environmental Funds and has written a project proposal for a local SME that aimed the control and reducing of the water pollution by modernizing the galvanization flux.

- partner in several projects belonging to the National Program for Research, Development and Innovation.

In 2008, CENTI became a partner organization of Enterprise Europe Network (EEN), as a member of the consortium of the Business Innovation Support Network Transylvania project- BISNet. As a EEN member, CENTI offers a large range of high quality integrated services, such as:

- dissemination of information regarding EU policies, programs and legislation; assistance in foreign business partner identification;
- organization of events related to communitarian information, participation in European projects competitions, innovation, IP;
- support regarding the SMEs participation in economic missions or brokerage events;
- assistance in writing project proposals for European financing competitions;
- services destined for boosting innovation, advanced technologies and technology transfer.

Beneficiaries: The target groups of CENTI are situated in the 12 counties of Transylvania region (RO1) and comprise: SMEs; large companies, entrepreneurial and sectoral associations; research and technology transfer institutions; universities.

For its activity and consequent results, in 2006, CENTI was awarded the prize of the Education and Research Ministry for the best results obtained by a Romanian technology transfer center.

2.3 Transilvania University & ITA Pro-Energ

Intellectual creation has always been a relevant coordinate of the whole activity in Transilvania University of Braşov. The main organizational interest on stimulation and promotion of intellectual creativity has been influenced, in time, by objective factors like: law foresights, material and human resources, but also subjective, circumstantial ones like the importance of managerial vision on protection and valorisation of the intellectual creation, the authors' interest to protect their original creations.

Founded in 1993, "The Centre of Technologies, Inventors, and Business (C.T.I.B.) S.A.", activates mainly as an interface between the university and the business environment, on three dimensions [3]:

1. Micro-production and technology transfer:
 - Creating prototypes and experimental models resulted from scientific research papers;
 - Transferring technologies from the university to the business environment;
2. Inventors – encouraging students, researchers, and teachers and supporting innovative activities in the university environment;
3. Supporting entrepreneurial initiatives of student - innovators through activities specific to business incubators. C.T.I.B., through its Inventors Department, has had, since 2000, the status of Regional OSIM - PATLIB Centre focused on Industrial Property Promotion, disposing of engineers and consultant lawyers specialized in industrial property and certified by OSIM.

One has made an IP data base and has organised a „Best ideas contest”, with prizes for the best ideas sustained for patenting.

Starting with 2007, in Transilvania University has been working the Department of Legislation and Intellectual Property (DIP). The first important activity of DIP was to establish procedures and needed documents, to recognise, identify and register IP products. During its first year of activity (2008), DIP registered 38 patent applications from Transilvania University of Brasov, the authors being professors, PhD students as well as students involved in scientific research activities.

Taking into account the major importance of IP protection and the necessity of competitive information management in the IP field, DIP focuses on IP promotion by developing a service system that offers useful information regarding industrial / intellectual property protection. DIP performs activities of

didactic staff training and scientific research, as well as student training concerning activities of patenting and/or artistic creation protection, and also concerning documentation in the IP protection field.

DIP has its own headquarters, equipped with all necessary office facilities and a specialised staff. The department consists of two sections:

- Intellectual Property;
- Legislation and Permanent Development.

The department is assisted by a Scientific Council, consisting of professors, researchers, specialists in the main IP scientific fields, technical science and technologies, modern art, natural sciences, legislative sciences, etc. The role of this Scientific Council is to analyze intellectual property objects (intellectual creations) and industrial property objects, which are liable to be protected by copyright laws or IP rights, according to the law. This council also has to offer counselling regarding the opportunity of requesting protection.

The IP Department has the following strategic objectives:

1. Annually attracting to the University and forwarding to OSIM a number of minimum 20 patent applications;
2. Enhancing the obtained patents (starting with 2010);
3. Training for patent implementation at interested firms;
4. Contacting firms known as producers of tools / devices similar to the patented ones;
5. Training activities in the field of patenting and IP in all university departments, concentrating on training and promotion activities for senior, Master and PhD students;
6. Displaying the obtained results and the semi annual updates on the university website;
7. Quarterly dissemination activities of updated results within the IP Department;
8. According to the patent type, achieving prototypes and contributing with them at profile exhibitions with the purpose of patent enhancement;
9. Starting 2010, editing a magazine centred on Inventors related activities.

Within Technical Faculties, the study programs of the 2nd and 3rd years of study include courses and seminars about Intellectual Property- identifying IP objects, ways to protect and enhance them. Within the Faculty of Product Design and Robotics, the disciplines Invents, Fundamentals of Technical Creation and Creativity Techniques and Methods, include chapters on IP.

The Faculty of Law has a course on Intellectual Property Rights, while the Master Degree programs include themes in the field of IP.

The Doctoral School holds an Intellectual Property Course (176 PhD students in the first year and 30 in the 2nd) with the following chapter-themes: Legislation in the field of Intellectual Property; Identifying Intellectual Property Objectives; Documentary Researches in Databases related to Industrial Property Objects; Patent Applications and How to Describe a Patent, Ways to Evaluate and Enhance Inventions.

DPI activity has been centred on supporting the deposit of CBI (demand of patent), but also, in the same time, on offering consultancy in IP resort, dissemination of IP notions by using fliers, brochures, books, and opening a new information / documentation centre at the University's Technologic and Business Incubator .

The promotion and protection of IP activities, as well as the obtained results were presented in 2008 OSIM Annual Report, where Transilvania University occupied a top position, on one of the first places among innovative R&D entities and universities.

Since "Transilvania" University of Brasov has decided to do something concrete to stimulate and support innovation within SMEs, a Technological and Business Incubator "Products and Technologies for Sustainable Energy" (ITA Pro-Energy) was built within. It was certified to work in February 2008, by NASR and MECI and is presently affiliated to: ARoTT – Romanian Agency for Technological Transfer; RENITT, being as well an active participant in an international consortium belonging to Enterprise Europe Network, affiliated to the European Community.

ITA Pro-Energy was created to initiate and develop innovative companies, based on advanced technologies in the field of Sustainable Energy, especially in: industrial processes' energy efficiency, renewable energy systems and buildings' energy performance [4].

The strategic goals are: consolidation of relations between the university and the economic environment to increase economic competitiveness in the field of sustainable energy at the level of Development Region RO7, especially for SMEs; increase the implementation rhythm of innovative results due to the enforcement of loading advanced technologies for energy efficiency, for buildings' thermal rehabilitation and for developing renewable energy systems by the economic environment; efficient use of the economic and human potential existing inside the university and in the region, its

orientation toward advanced technologies in the field of sustainable energy; development of competence level and entrepreneurial spirit, especially for young people from the university, and support for physical implementation of innovative ideas, limiting thus the intelligence exodus.

The daily activities of ITA Pro-Energ consist of:

- incubation activities for investments and business;
- activities of technology transfer and entrepreneurial training;
- promotion of inventions and innovations; development of entrepreneurial spirit to the specialists community, researchers, professors, designers, students and also the stimulation of private initiative;
- attracting of private investment in the R&D field, creating new jobs in small companies;
- knowledge dissemination – organizing seminars, workshops, demonstrations; business consulting – analyses, offers, partnerships assurance, promotion etc.;
- specialized assistance – investments at product level, increasing efficiency for time to market;
- innovative ideas promotion by means of projects, training for writing successful projects, accessing finances due to eligible projects, partnerships assurance, promotion etc.;
- expressing of strategies for cooperation with local, regional and national authorities.

Following its goals and the very essence of a business incubator, ITA Pro-Energ offers its incubated SMEs all sorts of facilities, helping companies to start-up and evolve, preparing them for the most important confrontation, that with the real, competitive market.

Due to its activities, besides common spaces, ITA Pro-Energ provides:

- accomplishment and promoting of activities in the field of sustainable energy;
- partnerships building and financial incomes through grants;
- logistic support for the incubated companies and partnerships created in the national industry;
- prototyping and micro-production in the sustainable energy field;
- testing and homologation for products and materials in the sustainable energy field;
- presentation of products, systems and results at fairs, exhibitions, symposiums and / or publishing scientific paper works;
- promotion of offers and necessities of incubated companies, innovations, inventions and technological transfer requiring systems through its own network and also through partnerships, at national and international level;
- the support needed by SMEs to remain successful in the competitive environment;
- human resources improvement, training courses, dedicated software; a company's level mainly depends on the company's accessibility to competitive human resources.

At present time, there are 7 real incubated SMEs and another 8 virtually incubated ones. They all benefit from the facilities offered by the incubator and beyond any reasonable doubt, they have developed, already proved themselves on the market (although the time since incubation started has been quite short) and most definitely they will maintain their market share in the future, if not conquer more and more of the specific activity field layer.

3. Conclusions

The existence of business incubators near universities, research institutes, R&D platforms, definitely stimulates entrepreneurial initiative, improves the innovative spirit, and contributes to regional technological development and economic growth.

Big companies have their own resources, but they are distant in assuming the risks that emerge from a quick development of the innovative field. SMEs are more flexible and interested in sustaining innovative activities but, they have no human, material or financial sufficient resources that are vital for innovative process's ignition.

Through their services, the business incubators are a real supporting instrument for the new-born SMEs, hoping to evolve to the rank of recognized competitiveness elements on the market.

ITA Pro-Energ has directed its effort to perform this important operation especially in sustainable energy field, alternative solutions for heat pumps, wind turbines, PV panels.

Today, it offers to its incubated SMEs modern locations, offices endowed with all necessary facilities, training, consultancy (including on intellectual property rights), financial facilities, access to the micro-production and testing infrastructure, prototyping and micro-production workshops, modern

manufacturing line for products in the field of sustainable energy, testing – homologations laboratory, material testing and characterizing laboratory.

Through their work, the technology transfer centres offer the SMEs and industry the possibility to help each other in becoming even more performing than before, assuring financial support for the transactions through research projects that foreseen technology transfer as one of the final indicators. If transfer is not possible yet because of some unforeseen delays, then, at least IP rights are to be obtained. The possible provided help would consist of completing the file the inventors need to deposit at OSIM, in order to obtain protection rights, that is prepared with the help of the IP counsellors from these technology transfer centres.

One last thing, important to be emphasized: since one of the reasons for the creation of the National Network for Innovation and Technology Transfer (ReNITT) has been to provide support for SMEs and innovative entities, the services and assistance provided are usually free of charge, up to a point. Beyond that, the required fees are far below the market prices.

All in one, one might say that it is really convenient: well prepared employees, free of charge or low prices professional services, best possible results.

The authors think it is worth a while.

Green Innovation - Value Oriented Design

Stefan Schmidt¹

¹University of Applied Sciences Munich and VWI (German Association for Business Administration and Engineering), Olching, Germany, stefan.schmidt-1@t-online.de

The value-oriented innovative design for the complete life cycle – with the Concurrent Costing-/DFMA-tools (Design For Manufacture and Assembly) has proven to be particularly beneficial in the concept stage. This approach aims to reduce the complexity and number of parts within a component/module design via parts synthesis as well as fulfil ecological requirements. Complexity reduction is very important for the automotive industry (e. g.), which has to cope with an enormous increase in the number of models and variants. This paper shows successful results of industrial applications such as: Preventive improvements in costs, quality, teamwork, creativity, and enhanced project management, solving problems and challenges in the early stage of product design, balance between manufacturing costs vs. environmental requirements and quality.

Keywords

Industrial application, Innovation, Life cycle design, Process optimisation, Teamwork-tool.

1. Introduction

We have now entered a time where global warming is an irreversible reality. A challenge of this magnitude calls for immediate and comprehensive response. The traditional automotive industry is a crucial part of this development. Will the traditional car companies go green? Sooner or later they will all have to be green – that is if they want to survive.

For the coming years, one solution to the problem could be the development of a value-oriented creative design for the complete life cycle, which fulfils ecological requirements and leads to: more creativity, fewer parts, less complexity, lower manufacturing costs, less weight, reduced CO2 emission, and better quality.

Figure 1 We can't stop climate change, but we can slow down climatic disaster [1]

Model	Bodies	Power trains	Paint-and-trim combinations	Factory-fitted options	Total number of variations	European sales 1 2002 [units]

Figure 2 The challenge of product variety [2]

The fulfilment of ecological requirements, costs and quality of manufactured products are largely determined at the early phases of the design stage. The shift from a Just-in-Time production system to a value-oriented innovative design and development for the complete life cycle means that it is possible to cut life cycle costs (including the costs of logistics), improve quality at an early stage, reduce time to market and enhance customer satisfaction. Team- and value-oriented innovative design and development for the complete life cycle aims to reduce the complexity and number of parts within a component/module design via parts synthesis. Complexity reduction is crucial for the automotive industry, which has to cope with an enormous increase in the number of models and variants. Even with shared platforms, chassis, motors etc. the total number of variants has risen drastically, as for examples Figure 2.

The goal encompasses the development of the design, purchasing and the supplier network into a strategic function that is now regarded as a key tool for greater competitiveness and profitability in an increasingly global and exacting business economy. In order to meet these challenges, the need for new ways of fulfilling ecological requirements as well as increasing productivity and quality is evident, and includes recent developments in team- and value-oriented innovative design for the complete life cycle – with the Concurrent Costing-/DFMA-tools (Design For Manufacture and Assembly).

2. Value Oriented Innovative Design and Development for the Complete Life Cycle

Lean production (or lean management respectively) gained popularity in several waves. Its roots can be traced back to Toyota's just-in-time production. In 1990 the report of MIT's "International Motor Vehicle Program" (IMVP) was published as book under the title "The Machine that changed the World" [3]. It illustrated the principles of a production system, which was superior regarding productivity and quality and coined the term "lean production". Such a "Big Bang" had rarely been seen in this industry. Seminars and conferences on this topic as well as pilgrimages to Japan by legions of managers and consultants demonstrated the frantic activity resulting from attempts to close the gap. Books depicting new methods of management were published every few months – looking back this could be called a "wave of new methods", e. g. [4].

At the time sustainability was still a widely unknown concept. The majority of companies were too preoccupied with other matters (development of a global player etc.). The last three decades have been filled with numerous attempts to apply these concepts in German companies. However, this has only been partially successful, as [4]. Even today enormous efforts continue to be invested in the implementation of lean production. However, the early phase of the design stage determines ecological requirements, costs and quality of manufactured products and a large percentage of the design tasks are executed by the suppliers.

Costs for manufacturing processes could be lowered substantially. While they are preoccupied with getting their manufacturing process under control, they lack the focus necessary to facilitate improvement by redesign [5]. In order to be able to cope with the development of complex products,

the design, procurement and supply have to shape up to a mutual strategic network [6]. Suppliers are not only required to deliver just in time, but will also collaborate from the early stages of design onwards. Value-oriented innovative design and development for the complete life cycle closes the gaps between design, procurement as well as suppliers [7]. Therefore the tools for the design for the complete life cycle are very profitable – refer to [8] for detailed descriptions and results.

2.1 Design for the Complete Life Cycle

Concurrent Costing®/Design For Manufacture and Assembly (CC/DFMA®) has been widely applied for the improvement of 'product profitability' by increasing manufacturing and assembly efficiency in the U.S.A. and now in Europe. Over 70 per cent of costs, quality and environmental impacts are determined during the early stages of design. CC/DFMA is a method for the value-oriented innovative design and development and is the only method for process and production orientated design, which promotes creativity [9]. The benefits are [5]:

- Team building in early stages and improved creative team work
- Enhanced quality and functional reliability
- Simplification of product design, leading to a reduction in costs / assembly time
- Integration of parts, resulting in a decreased number of parts
- Weight reduction
- Realisation of ecological requirements / sustainable manufacturing
- Reduced development time and shorter time to market

The tools of the CC/DFMA-software lead the team of experts methodically and step by step through the analysis and optimisation process, thereby supporting each procedure. A team consists, for example, of a project leader, designer, production planner, technology expert, after sales service, controlling, quality, procurement and supplier. The effects on costs of design decisions and potential future manufacturing problems will be quantified by the system. This gives the team direct feedback regarding the cost of their ideas and plans. The teamwork is speed up and, by having this direct feedback of improvement or deterioration, the time spent on product and process development is drastically reduced. In order to be able to cut complete life cycle costs at an early stage, the following teamwork-tools have been developed:

- DFM® Design for Manufacture
- DFA® Design for Assembly
- DFS® Design for Service
- DFE® Design for Environment (® of BDI and amc)

Considerations of environmental impact, recycling and disposal must take place at the early design stage. This relates to individual materials and processes in order to minimise material and energy use as well as to reduce toxic wastes that may occur during manufacture and from eventual disposal. The structure of the product must also be taken into account. This must also include the goal of a simple structure with a minimum number of different materials and parts, as well as an overall reduction in the amount of material used in manufacture. To tackle this issue, Design for Environment (DFE) has been developed and used successfully in different projects.

With the above mentioned tools, it is not only made possible to optimise one single aspect such as cost reduction for manufacturing proactively, but it also enables an overall optimised process over the whole live cycle of the new product, including the collaboration of the suppliers network. It begins with the complexity reduction and cost optimisation of the first step in manufacture and reaches right up to the optimisation of toxicity, energy and costs of the last step in recycling and disposal. This renders CC/DFMA a powerful management tool for both value-oriented innovative design and development for the complete life cycle, including the concurrent control of costs, and a strategic launch of new products [5], [6].

2.2 Design For Environment DFE at EDS in Germany

The task of optimising products while at the same time minimising the impact on environment over the complete life cycle leads to a significant improvement of environmental characteristics by using DFE:

Reduced use of material, energy and emission, minimised scrap, easy to disassemble and to recycle, low in harmful substances and suitable for the environment and live cycle. Improved costs by using DFE: Manufacturing, assembly, service, disassembly, recycling and operational costs. Disassembly of old products is important and necessary because of:

- Removal of harmful substances or components
- Disassembly of components for re-use
- Disassembly of required parts according to legislation

The recycling company EDS GmbH uses DFE in many consulting projects ([1], [5], [6], [10]). Among the goals of the redesign were the ease of disassembly and saving of material. As an example Figure 3 shows a comparison of the actual design of a converter and the same converter, redesigned with DFE. The redesign results in reduced part count, disassembly time and costs, assembly time and costs, total weight and significant improved MET points (converter totally scraped / disposed from - 58,7 to -30 MET points; converter totally disassembled / recycled from -30 to -7,8 MET points). The result of the redesign of a converter is shown in Figure 4.

	Actual Design of Converter	Redesign with DFE	Average Reduction (%)
Part count	180	150	17
Disassembly time (s)	600	400	33
Disassembly costs (€)	ca. 5,00	ca. 3,30	33
Assembly time (s)	8450	7400	12
Assembly costs (€)	ca. 90	ca. 75	17
Total weight (kg)	32,6	29	11
MET points: converter totally scraped & disposed	- 58,7	- 30	49
MET points: convert. totally disassembled & recycled	- 30	- 7,8	74

Figure 3 Comparison actual design and redesigned converter with DFE

The costs are calculated for the whole life cycle of the products with the DFMA tools, but DFE determines the environmental impact with a value-assessment, called MET points. They also display the use of material and energy and the toxicity. The material assessment considers the product's impact on the exhaustion of the earth's resources. The energy portion examines energy-related effects, such as the greenhouse effect, acidification, and smog. The toxicity factor measures toxic effects in terms of humans and ecotoxicity.

The MET points are used as an indicator to measure ecological implications of design choices in a quick and easy way, rather than providing an extensive analysis - it is not necessary to make ecological experts out of designers. They offer immediate results while maintaining a broad scope for the life cycle analysis and do not require a special ecological background. MET-points are a practical decision support tool, using a single figure indicator, which evaluate environmental effects. They are always negative. One MET-point is the equivalent effect of one average citizen on one day in a political desirable (or sustainable) situation (e.g. 1 kg of virgin ABS represents 1.16 MET).

As questions in the disassembly and environmental sections of the software are answered, step-by-step change-and-improvement options are presented along with the product structure, costs, and eco-

Figure 4 Design of a converter

effects. A graphic display summarises the entire product analysis and allows tracking of disassembly costs with environmental impacts. Alternative designs or disassembly sequences can be compared on a single graph, allowing for various scenarios. The ecological line is the sum of all effects (production, incineration, landfill, rest fraction disposal, reuse, recycling).

2.3 Successful Concurrent Costing / DFMA Applications

The CC/DFMA procedure as a preventive optimisation process is profitable when a new product has to be designed and marketed or if an existing one needs to be improved upon in order to meet new targets of costs and functions. Results of some applications are shown in the following [6], [8]:

- Automotive industry: Reductions of the number of parts and operations per glove box by 42 per cent, and of the assembly time and costs by 52 per cent [11].
- Electrical industry: Improvements of the DFA index, reduction of assembly time/production costs by 80 per cent and a part count reduction by 60 per cent.
- White goods industry: A project has been performed and implemented within a time span of only nine weeks. The results show significant product improvements, complexity reduction and savings of several million Euros.
- Designer products: This winner of nine design awards in one and a half years reduced the costs by 15.4 per cent and the number of parts by 23 per cent which is equivalent to a saving of 15 millions Euros [12].
- A redesign of the front end of an automobile saved more than 30 kg in weight. This reduction of the vehicle's dead weight will save 400 to 800 litres of petrol over its entire life-span, which represents a reduction between one to two tons of carbon dioxide emission and 30 kg of material less to recycle [6].

2.4 Case Study: Product Development System Automotive Industry

The following 13 management principles of a product development system should include the fulfilment of ecological requirements in all essential points as listed below [13]:

1. Establish customer-defined value to separate value-added activity from waste.
2. Front-load the product development process while there is maximum design space to explore alternate solutions thoroughly.
3. Create a leveled product development process flow.
4. Utilize rigorous standardization to reduce variation, and create flexibility and predictable outcomes.
5. Develop a chief engineer system to integrate development from start to finish.

6. Organize to balance functional expertise and cross-functional integration.
7. Develop outstanding technical competence in all engineers.
8. Fully integrate suppliers into the product development system.
9. Build in learning and continuous improvement.
10. Create a culture to support excellence and relentless improvement.
11. Adapt technology to fit your people and processes.
12. Align your organization through simple, visual communication.
13. Use powerful tools for standardization and organizational learning.

The Toyota Prius, the first mass-produced hybrid car in the world, was introduced in Japan in 1997 and three years later in Europe. As the Prius was named “Car of the Year” by the European media in 2005 and Toyota replaced Ford as the second largest car manufacturer in the world, the car industry was torn from its sleep: Toyota displayed development competence and was poised to become the market leader and then to hold that position for a long time.

According to a statement from Toyota’s procurement manager on June 18th 2010 the company aims to lower its total costs by 30 % by 2013 through the development of 165 model independent modules [14]. Another measure is a radical redesign of the components as in [15], [16], see (Fig. 5). Toyota already released a motor with 30 % less parts and potential savings of similar proportions as early as 1996 [17]. Even today this achievement has gathered little attention. Only four different types of screws are required for a motor whereas 24 are used in the German premium automotive market.

Radically redesign of components.

**“Let’s take nuts and bolts, for example.
What if we were to develop components that don’t
require screws? That’s the kind of thinking we’re after.”**

Mitsuo Kinoshita, senior managing director & chief purchasing officer

**Our goal in the next years – to develop automobiles,
which only “consists half of the parts”
as well as save costs of 6,5 bn Euro or ca. 750 Euro
per car in the next 3 years.**

Toyota – Ex-President Katsuaki Watanabe

Figure 5 Radically redesign of components at Toyota [15], [16]

The challenge of green design shows Figure 6: Double the output with half the input.

2 x 2 = 4

Green Design does not save the world !!

But:

- ½ Time to Market**
- ½ Manpower**
- ½ Budget**

Figure 6 Challenge of green design [18], [19]

3. Conclusions

The benefits of a value-oriented design are: team building and teamwork, better communication, a reduction of product and manufacturing costs, assembly time, number of parts, weight, development time and time to market as well as enhanced quality, a standardisation of parts, complete

documentation and a realisation of ecological requirements. The result of an automotive project shows:

**Less parts, less complexity, less manufacturing costs, less weight, less logistics,
less CO₂ emission, less environmental impacts, more creativity and better quality!**

Its special benefit is the optimisation of the product development process and the creation of new innovative solutions. An analysis requires only a few weeks instead of many weeks or months of product development time. This makes value oriented design a powerful management and teamwork tool for the launch of new products and it closes the gap between design and procurement as well as integrates the suppliers into a strategic network.

Value oriented design is one solution to be considered for the next few years. The Concurrent Costing-/DFMA-tools enhance creativity including the fulfilment of ecological requirements. A business model and paradigms for a sustainable enterprise has to be developed. To a certain degree, electric cars will be a solution in a few years time. But we have to react right now in order to be successful in securing not only the future of businesses but also contribute to a sustainable ecological environment and improve innovative product development:

**Value-oriented design creates economical value, it is lean design
Value-oriented design meets economical requirements, it is green design**

The modern working conditions impose an implementation of dynamic management process that will be able to respond to the challenges of the global economic processes, which above all means the creation of products and services that will be more competitive in the global marketplace.

Each state or region, based on their own human, capital and natural resources is trying to create a favorable business climate that will enable the development of the companies in order they be able to compete in their industry and create conditions for sustainable living standard.

Creating of strong competent domestic enterprises opens the door for entry of big foreign companies in the country and thus contributes to a more regional as well as general economic development of the country.

In this process of creating of the regional competitiveness that brings a development, key roles have more factors of the public and private sector.

In this paper are analyzed factors that form the working strategy of the private company ING-LULI in Struga, Republic of Macedonia, the real possibilities of the company for development and growing in its industry branch, and at the same time its contribution to the regional development.

Keywords:

Regional competitiveness, Development, Global economy, Public and private sector, ING-LULI, Struga, Macedonia.

1. Introduction

Contemporary world today with the development of technologies and techniques offers great chances to subjects of small and medium enterprises, being more competitive in a market economy, economic and initiative of national and international development. Prosecution of economic entities means the process of transformation from the existing situation in the new one.

Challenges of globalization with which face obviously small and medium economic subjects in R. of Macedonia are imperative for the establishment of strategic objectives and maintain competitive advantage in the market.

One of the main issues for the economy of the Republic of Macedonia is the definition for open market economy, which means liberalization and integration of markets, rapid economic development, improving business and investment climate, free products, with quality and popular, which guarantee solving current problems, especially now days when we are in time of slow recovery phase, but rather, increase its stable and recession, which will continue during 2011 and 2012 (Sources: From the World Bank report and its global economic prospects for the year 2011)[1].

Considering the fact that economic efficiency and regional competitiveness is a complex phenomenon and Regional Development, Ministry of Economy through the Program for development of entrepreneurship, competitiveness and innovation of the small and medium enterprises, program for development of clusters, industrial policy, international cooperation, promotion of foreign and local investment, are working actively in creating a more favorable climate of work and promotion in the economic competitiveness of firms also[2].

Contemporary trends as a result of the development of economic entities, individual equity, bend it increasingly at the center of tools, for increasing the sustained competitive of ability, becoming an important factor of entrepreneurship, as well as specific guarantees of the future of their business, limited by a number of products or services (Horvat, 2003). Taking in consideration that, small enterprises today are over 90% of companies in the EU, as a result of this, many national organizations for promotion of export, increasingly see necessary to support the small sector of the economy as the incentive to create new values through development programs, characterized by flexibility and innovation[3].

The main strategic goal is the realization of competitive advantage, because the strategy enables small enterprises, to exploit the weakness of competitive and affordable suburbs in the market, suitable for the development of business culture, which they constantly upgraded, with which increases productivity and quality. For private and public businesses to be successful, the management strategy focuses on information systems that are in the service of decision making, and when the company balances long-term risk with short-term commitments, achieves the improvement of activity of the organization and ignores all the opportunities, which are not related to its basic technology.

In continuation we will mention, strategy as central categories of small and medium economic subjects, theoretical data on competition, local and regional development, regional development program for regional development in Macedonia, respectively south – west regional development plan, vision, goals, priorities and activity of the company ING-LULI, Struga, Macedonia.

2. Strategy as a central category in the small and medium economic subjects

Last decades, great changes of political, economical, technological, the role of state and free market competition, and the internationalization of businesses, have made the environment in which operate, businesses to be quite complex. Then for the Future of such a necessary environment have to use the strategy of a business organization. However, regardless of the environment in which business operates, specialized for a limited number, they will be subject of competitive pressures; this is why competitive strategy problems are especially important for growth of small and medium economic subjects. Through the strategy, business executives need to answer questions, where they are, where they should arrive and what to undertake to achieve certain goals. Conceptually, the strategy sets out the definitions of the market, competition, customer needs, technology, demographic changes and a large number of other factors that determine the strategic formulation of action.

SWOT analytical method creates the optimal combination between the possibilities and limitations of the environment. A strategic decision for development is the result of managerial ability and creativity, always seeking competitive advantage and successful positioning in the regional market.

3. Study on regional enterprises, competition and development, opportunities through the regional program, of the Republic of Macedonia.

Regional Development Strategy of Republic of Macedonia, according to the program 2009 - 2019 (Official Journal of the Republic of Macedonia no. 119/09) is one of the main strategic documents for planning the development of R. Macedonia[4].

Strategic goals of the regional plan based on regional development program for the Republic of Macedonia 2009 - 2019 are:

- 1 Competitive region in the framework plan national and international, which will be characterized by rapid, dynamic and sustainable development.
- 2 Social cohesion, economic and spatial development between urban and rural municipalities within the region with its optimal, special and specific use.

Its purpose is to accelerate in the integration processes in the EU and NATO because, according to experts, the process is frozen in these institutions, causing uncertainty to potential foreign investors in Macedonia. According to the statistics we have a decline since 2009 (145 mil.EU) and 2010 (132.5 mil.EU)[5]. Therefore, the objectives and priorities identified in the overall strategy, in accordance with the basic use of the document, measures and instruments to encourage the development of regions, and their financing, the relevant institutions and mechanisms for implementation, are specified in

Action plan (2010 - 2012) for the implementation of regional development strategy, which in accordance with the law for balanced regional development have been approved for a period of three years, and is in final stages of preparation, supported financially by the state, donors and stakeholders at regional and local levels.

3.1 National strategy of developing the small and medium enterprises

Today, the national strategy (continuous program of the government) of the development of small and medium enterprises (SME), provides basic orientation for the realization of the vision, goals and priorities set out in the field of entrepreneurship and small and medium enterprises for a long time period. Strategic goals are to increase the number of SME, increase the number of employment in SME, and increase the contribution of SME in the creation of gross domestic GDP (national strategy for development of small and medium enterprises, 2002 - 2013). So, for a period of three years in R. of Macedonia, European funds available, the competitiveness and growth of IPA, regional and rural development for small and medium firms. For 2011 are exploited, 98 million EU, for the year 2012 are exploited 105 million EU, and in 2013 will be used 117.2 million EU. (Sources issued by the Chamber of Commerce of the Republic of Macedonia)[6].

4. ING – LULI, Struga, Macedonia, Development possibilities

According to the terms of financing, establishment and management businesses, exist public and private sector. The difference between them is the private sector which is established and managed as a result of private initiative, the axis of which is private and public ownership to be established, managed and financed by the state or government agencies. The advantage of small firms is important in the framework of market economy that offers great opportunities for employment, reduction of unemployment, it has also an important role in economic development because they are a leading providers and force drivers of economical activities. In this paper as business case studies, like a presenter is taken the company to private ownership structure ING - LULI, Struga, Macedonia, founded by 12.07.1994.

The activity of the company today possesses modern equipment for the production of: adhesives for construction and decorative plaster, with the highest quality products **Pevalit**, resulting in the internal market and outside of the Republic of Macedonia. Prices of the enterprise market are adequate to the same products that we offer competitive market. Undertaking from the beginning onwards the enterprise marked growth in development trends as shown in **table no.1**.

Table 1 Business result in period of 2005 – 2009

Enterprise ING-LULI, its activity has started as a commercial enterprise, for retail and wholesale building materials supplied by the country and abroad. In 1998, begins to draft a program, for the production of adhesives for construction. With such products in the domestic market, emerged in June 1999, with capacity of our 10 tons in one shift, with high quality according to European norms, that affected in economic growth and mitigating the economy. Since 2000, the business environment for the distribution of goods, within and outside the country had increased continuously in production and general revenues of the enterprise.

There are enhanced programs of the **Pevalit products, graphics 1**, which includes all finite stages in construction. **Our tendency is**, that this range of products, to extend and complete with all products required today in construction, structural increase in the number of workers and expansion of commercial space[7].

Figure 1 The trend of increasing

Graphics is understandable that the dynamics of production in tons has followed the dynamics of sales shown in the table 2.

Table 2 The trend of growth in tons

year	2005	2006	2007	2008	2009	2010
tons	3212,8	4247,3	6722	7884,3	8219,3	9630

In 2005 with assistance and grant provided by the European Bank for development, part of our products by the Institute of Accredited "ZAG Ljubljana" (Institute for construction in Ljubljana), Slovenia, benefits the certificate, for standardized quality norms with the new European EN 12004. This certificate and secure means access is available in the market of Western Europe. We have a stable market in Macedonia, with continual sales, export continuously in the Kosovo market, included in 1 / 3 of our products, we work with partners to secure the market there, mostly because of quality products and services and respect for deadlines. Since 2005 we export to Switzerland and Germany, where there is gradual increase in production. However, our enterprise also has plans for future development. This is the result of gradual development and expansion of sustainability to today's market.

The best competition for a clear definition of the company is, achieving the vision to compete in the market, where the objective is, developing new products for existing markets (replacement of some components of the product with new ingredients), developing the products with certain types of qualities, developing new size in order to extend product life cycle of existing or to benefit, also to entice consumers with new product. To achieve success in the organization is required a study of macroeconomic and external environment micro that will lead to satisfying the needs of the

organization. How strategic goal will be achieved in competition with other companies, with similar products is necessary that the company find a way how to do this, namely to develop strategic analysis of external and internal environment, who are incoming information tools for enterprise decisions to business success. In a better way this identification will be shown by strategic analysis, ordered of importance monitoring of the external and internal environment to the company, procedures developed as follows tab.3.

Table 3 Internal environment and external environment

Internal environment	
<p>Forces – advantages can be:</p> <ul style="list-style-type: none"> • High Efficiency, • High quality and innovative product for buyers, • Utilization of modern technology for manufacturing, • Good contacts with buers, suppliers – customers, • Perfection in organizational processes, • Minimum cost leader, with maximum response to customers, • Higher motivation of workers, • Standard of conduct to suppliers,competitors,buyers, • Intensive investment in developing new products and technology • Strategy pricelists, • Positive image, • Increase the presence and productivity 	<p>Weaknesses can be:</p> <ul style="list-style-type: none"> • Sensitive to removal of specialized staff for several directions, • Lack of training of workers, • Lack of circulation of information within the company intranet, • Lack of research and development for the renewal of products.
External environment	
<p>Cases can be:</p> <ul style="list-style-type: none"> • New segments of buyers, • Global trend, • Increasing demand for manufacturing • New automated technology, • Where we exercise our business sector and the increasing trend, • Encourage local and central government with its programs for small businesses, • The slowdown of our competitors in adopting new technologies, • Improved infrastructure • Tax reduction, • Sales through internet 	<p>Threats can be:</p> <ul style="list-style-type: none"> • the fall of the requirements for manufacturing • introduction of new powerful competitors and appearance of new enterprises, • threats or replacement products • strategic change to a big and strong competitor • customer dissatisfaction regarding the distribution system • economic crisis • the possibility that technological developments automated walk faster than our ability • the existence of monopolies in the market • unstable political • Unfair competition • Higher taxes to products • long-term procedure for registration of new production • Opportunities for export to foreign countries with low clearance • functional strategy of competition

Based on this analysis and based on analysis of macro and micro environment, define the possible directions of development of short-term and medium businesses in enterprises, ING-Luli, Struga, Macedonia

Short-term are:

- Reinvestment in addition to the capacity of products
- Expanding market (mapping)
- Marketing Strategy
- More investments in training staff - person qualified management and employees
- Better knowledge of English, so it can be used for computing benefits of this technology in business.

Medium-terms are:

- Reinvestment of technology, to save time and other resources, simultaneously increases productivity because, they are in step with the trends and benefits of computing, because it offers more opportunities for business, as the placement of goods and communication both local and abroad.
- Addition of games, that are required in standardized products in construction today.

The result of these spatial data means, sustainable development in the future market, opportunities for better access to Western market and beyond, compiled by project plan developed in this company. Activation strategic plan, defined before, which bring major changes in environment, means implementation of the strategy that brings, the best growth conditions in all phases of business of the enterprise.

5. Conclusion

Competitiveness and regional development in small business, has an important role in the marginalization of market economy that offer great opportunities, for employment and economic development, because the subjects are stimulating innovation in economic activities, thus enabling a quality of life for the community. Challenges facing small economic entities are imperative for establishing strategic objectives, and maintaining competitive advantage, which means superior or otherwise being in the market.

Strategy of the Republic of Macedonia under long-term plans for developing programs through entrepreneurship, competitiveness and innovation of the enterprises of small and medium enterprises, industrial policy, international cooperation, works to promote the competitiveness and development firms.

Surroundings are crucial to business success and existence; therefore they must do their best to known factors in the external and internal environment which affect their work.

The purpose of small businesses is to focus on management development strategy, this means that companies should be prepared for innovation - the driving force of national and world competition on a market economy, to maximize competitive ability through pricelist and functional strategy and minimize weaknesses competitive.

Enterprise ING-Luli, Struga, Macedonia holds leading role in the local market and overseas because the products are quality, sustainable and competitive prices and sufficient services to buyers and use a perfected technology, as an important competitive factor.

Development opportunities for growth and development in this Company are medium and short-term.

ePortfolio – identity and professional development

Elena Shoikova¹, Anatoly Peshev², Milena Krumova³

¹Faculty of Electronic Engineering and Technology, Technical University – Sofia, Bulgaria, shoikova@tu-sofia.bg

²Faculty of Electronic Engineering and Technology, Technical University – Sofia, Bulgaria, peshev@tu-sofia.bg

³Faculty of Electronic Engineering and Technology, Technical University – Sofia, Bulgaria, mkrumova@tu-sofia.bg

This paper reports work-in-progress for a project to create an electronic portfolio for the Technical University-Sofia students. The methodology of the present research follows the goal “to be identified the road and success factor for design and implementation of ePortfolio at the Technical University-Sofia applicable to SharePoint 2010 platform”. This research goal covers the following objectives: Define the latest concepts of electronic portfolios; Address ePortfolio standards; Define the ePortfolio requirements; ePortfolio implementation in SharePoint 2010.

In the academic context, an ePortfolio may assist learners with their personal development by providing a single, organised repository which affect teaching philosophy, pedagogies and curriculum. As a part of a strategic approach to learning and teaching, ePortfolio systems and tools provide a better dimension to learning focused on personnel identity, representing critical thinking, reflection and professional development. With the growing use of eLearning and social applications many teachers increase their understanding of ePortfolio-based learning and develop student-centred learning activities to enhance the quality and sustainability of learning outcomes. In the process of educational innovation, the ePortfolio focus on competence based education and is also frequently used as an aid for guiding the learning process.

This paper defined the ePortfolio features and its implementation in the SharePoint 2010 Platform for collaboration, communication and learning developed at the Technical University-Sofia R&D Laboratory on eLearning Technology and Standards. The ePortfolio was designed in a competency-based-approach and included mapping the competence profile of the learner throughout his life. It is a witness to the evolution of competence and support is essential to customize not only the evaluation but also learning. The pilot test of the ePortfolio solution was conducted with students from the English Language Faculty of Engineering during Semester 1, 2010 in a course on E-Learning. The pilot proved that ePortfolios have a potential to turn information and data into knowledge through two important practices: reflection and social construction allowing students to plan, document, assess, and improve upon their learning by significantly changing the manner in which their education is understood and managed.

Keywords

ePortfolio concept, ePortfolio types, ePortfolio standards, SharePoint, Web 2.0

1. ePortfolio Concept

For years the term ePortfolio has been used in academic and corporal environment. Social studies however show that most people can't define or explain what an electronic portfolio is; furthermore they have no idea of all its purposes and aspects it involves and therefore do not realize what an incredibly

useful and powerful tool it is. Laying aside new-technology hype and enthusiasm, e-portfolios can best be viewed as a reactionary response to fundamental shifts in learning, teaching, technology, and learner needs in a world where learning is no longer perceived as confined to formal education.

Definitions for e-Portfolio include [1, 2, 3]:

- “A collection of authentic and diverse evidence, drawn from a larger archive, representing what a person or organization has learned over time, on which the person or organization has reflected, and designed for presentation to one or more audiences for a particular rhetorical purpose” (NLII).
- “An eportfolio is a web-based information management system that uses electronic media and services. The learner builds and maintains a digital repository of artifacts, which they can use to demonstrate competence and reflect on their learning.” (ePortfolio Portal)
- “Portfolios are collections of realia that have been assembled by a person and are retained and curated by them because the objects contained in the collection evidence or attest to claims that a person might make to themselves or to others about their life.” (The E-Learning Framework)

Most definitions include the notion of a digital resource (personal artefacts, instructor comments) demonstrating growth, allowing for flexible expression (i.e. customized folders and site areas to meet the skill requirements of a particular job), and permitting access to varied interested parties (parents, potential employers, fellow learners, and instructors).

The e-Portfolio can be viewed as the digital identity (imprint) of a person or an organisation constructed through reflective learning:

- An ePortfolio can be aggregated dynamically to other portfolio to create social networks or learning communities
- ePortfolio services allow ePortfolio owners to exploit their personal assets (competencies, knowledge, networks)
- Planning, reflexion, feedback, accreditation of prior learning
- ePortfolio services allow ePortfolio managers (educational institution, awarding bodies, employers, professional associations) to manage their organisational assets (talents, competencies, networks, subcontractors)
- Accreditation of prior learning, offer a job, annual review, competency development, managing learning quality

ePortfolio implementations can best be viewed as a continuum. ePortfolios are driven by the intended task: assessment, professional/personal development, learning portfolio, or group portfolio. The expressions of learning in an e-portfolio can range from simple blogs to enterprise-level implementations. The intended task of the portfolio is the ultimate determinant of value. For certain courses or programs, a blog may be all that is required. Regardless of the format selected, each ePortfolio effort should encourage learners to develop the skills to continue building their own personal portfolio as a life-long learning tool. The fact that a portfolio is electronic contributes in the following manner: The paperless portfolio - Dematerialises documentation; The workflow portfolio - Supports processes such as learning, assessment, recruitment; The knowledge portfolio - Provides the elementary bricks of KM systems; The socialite portfolio - Interconnects digital clones of knowledge workers.

The latter advantages can be divided in two types- one part classifying the ePortfolio as a product, and the other half – as a process (fig.1). When an individual decided to start an ePortfolio, pick a type, collects evidence, interprets it and makes plans for his future development- that is a process. Simply put, the ePortfolio is a process, representing critical thinking, reflection and goal setting for ongoing professional development. However the published and presented ePortfolio is a product. Learners define the evidences for their e-portfolio through a self-reflection process through which they attribute their competences to learning products or outcomes, and reflect on how they acquired such competences. From the pedagogical point of view, this process helps learners better to understand how they learn and become self-directed learners. Learners, how-ever, can use ePortfolios for multiple purposes such as: learning, professional development, assessment, job applications and promotions, showcasing, developing personal plans, accreditation, collaborative learning, and receiving feedback. Likewise, ePortfolios can be used for tracking learners' development within a program and monitoring and evaluating their performance.

Processes involved in the ePortfolio cycle are: Collecting evidences; Reflect; Organize; Revise; Present; Assess; Socialize and receive feedback. Creating a reflection is a five-cycle process: Self-awareness >> Description >> Critical analysis >> Synthesis >> Evaluation.

2. Types of e-Portfolios

According to their purpose and other characteristics there are determined several types (Fig.2) of e-portfolios [4]:

Assessment ePortfolios are used to demonstrate achievement to some authority by relating evidence within the ePortfolio to performance standards defined by that authority. Rubrics are commonly used to score assessment portfolios. Departments may use assessment ePortfolios for accreditation purposes.

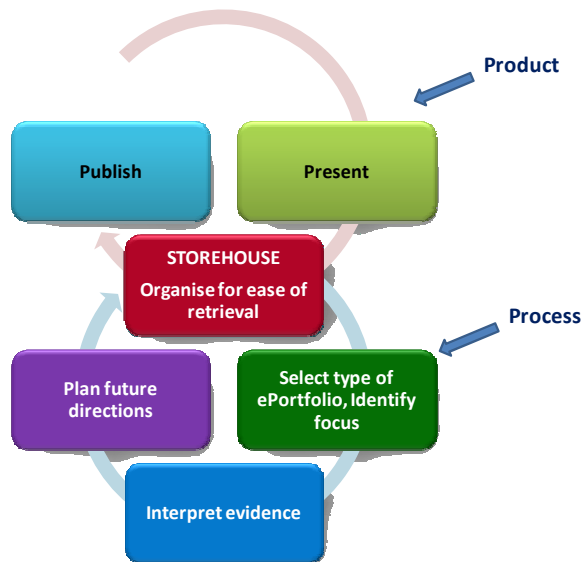

Figure 1 Portfolio as a product and process

Figure 2 Types of e-portfolios

Presentation portfolios are used to evidence learning or achievement to an audience in a persuasive way. Presentation portfolios often contain instructions about how their contents should be rendered. Presentation portfolios are often used to demonstrate professional qualifications. For example, a software engineer might create a presentation ePortfolio that incorporates and shows the relationships between professional certifications she has received, code she has written, and her employment history in order to convince a potential employer to hire her. Faculty members might use presentation ePortfolios to collect materials for tenure track review purposes.

Learning ePortfolios are used to document, guide, and advance learning over time. They often have a prominent reflective component and may be used to promote metacognition, to plan learning, or for the integration of diverse learning experiences. Learning ePortfolios are most often developed in formal curricular context

Personal Development ePortfolios. Personal development planning is defined as "a structured and supported process undertaken by an individual to reflect upon their own learning, performance and / or achievement and to plan for their personal, educational and career development." Thus, an ePortfolio for personal development planning contains records of learning, performance, and achievement which can be reflected on, and outcomes of that reflection, including plans for future development. This could include a learning ePortfolio, but goes beyond that, as it is often related to professional development and employment, so also possibly used as a presentation ePortfolio.

Multiple Owner ePortfolios are used to allow more than one individual to participate in the development of content and presentation. A multiple owner ePortfolio might combine elements of the above portfolio types, but most likely takes the form of a Presentation ePortfolio when used for such purposes as a website or group blog and a Learning ePortfolio when used by a group of learners to present evidence of their academic growth through the group collaboration. Multiple Owner ePortfolios are often used to represent the work and growth of an organization or organizational unit and, when so employed, may be referred to as program or institutional portfolios.

Working ePortfolios combine elements of all of the preceding types. They often include multiple views, each of which may be analogous to an assessment, presentation, learning, or development ePortfolio. A working portfolio is the larger archive from which the contents of one or more ePortfolios

may be selected. The whole of a working ePortfolio is generally accessible only to its subject, while views are made accessible to other individuals and groups.

3. The impact of ePortfolio on learning and personal development

When taking our research, we encountered a great number of different ways of looking at ePortfolio-learning, its goals and benefits. The ePortfolio is an environment with multiple uses. In the context of the workplace and lifelong learning, an ePortfolio is used for managing human capital assets, developing and utilizing social capital and ultimately for management of digital identity. The ePortfolio is a mean to develop social capital: friends, colleagues, and more general contacts to use for financial and human capital development, perhaps as references or collaborators. A diversity of web learning tools can shape learner identity to one that enables the learner to participate in a rapidly changing digital globalised world that demands construction and reconstruction of knowledge rather than pure consumption.

A way to present yourself, telling your own story. When a learner tells the story of a learning experience, or of his or her life, 'deep' learning takes place, and video, blogs, wikis and websites are considered to be powerful ways to facilitate this.

A tool for assessment of student competences. ePortfolios are also seen as a way to assess the attainment of standards. After the student submits evidence in a certain form, the assessor can determine and store a certain competence-level. Sometimes this can be judged based on the materials alone, sometimes the assessor also has observed the behavior of the student first-hand

A tool and file-format to help transitions to other institutes. An ePortfolio can also be seen as primarily a structured (XML) file that contains all information that is needed for the easy transition of a student or worker from one organization to another. In other words, an "ultra-CV".

A way to facilitate coaching by providing insight into the learner. When an ePortfolio contains a set of personal information such as interests, work experience, affiliations, qualifications, etcetera, along with the student's Personal Development Plan, current competency status, and all the learning products that have been created up to a certain point, there is no doubt that this is a valuable resource for a coach. In such an ePortfolio, the coach can access this information in real-time, and quickly form a picture of areas in which the student could use guidance.

Helping personal development. An ePortfolio can also be seen as a tool that facilitates personal development. Almost every book on 'success' emphasizes the need to be clear about your values, goals, talents and weaknesses. And not just know them, but write them down and regularly reflect on them: are you achieving your goals or are you missing the mark? And if the latter, what's missing? An ePortfolio can not only provide a place to store these goals and reflections on them, it can also make them available to your coach and to others in the community of the student. The premise (and paradox) is that personal growth is easier done together with others.

A tool for networking and collaborative learning. Using an ePortfolio, a student can easily put her/his learning results on-line for others to review and give feedback on. This facilitates collaborative learning and the formation of social networks of people with similar skills, experiences and interests.

4. The ePortfolio standards and interoperability - a rapid state of art

ePortfolio standards are needed to enable portability of ePortfolios across applications, to allow comparability of portfolio data across organizations and for the interoperability of applications with other systems. Interoperability that enables the distribution and migration of portfolios as integral wholes between venues requires the ability to describe, encode, and transmit the relationships between assets within the portfolio and its information architecture and visual design in a format that both human and computer audiences can understand.

The following list presents a series of application profiles (data formats) that have been studied [5]:

- Employability ePortfolio (NL) is based on IMS ePortfolio (which includes IMS Learner Information Profile — IMS LIP).
 - Compliant Solutions: eXact Folio (Giunti), Winvision.
- UK Leap (UK) is based on IMS LIP (which is more restrictive than IMS ePortfolio). Compliant
 - Solutions: PebblePad, ePet (University of Newcastle).
- HR-XML application profiles — there are a number of HR-XML application profiles dedicated to specific communities: iProfile (HR-XML CV profile), is implemented by SkillsMarket in UK, which

hosts more than 2 millions CVs for recruiting agencies; GermanCV (HR-XML CV profile) is used by job boards in Germany.

- HR-XML Europass CV (EU) is a binding of Europass (a European CV format) using HR-XML specifications as well as external competencies definition based on IEEE RDC. Compliant
 - Solutions: ePet (University of Newcastle), Eurocv.eu, Kite, CVUniversel / Universal CV.
- hresume microformat — It is used for LinkedIn public profiles (several million users).

If we take into account the difference between individual ePortfolios (that could be developed with any kind of tools) and ePortfolio Management Systems that institutions need to manage a number of ePortfolios for specific processes, then a number of additional emerging standards should be taken into account:

- Identity Management such as Liberty Alliance federation of identities and services, OpenID or CardSpace will play a central role in the seamless exchange of information across services used by ePortfolios.
- Interoperability frameworks such OpenSocial (used by Google, Plaxo, etc.) and Dataportability.org are emerging and open a new kind of door to the exploitation and sharing of personal in a professional perspective.

5. Building ePortfolio in SharePoint 2010

The TU-Sofia increasingly extends the classroom environment to the online environment, sites for communication, collaboration and resource sharing. Most of the subjects are still face-to-face although increasing number of students who use web 2.0 technologies. The process of developing and implementing a successful ePortfolio project - one that works and is adopted by users - involves many challenges that must be tackled [6,7]. An ePortfolio software environment has to be sticky to end users and sustainable as a new enterprise service for students, alumni, and lifelong users. Three key steps are necessary to complete the development of a new ePortfolio system. The initial step is to conceptualize and define the overall system operation as determined by a delineation of the functional and technical requirements. The second step is to design the software and develop an environment that intelligently affords those requirements specified in the first step. During this stage, both human and technological aspects have to be considered.

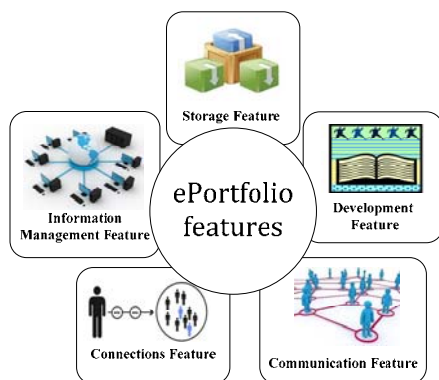

Figure 3 The ePortfolio features

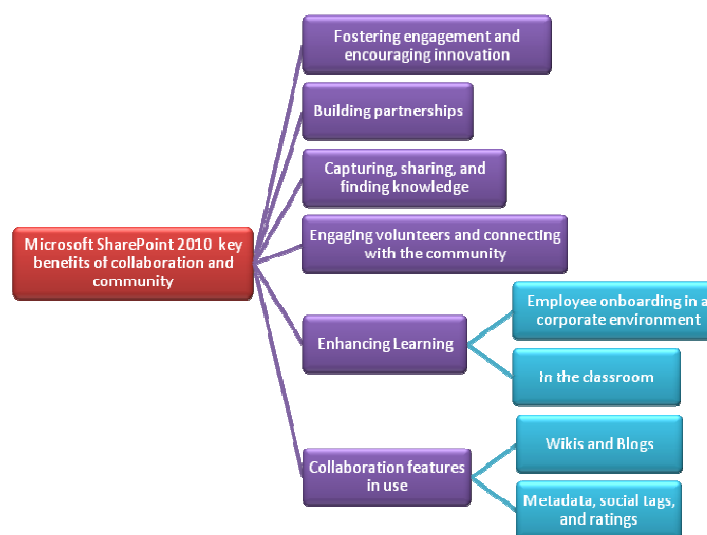

Figure 4 Boosting collaboration with wikis, blogs, My Portfolio, ratings, and tags

The human aspects are certainly the most problematic project issues to be addressed, since they directly affect both usability and user acceptance - issues that can make or break the success of an application. The third and last step is to implement and maintain the project, covering business plan, daily operation and software upgrade. The identified ePortfolio features are presented on fig. 3. Functional requirements are summarised in Table 1. The right column outlines the main SharePoint technology features needed for successful ePortfolio development.

Table 1 ePortfolio requirements

<i>Function</i>	<i>Description</i>	<i>SharePoint Tools & Services</i>
STORAGE	An ePortfolio is a web-based repository for documents. It functions much like a file cabinet, with file drawers and file folders. Students store artifacts (academic records, resumes, letters of recommendation, mixed media files, along with special-interest, personal and professional development-related content, etc.), within its organizational categories.	Lists, libraries, and sites. Accessibility features.
INFORMATION MANAGEMENT	<p>The challenge today is to filter what is most useful out of the barrage of information thrust upon students. To meet this challenge, students will need technical and organizational knowledge, as well as an understanding of how people seek, obtain, evaluate, use, and categorize information. That is, students will need information management skills.</p> <p>Information management processes are inherent in the creation and maintenance of an ePortfolio. <i>Collection</i> — gather, save, and store information and artifacts. <i>Selection</i> — review and evaluate information and artifacts, identifying those which are useful and important. <i>Reflection</i> — become reflective practitioners by documenting and evaluating their own growth over time. Information Management is an integral part of ePortfolio creation and maintenance; it is also an essential skill for students to learn, as they attempt to qualitatively sort through the overabundance of information available today.</p>	<p>Lists, libraries, and sites. Managing and working with content. Tracking versions.</p> <p>Lists, libraries, and sites. Managing and working with content. Tracking versions. Managing access to content.</p>
CONNECTIONS	ePortfolios also provide a medium for students to navigate through the vast networks that make up a university or college. By linking departments and resources directly to the categories of an ePortfolio, students will, in the process of managing and storing information, become connected to resources that are currently available, and yet underutilized. These sources would, then, connect the student with local and corporate programs who provide opportunities in the community and in the real world. Giving students a tool to connect with the larger educational community will improve student awareness of what resources are available and why they are valuable.	Lists, libraries, and sites. Navigating to content. Managing and working with content. Working with content types. Managing access to content.
COMMUNICATION	<p>ePortfolios would have one main interface (private web page), from which students would navigate and manage information and, in addition, create what are called "presentation pages" (public web pages). By creating presentation pages for specific objectives, students learn how to communicate with various audiences, how to present documents for a purpose, and how to constructively reflect upon and write about artifacts. Students would control access to these presentation pages, restricting them to certain audiences, e.g., classmates, faculty, employers, graduate schools, friends, or family. In the end, students would have a number of presentation pages, built from the student's main interface, and designed for specific purposes and specific audiences.</p> <p>ePortfolios are very much a collaborative tool. They also allow students to solicit and receive feedback from faculty, advisors, and others about shared documents in their collection. In fact, ePortfolios are being linked directly to classroom learning systems. Such linking allows faculty, advisors, and others to communicate with students about the artifacts in their collection, whether they are papers, resumes, or various multimedia items. ePortfolios would also enable students to track graduation requirements more closely, allowing for more precise communication with advisors. ePortfolios involve more than collecting artifacts and reflecting upon them, they involve purposeful communication, as students present artifacts and receive feedback.</p>	<p>Lists, libraries, and sites. Working with content types. Managing access to content.</p> <p>Lists, libraries, and sites. Working with content types. Navigating to content. Managing access to content.</p>
DEVELOPMENT	<p>The history of student affairs is one of an enduring and distinctive idea: "the consistent and persistent emphasis on and commitment to the development of the whole person.</p> <p>Specific developmental skills are cross-referenced with the ePortfolio categories, e.g., communication skills could be cross-referenced to specific courses, jobs, and so on. By utilizing and customizing the competency matrix, students would be able to comprehend knowledge and skills, such as leadership and social responsibility,</p>	<p>Managing and working with content. Tracking versions.</p> <p>Lists, libraries, and sites. Working with content types. Navigating</p>

Function	Description	SharePoint Tools & Services
	relative to coursework, personal interests, and career possibilities. A competency matrix provides students a context in which to understand how to acquire and employ the knowledge and skills they accumulate over the course of their college career. A matrix also allows students a way to see the big picture in terms of their educational requirements, to visualize a trajectory of their development, and to articulate competencies and experiences to employers and graduate schools in a more concrete manner. Applying developmental theory within the functionality of ePortfolios can deepen the commitment of student affairs to the enhancement of the whole student.	to content. Managing access to content.

The learning ePortfolio tool was built into SharePoint collaborative and learning platform - which itself is a comprehensive environment for collaborative work, communication and learning (fig.4, fig. 5, fig. 6). The ePortfolio was designed in a competency-based-approach and includes mapping the competence profile of the learner throughout his life. It is a witness to the evolution of competence and support is essential to customize not only the evaluation but also learning. Portfolio-based learning was increasingly being implemented and piloted in a range of educational and professional learning contexts in order to monitor students' professional development. The place of ePortfolio is very important as a potential actor in the learning system. The pilot test of the ePortfolio solution was conducted with students from the TU-Sofia English Language Faculty of Engineering during Semester 1, 2010 in a course on E-Learning

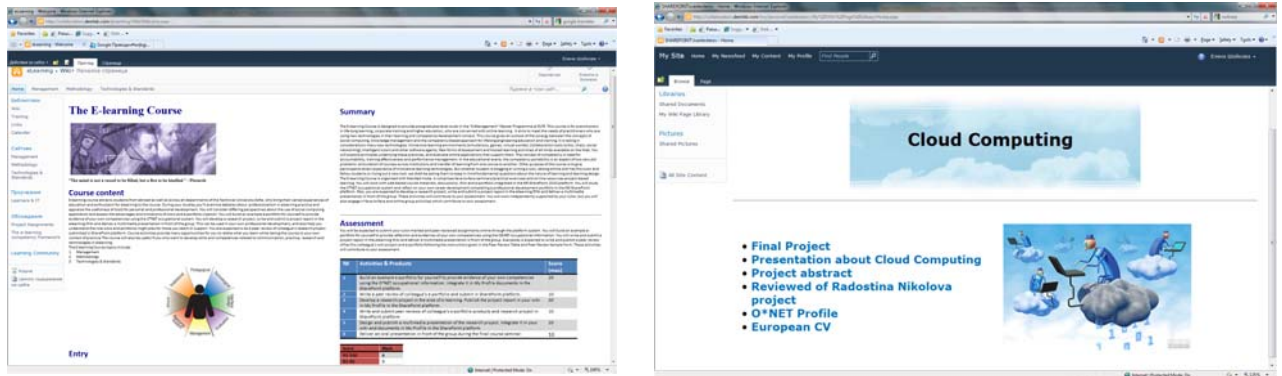

Figure 5 The eLearning course home page and ePortfolio elements in SharePoint 2010 platform

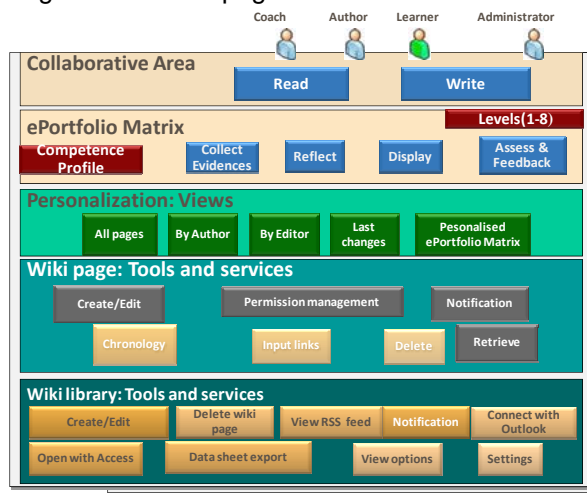

Figure 6 Wiki Learning ePortfolio in SharePoint

The pilot proved that ePortfolios has a potential to turn information and data into knowledge through two important practices: reflection and social construction allowing students to plan, document, assess, and improve upon their learning by significantly changing the manner in which their education is understood and managed.

5. Conclusion

The electronic portfolio helps in the construction of knowledge, and promotes a critical and reflexive process in the students' identity and professional development. In some ways the use of ePortfolios points to an innovation in the education system. In many places, ePortfolios are used to achieve a greater level of individualisation in education. Increasingly, each student is looked upon as the owner of his or her own individual education. ePortfolios are a very functional means of keeping track of this "individual" educational process. The usage of ePortfolios makes a learner's identity concrete not only for evaluation by educators, but also for learners to understand themselves and to make their way into the wider world. When viewed through the lens of learner identity, the organizational principles of ePortfolios take on an added significance. It is probably beyond the realm of possibility that the online teacher, by aligning the basic raw material of learner identity with the firmly practical notion of ePortfolio development, we hope to highlight the fact that the educator is connected to final outcomes of online education in serious and meaningful ways.

A common theme of student ePortfolios is their potential to turn information and data into knowledge through two important practices: reflection and social construction. How? By giving students the tools and the context necessary to construct and reflect upon their identity over time.

6. Acknowledgements

The research is jointly supported by the METASPEED Project funded by the Bulgarian National Science Fund, 2008-2012 as well as by the TU-Sofia R&D Sector within the framework of the research project "Learning and Knowledge Management Powered by ILIAS", 2011.

The EU and the countries of South East European region signed an ECAA agreement to provide a framework for the development of air services between EU and South East Europe. Development of air transport infrastructure of South-East Europe is prominent segment of connecting countries within the region and integration of the region itself in becoming one of the economic centres of Europe. Memorandum of Understanding, signed in year 2004, among regional participants from South-East Europe defines the basis for development of Core Network of South-East Europe as a part of which eleven Core Network airports were defined. After additional analysis of other six South East European international airports, which weren't originally part of Core Network, on the basis of their traffic volumes and regional importance, in year 2009 they became a part of Core Network. The geographical location of South East European airports, positioned close to national borders, and considerably small size of national markets implicates importance of airport integration in transport multimodal network. This paper will consider the levels of achievements in traffic results of airports of the Southeast Europe including organizational and infrastructure analyses of 17 Core Network airports. The paper also reviews the status of air transport sector in South East Europe in the context of intraregional air transport integration as well as integration in European air transport network.

Keywords

Airport, Air transport infrastructure, Core Network, South East Europe

1. Introduction

The break-up of Yugoslavia and associated confrontations caused geopolitical and economic changes in the region which influenced the reduction of air transport sector in South East Europe (further referred to as 'SEE') to a shadow of its former self. Overall traffic carried on the SEE territory by regional airlines in year 2001 represents approximately 50% of passenger kilometre (PKM) carried by Yugoslavian JAT in 1989 [1]. The creation of autonomous countries led to the creation of new national flag carriers. In year 2010 cumulative traffic volume of SEE airlines (JAT, Montenegro Airlines, Adria Airways, Croatia Airlines, Air Bosna, Air Srpska, Albanian Airlines) was three times lower than neighbouring Austrian Airlines traffic volume which reflects enormous change considering a pre war period (1989) when Yugoslavian JAT alone carried double passengers than Austrian Airlines. Comparing the CN airport performance in pre and post war period, only 3 CN airports in year 2001 traverse the traffic figures from year 1987 [2].

In recent years European airports have faced capacity crunch problems and despite 41% of capacity increase (5 new airports and 79 new runways) 11% of demand is still not accommodated [3]. This is the segment in which future role of airports in South East European region, still partly underdeveloped and with its potentials insufficiently exploited, is recognised. Accordingly, South East European Observatory's (SEETO) role is recognised in the process of upgrading the existing infrastructure to the European Union countries level. Setting up the Core Network in year 2004 among other transport modes included 11 Core Network (further referred to as 'CN') airports as a part of air transport infrastructure. Considering its traffic performance and regional importance in 2009, additional six

international airports became a part of Core Network. Regarding regional importance of retrospectively introduced six Core Network airports and recent changes in airport organisational structures and infrastructural developments, additional detailed analysis on airport infrastructure in South East Europe was perceived.

2. State of the air transport industry in South East Europe

Today, SEE region, concerning air transport, is a modest, undeveloped region, which represents only 1.3% of passenger transportation in the world schedule traffic and 1% of the number of international airports in the world [1]. Intercontinental transport was very significant in JAT's operations in year 1989 and today apart from middle range routes to Middle East and North Africa, does not exist from the CN airports. The densest routes are international, mainly to and from European Union, due to relatively small SEE countries areas which implicate lack of domestic traffic with exceptions in Croatia and partially Serbia. That fact highlights the importance of cross border international traffic on regional and European level. After signing the ECAA agreement liberalisation of air service occurred and the route network has grown rapidly. New established routes are connecting European destinations with SEE region serving neighbouring hub airports as feeders while main regional airport which could compare to European hubs has not yet been established. Main airports offering connecting flights are Belgrade and Zagreb although with 2.7 and 2.1 million passengers in 2010 remain small by European standards.

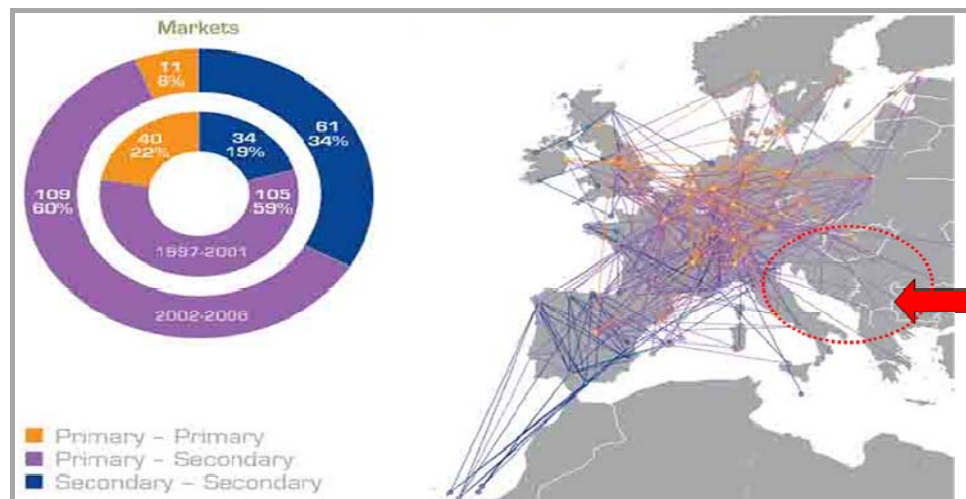

Figure 1 Segmentation of air transport routes in Europe [4]

Apart of the recent global economical crisis that effected almost everybody in the world the economical progress achieved in the region in last ten to fifteen years is significant. After war boosted economy has tackled people to travel by both business and leisure reasons and such situation has created various new trip generators. Tourism development positively affected on economical situation in SEE countries and is taking more and more important role in stimulating air transport in the region. Concerning airline industry, recent economic crisis caused global airline industry net loss of 11 billion Euros in 2008 and 4 billion Euros in 2009. Drop of passenger carried and particularly the cargo traffic (-13%), witnessed the drop in demand during the year 2009 as a result of heavy turbulences on the global market. Airlines in SEE are not doing any better where Croatia Airlines recorded 13,7 million Euros loss in 2009. Even though BH airlines had 11.9 % increase of passengers' number in 2009 due to load factor hefty decrease losses were recorded. Montenegro Airlines flew 527,000 passengers in 2009, up to 4.6 % from the year earlier, but even though financial loss of minus 3 million Euros remained. MAT Macedonian Airlines is no longer flying and Kosovo Airlines does not exist anymore [5].

Table 1 Indicators of air transport in South East Europe (2009)

Country	Passengers (000)			Cargo (kg)	Number of CN airports	Number of Airlines
	International	Domestic	Total			
Albania	1.394.688	-	1.394.688	1.863.265	1	3
B&H	532.867	221	533.915	1.923.936	2	2
Croatia	4.000.413	933.488	4.968.381	11.872.722	7	4
Former Yugoslav Republic of Macedonia	634.591	-	634.591	2.125.462	2	1
Montenegro	982.656	-	982.656	1.482.512	2	1
Serbia	2.401.185	51	2.401.236	7.080.645	2	3
Kosovo (under UNSCR 1244/99)	1.191.978	-	1.191.978	1.301.974	1	-
Total	11.138.378	933.760	12.107.445	27.650.516	17	14

3. Analysis of air transport infrastructure in South East Europe

In last decade SEE region recorded significant growth in airport traffic volumes, in some SEE countries exciding even 10%, as well as constant changes in traffic volume figures varying from - 49% in Former Yugoslav Republic of Macedonia (2001) to 109.24% in Kosovo (under UNSCR 1244/99) (2002). Such developments in traffic volumes are partly caused by the Low Coast carriers' entrance on SEE market in 2003 which is visible in traffic increase from 5.7 million in 2002 to 8 million in 2004. In last decade (2000-2009) annual growth rate of passenger traffic volumes was 7.3% and in cargo 48.14 %.

Table 2 Core Network airports passenger volumes growth by regional participants (%) [6]

	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	Average
Albania	N/A	N/A	N/A	N/A	N/A	15,43	22,04	14,58	10,07	-13,87	9,65
Bosnia and Herzegovina	-9,97	-4,18	17,61	9,63	8,41	5,17	9,03	2,75	4,61	-3,01	4,00
Croatia	6,97	6,40	42,12	12,51	18,77	12,22	11,57	5,49	-5,72	-2,53	10,78
Former Yugoslav Republic of Macedonia	-49,43	3,52	-4,07	-3,34	9,14	3,03	13,34	3,72	-8,69	-8,44	-4,12
Montenegro	N/A	N/A	N/A	9,77	4,90	15,59	24,11	7,26	-11,42	15,40	9,94
Serbia	16,95	8,30	14,13	11,52	-0,25	2,57	20,42	5,09%	-10,16	8,14	7,67
Kosovo (under UNSCR 1244/99)	1,69	109,24	-1,07	9,07	2,15	-5,12	12,18	14,18	5,43	N/A	16,42

In spite of mentioned high air transport growth rates in the region the gap between the growing needs and demands of the travelling public, existing transport facilities and offered possibilities and capacities is vast. Recent investments in some of CN airports upgraded the level of service and increased terminal capacity but on most CN airport further investments in infrastructure and equipment are needed.

3.1. Analysis of Second category Core Network airports infrastructure

According to the TEN-T categorization second category airports are referred as Community connecting points. The categorisation includes all airports or airport systems with an annual traffic volume of:

- between 1.000.000 minus 10% and 4.499.999 passenger movements, or
- between 50.000 and 149.999 tonnes freight throughput, or
- between 500.000 and 899.999 passenger movements, of which at least 30% are non-national, or
- between 300.000 and 899.999 passenger movements and located off the European mainland at a distance of over 500 km from the nearest international connecting point [7].

Table 3 Sample Second Category Core Network airports infrastructure indicators

	Operational hours	IATA Level	No Runways	Runway lengths	No Pax Terminals	Pax Terminal Area (m2)	Apron Area
Tirana	24h	NA	1	2750	1	13.000	55.500
Sarajevo	06:00 - 22:00	2	1	2600	1	46.000	8.000
Dubrovnik	4:00 - 21:00	1	1	3300	1	N/A	110.500
Split	06:00 - 22:00	2	1	2550	1	10.800	50.000
Zagreb	24h	1	1	3252	1	15.000	168.000
Skopje	05:30 - 22:30	2	1	2450	1	4.000	64.170
Podgorica	04:00 - 22:00	1	1	2500	1	5.500	33.220
Tivat	07:00 - 16:00	1	1	3252	1	4.050	40.000
Belgrade	05:00 - 23:00	1	1	3400	2	51.000	163.350
Pristina	24h	NA	1	2500	1	3.938	46.020

Applying TEN-T categorisation on Core Network airports can be noted that 10 airports based on their traffic performance (Tirana, Sarajevo, Zagreb, Dubrovnik, Split, Skopje, Podgorica, Tivat, Belgrade and Pristina) are in *second category* as Community connecting points. Second category CN airports are equipped with one runway longer than 2400 meters enabling operations of narrow and wide body jets such as B767-300 and A310-300, while airport Belgrade, Dubrovnik, Zagreb and Tivat runway systems are able to accept even wide body passenger aircrafts (B474-400, A380, A340-500). Apart from runway, other airport capacity limitations in taxiway systems, apron, gates and passenger terminal areas are probable and even though second category airport runways are capable to accommodate largest passenger aircrafts limiting factors preclude its usage. In a view of airport expansion and modernisation, preliminary process focuses on identification of priority capacity limitation facilities.

Recent decade was characterised with CN airports facilities expansions, modernisations and extensions. As a part of airports Belgrade development strategies in order to gain additional traffic volumes Terminal 2 was constructed in 2006. Today airport Belgrade is the only second category CN airport which operates on two passenger terminals comprising passenger terminal area of 51.000 m² and capacity of 5.6 million passengers annually. Prior the airport Belgrade extension, modernisation and reconstruction of airports Sarajevo (2001), Tivat (2003) and Split (2005) were made. Airport Skopje is currently implementing the project which comprises the construction of a new 40.000 m² terminal building with 6 passenger boarding bridges. By the end of construction the new airport will be able to handle a capacity of 6 million passengers per year [24]. Podgorica is second Montenegrin airport where reconstruction of terminal building in 2006 and construction of new administrative building in 2009 took place as a part of 30 million Euros worth project of Montenegrin airports modernisation and expansion supported by EIB(EIB – European Investment Bank) and EBRD(EBRD – European Bank for Reconstruction and Development) [8].

Apart from terminal and runway facilities, existence of minimum navigation aids such as runway and taxiway lighting, precision approach path indicator (PAPI), VOR(VHF Omni - directional Range), NDB(Non Directional Bacon) or DME(Distance Measuring Equipment) and ILS(Instrument Landing System) CAT(Category) I are a standard requirements for the airlines to start scheduled services from

the airport. Airports Pristina and Sarajevo are subservient to bad weather conditions which reduce visibility for aircraft pilots and preclude scheduled air traffic. Most CN airports are equipped with minimum navigation aids and ILS CAT I what enables precision instrument approach and landing with a decision height not lower than 61 m above touchdown zone elevation and with either a visibility not less than 800 meters or a runway visual range not less than 550 meters. Airports Zagreb and Belgrade are equipped with precision instrument approach and landing system ILS CAT IIIb where decision height is lower than 15 meters above touchdown zone elevation, or no decision height and runway visual range less than 200 meters but no less than 75 meters.

3.2. Analysis of Third category Core Network airports infrastructure

Third TEN-T airports categorisation defines airports as regional connecting points and accessibility points and includes all airports or airport systems with a total annual traffic volume:

- of between 500 000 and 899 999 passenger movements, of which less than 30 % are non-national, or
- with an annual traffic volume of between 250 000 minus 10% and 499 999 passenger movements, or
- with an annual traffic volume of between 10 000 and 49 999 tonnes freight throughput.

Beside passenger and cargo volume requirements, additional criteria for airport inclusion such as location of airport on island or landlocked area of the Community with commercial services operated by aircraft with a maximum take-off weight in excess of 10 tonnes, was retrieved. A definition of landlocked area includes radius of over 100 km from the nearest international or Community connecting point. Accordingly it is noted that seven CN airports are in third category of which only Pula and Zadar meet the traffic volume criteria while the rest meet location criteria.

Figure 2 Passenger traffic volumes on Third Category CN airports [6]

As second category CN airports, third category airports runway systems were formally used in military services and therefore its average length is 2500 meters. Lower level of third category airports importance for national governments is noted in relatively small amount of its recent reconstructions and developments.

Table 4 Sample third category Core Network airport infrastructure indicators

	Operational hours	IATA Level	No Runways	Runway lengths	No Pax Terminal	Pax Terminal Area (m2)	Apron Area (m2)
Banja luka	NA	NA	1	2400	1	800	21.600
Osijek	07:00-14:00	1	1	2500	1	1.536	27.000
Rijeka	04:00-20:00	1	1	2500	1	7.800	33.600

	Operational hours	IATA Level	No Runways	Runway lengths	No Pax Terminal	Pax Terminal Area (m2)	Apron Area (m2)
Pula	W8-16; S8-20	1	1	2946	1	5.400	64.200
Zadar	06:00-22:00	1	2	2500	2	4.044	32.420
Ohrid	NA	NA	1	2550	1	2.500	38.700
Niš	Request 24h	1	1	2500	1	2.000	27.500

Even though airport Pula has highest passenger traffic of third category airports, last airport expansion and modernisation was made in 1989 when new terminal building was constructed enabling the airport to cope with passengers throughput of one million passengers. Airport Osijek has the smallest passenger traffic of all third category CN airports and its further development is related to the potential cargo traffic growth for which the airport has cargo storage of 2.400 m². Ohrid airport runway system, Zadar airport terminal building and Niš airport apron reconstruction were recent expansion and modernisation projects in mentioned category [9].

4. Future air transport infrastructure developments in South East Europe

Considering the valorisation of current airport infrastructure in South East Europe it is visible that future infrastructure developments are foreseen. The sector is characterised with concessions in which contracts for future 20 years and its infrastructure developments are defined. Some of airports like Tirana already finished contracted construction works and expansions and it doesn't have any huge developments on the way. Airport Podgorica was completely refurbished a few years back and today is able to accommodate one million passengers annually. Some of Core Network airports such as Airports Banja Luka, Pula, Osijek and Rijeka do not have in its short term development plans ambiguous expansions and constructions due to small traffic volumes and no potential for its increase in near future. Airports Belgrade with future investments of 118 million Euro, Zagreb with 270 million Euros and Pristina with 140 million Euros are contrariety and its development plans for expansions and modernisations will be shortly in the process. The management of Belgrade airport and the Government of Serbia plan to invest 118 million Euros into the expansion of the terminal building, a second runway and an office block for the airport's management. The expansion of Terminal 2 would upgrade the airports capacity to over five million passengers per year.

According to accepted proposal, investments needed to extend and modernise airport Zagreb in predicted amount of 270 million Euro are double higher than the ones needed for airport Belgrade [9]. The multi million Euro project will be carried out within the next ten years and it will be carried in three stages with the final goal of increasing airport capacity from current 1.5 million to 4 million annually. Final airport capacity would be 5 to ultimate 5.5 million passengers while terminal building would consist of 9-10 air bridges, 15 gates and apron would be able to accommodate 20 aircrafts [10]. It is the most enthusiastic project in the region but due to financial crisis the realisation of the project is uncertain at the present time. One of the investments solutions, beside cohesions funds, is private sector investment through a concession agreement similar to one, which was done in airport Pristina [11].

Comparing development plans of airports Belgrade, Zagreb and Pristina which have highest development potentials, certain similarities of terminal buildings capacity projections (4 - 5.5 million passengers) are visible while only airport Belgrade plans to construct new runway and it can be stated that airport Belgrade with two runways might have a sort of advantage in taking over a position of a regional hub. Airport Skopje, with TAVs 200 million Euros foreseen investments and current capacity extension to 6 million passengers yearly, is also in competition for taking over the title of a regional hub.

Figure 3 Future layout of airport Zagreb

Summarising all stated future investments it can be noted that airport Skopje is planning to make largest airport capacity expansion to 6 million passengers annually, Belgrade and Sarajevo are planning to construct additional runway while Zagreb is planning to make new modern terminal with highest investment need. Regarding airport infrastructure in correlation with current and future traffic volumes airports Belgrade and Zagreb, if they manage to accomplish their development plans, have highest potential to become regional hubs.

5. Conclusions

More and more European airports are facing congestion problems as the gap between airport capacity and the demand for airport services is widening. Core Network airports are situated in relatively undeveloped region and with its current sufficient capacity and its future development plans are seen as a potential solution to the 'capacity crunch'. A better use of existing airport capacity and support of new infrastructure, development of new technologies and integration and collaboration with other transport modes promoting multimodality is a key to success, while the lack of multimodal connections with other transport systems (rail in particular) goes to further undermine the efficiency and potential of Core Network airports. In the transport infrastructure and the multimodal connections upgrading process, South East Transport Observatory is an important mean and its role has been recognised. Even though many CN airports have sufficient infrastructure capacity, lack of correspondent passenger throughput enable airports to cover its investments into new infrastructure which is the reason for applying other investments possibilities such as concessions. With the right policy framework and a privatization of state owned airlines and airports, the private sector should be able to stem most of the investment needs for fleet renewal and infrastructure expansion. After possible initial costs associated with sector restructuring, the net effects of air traffic growth are thus likely to increase the fiscal space of governments, rather than reduce it, while economical improvement of the region and improved intraregional connectivity would have positive effect on overall regional development.

Current world economy crisis change a major recognition about definition of free market and liberalization. According to estimation of WTO, in 2009, world trade volume would be lesser by 9% at least, in relation with previous year. Up to now, trend of international trade indicate continuing and accelerate growth. However, World Bank' projections reports decreasing of prices of many products (i.e. oil, raw material, non ferrous metal, products of black metallurgy) and various types of services in current year related with previous.

Recent forecasts predicted that value of world trading of products and services will significantly lesser than in last period. This tendency already hardly affected countries which have extremely high so-called export ratios and it will have negative consequences for countries where earnings from service' export hold very high position in FX income. This study predicts that dozen countries with extremely high indebted, should face with huge problems because of abovementioned problem. A number of other countries, due to decreasing of value of export products and services, will be included in the category of highly indebted. It wills, of course, multiple impacts on the competitiveness of countries in transition, where Serbia belongs. As country with very high extern debt, Serbia has, in its recent history, one of the most in the exchange of goods and services - 11.51 billion dollars

This work is aimed at identifying the most important factors of financing sustainable growth in terms of global financial crisis and overcoming the most often obstacles.

Keywords

Sustainable growth, global economic crisis, financing, liberalization

1. Introduction

In the past 15 years, developing countries, their growth and share of global trade has shifted the direction of the trade flows and the political power equilibrium. The economic and financial crisis, which has taken a heavy toll on poorer countries, has added new pressing challenges and brought to the attention of the international community the need to rethink the overall structure of global governance. Beyond the political and economic sphere, the forces shaping world trade can also be identified in the increasing role of non-state actors, the growing pull of social demands and the technological changes that influence the way business is conducted and the way people interact. The link between these forces raises both hopes and concerns on how they impact on economic growth, poverty reduction and the sustainable development, as well. According to estimation of WTO, in 2009, world trade volume would be lesser by 9% at least, in relation with previous year (3). Up to now, trend of international trade indicate continuing and accelerate growth. However, World Bank' projections reports decreasing of prices of many products (i.e. oil, raw material, non ferrous metal, products of black metallurgy) and various types of services in current year related with previous.

Ever since the western Balkans' emergence from the violence of Yugoslavia's demise, the region has exhibited a growing democratic maturity. Elections have successfully been held in the region, and most states have seen peaceful changes of government. Some of these governments are unstable,

but then so are many coalitions elsewhere in Europe. The democratic transition in South Eastern Europe is today clearly irreversible.

Despite years of progress, however, the work of the region's good neighbours is not over yet. Numerous bilateral conflicts still exist and peaceful relations between these societies are far from guaranteed. Slovenia is the only ex-Yugoslav state to have joined the EU so far, and the membership prospects of the others remain clouded. The fight against organized crime is in most of these countries another formidable challenge, and one which has direct implications for the rest of Europe.

2. Serbia and sustainable development

At the end of 2006, countries of South East Europe signed unique multilateral free trade agreement and they expand existing CEFTA, under revised conditions for countries which has not yet become members of World Trade Organization (Serbia, Bosnia Herzegovina and Montenegro). The new multilateral agreement regulates investment, non-tariff barriers, intellectual ownership, protection criteria's, solving litigation and arbitration.

As key point of the Agreement, the rules of diagonal accumulation of origin of merchandise is created this implies that products from free trade area bring mark, made in CEFTA "in case of export to other countries?

Ratification of CEFTA has strong marketing aspect for Western Balkan countries; by reason of guarantee to foreign investors that invest in region is good decision (2). Key problems of this agreement are non-custom barriers.

Therefore, improvement of business and investment environment is imperative for South Europe's countries, as well as for Serbia. Considering macroeconomic stability is almost accomplish (although reform processes in all countries are not fully complete yet), infrastructure is on satisfactory level, political and institutional stability for region's countries is still significant factor which effects level of investment in these countries. Considering that development of countries in region is based on foreign direct investments, there is a need to observe its real influence on economic growth of every individual country. Moreover, Serbia needs to promote attractive investment politics for the region which will in turn stimulate and expand foreign investment (4).

3. Doing business in Serbia

Serbia is ranked 89 out of 183 economies and 83 overall for Starting a Business in 2011. That includes that Serbia has improved her business and investment environment, despite very difficult economic occasions.

Table 1 Performances of Serbian economy

REGION	Eastern Europe & Central Asia
INCOME CATEGORY	Upper middle income

Enforcing Contracts	94	94	No change
Closing a Business	86	101	↑ 15

Source: Doing business in...Serbia

Economic environment in Serbia, by many criteria's, is much more attractive then before for setting up of new CEFTA, and its possibilities which arise due to extension of markets for more then 30 million citizens (after acceptation Bulgaria and Romania in EU).

Serbia will be very attractive location for investments in next few years, because of stronger integration processes in field of trade liberalization will make the small and uninteresting markets to become one large and „investor friendly“destination. Also, adjustment of institutional regulative and laws in field of investments, as well as stronger protection for investors in region are already giving tangible results.

Due to this task, there are many programs and subsidies lunched in Serbia to stimulate foreign direct investment, as a key factor for achieved sustainable development in long terms.

Companies in Serbia will now be eligible to receive higher subsidies from the National Employment Agency for hiring workers ranging from 100,000 to 400,000 dinars (roughly €1,000-4,000) per new worker (5). The main criterion for determining the level of subsidies is the development level of the municipality. When discussing grants that the Ministry of Economy gives to investors who employ new workers a total of 151 projects worth 691.5 million euros had received financing and that various companies had been granted 84.9 million euros worth of grants from the program. Due to these grants, 22,719 have been employed, while the average value of subsidies per newly employed worker amounts to EUR 3,413. Investors do not get subsidies on the basis of a promise that they will hire workers. Instead, they must submit a bank guarantee that will be charged, along with the interest, if they do not fulfill their obligations.

Serbia has signed a bilateral protocol on the liberalization of markets for goods and services between Serbia and the EU within the framework of Serbia's accession campaign to the World Trade Organization (WTO).

The protocol is crucial for concluding bilateral talks with other WTO members, which is a sign that Serbia's accession process is entering its final stage. Serbia began the WTO accession process, which requires the full alignment of the country's entire economic system with the rules of this organization, in February 2005. WTO membership brings a variety of benefits, the most important of which are predictability and a more stable environment for foreign investors.

4. Conclusions

Just two of the seven western Balkan countries – Croatia and Macedonia – are official EU candidate countries. The international outlook for south east Europe is also very different from a decade ago. After NATO intervened in the Yugoslav conflict, the Stability Pact for South Eastern Europe was founded to provide crisis management. The uneasy truce was at first only possible thanks to intervention by the U.S. and the European Union. Now, countries across the region have a clear European perspective and multilateral contacts between national governments are well established.

Despite years of progress, however, the work of the region's good neighbours is not over yet. Numerous bilateral conflicts still exist and peaceful relations between these societies are far from guaranteed. The fight against organised crime is in most of these countries another formidable challenge, and one which has direct implications for the rest of Europe

Probably the greatest concern for south east Europe, and Serbia, too, is the economy. Important foundations have been laid to improve the country's economic situation, and growth rates have risen substantially. But the pace and sustainability of this expansion are cause for anxiety, especially in the current financial crisis. Development in Serbia has been uneven, and what direct foreign investment there is it has been spread unequally. The income gap between rural areas and the capital cities is still sometimes very wide, and parts of the country suffer from high unemployment and serious shortages of investment capital. International loans to increase investment will inevitably become even harder to obtain now that the financial impact of the global banking crisis is worldwide. Continued regional development requires stability and yet more economic reforms, combined with a stronger focus on the social consequences of the current situation.

All these economic difficulties should not, however, obscure the progress achieved so far, nor should the vital contribution of the international community be overlooked. Development has relied on coordinated international support, particularly from the EU, and this will continue to be of critical importance. The Central European Free Trade Association has now established a market of 55m consumers, and the current initiative for an Energy Community of South Eastern Europe is a training ground for future integration into the internal European energy market. It should be seen as a form of pre-emptive sectorial integration into the EU.

Obviously, significant issues remain outstanding for Kosovo. Recently discoveries about war crime done by Kosovo's officials put Kosovo in very unlikely position. Even if attempts to attract inward investment to Kosovo are successful, it will be impossible to create enough jobs for the whole working age population. Some 70% of Kosovo's population are less than 30 years old, so its unemployed youth will many of them be forced to leave the country. Until a solution is found, Kosovo risks becoming a black hole on the Balkan map, unable to take part in cooperative ventures with the rest of the region. That would help neither Kosovo nor the other Balkan countries.

The future Serbia within the EU is therefore still in the balance. On the one hand, Serbia will have to wait on developments in Brussels and other EU capitals. On the other, the most essential decisions lie within the country's own grasp. These countries still have further to travel in the right direction and they have to be able to stick with the Copenhagen-criteria for EU membership. Perhaps the next year or two may mark a turning point on some of the outstanding issues to be resolved before country can expect to join the EU. In a world preoccupied by economic recession and the global banking crisis, the Balkans remains part of Europe, and will loom ever larger on its list of unfinished business.

This paper aims to analyse whether the new venture creation is stimulated by practices developed by higher education institutions through innovation networks. Thus, the study examined the relation between the propensity of creation new firms and six factors determinants, namely: the best forms used by HEIs for fostering new venture creation, prior entrepreneurial experience in creation of firm; prior experience in sector, type of higher education institution, levels of education and area of education. We included three control variables associated individual level characteristics, namely: age, sex and perceived family business support. To gather data, a questionnaire was completed by nascent entrepreneurs born within HEIs, and 255 answers have been collected. The empirical research uses binary logistic regression analysis and is based on a University sample of nascent entrepreneurs and Institute Polytechnic sample of nascent entrepreneurs in Portugal. Results show a positive relationship between prior entrepreneurial experiences increases the probability of to entrepreneurial intentions for creation a new firm, as well as the prior experience in sector. The propensity of creation new firms differs in the tow higher education institution. The results obtained about the best forms used by HEIs for fostering new venture creation, show that cooperation and research and development developed in HEI in result of relationships with other agents in the innovation network emerge as the main form through which HEIs stimulate new venture creation. In general the empirical research found strong evidence of the importance of HEI to fostering the new venture creation when inserted in innovation networks. The main contribution of the present study is to propose a model which embraces internal and external factors, to determine the propensity of creation new venture aiming to increase the comprehension of entrepreneurial process and identifying the main factors in this process.

Keywords

Higher Education Institutions, Innovation Networks, Nascent Entrepreneurs, New Venture Creation of Firms,

1. Introduction

Within the framework of intense globalization and increasing competition of all economic activity, new venture creation contributes to the introduction in the business sector of new technologies, new products/services and new forms of organization, and has been found to be one of the fundamental factors of economic growth, job creation, market efficiency, renewal of economic structure and spread of innovation, as well as one cause for improved global competitiveness ([1], [2], [3], [4], [5], [6]). In

parallel, innovation networks have been recognized as an important enabler and catalyser of firm creation since, besides allowing the reduction of uncertainty through cooperation among agents, they also facilitate the production and sharing of knowledge and of other scarce resources, of costs and risks, and, among other benefits, allow efficiency gains due to different forms of work allocation ([7], [8], [9], [10]). In advancing and energizing innovation networks, higher education institutions (HEI) play an important role since they act as hubs where the various contributions offered by the network are ignited and disseminated, not only locally and regionally but also nationally and globally through different means as, for instance, the production of this humble paper ([9], [11], [10]).

Currently, in the European Union, with escalating unemployment rates and lethargic economic growth, to stimulate a *certain kind* of entrepreneurship that may lead to venture creation is a measure favoured by many governments as a possible contributor to the minimization of economic and social problems. This is also the case in the Portuguese context where these problems are particularly serious. Considering the recognized importance of innovation networks in firm creation and of the role HEI play in stimulating these innovation networks; considering also that this phenomenon has been little studied in Portugal, this research intends to analyse a specific set of factors that the literature has established as contributing to venture creation and answer the following broad question: Considering the role that Higher Education Institutions play within innovation networks in promoting venture creation, which variables are most likely to influence nascent entrepreneurs to start a company?

The paper is structured as follows: the first section reviews the literature on venture creation associated with innovation networks. Next, we present the research design and the method that led to the construction of the conceptual model guiding the research. The following section describes the model and hypotheses. In section five, the results are presented and discussed. Finally, the sixth section presents the final conclusions and offers suggestions for future research on the topic.

2. Literature review

Innovation networks are systems composed by diverse subjects/entities whose interactions, dynamism, trust and relationships enable knowledge and innovation transfer. For the last two decades, the phenomenon of entrepreneurship has emerged in connection with network research ([12], [13]) as its very significance – inter-personal and inter-organizational relationships – is seen as the means by which actors gain access to a variety of resources (including knowledge) helped by other actors ([12], [14]). HEIs are, by nature, an important source of knowledge. When competitiveness was based on routine tasks, HEIs played an important social, political and cultural role, but their role in economic terms was less evident and mainly consisted in the training of future venture collaborators ([11]). As competitiveness befell dependent on knowledge, ideas and creativity, HEIs became crucial for economic development, the concept of entrepreneurial universities emerged ([15], [16], [17], [18], [19], [11]) and they gradually became central actors in a knowledge-based economy. The expectation is for universities to be active in promoting innovation and technological change ([20]).

In this context, entrepreneurial universities are themselves actors in an innovation network made up of diverse actors where government and public policies also have a relevant role. If, to be able to more effectively disseminate their knowledge to other actors, HEIs would better be inserted in innovation networks, how can they stimulate the proliferation of knowledge and venture creation within them? Venture creation relates to any newly and legally set up company that is at a launching or initial stage and is less than 12 months old from the date of the declaration of beginning of activity.

The process of developing an innovation network is related to the very characteristics of the entrepreneurs at the initial stage of creation. When, for example, an entrepreneur develops his business plan within an innovation network, it is expected this will be of higher quality since he will be able to incorporate the benefits of the network in the plan: the closer the contacts between the various network actors, the higher the quality of information ([12]).

The entrepreneurial process, according to [21], consists of distinctive activities, such as identification of opportunities, mobilization of resources and creation of an organization. It follows that HEIs will be understood as actors *par excellence* to integrate an innovation network, since they possess teaching staff and various units of research that can help venture start-ups and young entrepreneurs to identify opportunities, mobilize resources and create an organization ([22], [9], [23], [24], [25]). In fact, they make key contributions by generating new ideas and knowledge and embedding them not only in the basic disciplines that are their traditional core, but in new programs as well. With the increase of demand for knowledge and practical applications these new programs tend to be more applied in nature and adapted to the world of work. A crucial distinction between applied programs and basic

disciplines is their orientation towards making a contribution to society beyond the walls of the HEI. To be sustainable over time, applied programs require a demand and interest outside the HEI. On the one hand, their development and evolution are typically formed by society's needs and interests; on the other, the evolution and development of basic disciplines tend to be moulded and influenced by the disciplines themselves (evolution of knowledge) ([11], [13]).

However, not even the addition of applied research and professional education generates sufficient spillovers from the source of knowledge – the HEI – to commercialize the increased generation of innovations in regional and national economies: to invest in traditional subjects and applied programs is not enough. In an effort to penetrate the knowledge filter and ease the spillover of generated knowledge and ideas from the HEI into the society, a third area has been developed representing the necessary means for transferring knowledge and technology created in the HEI, namely: technology units, incubators and research centres. These units have mechanisms that aim to facilitate the spillover of internal knowledge to the outside ([13], [26], [27], [28]).

As referred above, knowledge spillovers are the way of transferring knowledge directly or indirectly from one party to another ([29], [30], [31]). They are generated by institutions that have innovative activities and are valid because these activities provide knowledge that is new and relevant to the receiving institutions ([29], [30], [31]). Therefore, HEIs will transfer the knowledge they create through an innovation network, but will also receive knowledge and innovation generated by the various actors making up that network.

3. Research Design

To answer the broad question articulated in section 1, we started by reviewing the literature on current approaches on firm creation through models of innovation networks to support the basic idea of the importance of such networks in the process of firm creation since they allow weaknesses to be overcome and positive aspects to be strengthened, and consequently influence the process of firm creation. Our main intention with this paper is to study a specific set of factors within HEI and their contribution to firm creation within innovation networks, and therefore we will not join the debate on whether or not innovation networks do support this process by consequently exposing their possible flaws: we assume that they do play a positive role and that this positive role by far exceeds any negative facet.

The literature review enabled to design a questionnaire sent to 834 participants in entrepreneurship events promoted by state-owned HEIs in Portugal. The questionnaire results were submitted to factor analysis and the ensuing factors enabled the construction of a conceptual model (Figure 1), which was then subjected to logistic regression. Next we present and discuss these results.

3.1 Sample and data collection

The data used were gathered from a questionnaire administered to nascent entrepreneurs linked to HEIs in the state-owned sector in Portugal. The questionnaire contemplated potential entrepreneurs, i.e. people who were interested in starting a new business, who hoped to be the owners of a new business or of part of it, and/or who had been active in trying to start up a new business in the last 12 months ([32]). In this study, the population is made of all potential entrepreneurs from universities and polytechnics in the state-owned sector, that is, of individuals who participated, of their own free will, in events aiming at venture creation and/or at the development of entrepreneurial initiatives, namely: (i) entrepreneurship competitions (Empreenda'09, PoliEmpreende 6th Edition and START 2009) and (ii) technologically-based entrepreneurship courses (CEBT and CEBCT). The questionnaire was sent to 834 participants and successfully completed by 255, which represents a return rate of 31% and produces a sample error of 5,2% according to the calculation method suggested by [33].

3.2 Factor analysis

The majority of respondents are male, belong to the sub-system of polytechnic education and are part of the age group between 20 and 30. In the case of the university education, the age-group of the majority of the respondents is between 20 and 35. According to [32], the age of nascent entrepreneurs is related to expectations of return on investment, together with their academic qualifications, aversion to risk and the characteristics of the region where they live. It can be summarized that the respondents, whatever the sub-system of higher education they belong to, have in most cases a first

undergraduate degree, mostly Economics/Business or Engineering (around 91% of respondents). Another finding within the general aspects of the research is that respondents stated to be willing to pay for specific entrepreneurship training but, in their opinion, this should be included free of charge in their academic studies.

The data obtained from the questionnaire were subjected to factor analysis in order for us to reduce observed variables and get a potentially lower number of unobserved variables called factors. Considering our aim to *identify the practices developed by HEI to stimulate venture creation* we used factor analysis with principal component analysis and varimax rotation with the Kaiser– Meyer – Olkin KMO (0,80) method Bartlett Test of sphericity =631,879 and significance < 0,001 providing support for convergent validity. From the data analysis three factors emerged: *Factor 1 - Cooperation & development* (composed by Partnerships with HEIs; Post-graduate courses; Masters; Organizations; Partnerships with businesses); *Factor 2 - Scientific research* (composed by Conferences and Seminars; Dissemination through articles; Publication of pedagogical material) and *Factor 3 - Training* (composed by Entrepreneurship courses; Entrepreneurship competitions; Subjects included in degree courses). We find that cooperation and development, which cover various forms of cooperation with other organizations and consultancy, are believed to be the best practices developed by HEIs, as they reach a wide public and are an excellent way for HEIs to encourage entrepreneurial activities.

Concerning the objective of *identifying what facilitates venture creation*, the data obtained from the factor analysis allowed the identification of two factors: *Factor 1 - Network actors* (composed by Training provided by professionals in the business sector; Participation/proximity of the school to organizations related to entrepreneurship); *Factor 2 - Organizational resources* (composed by Services provided to the Community; Information, orientation and accompaniment provided by bodies existing in the school; Training given by teaching staff). Principal component analysis and varimax rotation with the Kaiser– Meyer – Olkin KMO (0,54) method were used, Bartlett Test of Sphericity = 93,994 and significance < 0,001, providing support for convergent validity.

Based on these results and on the literature review, we propose a conceptual model and a set of hypotheses as described in the chapter that follows.

4. Model and hypotheses

The proposed model is presented in Figure 1. It considers that the dependent variable – the propensity for new venture creation – is explained by a set of explanatory (independent) variables under the above mentioned two groups of factors: (i) “practices developed by HEIs” include: cooperation and development, scientific research, training supply; and (ii) “factors that facilitate venture creation” include: network actors and organizational resources.

Figure 1 Proposed Model

From the literature review and the conceptual model proposed, a set of hypotheses has been formed and will be tested empirically. Concerning the practices developed by HEIs that influence venture creation, the present research considers three factors: (1) the *cooperation and practices developed* by HEI in terms of partnerships with agents and business and courses that involve the participation of these partners; (2) *scientific research* comprising conferences, seminars, publications and other forms of dissemination; and (3) *training supply* provided by HEIs. Therefore, the following hypotheses are presented:

Hypothesis 1: The capacity the HEI has to cooperate and build relationships with other agents is positively related with the propensity of the nascent entrepreneur to create new firms.

Hypothesis 2: The capacity the HEI has to develop scientific research is positively related with the propensity of the nascent entrepreneur to create new firms.

Hypothesis 3: The training supply provided by HEIs is positively related with the propensity of the nascent entrepreneur to create new firms.

It should be noted however that, in a knowledge and information society, the people best prepared to create and grow ventures based on new technology, and therefore with high added value, able to compete internationally and create well-paid employment, are those who are technically better prepared and motivated ([10]). Both factors will contribute to increased entrepreneurial capacity and this, in turn, will influence future economic development ([34], [20]). Our aim is then to identify and analyze the *organizational resources of the HEIs and networks used by HEIs* to encourage venture creation. The following hypotheses are intended to investigate whether the second group of factors in the model influence the propensity of a nascent entrepreneur to create firms are presented:

Hypothesis 4: HEI networks with other agents influence positively the propensity of the nascent entrepreneur to create new firms.

Hypothesis 5: The organizational resources of the HEIs influence positively the propensity of the nascent entrepreneur to create new firms.

5. Logistic Regression Model

From the theoretical literature review and the proposed conceptual model it is clear that new venture creation is a complex phenomenon influenced by a wide range of factors. Being essential to our research to explore the relationships between these factors and the propensity for new venture creation, specifically the statistical relationship between one dependent variable and more than one explanatory variables, we decided to use the Logistic Regression Model (Logit Model). This model has been one of the most frequently used in empirical studies ([33]) thus constituting an appropriate analytical technique in terms of the proposed conceptual model since this includes one categorical dependent variable (binary or dichotomic), several independent variables, also categorical, and control variables, as follows:

$$NVC = \beta_0 + \beta_1 F_1 + \beta_2 F_2 + \beta_3 F_3 + \beta_4 F_4 + \beta_5 F_5 + \beta_6 F_6 + \beta_7 F_7 + \beta_8 F_8 + \beta_9 LE_1 + \beta_{10} LE_2 + \beta_{11} LE_3 + \beta_{12} LE_4 + \beta_{13} LE_5 + \beta_{14} AE_8 + \beta_{15} AE_1 + \beta_{16} AE_2 + \epsilon_i$$

Where: NVC = New venture creation; ϵ_i = error term β = Coefficients F_1 = cooperation and develop; F_2 = Scientific Research; F_3 = Training supply; F_4 = Network actors; F_5 = Organizational resources; F_6 = Prior entrepreneurial experience; F_7 = Prior experience in sector; F_8 = type of HEIs; LE_i = Level of education; AE_i = Area of education.

1) Dependent and Independent Variables: In this study the propensity to create new ventures is measured from the information gathered about potential entrepreneurs' intentions to create a new venture or to develop a new project within an existing venture. Thus the propensity of the potential entrepreneur to create a new venture is considered as the dependent variable (CNV). This dimension is a dichotomic variable based on binary data. It takes the value 0 for potential entrepreneurs who do not have the intention to create a new venture and the value 1 for those who have the intention to do so. Concerning independent variables, these are represented by the factors that stimulate venture creation (F_i). This research only took into account whether the factor functioned as a driver for new venture creation. The independent variables were subjected to factor analysis and are represented by the best practices that stimulate venture creation and by the factors within HEIs that facilitate venture creation.

2) Control Variables: We included the following controls for the potential entrepreneur: (i) prior experience; (ii) the type of HEI attended; and (iii) the subject level and area of education. "Prior experience" represents both experience as an entrepreneur and sector experience. Previous professional experience can provide useful skills that will be extremely important in the process of creating a business ([35]) and the survival and success of new organizations largely depend on their founders' previous experience ([36], [37], [38], [39], [40], [41]). The control variables *prior entrepreneurial experience* and *prior experience in the sector* are also dichotomic variables based on binary data: they take the value 1 if the respondent has prior experience and value 0 if he does not. [42] claims that the knowledge and skills entrepreneurs possess are not only the result of their previous professional experiences but of education too. Therefore the type of HEI attended is also considered a critical control variable and we distinguish it according to whether the subject attended a university or a polytechnic institute. The variable *type of HEIs* is again dichotomic based on binary data: it takes the value 1 for university and value 0 for polytechnic institute. Other critical control

variables are directly linked to the level and area of education of the nascent entrepreneur. In order to measure levels of education, five variables were created: (1) primary; (2) secondary; (3) undergraduate; (4) master and (5) doctoral level. As to area of education three variables were created: (1) economics and management; (2) engineering and (3) other areas of education.

According to the Wald statistics we detect that all the estimates of the regression parameters are statistically significant up to 5%, except for the relationships established with competitors. The regression results for the model show that not all regression parameter estimates are statistically significant at a level of 5%. Regarding adjustment quality of the model, the results show that the predictive capability of the model is 82,7%, which is a consequence from the comparison between the values of the variable "response values" predicted by the model and those observed. The Chi-square statistic test has a value of 77,281 with proof value less than the significance level of 0,001. The log-likelihood statistics, with a value of 191,797, corroborates the global significance of the model.

Hypothesis₁ relates the propensity of the nascent entrepreneur to create new firms with the capacity of the HEI to cooperate and build relationships with other agents and to develop courses that involve the participation of these partners. This hypothesis is presented as being significant at a level below 0,05 and with a positive effect. In this way, the nascent entrepreneurs linked to HEIs that have cooperation and develop these practices are more prone to create a new venture than others. This finding is corroborated by results obtained by [25], [14], and [41]. *Hypothesis₂* associates the capacity of the HEI to develop scientific research with the propensity of the nascent entrepreneurs to create new firms. Results show that this capacity does have a positive and significant effect in the propensity of the nascent entrepreneurs to create new firms (0,672) thus strengthening the conclusions of studies carried out by [26], [14], and [25]. *Hypothesis₃* is aimed at studying empirically if the training provided by HEIs relates positively with the propensity of nascent entrepreneurs to create new firms. However, results show that the training supply provided by HEIs does not have statistical significance in the model, so there is no conclusion to be drawn from the effect of this factor. *Hypothesis₄* associates the capacity of the HEI to develop contacts between the various network actors with the propensity of the nascent entrepreneurs to create new firms. Results show that this capacity has a positive and significant effect in the propensity of nascent entrepreneurs to create new ventures (0,687), which supports the conclusions of studies carried out by [12], [23], and [14]. Concerning *Hypothesis₅*, the results do not have statistical significance in the model. Therefore nothing can be concluded as to the influence of organizational resources of the HEI on the propensity of nascent entrepreneurs to create new firms.

By adding the control variables we intended to test the robustness and consistency of the explanatory variables of the final model compared to the initial model. With this inclusion and analyzing the explanatory variables of the final model compared to those of the initial model, we found they have the same behaviour, concerning both the exact estimate of parameters and the level of significance. It is therefore possible to confirm the consistency of the variables and the robustness of the model.

6. Conclusions

This study is a guide to allow higher education institutions to identify and analyze the possible relationships between the nature of HEI actions and new venture creation within innovation networks. As the literature demonstrates, venture creation is influenced by a vast and complex number of factors, which only partially are dealt with in this study as per the model in Figure 1. However, a set of internal and external factors of HEIs stood out as being able to influence venture creation within innovation networks. By analyzing the contribution of each one of these factors to the phenomenon of venture creation triggered by HEIs, it was found that the variables associated with HEIs and innovation networks are connected to the relationships HEIs form with existing organizations, with the knowledge they have available, with the training they provide, and with the forms and activities that stimulate venture creation and which they use.

As to *identifying the practices developed by HEIs to stimulate new venture creation*, according to the literature, cooperation and development are considered the best ways for HEIs to encourage entrepreneurial activities. However the respondents in our study also favour scientific research, a situation that will probably have to do with the demands of the market to guarantee the creation and development of new businesses by nascent entrepreneurs. Regarding the objective of *identifying what facilitates venture creation* the nascent entrepreneurs surveyed selected as the most important the factor "network actors". As the very name indicates, this factor covers whatever incentivizes and dynamizes the diverse elements integrating the innovation network, promoting knowledge sharing and support to nascent entrepreneurs at the various stages of venture creation. Concerning *prior*

experience, we can conclude that a prior entrepreneurial experience influences positively the propensity of the nascent entrepreneur to create new firms. From the answers given by the respondents, we can verify that the nascent entrepreneurs with previous entrepreneurial experience have an advantage in developing activities related to creating new firms compared to other entrepreneurs. We can also verify that a prior sector experience influences positively the propensity of the nascent entrepreneur to create new firms because they have an advantage in developing projects and in creating firms, compared to others. Therefore we can conclude that previous experience in the sector has a significant and positive effect on nascent entrepreneurs' propensity to create firms. This study is not, of course, without limitations. The main limitation is certainly that the subjects are only drawn from participants in selected competitions and training courses. Considering how important it is for Portugal to get broader and deeper understanding of the factors that HEI can improve in order to increase venture creation, future research could broaden this scope and could also study the various ventures formed identifying which institutions stimulated their creation.

We analyze how innovation in the U.S. wind energy industry has been impacted by changes in federal government wind energy R&D funding and by technology information flows from wind turbine manufacturers in Europe.

The U.S. is the birthplace of the modern wind industry, with policy initiatives following the 1973 oil crisis resulting in the California “wind rush” and the development of wind farms in the 1980s. However, the industry soon became dominated by European firms, with Danish manufacturers responsible for half of the turbines in the U.S. by 1986. During the late 1980s and 1990s, U.S. manufacturers continued to lose ground to European competitors, particularly from Denmark, Germany and the Netherlands. However, several “green energy” policy initiatives revitalized the U.S. industry from 1999 on. Since 2005, the number of new wind energy installations in the U.S. has grown by 50 percent a year, and the increasing demand for wind energy has spurred domestic production of wind turbines.

We find that reductions in government wind energy R&D funding have resulted in greater technology transfers in wind energy innovation from Europe to the U.S., but that a larger impact on technology transfers comes from rising oil prices.

Keywords

Innovation, patents, wind energy

1. Introduction

The U.S. is the birthplace of the modern wind industry, with policy initiatives following the 1973 oil crisis resulting in the California “wind rush” and the development of wind farms in the 1980s. However, the industry soon became dominated by European firms, with Danish manufacturers responsible for half of the turbines in the U.S. by 1986. During the late 1980s and 1990s, U.S. manufacturers continued to lose ground to European competitors, particularly from Denmark, Germany and the Netherlands. However, several “green energy” policy initiatives revitalized the U.S. industry from 1999 on.

During the last few years, the number of new wind energy installations in the U.S. has grown rapidly, and the increasing demand for wind energy has spurred domestic production of wind turbines. By 2008, the U.S. had passed Germany to become the world’s largest producer of energy from wind and with the world’s largest installed capacity of wind power [1]. The U.S. wind industry broke industry records by installing close to 10,000 megawatts of new wind power capacity in 2009 [2], but China became the largest manufacturer of wind turbines [3].

U.S. President Barack Obama put great emphasis on creating incentives to invest in clean energy in his January 27 2010 State of The Union address stating that “providing incentives for energy-efficiency and clean energy are the right thing to do for our future – because the nation that leads the clean energy economy will be the nation that leads the global economy” [4]. In April 2010, the Obama administration gave approval for the country’s first offshore wind farm, to be built off the coast of Cape Cod, Massachusetts.

In this paper, we analyze how innovation in the U.S. wind energy industry has been impacted by U.S. government funding for wind energy R&D and by technology information flows from wind turbine manufacturers in Europe. The extent to which manufacturers in the U.S. wind power industry “learn” from inventors and competitors in other countries has relevance to the manufacturers themselves (in terms of their own R&D efforts) and to policy makers (in terms of the optimal level and form of government incentives). For example, [5] investigate the effect of international knowledge flows on the development of innovations that deal with reducing or stabilizing greenhouse gas emissions. They use a World Induced Technical Change Hybrid (WITCH) model to simulate a transmission channel across research sectors and find that including international knowledge spillovers results in lower levels of optimal R&D investments, particularly in high income countries.

2. Literature Review

The focus of our paper lies in the intersection of two research areas: (1) Innovation in the wind energy industry and (2) knowledge flows.

2.1 Innovation in the Wind Energy Industry

Because it is relatively young, few researchers have looked at innovation issues in the modern wind power industry. [6] study the effect that public R&D has on cost reducing wind turbine innovation in Denmark, Germany and the U.K. during the 1990s. [7] model how different government policies affect the diffusion and innovation of wind power, with estimations using data for Denmark, Germany, Spain and the U.K. from 1986-2000. The learning curve models used by both [6] and [7] involve learning-by-doing and learning-by-searching, but do not account for knowledge spillovers between countries. [8] find that the major piece of national legislation dealing with wind energy incentives in the U.S. – the Federal Renewable Electricity Production Tax Credit (PTC) – is a significant stimulus to wind power capacity. They also find that the off-again/on-again nature of the PTC has led to erratic growth in capacity investment, with installations peaking in years when the PTC is set to expire. Using U.S. patent data for 1970-1994, [9] finds that energy-saving innovations are affected by both energy prices and the stock of energy-related knowledge. The energy areas [9] looks at include coal and solar, but not wind energy. [10] extends this analysis to investigate the issue of the quality of the knowledge stock of such energy-related patents. He finds diminishing returns to the usefulness of energy patents and a higher likelihood that government energy patents filed after 1981 will be cited by others than for those government patents filed earlier.

2.2 Knowledge Flows

Within the literature on the diffusion of technology, the subsection dealing with international knowledge spillovers falls into two categories: (1) those obtained through foreign direct investment (FDI) or international trade and (2) those obtained directly from the R&D performed in foreign countries. There is much agreement that trade and FDI have a positive impact on technical diffusion. [11] and [12] find that international trade plays a significant role in technological spillovers in developed countries, while [13] and [14] get similar results for developing countries. Positive spillover effects have also been found for FDI flows [15-17]. There is also general agreement that R&D has a positive impact on the international diffusion of technology, with patent data frequently used to measure spillovers. For example, patent citations are used by [18] to measure spillovers from the U.S. and Japan to South Korea and Taiwan, by [19] to measure spillovers in the U.S., German and Japanese automobile industries, and by [15] to measure spillovers arising as a result of Japanese multinationals undertaking direct investment in the U.S. It is also important to recognize that the diffusion of technology may work differently for different countries. For example, [20] find that the technology embodied in imports is the primary method through which knowledge is transferred from the U.S. and the U.K., that non-trade channels are the primary conduit of technology diffusion from Germany and Japan, and that both trade and non-trade channels are relevant to technology diffusion from Canada and France.

3. Methodology

3.1 Data

We obtain data on public R&D spending on wind energy and the price of oil in the U.S. and Germany from 1985 to 2005 from the International Energy Agency's online database (<http://www.iea.org/stats/rd.asp>).

We obtain patent data from the U.S. Patent and Trademark Office's online patent database (<http://www.uspto.gov>).

The application and approval process for U.S. patents involves a search of existing domestic and international patents, which are known as "prior art." Patents must list the relevant prior art as citations or references, along with their country of origin. Included in the patent's information is the country of origin of the inventor or co-inventor, as well as the country of origin of the patent's owner (assignee). Thus, for example, a patent listing Clipper Windpower as its assignee might have an individual in Denmark as its inventor and include references to U.S. and German patents as prior art.

The international flow of knowledge could show up in the U.S. patent system as (i) wind energy-related innovations made by an inventor in another country and patented in the U.S. and (ii) innovations made by an inventor in another country which are patented in that country and subsequently cited as "prior art" by wind energy-related innovations patented in the U.S.

We thus measure the knowledge spillovers from either Germany or Denmark to the U.S. wind energy industry by counting the number of granted U.S. patents which explicitly refer to wind energy, wind turbines, or wind power and which

1. have an inventor from the relevant country (Germany or Denmark) *or*
2. cite a patent from that country

We restrict our analysis to spillovers from Germany and Denmark because of the lack of consistent wind energy patenting and citations arising from other countries during the time period of our study.

As it can take several years for a patent application to be either granted or denied, we use 2005 as the cutoff date. Unfortunately, the patent review process varies. Several researchers have found that the patent examination process takes longer for more important/more complex innovations [21-24], while others have found a longer examination time as the result of procedural options chosen by the applicant, possibly as a deliberate strategy [25-26]. To test if there is a significant effect from patents filed in 2005 that have not yet been granted, we ran a specification of the base model with a 2005 dummy variable. Because this dummy is not significant, we do not include it in the specification of the model below.

Though there is an extensive literature using patent data to measure spillovers it is not a perfect measure. A major concern is the extent to which patents and citations accurately reflect spillovers of knowledge. Patents exhibit spatial relationships: [27] find that citations to patents are more likely to come from the same state and the metropolitan statistical area, while [28] find that a firm's patents are more likely to cite other patents from that firm, and inventors are more likely to cite others from the same country.

[27-30], amongst others, find patent citations to be a valid, albeit "noisy," measure of technology spillovers, and conclude that "aggregate citation flows can be used as proxies for knowledge-spillover intensity...between countries" [30], p. 218.

In their analysis of the geographic localization of patents and citations, [27] discuss three classifications that are relevant when using patent citations to measure spillovers. Adapting this to reflect our choice of counting patents with a foreign inventor as well as patents with foreign citations, the relevant classifications are: (1) spillovers accompanied by foreign citations/inventions; (2) foreign citations/inventions that occur where there was no spillover; and (3) spillovers that occur without foreign citations/inventions.

Our study focuses on the first classification. The second classification above is the most problematic in this field. [27] posit that most of the citations occurring when there is no spillover involves citations of patents that the inventor was not aware of and that were added by the patent examiner. They argue that such citations would not exhibit a geographic bias, and that a large number of such citations "introduces 'noise' into citations as a measure of spillovers, and biases the results away from finding significant localization" [27], p. 584.

The third classification reflects spillovers that would not be counted in our analysis. These types of spillovers would imply that our citation/inventor data undercount the volume of spillovers. [27] argue that spillovers that do not generate a citation are more likely to be a result of extremely basic rather

than applied research, as the former is more likely to be disseminated via non-patent means, such as journals.

Another problem with relying on patent data is an apparent change in the propensities to patent in the U.S. [31] attribute part of the surge in patenting in the U.S. since the mid 1980s as a reaction to the strengthening of patent protection, highlighted by the formation of the Court of Appeals for the Federal Circuit in 1982. As the starting year for our knowledge flow data is 1985, our expectation is that changes in patent protection in the early 1980s would certainly contribute to a larger propensity to patent during the time period of our study (compared to earlier decades), but not to a *change* in the propensity to patent *during* that period.

In contrast to [31], [32] find that the increase in patenting since the mid 1980s is due to an increase in research productivity as a result of a shift in focus away from basic to applied research. Over time, patents have also increasingly been granted for minor innovations, compared to the more substantial scale of innovation representative of patents in earlier decades. [33] blame this in part on changes started by the U.S. Congress in 1990, which converted the USPTO from being funded by tax revenues and nominal patent application and maintenance fees to being funded by its own fees. These changes in the type of research undertaken by firms and an increase in the “patentability” of innovations could result in a greater number of patents with foreign citations/inventors over time and would thus bias our results. As shown in the Model section, we address this by including a time trend variable in our analysis.

Another issue to consider is how the propensity to patent varies across firms. [34] find that, controlling for the level of innovation output, smaller firms are less likely to apply for a patent. As shown in the Model section, we address this by deflating the variables by the total number of wind energy patents.

3.2 Model

We begin by modeling knowledge spillovers from the foreign country to the U.S. as a Cobb–Douglas style production function. Following [36], [31] and [37], the expected number of patents obtained by a firm in any given year can be hypothesized as an exponential function:

$$(1) \quad E[\text{PATENTS}_{kt} | X_{kt}] = \lambda_{kt} = \exp(X_{kt}\beta)$$

where X_{kt} consists of the independent variables listed above. This estimation can be handled by a Poisson fixed-effects regression since *SPILLOVERS* is a non-negative integer:

$$(2) \quad \text{SPILLOVERS}_{kt} = \alpha + \beta_1 (\text{PERCENT WORLD CAPACITY}_{kt}) + \beta_2 (\text{PERCENT WORLD CAPACITY US}_t) + \beta_3 (\text{CHANGE US FEDERAL R\&D}_t) + \beta_4 (\text{POSITIVE CHANGE US FEDERAL R\&D}_t) + \beta_5 (\text{RISING REAL OIL PRICES}_t)$$

where

SPILLOVERS_{kt} is the number of granted wind energy patents that were applied for in the U.S. in year t , which cite a patent from country k or which have an inventor from country k .

$\text{PERCENT WORLD CAPACITY}_{kt}$ is the natural log of the wind energy capacity installed in country k in year t , divided by wind energy capacity installed worldwide in year t . This is a proxy for how important wind energy is in country k .

$\text{PERCENT WORLD CAPACITY US}_t$ is the natural log of the wind energy capacity installed in the U.S. year t , divided by wind energy capacity installed worldwide in year t . This is a proxy for the changing US interest in wind technology.

$\text{CHANGE US FEDERAL R\&D}_t$ is the natural log of the absolute value of a year over year change in U.S. Federal spending on wind energy R&D in year t . U.S. Federal R&D spending shows the level of support for wind technology from the U.S. Federal Government.

$\text{POSITIVE CHANGE US FEDERAL R\&D}_t$ is the natural log of the absolute value of a year over year change in U.S. Federal spending on wind energy R&D in year t if the change in federal spending is positive. This allows us to follow both the negative and positive changes in Federal R&D.

$\text{RISING REAL OIL PRICES}_t$ is a dummy variable that is 1 if the price of oil is rising in year t . This tracks the change in price of a substitute for wind energy.

In Table 1 we provide the summary statistics for the independent variables.

Table 1 Summary Statistics

Variable	Mean	Std. Dev.
PERCENT WORLD CAPACITY _{kt}	-2.12	1.60
PERCENT WORLD CAPACITY US _t	-1.18	1.62
CHANGE US FEDERAL R&D _t	1.61	1.50
POSITIVE CHANGE US FEDERAL R&D _t	.67	1.13
RISING REAL OIL PRICES _t	0.54	0.50

Two issues that we need to address with the model are heteroskedasticity and the possibility of a unit root. Tests for heteroskedasticity can not be rejected; we address this by using robust (White corrected) standard errors. Using a Fisher-type unit-root test, the null hypothesis of “all panels contain unit roots” is rejected with $p < .01$ for all variables, but with drift. We control for drift by including a trend variable in the model. In addition, Table 1 suggests there is overdispersion for some independent variables. Using robust standard errors with the Poisson regression should provide consistent estimators.

4. Results

Table 2 shows the results from the Poisson regressions.

Table 2 Basic Model Results

Variable	Fixed Effect Poisson Model
PERCENT WORLD CAPACITY _{kt}	.023 (0.62)
PERCENT WORLD CAPACITY US _t	.074* (2.28)
CHANGE US FEDERAL R&D _t	.167*** (3.55)
POSITIVE CHANGE US FEDERAL R&D _t	-.117* (-2.42)
RISING REAL OIL PRICES _t	.392*** (3.95)
Year	.163*** (19.96)
N	70
T stats below coefficient found using robust standard errors	
* $p < .05$; ** $p < .01$; *** $p < .001$	

The coefficient on *PERCENT WORLD CAPACITY US_t* shows that an increase in the relative importance of wind power in the U.S. results in greater knowledge spillovers to the U.S. However increases in the same variable for other countries does not. Decreases in U.S. Federal R&D result in increases in spillovers from other countries. Increases in U.S. Federal R&D (the joint test of *CHANGE US FEDERAL R&D_t* and *POSITIVE CHANGE US FEDERAL R&D_t*) do not give a statistically significant effect. Finally, *RISING REAL OIL PRICES_t* generate positive knowledge spillovers to the U.S.

From previous studies, such as [8], it has been shown that the changes in U.S. tax incentives have resulted in increased installation of wind energy generation. This increase in needed generation has resulted in an increase for information being cited from the countries that have been leading in wind energy technology though the 1990s and early 2000s. However, decreases in U.S. government spending on R&D for wind power actually increase the spillovers measured by citations from other counties. This could be a result of government funding more basic research with the limited

engineering capacity for wind R&D. Finally, the strongest incentive for spillovers is changes in the price of substitute energy costs. Rising energy costs result in more capacity installation, but also lead to a need for better technology faster. The combination shows that incentives for private sector investment in wind energy result in greater cross country spillovers than government funded R&D alone.

Code of ethics as a tool for Innovations in ethical Practice in the Organization

Andriana Skerlev-Cakar¹

¹Lawer,MSHRM, skerlevcakar@gmail.com

Today most experts from the international business, agree that what is essential for the business in 21st century actually for the global economical survival in business, is the need from looking for more innovative ways for building an international business ethical code, and not ethical codes which will origin from every individual culture, which on other hand is supported by it selves' other norms and practices.

For the ethical code to have a meaning, it must be clearly stated the basic principles and expectations; have to deal with the potential ethical dilemmas that the employees are faced with; and must be applied. It must be accepted and adopt by the staff because that is the condition for its use. That means that, the managers must take into account not only the content of the code but the process of determination of its content. But, for a code to be applicable wider internationally, managers should incorporate more innovative ways for communication during the process of creation of the code, for to facilitate specific ethical challenges.

Key words

Code of ethic, Communication, Organization.

1. Introduction

Ethics, values, rules of conducting! It is heard and talk about this every day. What do they mean and how the organizations can be sure that they have developed and implemented them right? It comes to the point where the question is: Is the term „organizational ethics”, by itself maybe contradictory?

In a time like today's, the challenge to provide ethical behavior in the organizations, maybe seems to hard. But, it is a challenge that shouldn't be ignored by the organizations, even if they have a feeling that the ethical code is not worth the paper on which is written, or even if the one who is on power wants totally to ignore the need of adoption. To provide a ethical code that could be applicable wider, among the organizations that are communicating internationally, is even more difficult.

The results of the interview conducted by Meredith Livingston, the author of the text "Ask the Ethicist", showed that 90% of the managers think that: " The ethical enigmas, are not coming in the some packet with the work!". The logic says that most of the managers would say that they collide with ethical dilemmas which come from their every daily duties that have been given to them, the regulations that need to harmonize their operations, and the many scandals in the organizations that we so often hear over the media. But, the managers "do not see" the ethical problems, that do not disappear. This only makes the whole situation worrisome. If a manager says that he never faced an ethical issue in his working, than he doesn't live in the real world.

It is a good start for start building or rebuild the ethical culture in the organizations is the formal adopting of an ethical code. For most managers, this means writing and implementing ethical recommendations, also a presenting of the existing values in the organization, or organizations that are doing their businesses internationally.

The literature of the business ethics is separated on few points of view, which talk about the motivation, and also for the reasons, why the business would have an ethical dimension. According to Harrison (Harrison J. 2001), there are two major schools of opinions. In the first one, belong the ones which assume that the companies, actually the organizations are institutions which drive profit and that is why the business ethics for them is just another way to win customers. The second one is supported by the corporate conscience and initiate motivation for acceptance of the business ethics. According to Paul (Paul S. 2001), the business ethics is considered for subjective by its nature and depends of the time and the culture.

It was established the claim that by passing of time, the business ethics included different cultural values and norms which lead it outside the frameworks of different national and regional boundaries. One of the major surveys performed in 1983 from Hofstede (Hofstede G., 1983), where were taken into account the national values, it showed that there are big differences in the ethical values among different nations, and also in the business ethics. The globalization, combined with the standardization made the businesses financially successful, but in the same time an efforts were made to create standardized guidelines for business ethics, outside of the national boundaries.

But, as far as business is considered, the ethical code is generally considered as an act which teaches from ethical aspect, what is good or bad in the workplace, and helps the decision made to aim the goal. The ethical codes are rules which helps to operate the ethical values when deciding. They are a sign of ethical philosophy of the company. The ethical codes are systematic set of relatively precise formulated moral norms of one certain moral, determinate by a written act, prepared by a people who are representatives of some group. Actually, that are statements for the norms and certificates of the organization and they express how the people on high levels in the company want others to think.

It is not a censorship. In the code are clearly marked the norms and the values of the groups. This kind of form provides the moral which creates, to enter fast in the peoples consciousness. The codes are important mechanism that can be used by the organizations as a tool that will signal the ethical direction in the organization. The intent of the organizations in adopting ethical codes is to encourage a certain manner of thinking and a model that will lead to the desired behavior.

2. Ethical code as a tool for innovations

In the researches performed by Ethics Resource Center in Washington, USA, the codes are seen as best mechanism which provides the ethical behavior. So, in 1987, the Centre performed a research in 2000 organizations in the USA, and a subject of research were their ethical programs and problems. The results from the research showed that most frequently used form for strengthening of the ethical behavior are the company's codes (79% of respondents), lectures (63%), seminars (53%), the case studies (46%), the film forwarded by a discussions (41%). So, according to Frank Navran from the same Ethics Resource Center, Washington, USA, in the article published in 2002, states that the interest of the organization for creating a code in the most cases is because of the need to strength the mechanisms for „soft control”, whereby often wants to conclude the following:

- Organization security;
- Public opinion;
- Respecting of the law;
- Regulation of the behaviour.

For the ethical code to have a meaning, it must be clearly stated the basic principles and expectations; have to deal with the potential ethical dilemmas that the employees are faced with; and must be applied. It must be accepted and adopt by the staff because that is the condition for its use. That means that, the managers must take into account not only the content of the code but the process of determination of its content.

To be efficient, the ethical code should develop and expanded in open, participative surrounding, including as much as possible employees. The building and the implementation of an ethical code is important for all of the organizations no matter their size. Besides that with the ethical code is projected the idea for honesty and openness in relation to business that the organization is concerned, the code can be used as a tool to encourage the employees to properly solve the problems found in the working place. But, for a code to be applicable wider internationally, managers should incorporate more innovative ways for communication during the process of creation of the cod, for to facilitate specific ethical challenges.

3. Internationalization of the business ethical code

Most experts from the international business, agree that what is essential for the business in 21st century actually for the goal economical survival in business, is the need from building an international business ethical code, and not ethical codes which will origin from every individual culture, which on other hand is supported by it selves' other norms and practices.

In the past decade many companies as Borg-Warner Corporation, Whirlpool, Johnson&Johnson have developed ethical codes published in their brochures, annual reports and programs for introducing the code. The study of the Ethics Resource Center, Washington, USA from 1979, indicates that more than 70% from the major corporations have ethical codes. The companies that want to have an influence of the ethical standards, as a first step in the process, introducing ethical codes. The Center estimates that more than 90% of the companies that are taking further steps to institutionalize the ethics announced their own ethical codes. The codes are often transmitted over written materials, using the advice of superiors, discussions for employments or at workshops and seminars.

The analysis, that was performed by the author of this paper was made on 22 ethical codes, among them were independent broadcasting authorities in Europe in the area of broadcasting, large global companies, local organizations, also codes of public administration and companies that are dealing with different business in Republic of Macedonia, provided to distinguish the following mutual general characteristics of the ethical codes, that makes them applicable wider internationally.

Ethical codes:

- They clarify the opinions of the managers for what it constitutes unethical behavior;
- Helps the employees to think for the ethical issues before they face with a real situation;
- Allow to the employees to refuse performing of unethical actions;
- Define the boundaries of acceptable or non acceptable behavior;
- Provide a mechanisms for conveying the philosophy of the managers in the area of the ethical behavior;
- Help to introduce the employees with the ethical behavior and the proper training.

All of these ethical codes had a list of principles of international ethics that were followed, including:

- **Integration** – Business ethics most take into account all the aspects of the organizational culture and to reflect the key systems for managing. The organizations start with integration of the ethics by setting goals and establishing of practices. When they promote the workers on higher levels within the company, the ethical principles should be stimulated over ethical programs.
- **Implementation** – The ethical behavior it is not just an idea. It refers to implementation of a plan for changing of certain parts from the working of the organization. Some examples show that those are efforts for modifying the personal valuable process, to make a promotion of the proven practices from the environment, and calls for help from the experts , when that is necessary.
- **Internationalization** – Increased internationalization, is a need which characterized all successful businesses of the 21st century. Internationalization is achieved by forming intentional partnerships, commercial blocks, implementation of GATT and other agreements for free trade. So, it is needed a clarification and confirmation of the organizational definition for the integrity, which transcends the national boundaries.

Also, all of the codes that were analyzed were composed from those four parts:

- Creed or a statement for the organizational philosophy or values;
- Guidelines for making decisions;
- Specific rules that prohibit certain actions or require certain behavior; and
- Definitions and illustrations;

For a code to be applicable wider internationally, it should be appropriate distributed among all the parties that will be affected by it, so they to know the standards and to understand the meaning of the code for their work. The conversations for the ethical codes should encourage an open atmosphere where all the employees from all the organizations that are expected to be affected by the code and are planning to accept it, to be encouraged to ask and to give suggestions about the code. There are organizations that support the idea working units to develop their own specific codes which refer to specific dilemmas that are faced in their working. These organizations consider that the participative methods are increasing the opportunity the codes to play the central role in conducting of the ethical behavior in the framework of their organizations. On the other hand, there are such an organizations that do not attach such significance of their own ethical codes. One of the ways for raising the awareness and acceptance of the ethical code from the employees is the organization of an ethical

training. However, no cooperative effort of the organization to influence of the ethical behavior will not succeed if it is not supported by the top management and by the culture of the organization. One of the manners for implementation of the support is forming of a structural mechanisms for the implementation of the ethic. There are many mechanisms that can be applied by the organization, created in aim the management can be informed about the ethic. Among the other things, those mechanisms are: monitoring of the ethical behavior of employees, transfer notices regarding the ethical policies, ombudsmen for ethical issues, reporting about ethical violations, etc.

4. Conclusion

Certainly, there is not an ideal or universal approach to the organizational ethics. Some organizations start with a creation of a creed that later is transformed to a code, and other are adopting a decision for creation of a code. The creation of a moral climate originates from the top management. The raising of the ethical awareness in the organization is not a simple process. It is necessary to communicate, many meetings, many hours spent, and a certain amount of money to create a good code which will communicate with all the employees and organizations to which it will refer to.

Although the existence of a business ethical code will not solve all the ethical problems, it is very useful for the organizations and for the society as a whole. Clear ethical code and clear ethical standards, are providing to the organization strict directions that provide handling with different situations in the interior relationships in the organizations by themselves, but also in the relationships out of them. Often, the interior ethical dilemmas are not black or white types of situations. They are complex problems, that require well defined politics which provide fair and moral management.

For the employees, the clear statement for the ethical politics that leads the organization, is very helpful for them to align their personal values with the values of the organization, and in that manner to create a strong relationship on the working place, with the colleagues and the superiors. The ethical code provides a tool to the employee as an individual from the possible abuses by the managers without scruples, i.e. the managers who don't care. Also, a well-defined code, it helps the worker as an individual, in the operation and management, in the conducting of a surveillance over those that are aligned, built teamwork associated with pride in performing everyday tasks that ultimately contributes to increased satisfaction from the work and productivity. Hence, the managers of the future will benefit from the moral and ethical standards that are introduced today. In the external relations with suppliers, customers, shareholders, the solid ethical code, is the best way to contribute in ensuring of the avoidance of making decisions, which in extreme cases could lead to government intervention and prosecution.

The ethical behavior in the organizations is a complex problem expressed by individual and situational dimensions. The efficient implementation of the ethical behavior requires from the organization to adopt ethics. Also, for a code to be applicable wider internationally, managers should incorporate more innovative ways for communication during the process of creation of the code, for to facilitate specific ethical challenges. However, organizations should be interested in those who produce behavior that it is required by the organization in the current period, because maybe next year will be necessary to include other, values different from the already established.

Use of Intelligent Agents and Rule Based Expert Systems in everyday Logistics Operations

Kostadin Solakov¹

¹*Infinite Solutions, Skopje, Macedonia, kostadin.solakov@infinite.com.mk*

In a World where technology is becoming increasingly integrated into so many aspects of our lives and society, operations planners are confronted with more data and information than ever before. To effectively make use of this data, a decision maker must be able to consider many different perspectives, and be able to analyze information to extremely detailed and specific levels. With emerging business concepts such as agile operations handling, it is more important than ever to ensure that an organization has the ability to react, and even be proactive, to changing demands and disruptions. In the modern-world evolution towards agile and responsive organizations, new approaches and methods will be required to assist decision makers in logistics operations planning. Having the right information at the right time will be, and always has been, essential.

The search for the right information to in order to perform critical decision-making can be a never-ending process. Sometimes acquiring the right information can be an expensive task, but there are also many cases where the best information is freely available from one of our society's largest and most valuable data resources - the World Wide Web. The problem with data mining the WWW is that the information contained there is typically unstructured, scattered, and meaningless if not combined together. The field of Computer Science has evolved significantly in recent years as new technologies have emerged, notably the "semantic web." These enhancements to the WWW are represented by a group of methods and technologies that allow machines to understand the meaning – or the "semantics" - of the presented data. Using this semantic meaning, the WWW can be used as an endless source for data from which information could be derived.

Simply obtaining the right data, or possessing the right information, may not always be enough to engage in decision-making. If operation planners do not have access to the right tools, this pool of useful information may easily become an ocean of useless data. Rule driven Intelligent Agents and Expert Systems can be used to process this data, help solve problems, identify alternatives, and provide advice based on the data that is fed to them. The goal of this resultant system is to develop a knowledge-base matching or exceeding the equivalent knowledge of a "human expert" in a particular field, with continuous improvement and learning capability based on a feedback loop of data inputs.

This paper studies how the data provided by internal (or intercompany) systems and on the Semantic Web can be processed by these Intelligent Agents and Experts Systems, and later be used as an input in the decision-making processes that are part of everyday Logistics Operations. Additionally as an example, industry related conceptual model is analyzed and compared against the current process models, with specific focus on advantages and benefits.

Keywords

Expert Systems, Innovative processes and models, Intelligent Agents, Logistics Operations, Process automation

1. Introduction

Deployment of the latest technology alone may not always result in creating new economic value and market growth of the enterprise. Value and wealth are created when companies combine technology with new ways of doing business; i.e. when some innovative technology triggers change in the way a business process is executed. Typically technology is used to automate certain stages of common business processes, and automation and optimization of tasks and processes can already be seen in various commercial, governmental and nongovernmental organizations. Common processes such as forecasting, supply chain management, Enterprise Resource Planning (ERP), Customer Relationship Management (CRM) and Human Resources (HR), are the most typical areas of focus in modern enterprise automation [1].

The Council of Logistics Management provides the following definition: "Logistics is that part of the Supply Chain Process that plans, implements and controls the efficient, effective flow and storage of goods, services and related information from the point of origin to the point of consumption in order to meet customers' requirements." The definition itself indicates that within these processes exists constant interaction and communication between the actors, and that there are many entities involved. The Internet along with its related technologies enabled these systems to become interconnected through well known standards for exchanging data, and in this way digitalizing the business processes. The data that is part of these processes can be combined in new ways to automate an increasing array of broader activities, from inventory management to customer service. Accumulated pools of data captured in a number of systems within large organizations or pulled together from many points of origin on the Web are the raw material for new information-based business opportunities. [2] Moreover, the aggregation of data through the digitization of processes and activities may create by-products, which companies can include as an input in their current internal business processes, or exploit them further for additional profit.

Even if all systems in one enterprise are fully integrated, and all tasks that can be automated are fully enhanced, the information that is used by the actors during the decision making processes comes only from internal sources. Collaboration and integration with systems that reside outside of the enterprise boundaries is limited and in most cases actions from some human actor must be taken for the task to be completed. The human actor in these cases acts as an aggregator, whose duties are to collect data from external sources and feed them in the "machines" that are part of the process flow. These "machines" process the data and use it in the decision making processes. We do not need any BPM (Business Process Management) [3] tool to identify the bottleneck in this scenario.

When you have things automated is when your business is running in its most efficient manner. Automation generally allows an organization to increase its operational efficiency. The goal of automation is to integrate human intervention only where it is absolutely necessary. This is already commonly achieved in a substantial amount of internal processes, for example in scheduling for production, or in manufacturing management systems. In these two examples, the human factor is replaced by intelligent systems that are trained and capable of decision making, using facts and rules that are stored in their knowledge base. The purpose of applying intelligent systems to solve scheduling problems is to make the scheduling system easier to design and implement, more robust and less prone to errors, easier to use, faster, cheaper, etc. These artificial intelligent systems have the knowledge of their human counterpart, or even from several human experts, but are capable of generating decisions in significantly shorter time frames.

While Decision Support Systems (DSS) can be very useful when they are implemented in a controlled environment (such as production and manufacturing management system), their usability is limited for interconnected systems and services which do not follow strict rules and patterns, and for systems within highly dynamic environments. The Internet and the World Wide Web (WWW) – with an almost endless source for information – clearly belong within this category. To automate data capture from highly dynamic sources, the systems that will work as aggregators must be both flexible, and capable of learning and later acting accordingly.

2. Intelligent Agents

Intelligent agents are autonomous software applications that are capable of reasoning, making decisions, and initiating activities based on some input of data they perceive and analyze from the environment they operate in. These software agents can also communicate with other agents, including humans. Intelligent software agents can act on several levels of autonomy based on the constraints that are assigned to them; these constraints can be driven by the environment they exist in

or simply by business rules and politics. Because services are best modelled as being autonomous and heterogeneous, they can be naturally associated with agents. These intelligent applications make it possible to capture the interactions among the services, and enable the creation of new services as subtle compositions of others.[4]

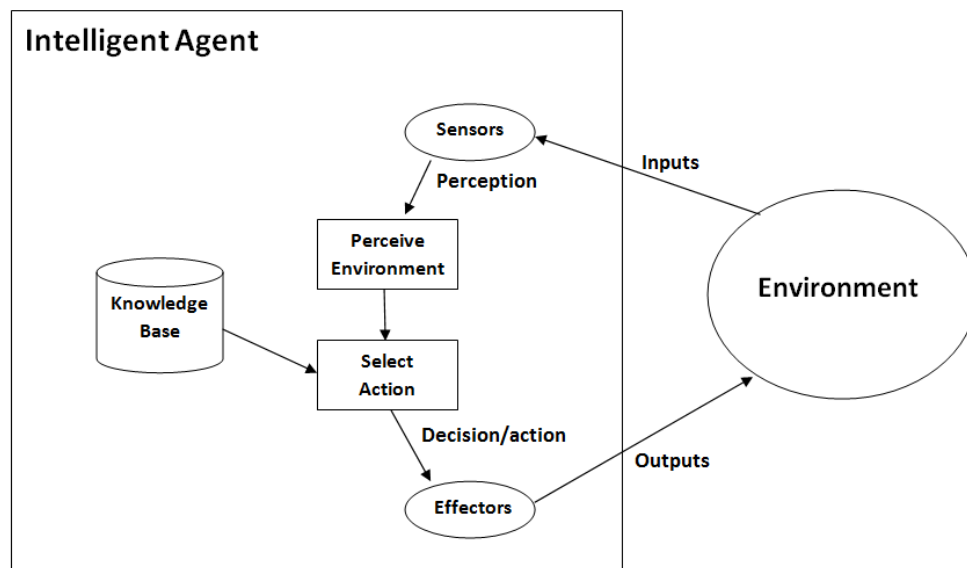

Figure 1: Architecture of Intelligent agent

Based on the predefined rules and patterns, agents can balance cooperation with self-interest. They also have the property of persistence, which is necessary to carry out business transactions, handle exceptions, and to build a history of interactions, which is necessary to establish trust. These properties, rules, and patterns that in practice administer agent's behaviour, are all subject to change as directed by the environment (more precisely, by the information). This characteristic enables intelligent agents to be adaptive to the environment they operate in, and to the results that have the biggest weight on their reasoning.

There are several types of Intelligent Agents, [5] including simple reflex agents, model-based reflex agents, goal-based agents, utility-based, and learning agents. Regardless of the classification, all agents are created with the same philosophy:

1. Perceive and gather the data from the environment or interacting services/agents;
2. Process the data using the predefined rules and the acquired knowledge base;
3. Update/adjust the knowledge base and decision making rules as needed;
4. Make decisions based on the results;
5. Return the results in the operating environment by initiating the needed activity;

The main difference between the different classes of intelligent agents is the way that they process the gathered information, and the principles on which they make decisions. Reflex agents follow simple rules (eg. *if condition then action*), and they react only when the condition is fully satisfied. Model-based and Goal-based intelligent agents store information about the desired state, instead of strict rules, so that during the decision making process the agent chooses the best possible solution to satisfy the goal or the defined model. Similar agents are utility-based agents, which enable every possible state to be marked according to how desirable it is. Later, during the decision making process the results are compared with the desired values and in that fashion the most desired state is selected.

3. Expert Systems

An integral part of the intelligent agent's architecture is its knowledge base. The way in which the knowledge is represented in most cases is the most decisive factor regarding whether the Agent will complete the assigned task successfully or not. The structure of the knowledge in the database also has substantial effect over the algorithms and procedures that are used during the decision making process.

Expert systems [6] are rule based software applications that use a knowledge base for problem solving and decision making in situations where normally consulting from one or several human experts is needed. The knowledge base is created with facts and rules that are defined by human Subject Matter Experts (SME) in the specific problem domain. Specific knowledge representation structures and knowledge engineering techniques are used depending on the application of the Expert system. Another integral part of every expert system is the decision making procedure where the definitions of rule-execution, and control of the facts which are part of the knowledge base, are stated. These definitions drive the decision making procedure; their weights and thresholds are usually subject to change while the expert system is trained, or when performances of the system are reviewed.

4. Integration of services

When we talked about agents, we mentioned that one of their characteristics is their ability to interconnect with other agents, services, or human actors. Given that the new emerging technologies such as web services and the semantic web enable development of new and existing services, it is only natural that we might want to put services together to create more sophisticated and valuable composite services. Service composition is about putting together services to create new functionality that will add additional business value to the company. Although in most cases, the composite service is used internally to automate some business process step, often the composed functionality would itself be exposed as a new service with a standard interface.

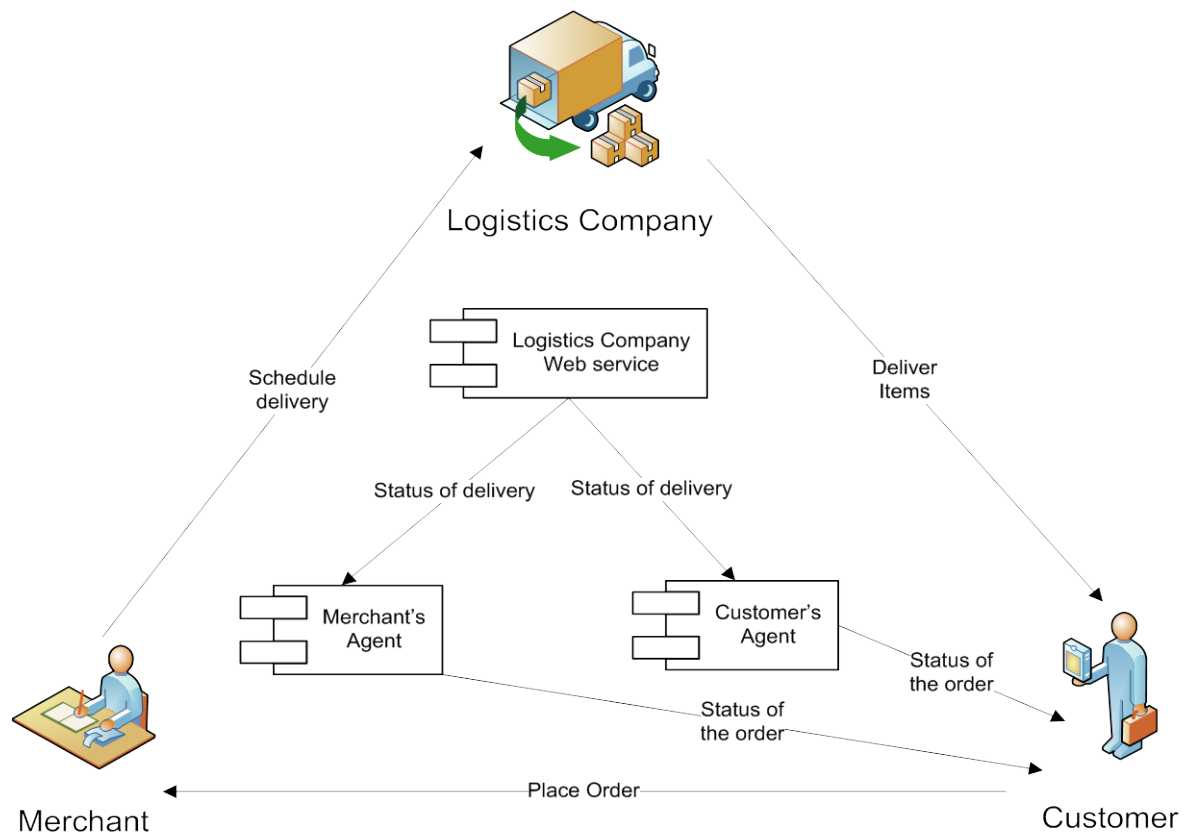

Figure 2: Integration of services (Merchant, Customer, Logistics Company)

Let us consider some challenges faced while composing services. As an example we will take a scenario that includes three actors: The Merchant whose business sells a particular good, the Customer who purchases these goods from the Merchant, and the Logistics Company responsible for delivering the purchased items from the Merchant to the Customer. Imagine that the Merchant would like to enable the customer to be able to track the shipping of the sold items. If the Merchant and the Logistics Company have their own isolated, mutually un-integrated systems, the best that the Merchant can do is to point the Customer to the Logistics Company Web site, and the Customer can then go there to check on the delivery status. If the Merchant could compose its own production

notification system with the Web services of the Logistics Company, the result would be a customized delivery notification service by which the Customer (or even better the customer's agents) could find the status of a purchase and the delivery in real time.

The previous example can be further enhanced using web services that are already available (and in most cases free of charge) on the Web. If the Global Positioning System (GPS) system of the Logistics Company uses Web services to enable the Merchant and the Customer to get information about the location of the vehicle that is delivering their goods, then the Agents on both Customer and Merchant side can integrate this data with Google Maps and visually get the location of their delivery.

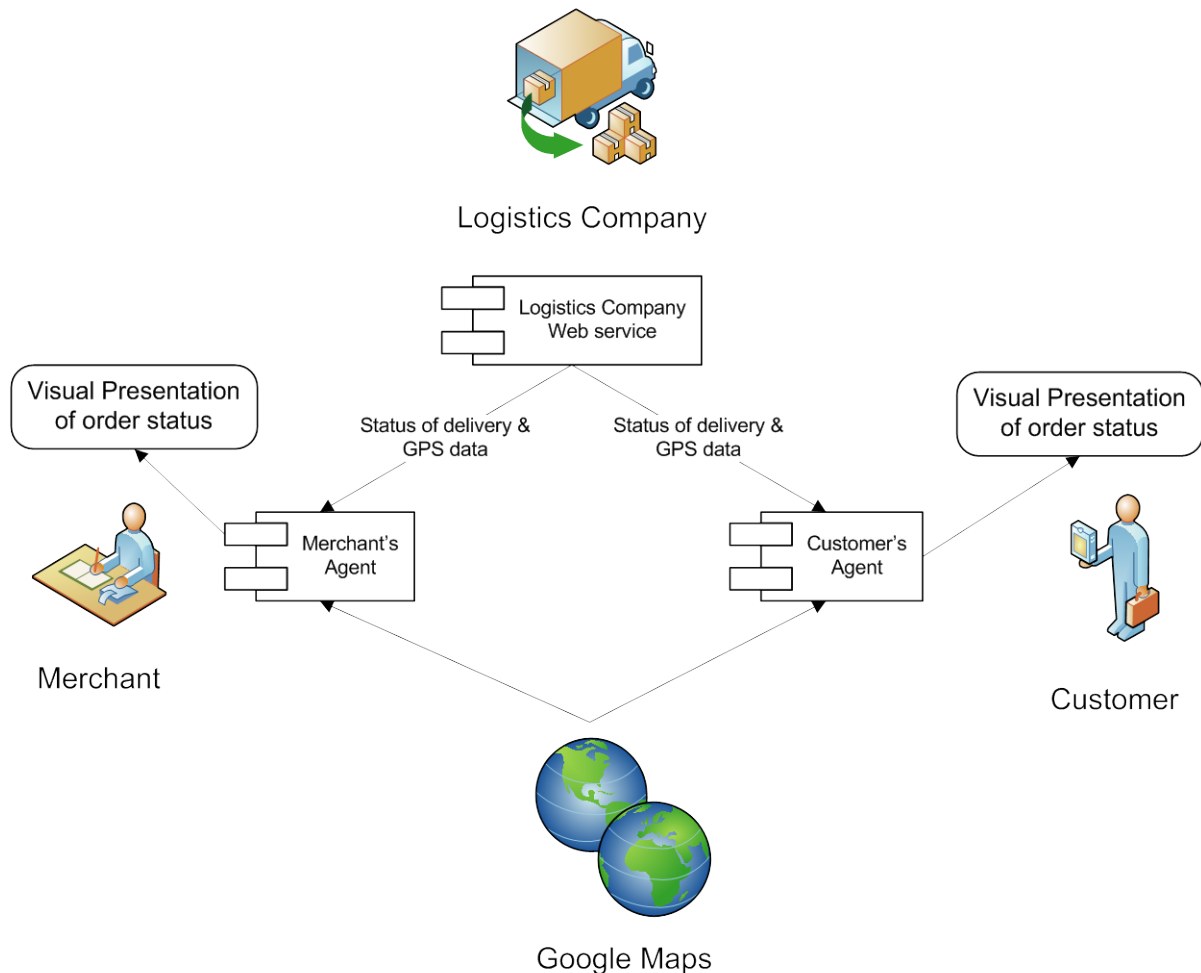

Figure 3: Enhancement of services for better Customer experience

This enhancement provides a better User Experience to both the Customer and to the Merchant, and the best part is that the data utilized is fully generated by machines or software applications. The location of the vehicle is generated by the GPS device that is installed; data that is received by the internal GPS system in the Logistics Company is processed by Software Agent; this output is transferred to the web service (without human interference); finally both Agents on Customers and Merchant side execute the tasks they are assigned to do and compose the services to generate the improved visual experience for both Customer and Merchant.

To complete the Supply Chain, the next step will be to include two more Actors in the scenario: the Wholesaler, and the Manufacturer. Without automated integration of the systems, the Wholesaler will only be notified for supply (purchase orders) by the Merchant when the Merchant hits critically-low stock level, or worse, is out of stock. This practice may lead to purchase order bottle-necks in cases multiple merchants with high simultaneous demand (eg. seasonal items), and may even lead to the Wholesaler having insufficient resources in goods supply or delivery windows to satisfy all of their Merchants.

A remedy to this potential lies in the integration between the Inventory Management application on Merchant side, and a Web service that enables the Wholesaler to track information about the

Merchant's stock level of the relevant goods. The Wholesaler's agent could integrate the retrieved Merchant stock level data with the information generated by the internal agent who analyzes the quantity that is usually purchased by the Merchant. The new composed service could generate notifications when the stock level in the Merchant's warehouse nears to his usual purchase quantity. This allows the Wholesaler to maintain the optimal stock levels for the Items that are needed by its customers. Further, the same type of integration could be leveraged further back in the value chain, between the warehouse on the Wholesaler side and the Production Planning department in the Manufacturer's offices. The Manufacturer's agent gathers the data from the services that expose inventory levels in Wholesalers warehouses, and combines this with information about current stock levels of raw materials. The new service gives information that is very useful both for Production Planning and for the Procurement department whose responsibilities are to keep the stock levels of raw materials on optimal level.

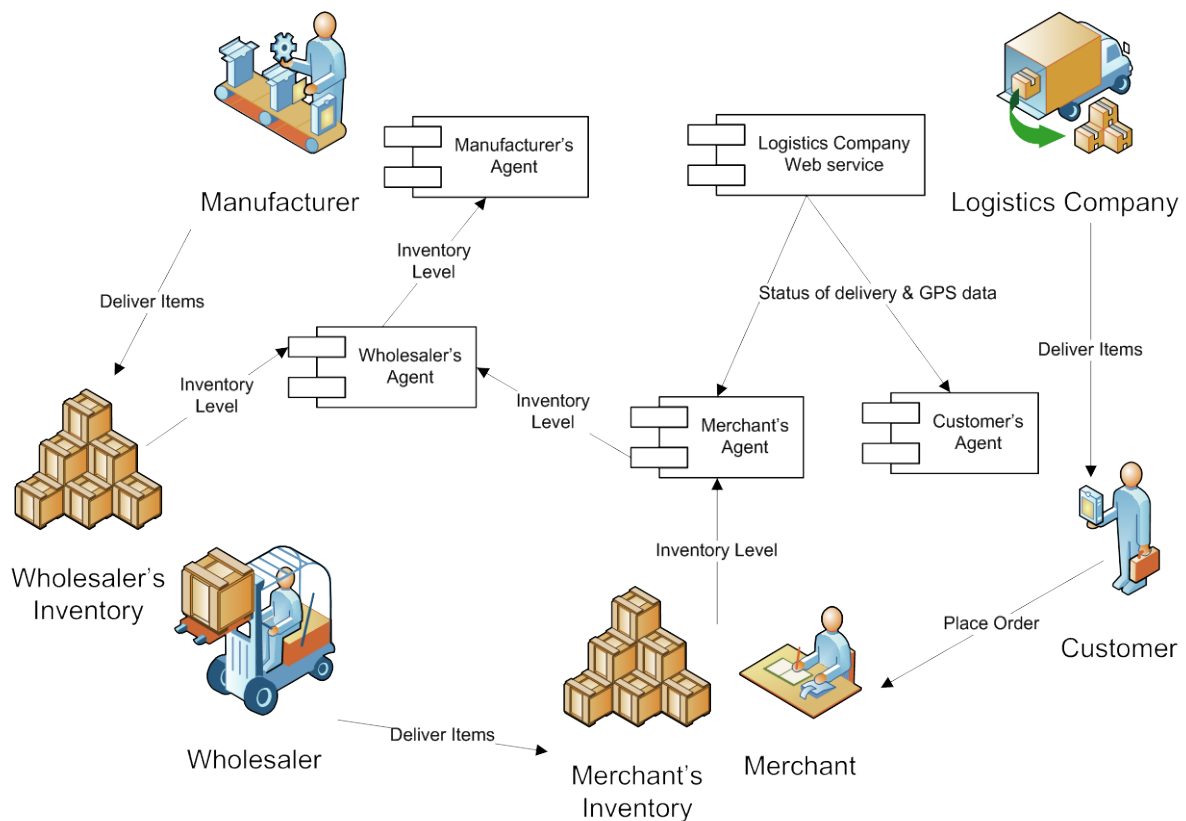

Figure 4: More actors are included to close the Supply Chain

5. Conclusion

There is still substantial headroom for automation in many repetitive tasks that are part of common business processes. In most cases these tasks are not yet mediated by computers at all, particularly in sectors and regions where IT is not fully embraced and it is adopted at a slower pace. The proposed enhancements that include extensive usage of Intelligent Agents will interlink these "offline" sectors and would result in reduced risk, reduced uncertainty, reduced costs, increased operational efficiency, and would allow managers and customers to engage in higher value-adding activities. Automation is a good investment if it not only lowers costs but also helps users to get what they want more quickly and easily.

E-business and intersystem integration and collaboration is ever-evolving in today's rapidly changing business landscape. Time is becoming an essential unit of performance measurement, and the internet-economy is characterized by the speed of execution. As demand changes, and orders are placed, it is necessary to quickly specify when, at what cost, and in which quantity the order will be delivered; response time is of utmost importance. Moreover, considering the high volume of individual and specific demands, with many product variations, mass customization is required for such

production systems that will enable the customer to be included in the early stages of product development. These characteristics combined imply a tremendous level of reactivity. At last, because of logistics reasons associated with these above-mentioned constraints, the customer is becoming the most influential figure in the scenario, and is progressively being included in decision-making across the entire value chain – from retail and transport, to wholesale and manufacturing.

The influence of innovations of working processes on the operational efficiency

Vasil Stamboliski¹, Vancho Donev²

¹EUROIMPEX DOO Skopje, Macedonia, vasil@euroimpex.com.mk

²Faculty of Mechanical Engineering, Ss. Cyril and Methodius University, Skopje, Macedonia, vandon@mf.ukim.edu.mk

The authors of this work have made a research regarding innovations, which is based on introducing a time reader at a service workshop as a part of After-Sales Department of a vehicles importer in the Republic of Macedonia. The researches were made in the period of 2008-2010, where the implications of introducing the innovation process, on increased efficiency, productivity of direct executors and increased customer satisfaction have been examined.

Keywords:

After-sale, clocking, costumer satisfaction, efficiency, implementation, innovations, norms, service, time reader, working time.

1. Introduction

Recent researches have confirmed the fact that increased number of managers is aware of the importance of the innovation and smaller number of managers is unsatisfied with the management of innovation in their companies (organizations). Moreover, the innovation performances considerably vary among different departments and divisions of the same department, suggesting that the structural as well as the organizational factors influence the effect of the innovation over the performance. The management researches confirm that the innovation organizations, that is, those which are capable to use the innovation in order to improve their processes or to differentiate their services, are improving their competitiveness, measured in terms of market share, profitability and development. Usually, innovation management, in fact is difficult and risky: most of the new technologies fail to be transferred into services and most of the new services do not mean a commercial success. In other words, the innovation can maintain the competitiveness, but it requires different set of management, knowledge and skills of the business administration. [1]

In order to answer the research requirements, an After-Sales Service Department of one of the baggiest vehicles import and maintenance centers in the Republic of Macedonia has been chosen as a target. After examining the current situation, by methodology of measuring and innovation proposal, its implementation and, at the end the given conclusion and results of introduced innovation, it will be achieved that the Import Centre will maintain and improve a high level of service at the After-Sales Department. [2]

2. Temporary situation, investigation and innovation:

In the operation of the After-Sales Service Department of an import centre which is chosen as a location for research and until 2008 when the research started, the evaluation and payment of the direct executors (employees at the vehicle service) was in accordance with the system of fixed salaries, namely, according to the agreement made at the beginning of the employment, without paying any attention to the professional competents, experience, the performance and responsibility.

This way of evaluation has been functioning until it has been noted that the lack of responsibility and unrealistic evaluation of the employees lead to decreased profitability, transferring of responsibility, decreasing of the customers satisfaction and consequently, to their decision not to return for undertaking another service.

All the above mentioned is supported by customers satisfaction survey performed during 2007. [3]

Figure 1 Bar 13 - Average satisfaction 2007

The bar number 13 shows an average customers satisfaction percentage equal to 78.8%, which is far from satisfactory percentage of a top quality import centre. For that purpose, the possibility of introducing an innovation in giving a service with an intention of improving the customer satisfaction and increasing the profitability of the Department has been considered.

2.1 Methodology

As the company working environment plays an important role in increasing the customer satisfaction, prior to giving the proposal for innovation a survey has been conducted in order to assess the current state. The survey was conducted via questionnaire composed of 14 questions about the satisfaction of the Service Department employees and their satisfaction from the management. [4]

Upon completion of the survey, the results showed that a part of the direct executors were not satisfied with the unrealistic evaluation, and therefore a proposal for innovation in a sort of motivation system for the employees in After-Sales Service Department was given.

On the basis of the requirements of the company's executive management, as well as on the basis of long term analyses and consultation of the professional literature, a proposal for motivation, bonuses and evaluation of the employees' performance were given.

Having in mind that all employees are not the same and not all of them have the same contribution in the profitability of the Service Department, they should be divided in groups as follows: [5]

Table 1

AM: Leading Mechanic	AE: Leading Electrician
BM: Mechanic	BE: Electrician
CM: Junior Mechanic	CE: Junior Electrician
DM: Beginner	DE: Beginner

Transferring from group to group is restricted by the following:

DM, DE: Beginner who has to spend 1 (one) year in order to apply for CM, CE. (In order to be transferred, he has to take an examination in front of the Department Commission).

CM, CE: Junior Mechanic who has to spend 3 (three) years in order to apply for BM, BE. (In order to be transferred, he has to take an examination in front of the Department Commission).

BM, BE: Mechanic who has to spend 5 (five) years in order to apply for AM, AE. (In order to be transferred, he has to take an examination in front of the Department Commission).

Depending on the group the employee belongs to, he receives the responsibilities and bonuses for the completed job. The analysis made has shown that each employee in order to earn the salary (salary proposal follows further below in the text) there is a need of the following:

First: To be physically present at work. The evidence is provided from the clocking device, which means that each employee must fulfill the determined monthly working hours that vary from 168 to 180 hours depending on the working days in the month.

Second: Each employee must fulfill the determined norm which has been foreseen in accordance with the group he belongs to. The norms have been made according to the analysis made during the past years, which is as follows: [6]

Table 2

AM: Leading Mechanic (30 hours)	AE: Leading Electrician (40 hours)
BM: Mechanic (120 hours)	BE: Electrician (60 hours)
CM: Junior Mechanic (100 hours)	CE: Junior Electrician (80 hours)
DM: Beginner (80 hours)	DE: Beginner (30 hours)

Third: All that is above the foreseen is paid as bonus in percentage as follows: [7]

Table 3

AM: Leading Mechanic	20%	AE: Leading Electrician	20%
BM: Mechanic	10%	BE: Electrician	20%
CM: Junior Mechanic	15%	CE: Junior Electrician	15%
DM: Beginner	5%	DE: Beginner	15%

Additionally, if not provided in the company food allowance and transport allowance (depending of the distance from the working area) should be paid to the above mentioned salaries. The proposal shows that the starting salary should be higher than the salaries of all employees in the general services (guards, maintenance, hygiene, cleaning, h...).

The leading repairman is double paid than the beginner.

These salaries vary in accordance with the degree of education and the knowledge which has to be confirmed by the professional commission of the Department.

In order to get those salaries there is a need of additional activities as:

- Tidy up the working space;
- Compliance to dress code;
- Compliance to job description;
- Team work;
- Showing initiative for increase of the productivity.

In accordance with the above-mentioned, there is a need of analysis for administrative and management staff who are employed in the Department, as follows:

Table 4

<u>AS Manager :</u>	X 2 from the salary of the best paid mechanic
<u>AS Deputy manager:</u>	-10% from the manager's salary
<u>Technical adviser:</u>	X 1.5 from the salary of the best paid repairman
<u>Service adviser :</u>	X 1.5 from the salary of the best paid repairman
<u>Service adviser:</u>	Equal with the leading repairman

The salaries of the above mention positions should be a bench mark and goal to be achieved. In order to achieve them there is a need of working experience and corresponding professionalism which is to be confirmed by a Department's professional commission. The amount of the starting salaries is determined by After-Sales Manager and he proposes their increasing depending on the engagement of the employees.

Measuring of the performance, that is, the time needed for performing the service operations is suggested to be measured by time reader which has to be connected with the existing Dealer Management System (DMS). [8]

2.2 Implementation

As it was previously mentioned, one of goals for increasing the employees' productivity is the innovation – introducing of working hours reader. For that purpose a servicing process diagram has been created with inserting the innovation: [6]

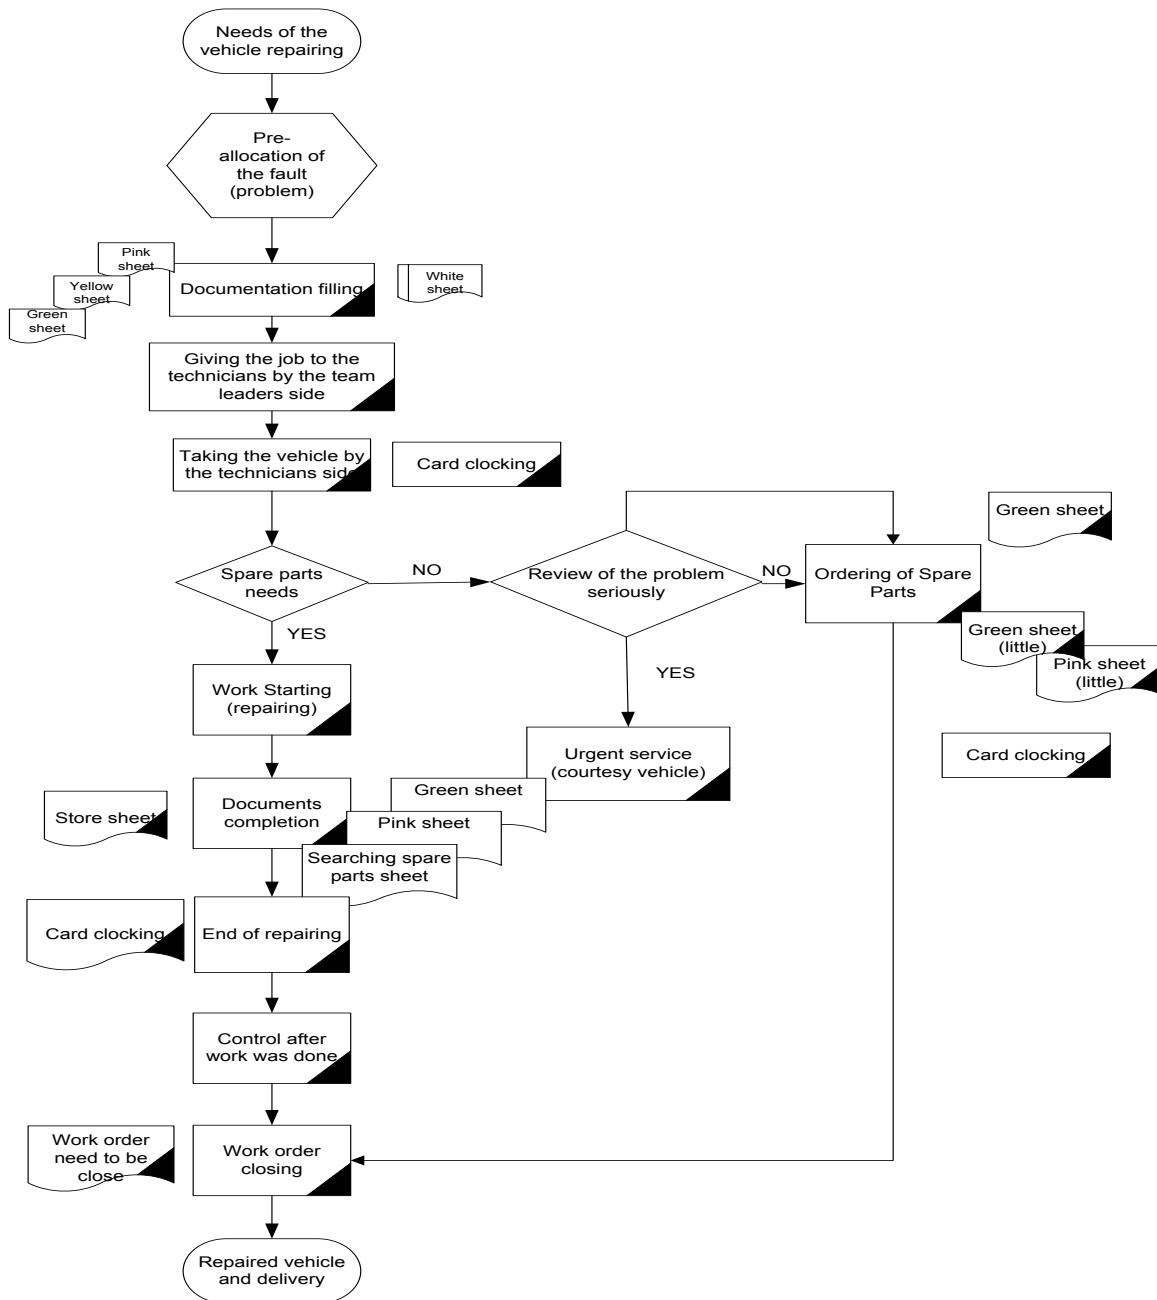

Figure 2 Servicing processes diagram block

The time reader does not have a direct influence on the productivity but it has an influence on the employees' punctuality and quality of performance. Each employee knows what he has accomplished and, if the tasks have been assigned previously as a motivation, he will have a higher motive for completion of tasks on a higher level, with high quality.

The program which is used shows the registration of the card at the beginning of the work, as follows:

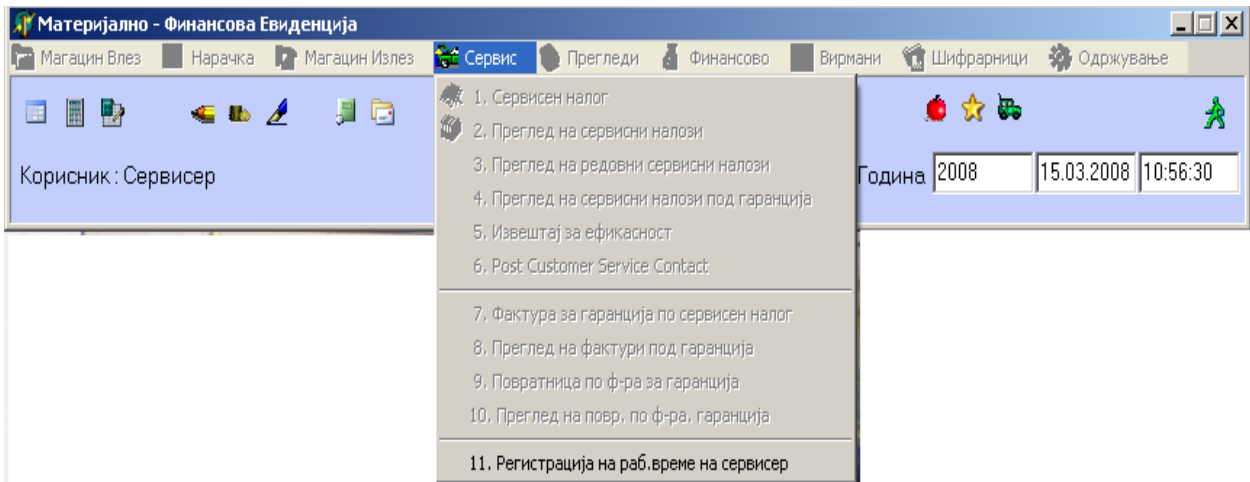

Figure 3 Fist page of the application

On the start of the program, working order supposes to be selected, that is, a working order is being activated.

While opening the working order a separate screen appears. It displays its number, chassis number of the vehicle that is to be repaired, register plates of the same vehicle as well as the vehicle model.

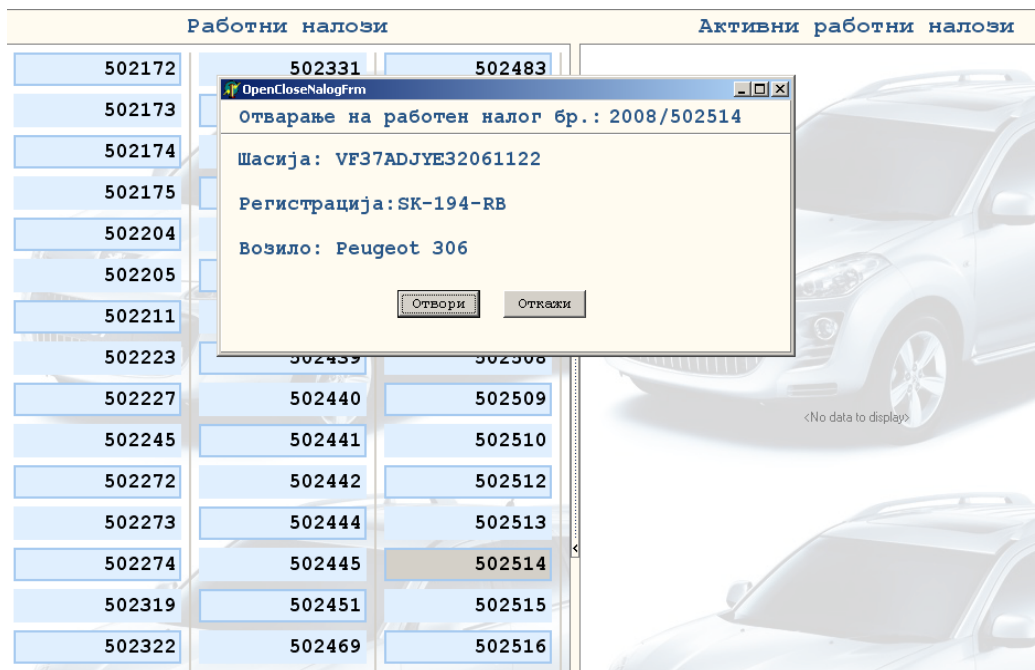

Figure 4 Choice of the working order

When the working order is open, it displays the last worker who was active and this screen displays the working order number, the name and surname of the employee, start of the operation, that is, the date and time when the worker starts his work. The chassis number, register plates and the vehicle's model are also displayed.

Figure 6 Closing a working order

The work measuring device shows how and in which way the activity has been done, upon which we can determine if the work is performed in accordance with the norms proscribed by the company. Thus, upon completion of the activities i.e. repair of certain vehicle, the time is measured from the opening of the working order until its closure, at which point it could be determined whether the time the worker needed for completion of particular activity is in accordance with the foreseen operation norms. If there is a great deviation then analyses on deviation is made in order to determine the same. They can be of a different nature: no spare parts on stock, lift-jack does not work, there is no adequate tool, lack of employees engagement and etc. Depending on the type of deviation, corrective measures are undertaken in order to decrease the deviation percentage and to achieve the goal. It shows whether the performance of the employee was effective and efficient.

3. Implications and Conclusions

Upon the opening of the program for financial and material data it could be noticed how long certain employee was engaged during the work and accordingly to be awarded. Below, the figure shows the engagement of an employee in After-sales department. An example of an employee is given in the following figure: [9]

Број док.	Датум	Име на сервисер	Ангажованост	Норматив	Производителност	Износ	Гаранција

Figure 7 Efficiency report

Upon implementation of the innovation the increase of the profitability of the Department is inevitable, firstly with reference to the financial input as well as with reference to the increased number of entrances in the Service Department. We came to the same conclusion upon completion of the customer satisfaction survey in 2008, 2009 and 2010 which showed 90% of satisfied customers and which has to be again set as a future goal to be reached.

Figure 8 Average customer satisfaction

Innovative Employee Reward Methods Use and Its Linkage with Employee Motivation and Performance

Ljubica Stefanovska¹, Emilija Ristova²

¹University "Goce Delcev" Stip, Macedonia, ljubica.stefanovska@ugd.edu.mk

²University "Goce Delcev" Stip, Macedonia, emilija.ristova@ugd.edu.mk

The presence of motivational methods and systems in companies defines its success. The perception of what motivates and should motivate employees towards achieving organizational and their own needs has been changed over the years and the era of technological change, economic crisis and new achievements. Recognition of employee's work and indentifying an innovative idea, followed by an innovative reward method can make a huge difference in the workspace and improve employee performance within the company. Does management encourage every single employee to contribute their ideas and implement the best ones? Many companies continue to offer employees the basic package that has been around for years like base salary, traditional benefits like health, welfare and retirement or maybe a profit-sharing plan. There are absolutely alternatives to consider. This is where manager's creativity takes place. Many of the traditional reward methods are tied to performance, but employers should also consider non-performance based methods. Another category of ideas is to consider motivating employees and maximise performance through implementing relationship-building programs. The lack of existence of innovative employee reward methods is identified in our research, which took place in 39 Macedonian organizations (218 employees). During the research we identified very few reward methods and many of them tie directly to employee performance. Considering the lack of the existence of innovative reward methods in our companies the basic step every employer should concentrate on, should be defining the right factors of motivation that are connected with other indicators and not just performance, as well as making this factors a part of an innovative employee reward method that will be accepted by employees and supported by the top management of companies.

Key words:

reward, reward methods, employee motivation, performance, innovative reward methods

1. Introduction

Reward programs followed by adequate recognition programs, are quickly becoming a staple in the way organizations attract, retain and motivate employees [1]. Today's dynamic workforce is looking for everyday recognition. According to a Gallup Poll in 2007, employees who receive regular recognition:

- Are more productive;
- Rate higher on customer satisfaction surveys;
- Increase co-worker's engagement;
- Have better safety records;
- Are less likely to leave the organization.

Reward has been defined as one of the leading factors that drive motivation. Many studies through the years have been made using reward programs as a basic factor of their research.

2. Linking motivation and performance

Motivation, as a driving tool that leads towards performance, has been a challenging issue through the years of technological change. The perception of what motivates employees has been changed. The needs employees had, well defined in the motivation based theories, are still the basic needs organizations use and try to fulfil in order to achieve better employee performance. Summary of motivation based theories is given below as shown in Table 1.

Table 1. Summary of theories based on motivation

Maslow	ERG	Herzberg	McClelland
<p><u>Self-Actualization</u></p> <ul style="list-style-type: none"> • Highest need level. • Involves an individual's desire to realize full potential • Can be satisfied without this level. <p><u>Esteem</u></p> <p><i>Self-esteem</i></p> <ul style="list-style-type: none"> • Need for personal sense of accomplishment, mastery. <p><i>Social-esteem</i></p> <ul style="list-style-type: none"> • Need for respect, recognition, attention, and appreciation of others <p><u>Social</u></p> <ul style="list-style-type: none"> • Need for love, affection, sense of belonging in one's relationship • Dealings with friends, family, and colleagues falls in here. <p><u>Safety and Security</u></p> <p><i>Relationships</i></p> <ul style="list-style-type: none"> • need for security in relationships <p><i>Physical</i></p> <ul style="list-style-type: none"> • need for security, protection from future threats, and stability. <p><u>Physiological</u></p> <ul style="list-style-type: none"> • Basic needs: food, water, etc. 	<p><u>Growth</u></p> <ul style="list-style-type: none"> • Desire for continued personal growth and development <p><u>Relatedness</u></p> <ul style="list-style-type: none"> • Desire to satisfy interpersonal relationships <p><u>Existence</u></p> <ul style="list-style-type: none"> • Desire for physiological and material well-being 	<p><u>Motivation Factors</u></p> <ul style="list-style-type: none"> • Improving factors leads to satisfaction, effort, and performance. • Related to job content; what employees actually do. • Factors: <ol style="list-style-type: none"> (1) achievement (2) recognition (3) work itself (4) responsibility (5) advancement (6) growth <p><u>Hygiene Factors</u></p> <ul style="list-style-type: none"> • Improving factors prevents dissatisfaction. • Related to job environment more than nature of work itself. • Factors: <ol style="list-style-type: none"> (1) policies and procedures (2) supervision (3) relations with supervisor (4) work conditions (5) salary (6) relations with peers (7) personal life (8) relations with subordinates (9) status (10) security 	<p><u>Need for Achievement</u></p> <ul style="list-style-type: none"> • a drive to pursue and attain goals • accomplishment is important for its own sake <p><u>Need for Competence</u></p> <ul style="list-style-type: none"> • a desire to do quality work • want to develop skills <p><u>Need for Power</u></p> <ul style="list-style-type: none"> • desire to influence others • desire recognition of others <p><u>Need for Affiliation</u></p> <ul style="list-style-type: none"> • a drive to relate to people effectively • desire for close relationships

In order to achieve the goals of this research and connect motivation theories with performance, as well as to make a study which will point out the motivation factors that lead to a better performance, a unique methodology has been created. Theoretical findings have built a path for making this research possible, pointing out the basic concentrations that needed to be explored. The fact motivation is something that cannot be uniformed, gives us directions for identifying a wider range of criteria that

needs to be satisfied too. The lack of performance measurement systems in organizations makes it hard for the managers to connect motivation and performance.

2.1 The importance of a performance measurement system in organizations

Reviewing the performance of an organization is an important step when formulating the direction of the strategic activities. It is important to know where the strengths and weaknesses of the organization lie as part of one measurement cycle. Measurement plays a key role in quality and productivity improvement activities [2]. Performance measurement frameworks play an important role in identifying and tracking employee and organizational progress, through measuring the achievement of organizational goals and identifying opportunities for improvement. They can be used as a tool for comparing performance against both internal and external standards. Recognizing people's achievements and strengths is a part of performance management. Feedback is the best way for informing employees about how well they are performing by reference to achievements and behaviours. They can also be helped to understand how they can do even better, by taking action to make the best use of the opportunities the feedback has revealed. There are two often-quoted statements that demonstrate why measurement is important. Using measurement can lead supervisors to a clear feedback about employees work and also create a firm ground for fair reward/punishment system. Yet it is surprising that organizations find the area of measurement so difficult to manage. Armstrong commented as long ago as 1976 that: "It is undesirable to have a direct link between the performance review and the reward review. The former must aim primarily at improving performance and, possibly, assessing potential. If this is confused with a salary review, everyone becomes over concerned about the impact of the assessment on the increment. It is better to separate the two [3]." Armstrong and Murlis comment that: "Some organizations separate entirely performance pay ratings from the performance management review. But there will, of course, inevitably be a read-across from the performance management review to the pay-for-performance review" [4].

2.2 Reward as a part of a motivation system that drives performance

Developing a performance measurement framework must be followed by a motivational system. A good performance measurement framework will focus on the customer and measure the right things. Performance measurement can provide a basis for motivating people by enabling them to develop their skills. They can be thanked, formally and informally, for what they have done. When looking at a task, we evaluate it in terms of how well it meets our needs to feel competent and in control. We will be intrinsically motivated to complete the task if we think we will be able to complete the task, requiring no further external motivation. Where a person has stronger internal locus of control they will feel they are in control of how they behave. Where they have a strong external locus of control, they will believe the environment or others have a greater influence over what they do. People may see external rewards as achieving some degree of control over them or may see the reward as informational, such as where they reinforce feelings of competence and self – determination. When people see reward as mostly for control, they will be motivated by gaining the reward, but not by enacting the requested behaviour [5]. This are the postulations of the Cognitive Evaluation Theory also called Self-Perception Theory [6]. Performance measures have to be very carefully chosen and have the following characteristics:

- Meaningful, unambiguous and widely understood;
- Owned and managed by the teams within the organization;
- Based on a high level of data integrity;
- Such that data collection is embedded within the normal procedures;
- Able to drive improvement;
- Linked to critical goals and key drivers of the organization.

Performance is considered to be a function of ability and motivation [7]:

$$\text{Performance} = f[(\text{ability}) * (\text{motivation})]$$
$$\text{Motivation} = f[(\text{valence}) * (\text{expectancy})]$$

Ability is defined as the variety of skills one person possesses, powered by employee trainings and available resources.

The best way for implementing a performance measurement system can be the acceptance of the basic strategies of motivation, while defining strategies and goals [8]:

- Positive reinforcement/high expectancy;
- Effective reward and punishment;
- Satisfying employees needs;
- Positive work environment;
- Setting work related goals;
- Restructured work places;
- Performance based rewards.

According to a 2003 survey conducted by WorldatWork and the National Association for Employee Recognition (NAER), the majority of companies maintain formal and informal reward and recognition programs and their use is becoming increasingly prevalent. The study identified the following driving forces for implementing and maintaining reward and recognition programs:

Figure 1. Key Goals of Rewards and recognition program [9]

In survey of 35.000 employees, researchers Joseph Cangemi and George Guttshalk, asked employees to nominate what they wanted most from their jobs. The research shows that there is no parallel that can be made between the “wants” of employees and supervisors. For many people there are few things more motivating than seeing the successful implementation of any idea they suggested. Supervisors overlook the possibility that their employees may be untapped mine of good ideas. An organization needs to evolve its own set of metrics, using any existing metrics as a starting point in understanding current performance. To ensure they trigger the improvement cycle, they should be in three main areas:

$$\text{Effectiveness} = \text{Actual output} \times 100\% / \text{Expected output}$$

The effectiveness metrics should reflect whether the desired results are being achieved, the right things being accomplished.

$$\text{Efficiency} = \text{Resource actually used} \times 100\% / \text{Resources planned to be used}$$

This is about the process input and measures the performance of the process system management cause it is possible to use resources efficiently but ineffectively.

$$\text{Productivity} = \text{Outputs} / \text{Inputs}$$

Productivity can also be quoted as:

$$\begin{aligned} \text{Expected productivity} &= \text{Expected output} / \text{Resources expected to be consumed}; \text{ or} \\ \text{Actual productivity} &= \text{Actual output} / \text{Resources actually consumed} \end{aligned}$$

The research which took part in the public and private sector in Republic of Macedonia has its basic accent on indentifying the reward methods that companies use and the factors that directly apply employee's motivation.

3. Innovative reward methods use – research

The research took place in 39 companies (219 employees). It is comparing theoretical postulations of motivation, linking them to performance and giving conclusions about the use of motivational systems and reward methods in our organizations.

Figure 2 Employee structure

Considering the structure of the employees that were included in this survey, we can highlight that 49% of them are middle level managers which are in charge of working groups that count less than 20 employees. Most of the employees are: (a) around 41- 50 years old, (b) 58,7% have a previous work experience, (c) 61,4% are men, (d) 10,9% of the employees are MSc and (e) 2,7% of the employees have a PhD.

The basic points of the research were the relevant factors that apply directly to employee motivation and its connection with performance. The significance of the *personal factors* are taken in consideration as well as *leadership factors*, *team factors* and *system factors*, as defined from Armstrong and Baron [10].

If we take a closer look at the results that apply to personal factors, we can point out the positive structure from the given answers. The work recognition employees get from their supervisors is rated as good - 46,7% of the employees defined it as level 3 on a scale from 1-4, where 1 is the lowest grade and 4 is the highest rating. These factors apply to personal skills, confidence, motivation and employee engagement.

Leadership factors, as quality of encouragement and support from employees and supervisors, can be stated as satisfactory (50,4% of the employees answered that their company encourages them to search for possibilities for their own growth and professional development). We have very disappointing results that are connected with the effort companies make to keep their high skilled employees, 34,8% answered that are partially satisfied with their company policy for keeping their high skilled employees (which is level 2 on a scale from 1-4, where 1 is the lowest grade).

We can highlight *work systematisation* as one of the issues that has an urgent need to be improved. Employees from private sector have a huge need of systematisation of their work, mainly because of the extra effort they put into their work and not getting a satisfactory award and recognition for it.

Figure 3 Reward systems in Macedonian Organizations

It seems like most of the organizations from the public sector have reward systems, but they are not implemented right. The picture in the private sector is different. Most of the organizations (42 organizations) have a reward system which is already implemented and works.

The rewards used as a part of the reward systems in these organizations, are mainly financial awards that employees receive for a complex work that has been properly finished and didn't suffer additional expenses. Rewards, as additional pay for extra work, and yearly paid bonuses are also mentioned. Innovative rewards have not been identified or used.

Very few organizations use performance evaluation plans for measuring their employees work. This is one of the basic issues that lead us to believe these organizations don't have a solid ground to create a strategy that will include implementation of a reward system.

One effective reward system should have the following characteristics [11]: (a) set high goals for performance, (b) develop accurate ways to measure performance, (c) train supervisors in performance appraisal, (d) link pay to performance and (e) make increases noticeable and meaningful.

The research has shown that the basic motivation method organizations use is the financial bonus given as a reward for the excellent work. Other mentioned rewards are: higher hierarchy position, public recognition, non-financial benefits etc.

Table 2 Expected rewards from employees

	1 (no)			2 (maybe)			3 (yes)

*Pr. Sec. – Private Sector

Every employee has a need for praise and recognition, and the more often they get it the better. Supervisors are in the best position to give recognition, but few do it often enough or creatively enough [12]. Employees have made it very clear that their performance depends on the reward methods used in their companies.

Figure 4 The case of existing rewards method: reward methods improve productivity

There are many kinds of rewards to choose from, besides regular awards. One of the easiest, most effective forms of rewarding is praise, which is misguided. Pay fails to motivate where bonuses or merit pay is too small, when there is non-existence link between pay and performance, performance appraisal is done poorly, when there is effect of unions and when employees have adaptation problems [13]. The fact that rewards tend to be given at big annual or semi annual awards ceremonies poses yet another problem. Since so much time elapses between awards cycles, the awards are typically granted for work that was accomplished many months in the past. This makes a very weak linkage between accomplishments and rewards. Employees need recognition more than once a year. Managers share the opinion that rewards may influence the financial picture of the company. Innovative rewards methods involve minimal or no cost. There are over 100 low-cost or no-cost programs which have been used successfully by companies [14]. Many of them are tied to performance [15], but employees should also consider non-performance based programs, which complement post-performance reward programs. Some examples of non-performance based programs include: (a) core hours (flexible work time), (b) Tips for improving performance (workshops on topics that affect some working issues), (c) casual dress program, (d) employee discounts for company goods etc. Another category of ideas to motivate employees and maximize performance are relationship-building programs [16]. These incentives may not be viewed by some as compensation because there is no exchange of cash or merchandise and no traditional or non-traditional benefits. These programs are a broad set of interactions which build open communication channels and break down organizational barriers. Some examples of a relationship building programs are: (a) executive coffee breaks, (b) family program, (c) cooperative charity day, (d) special dress days etc.

4. Conclusion

Companies are not bound by tradition when it comes to rewarding, compensating or motivating employees. It is a fact that good motivation leads to a better performance [17]. Implementation of a precise reward method is one way of achieving higher employee motivation and improving performance [18]. The use of innovative reward methods can create a positive working environment. Managers should consider the fact that not all rewards involve cost [19]. A need for developing and implementing an employee recognition programs is identified in our organizations. Employees are motivated to work towards achieving organizational goals [20]. Activities that are needed to be taken in consideration by the top management are: reducing ineffective work time and implementing an innovative reward methods system. The current motivation factor in our organizations are money, work recognition comes next, positive working environment is third and continuing training in the field of work, is also considered as one of the factors that lead to a better performance. All of these factors should be taken in consideration while projecting a work frame that can be used for future development of an innovative reward method - system.

³ Faculty of Technology, University of Banja Luka, Republika Srpska, BiH,

Odds ratio (U.S. odds ratio, OR) is one of several statistical tests, which becomes increasingly important in the Internet-computer research and decision making. Since this is a test of the sample size is particularly useful because computers offers a clear and direct information on how to access security has the best chance for the benefit of users. Tests of statistical significance used for the ratio of the probability of Fisher's exact test, chi-squared (c2) probability ratio test and Pearson chi-squared (c2) test. Typically, the data consist of values for each pair of conditions and outcomes and are presented in table form. Occurs most often forms of 2 x 2, although possibly larger tables. Since it is easy to calculate, $OR = (a \times d) / (b \times c)$, OR can be calculated by hand on the spot, if it is necessary to determine the chances that a particular event will occur to the user at risk for this event. OR helps the computer professionals in making decisions about the implementation of security measures, since it offers a simple information that the users themselves can understand the network, and thus participate in decisions about the implementation of the protection of computers in a network that will be based on the prospects of successful implementation of prescribed measures.

Keywords:

Odds ratio, chi-square test, computer protection, security in the network

1. Introduction

In order for the safety of the working environment was satisfied it is necessary to adhere to clear the table. Among other things, the user is obliged to observe the following rules:

- important information must be physically inaccessible to all persons who have no access to them,
- when not in the vicinity of the workplace user must disable access to the contents of your computer.

1.1 Using e-mail

Electronic mail is part of everyday communication, business and private, but its use can seriously jeopardize the safety of information systems. Potential threats and vulnerabilities in e-mail:

- Viruses of electronic mail can be malicious in character - as an attachment is a file that contains a virus,
- Uncertainty about the protocol messages travelling in plain text, and is easy to read or edit content, is easy to forge the sender's address ,
- Accidents on pressing the wrong key or selecting the wrong user in the directory message may be unwilling to (or more).

- That the threat of information system caused by inappropriate use of e-mails to a minimum, should observe the following rules:
- e-mail may not be used to send insulting, disparaging, disturbing sexual and other messages of similar content,
- not allowed to send chain messages that are burdening network resources,
- each written message is considered a document. You do not have the right messages that are sent to you personally to distribute without author-s permission,
- each message containing a suspicious attachment, you must check the contents of an antivirus program,
- Bureau has the right to filter messages in order to stop unwanted email (spam Eng.),
- in the case incident, the Department has the right to review all data (including electronic mail),
- messages that are part of the business process it is necessary to archive and preserve the prescribed period of time,
- the user may not send mass messages, regardless of their content.

1.2 Social Engineering

Social engineering is the kind of attacks on computer systems with the aim of persuading people to meet the demands of the attacker. This is primarily a way of collecting data to which the attacker legal channels could not reach. When it does not exploit failed implementation of operational systems, protocols and applications, but the assault was directed at the weakest link of the entire chain - the human factor.

2. Methods of protection

Only possible way to protect against social engineering is education users with implementation of security access control and physical security. All other methods of automatic detection, recording and opposition to this type of attack are not effective. Educating users to prevent those attacks in which victims of ignorance give the attacker the information you want. Educating users should include instructions on how to recognize social engineering and how to react properly.

There are a number of statistical tests that can help in making decisions about the choice of computer protection interventions, drawing conclusions about the effects of various causes of action or events in situations related to computer security. One of the tests that are commonly encountered is the odds ratio (U.S. odds ratio, OR). The odds ratio is estimated that the odds of a particular event or outcome in the same two groups. Explained in more detail, OR the odds seem to be the result of an event or perform, and it seems that this event will be absent. Computer terms, this often means that the researcher measured the ratio seems to be whether to develop some attempt to attack a computer or perform "death" of computers, due to attempts to attack or threats or attempts of computer security threats around the computer will perform. OR is used in the measurement of one of two possible events or outcomes in case of alleged causal factor. OR is statistically reliable test that can have a different application. For example, it can be used for the calculation seems to be some event occur due to certain protection measures carried out (1). It can calculate the odds of the outcome of a computer due to the exposure, or unexposed an attack or incident (2). OR is a measure of effect size (U.S. size effect) (as is the Pearson correlation coefficient) and therefore informs on the strength of association between two variables. However, OR is an indirect measure, which we will explain in more detail in the section on interpretation of statistical tests. Calculating the odds ratio calculation of the ratio seems pretty simple. The formula is as follows:

$$\text{Odds ratio} = \frac{PG_1 / (1 - PG_1)}{PG_2 / (1 - PG_2)}$$

where PG_1 is a chance for the tested event for group 1, and PG_2 is a chance for the tested event for the group second Another way of presenting the formula is a tabular form:

	Standard protection	For better protection
Event	a	b
No events	c	d

Table 1

Odds ratio = $(a / b) / (c / d)$ or: odds ratio = $(a \times d) / (b \times c)$

The mathematical rule sharing twin fractions other formula will give the same results as the other two formulas to calculate the OR. Another form of formula more frequently encountered in research.

2.1 Tests of statistical significance OR

First thing we need to understand the tests of statistical significance of odds ratio is that the true value of the neutral (which indicates equal chances for both conditions), one (1), rather than zero (0). For the odds ratio can be used several tests to assess statistical significance. The most common are the Fisher exact test, Pearson-s chi-squared (c2) test and chi-squared (c2) test ratio probability.

Fisher-s exact test

Data to calculate the OR is often displayed in a table with fields 2 x 2 and then used Fisher-s exact test. Its formula is

$$p = \frac{(a + b)! (c + d)! (a + c)! (b + d)!}{n! a! b! c! d!}$$

where p is the value of Fisher exact test, a, b, c and d represent the numbers in the fields of the table, and n is the total value of all four fields of the table.

Chi-square (c²) test

If table contains more than 4 fields (or, if it suits the researcher), you should use a chi-square test. Chi-square assumes that the numbers in the fields represent the values and not ratios or mean, and assumes that the expected value ≥ 5 in 80% of the fields. In order to obtain the level of statistical significance test, the probability value obtained must be compared with values that are evident from the table for Fisher-s exact test for some degree of freedom. Many statistical computer programs, such as Stata and SPSS, calculate the value of Fisher exact test and chi-square test and give information about the statistical significance test. The formula for Chi-square test as follows:

$$\chi^2 = \sum \frac{(o - e)^2}{e}$$

where O represents the observed frequencies, and e expected frequencies.

Chi-square likelihood ratio test

Like all statistical tests to calculate the probability ratio, chi-square test of probability ratio is a logarithmic formula. If the data entered into the program for statistical analysis, this is the most appropriate test of statistical significance for the OR. The formula is:

$$G = 2 \sum f_i \ln \left(\frac{f}{f_i} \right)$$

Where G is the value of the probability ratio test, the observed frequencies f, f_i are the expected frequencies, and ln represents natural logarithm.

2.2 Determination of standard errors and confidence intervals for OR

OR values have normal distribution, so it is not possible to directly calculate the standard error (U.S. standard error, SE). However, the standard error can be calculated simply from the natural logarithm of the OR. It is calculated as follows:

$$SE = \sqrt{\frac{1}{a} + \frac{1}{b} + \frac{1}{c} + \frac{1}{d}}$$

In order to be found around the natural logarithm of calculated confidence interval (U.S. confidence interval, CI), will be the upper formula to calculate the SE, and the value (or a multiple of this value) OR add the logarithm of the value to obtain the upper limit of confidence intervals, respectively, and values (or multiples of that value) seized the logarithm value of OR to obtain a lower limit of CI. It should be remembered that the concept of "no statistically significant differences" in most statistical tests related to the difference is 0, and that generally means a variable extent, or when the situation is different. The term "no statistically significant differences" to test the statistical mean value of 1. Therefore, when the CI includes the value 1, a researcher and computer will immediately know that the prospects of the tested outcome the same for both (or all) groups to implement measures of protection (we call it in your own words, "treat the computer"), even if they do not examine statistical significance.

2.3 Examples of use of OR

Determination of test results carried out a measure of protection OR is often used in determining the effect size differences between the two treatments applied to the computer. Take the example of protection for users of infected computers from spam. Although the collapse of the computer from infection, and the range from 25% to 47%, assuming that the rate of the tested computers of his "death" of 38% with a standard anti-virus protection program. However, developing new malicious is much more dangerous viruses that attack your computer. The question is: what are the odds that your computer will be ejected from the function (call appearances of his "death") by taking a new medication (protection) compared with standard treatment malicious programs? OR has a way with which one can compare the odds of whether a particular outcome the same for two different groups. OR is the ratio of the following two ratios: the ratio of the standard "treatment" and a "treatment" in a group of computers that are thrown out the functions and the ratio of the standard treatments and new treatment in a group of computers that have survived. According to the values from Table 1, calculated as follows:

$$\text{Odds ratio} = (a / b) / (c / d) = (152/17) / (262/103) = 8.94 / 2.41 = 3.71$$

The formula can be expressed as $(a \times d) / (b \times c)$, and the result is the same:

$$\text{Odds ratio} = (152 \times 103) / (17 \times 248) = (15656/4216) = 3.71.$$

The result of calculating the OR can be interpreted as follows: in a group of computers that were treated with the standard way of protecting mortality was 3.71 times higher than in groups of computers that are treated with the new "drug". Based on these results, the researcher should conclude and suggest that all four machines that were diagnosed with malicious code prescribe a new drug protection. In making these recommendations certainly implies that both therapies have similar accompanying disadvantages.

How to interpret the results for the second OR: if OR is 1.00, meaning that it is equally likely that both groups investigated the computers to be completely infected - our words, they will "die". OR greater than 1 means that it is likely that respondents in the first group of computers (in this case, the computer treated with standard methods) to perform the event (death) than in other groups of respondents. OR less than 1 means that it is less likely that this event will occur in the first group examined the computer. However, the OR values less than 1.00 can not be directly interpreted. OR does not provide a result that tells us how far less likely that this event will occur in the first group examined the computer. It is important in the first column put the group which is expected to have a better chance for a performance event. Not worth trying to determine exactly how much less likely that the first group doing performances in comparison with other groups. If the chances of the first group, in which the event occurred, it seems less than other groups, will be replaced with seats in the table so that other groups came in the first column, a first in the second. You will then be able to interpret the statistically significant difference because the team relocating to calculate how many times an event occurred in the second group than in the first.

	Standard protection of computer	The new "cure" from the protection	Odds
"Death" of computers Died	152 (a)	17 (b)	152/17 = 8.94
Survived a computer attack Survived	248 (c)	103 (d)	262/103 = 2.41
Totals	400	120	8.94/2.41 = 3.71

Table 2

If you replace the columns in the above example, the OR will be at

$$(5 / 22) / (45/28) = (0.2273 / 1.607) = \mathbf{0.14}.$$

As you can see, it does not tell us that the group examined the computer "treated" the new anti-virus was 0.14 times less "death"; cases, but the tested computers where the "treatment"; standard mode. In fact, this procedure gives a result that can only be interpreted in the following manner "likely to occur in the first group event less than likely to occur in the event of another group". To what extents are correct, the chances of the first group are less than appears in other groups is not known.

3. Conclusion

Great importance ratio seems to lie in the fact that is easy to calculate, very easy to interpret and give the results by which they can make a managerial decision. Furthermore, sometimes in certain situations, it helps you to computers; we can explain how the odds are one outcome, and what else. If you know what are their chances to achieve the desired result of protection, users can easily decide on the acceptance or rejection of expensive anti-virus protection. Many users want to participate in decisions about their care, but in order to effectively participate must obtain information about the probable results on the Code of Conduct. In the industrialized world's; most knowledgeable enough to be able to understand the basic calculation of percentages and meaning of the concept of probability. OR provides information that is used to protect managers and users in decision making.

OR is one of the categories of statistical tests are often used by managers in making decisions about the implementation of protection strategies. Other statistical tests are often conducted to make decisions about the protection of statistical tests include risk assessment, such as the statistical test for absolute risk reduction (U.S. *absolute risk reduction statistics*) test and relative risk reduction (U.S. *relative risk reduction statistics*). OR values reveal information about the prospects for a particular outcome in relation to the prospects for the second outcome, and thus this test helps in making managerial decisions. Statistical tests of relative risk assessment (U.S. *relative risk assessment statistics*) are particularly suitable for setting diagnostic state computers and making decisions about the implementation of protection, and will talk more about them in a future study. The objectives of this study are to draw attention to the daily attacks on Web sites, as well as to draw attention to the consequences of exploitation of vulnerabilities in attack. The paper should: - indicate the obvious omissions in the information that the business of designing systems and their rehabilitation. Almost always, the web portal has the basic purpose and functions (business, communication, interaction). But their safety (the interface, technology, location, data) is very questionable. We set ourselves the question: what does this mean for end-users (the needs, habits, confidence). Is all this at risk? We took the types of vulnerabilities and attacks by - OWASP TOP 10.

Table 3

OWASP Top 10 – 2007 (Previous)	OWASP Top 10 – 2010 (New)
A2 – Injection Flaws	A1 – Injection
A1 – Cross Site Scripting (XSS)	A2 – Cross-Site Scripting (XSS)

A9 – Insecure Communications	A9 – Insufficient Transport Layer Protection
<not in T10 2007>	A10 – Unvalidated Redirects and Forwards (NEW)
A3 – Malicious File Execution	<dropped from T10 2010>
A6 – Information Leakage and Improper Error Handling	<dropped from T10 2010>

Attackers can potentially use many different paths through your application to do harm to your business or organization. Each of these paths represents a risk that may, or may not, be serious enough to warrant attention. Sometimes, these paths are trivial to find and exploit and sometimes they are extremely difficult. Similarly, the harm that is caused may range from nothing, all the way through putting you out of business. To determine the risk to your organization, you can evaluate the likelihood associated with each threat agent, attack vector, and security weakness and combine it with an estimate of the technical and business impact to your organization. Together, these factors determine the overall risk.

Science, Technology and Innovation (STI) and the Knowledge Economy: Implications for the Republic of Macedonia

Mahfouz E. Tadros¹

¹Former Senior Advisor to the Director General Kuwait Institute for Scientific Research (KISR) and Former Manager at the World Bank

This paper highlights the importance of Science, Technology and Innovation (STI) in the new economic growth model leading to knowledge-based economies. It identifies the main drivers of the knowledge economy. It reviews various STI Indicators for selected countries. It identifies sources of financing Research and Development (R&D), and highlights the role of public and private sectors. The paper reviews funding sources and instruments for R&D. The role of Foreign Direct Investments (FDI) in technology transfer and the spillover effect are examined. The need to create the enabling environment for investments, including proper regulations to facilitate doing business are essential. The importance of venture capital for commercialization of proven technology is addressed. “Ease of Doing Business” indicators for selected countries using the World Bank/IFC Doing Business 2011 Report are presented. The paper will conclude that STI will enable countries to embark on knowledge-based economies to join the 21st Century. The paper makes some suggestion for consideration by policymakers in the Republic of Macedonia (Macedonia).

Keywords

Science, Technology and Innovation (STI), R&D, knowledge-based economies, Indicators

1. Introduction

Many small countries such as Finland, Ireland, the Republic of Korea (Korea), Malaysia, Singapore and Taiwan have achieved knowledge-based economic growth by building up their national Science, Technology and Innovation (STI) capacity and implementing STI strategies. In Korea the Government has established a “Ministry for Knowledge Economy” and Ireland has articulated an explicit knowledge economy strategy. The emergence of Information Communication Technology (ICT), Biotechnology and Nanotechnology provide great opportunities for small and large countries to attain knowledge-based economies.

The World Bank identified (World Bank Institute (WBI) – Building Knowledge Economies, 2007) Four Interactive Pillars for Knowledge Economy, namely: (1) Economic and Institutional Regime: Provides incentives for the efficient creation, dissemination, and use of existing knowledge. (2) Education and Skills: An educated and skilled population can use knowledge effectively (3) ICT Infrastructure: Facilitates the effective communication, processing and dissemination of information, and (4) Innovation System: A system of organizations that can tap into global knowledge to assimilate and adapt it, as well as create local knowledge. The rationale of the four pillars is that “Knowledge economy relies on knowledge as the key engine of economic growth. It is an economy in which knowledge is acquired, created, disseminated, and applied to enhance economic development”. WBI also developed a Knowledge Economy Index to measure countries “knowledge economy readiness”.

The United Kingdom Economic and Research Council, in 2005, described the process of knowledge economy as “economic success is increasingly based on the effective utilization of intangible assets such as knowledge, skills, and innovative potential as the key resource for competitive advantage. The term knowledge economy is used to describe this emerging economic structure.”

Main Drivers for Knowledge Economy: The main drivers for STI leading to knowledge-based economy include investments in: (i) education, at all levels, (ii) R&D, including capacity building and collaborative research, (iii) venture capital, (iv) techno-parks (science parks) and business incubators,

entrepreneurship, and (v) commercialization of proven technology. These investments will not yield the desired results unless (a) there is an overall macroeconomic framework with continues structural reform, (b) the enabling environment to encourage private sector development, and (c) removing the administrative barriers to facilitate the ease of doing business. These are important factors to encourage Foreign Direct Investments (FDI), which will also lead to technology transfers and spillover effects.

Policymakers and economists in industrialized countries view Science, Technology and Innovation (STI) and investments in R&D as the “Engine of Economic Growth” (Rand Report). According to the new economic growth model, economic growth is rooted in education, research, technology and innovation. Thus, investments in R&D could result in higher economic growth and have direct impact on the national economy and the well-being of the society. I believe that policymakers in Macedonia share this view.

2. Science, Technology and Innovation (STI) Indicators

Various indicators are used to monitor and measure STI. These indicators include, (i) Gross domestic Expenditures on R&D (GERD) as percentage of GDP, (ii) Number of Scientific and Technical Journal Articles, (iii) Number of Researchers in R&D per Million People, (iv) GERD per Researcher, (v) Number of Patents Applications filed, and (vi) High-Technology Exports as percentage of manufactured exports. In addition, Science Citation Index (SCI) is the most commonly used indicator to measure scientific output. It should be noted that STI Indicators which were relevant in the past may be less relevant today and should be complemented by indicators such as the number of internet users per 1000 people. The following section reviews some of these indicators for selected countries, with special focus on Macedonia.

Table 1 Key STI Indicators for Selected Countries

	R&D Expenditures as % of GDP	Researchers in R&D per Million People	High-Technology Exports as % of Manufactured Exports	Number of Patents filed by Residents	Number of Patents filed by non-residents
Israel	4.74*	NA	16	1,528	7,263
Finland	3.47	7,382*	21	1,799	205
Korea, Rep.	3.47	4,627	33*	127,114	40,940
USA	2.67	4,663	27	231,588*	210,062*
Austria	2.52	3,774	12	2,298	745
China	1.49	1,071	29	194,579	80,155
Montenegro	1.18	NA	NA	NA	NA
Croatia	0.93	1,384	9	330	122
India	0.80	137	6	5,314	NA
Moldova	0.55	724	4	273	9
Greece	0.50	1,873	10	803	NA

Egypt	0.23	617	1	516	1,008
Macedonia	0.21	521	1	34	NA
Bosnia	0.03	197	4	59	NA

Source: World Bank – World Development Indicators (WDI) 2010

All data are for 2008 or 2007. If data is not available for these years; the most recent data from previous years are used. *Highest score for each indicator.

It should be noted that Israel has the highest ratio in the World (4.74%) of R&D expenditures as % of GDP. Finland and Korea are the second highest ratio of 3.47%. This is compared with a very modest ratio for Egypt (0.23%) and Macedonia (0.21%).

The highest number of researchers per million people is recorded in Finland (7,382) compared with 617 and 521 in Egypt and Macedonia, respectively.

The highest ratio of high-technology exports as % of manufactured exports is in Korea (33%) followed by China (29%) where as Egypt and Macedonia record only 1%.

The USA registered the highest number of patents 231,588 (residents) and 210,062 (non-residents) followed by China 194,579 (residents) and 80,062 (non-residents). This is compared with Egypt 516 (residents) and Macedonia 34 (residents).

R&D Expenditures as % of GDP: This is equivalent to the GERD as % of GDP, which is being used by the UNESCO Science Report 2010. This includes capital and current expenditures by both public and private sectors. While this is an important indicator, one should analyze the composition of these expenditures. In some countries these expenditures include very high amounts (about 85% – 90%) for salaries of researchers and technicians; which leaves little funds for buying equipments and materials for conducting research.

Researchers per Million People: While the number of researchers and technicians are important, it is the quality, the skills and competencies of the researchers that are more significant.

Ratio of High-Technology Exports: The higher the ratio of high-technology exports to manufacturing exports the more likely the country is moving toward a knowledge based-economy.

Scientific and Technical Articles: The number of these articles is important. However, how many of these articles are patented and commercialized is the “acid test” for contributing to the knowledge-based economies.

Patents: Scientists and researchers should be encouraged to register patents, but it is more important to commercialize patents and proven technologies

3. R&D Financing Sources and Instruments

This section of the paper summaries the main sources and instruments for financing R&D, as follows:

- **Government/Public Sector:** Direct budget funding (core funding) of national research institutions and university research. Governments also finance some research projects carried out by universities and private sector corporations/companies such as: Airbus, Philips, Siemens, Ericson, Nokia, IBM, GE, and Lockheed Martin, etc.

Table 2 and Chart 1 show the trends (2000-2008) of GERD as percentage of GDP for selected countries.

Table 2: Trends of GERD as % of GDP in Selected Countries*

	2000	2001	2002	2003	2004	2005	2006	2007	2008
Israel	4.32	4.6	4.59	4.32	4.26	4.37	4.42	4.76	4.86

Source: UNESCO Science Report 2010

* The numbers in the above table are slightly different from the numbers given by the World Bank – World Development Indicators (WDI) 2010 shown in Table 1.

Figure 1 Trends of GERD as % of GDP in Selected Countries

Source: UNESCO Science Report 2010

It should be noted that Korea's GERD as % of GDP has increased by almost 1% between 2000 (2.3%) and 2007 (3.21%). China's GERD as % of GDP has increased from 0.9% in 2000 to 1.44% in 2007, an increase of about 0.5% over 7 year period. This perhaps explains why Korea and China's high-technology exports as % of total manufactured export are 33% and 29% respectively compared with 27% for the USA (Table 1). Korea is planning to raise its GERD/GDP ratio to about 5% by 2012 compared with 3.21% in 2007. China is planning to raise the GERD/GDP ratio from 1.44% in 2007 to 2.5% by 2020. In the United States the Obama administration is to increase GERD/GDP ratio from about 2.7% to 3.0%. In 2009, the second stimulates package included significant investments in STI, including R&D. While higher spending on R&D is important, equally important is increasing expenditures on knowledge-based intangibles, such as ICT, skills and competencies to prepare "knowledge workers" to support knowledge-based economies.

- **Private Sector:** Many corporations/companies, including Small and Medium Enterprises (SMEs) directly invest in R&D by: (i) carrying out their own R&D, and (ii) financing specific R&D projects in public research institutions and universities. In Kuwait the private sector indirectly finances R&D through contributions (currently 1% of net profits for companies registered in the Kuwait Stock Exchange) to the Kuwait Foundation for the Advancement of Science (KFAS), which finances, among other activities, R&D projects and training in Kuwait and outside Kuwait.

Public Sector funding for R&D is declining: The share of public sector funding for R&D expenditures over the years has been declining. About 70% of all OECD R&D was performed by the enterprise/private sector in 2000, compared with about 10% by government sector and about 17% by universities (UNESCO – Global Investment in R&D Today, 2003). The share of private sector financing of R&D in the Arab World is rather low -- only about 3% -- (compared with about 70% in OECD countries), while the public sector financed about 89% and other sources funded about 8% (UNDP - Arab Human Development Report, 2003). Chart 2 shows the declining trends in public sector funding for R&D in selected countries.

Figure 2 Trends of Public sector Funding for selected Countries

Setting Targets for R&D Investments: In 2000, at the Lisbon Summit the European Union made a commitment to increase R&D spending to 3% of GDP by 2010. This target has been reconfirmed during the European Council meeting in Barcelona in March 2002. The Barcelona meeting set a target of 3% of EU GDP for investments on R&D by 2010, with at least two-thirds (2/3) of R&D funding coming from the private sector. According to the UNESCO Science Report 2010, it seems that the EU is unable to meet the Barcelona target of 3% of GDP by 2010. It should be noted that in the United States, the business (private) sector accounted for 73% of R&D spending in 2008 (NSF 2010 Report).

- Taxes Incentives are specifically targeted to finance R&D. Many countries provide tax breaks for companies' expenditure on R&D. Such tax breaks could result in additional expenditures by companies in R&D. For example, (i) in the Netherlands, a one Euro of tax alleviation for companies have resulted in an added 0.01-0.02 Euro in R&D expenditures and (ii) in Jordan the Companies Law No.22 of 1997 and its amended Article 188 stipulate that "A Public Shareholding company should allocate at least 1% of its annual net profit to be spent for supporting scientific research and vocational training.....". Such an allocation is spent on "in-house" R&D and/or the company's human resources development. Turkey provides tax incentives for techno-parks (Science Parks), of which there were 18 in 2008 (UNESCO 2010 Science Report). In the United States, the Government promotes the conduct of R&D through tax incentives. About 11,000 companies claimed an estimated \$7.3 billion in federal research and experimentation tax credit in 2006, compared with \$6.4 billion in 2005 (NSF 2010 Report).
- Non-Profit Organizations, Grants, Endowments and Wills are means of financing R&D in many countries. Some private citizens and foundations, such as Melinda and Bill Gates foundation provide funds to carryout research in various areas such as cancer, HIV/AIDS and Alzheimer. Some not-for-profit organizations such as the International Development Research Center (IDRC) in Canada, the US Civilian Research & Development Foundation Global (CRDF Global), in the USA, finance R&D in their home countries and overseas.
- Collaborative research: A great deal of resources is available for financing collaborative research in various countries, e.g. the National Technology Agency of Finland (Tekes), Sandia National Laboratories in the USA, etc. A Rand Report prepared for the World Bank in 2001 indicated that about \$1.4 billion are available annually to finance collaborative research between scientifically advanced countries and other countries. More recent estimates indicate that collaborative research in the EU amounts to about Euro 60 billion annually. Collaborative research is important for countries since it (i) addresses common areas for local, regional and international issues and challenges, (ii) provides an additional source for funding R&D, and (iii) increases interaction and collaboration between scientists from different countries, which contributes to capacity building for scientists. CRDF Global, with the support of the State Department of United States, lunched in 2010 a Global Innovation through Science and Technology (GIST) Initiative. The GIST Initiative is one of the components of Science and Technology collaboration proposed by President Obama in his Cairo speech in June 2009. The first event of the GIST initiative was launched at the Library of Alexandria in December 2010. The main objective of this initiative is to enable policymakers,

research institutions, scientists, private sector and civil society to promote innovation, invention, and entrepreneurship to commercialize technologies and create knowledge based economies. The second event was held in Kuala Lumpur in February 2011 to focus the ideas and proposals from the Alexandria event on how to brighten the innovation environment to catalyze technology transfer for commercialization and promote technology entrepreneurship. GIST programs and their implementation guidelines will be announced at a conference entitled “Economic Development through Science and Technology Innovation” in Rabat, Morocco in June 2011. (GIST Website).

- Foreign Direct Investments (FDI) and Offset programs are good sources of financing R&D. Norway has required oil concession holders to spend certain portion of revenue on R&D. Oil companies fulfilled these obligations by funding R&D at Norwegian institutions. Kuwait had also reached a similar agreement with the Arabian Oil Company and KISR was the first product of such agreement. Thus, KISR is the first product of the offset program in Kuwait.
- National and International prizes provide incentives for quality R&D on specific topics and challenging areas of research.

4. Investing in Macedonia

Macedonia has been encouraging investment by making it easier to do business. PRICEWATERHOUSECOOP'S report entitled “Guide to Doing Business and Investing in Macedonia 2010 Edition” documents the Business Environment, Foreign Investment, Banking and Finance, Importing and Exporting, Business Entities, Labor Relations, Auditing and Accounting, and Taxation. Macedonia has also made advertisements on CNN to entice foreign investment. Table 3 shows the ranking of Macedonia and selected group of countries in the World Bank/IFC “Doing Business Report 2011”.

Table 3 Ranking of Selected Countries For Ease of Doing Business

	2011 183 Countries	2010* 183 Countries
Macedonia	38	36
Slovak, Rep.	41	40
Slovenia	42	43
Armenia	48	44
Croatia	84	89
Serbia	89	90
Egypt	94	99
Greece	109	97
Kosovo	119	118

Source: World Bank/IFC: Doing Business 2011

*2010 rankings are adjusted to the 9 topics used in the 2011 Rankings, and reflect corrections from Doing Business 2010. The 9 topics are: Starting a Business, Dealing with Construction Permits, Registering Property, Getting Credit, Protecting Investors, Paying Taxes, and Trading Across Borders, Enforcing Contracts, and Closing Business.

It should be noted that Macedonia ranked number 38 out of 183 countries who participated in the Doing Business Survey in 2011. Macedonia's rank was by far better than Egypt and Greece whose rank was 94 and 109 respectively in the same survey in 2011. Starting a business in Macedonia was much easier than in any of the selected countries in Table 3. Encouraging investment and making it easy to do business in Macedonia are important factors in paving the way for knowledge-base economy.

5. Conclusions and Recommendations

As a small country, Macedonia has a limited market. Macedonia, however, should target its R&D to regional markets. Based on the analyses made in this paper the following conclusions and recommendations emerge for the consideration of the policymakers of Macedonia:

Setting a Target for R&D Expenditures: As indicated earlier, Macedonia currently invests about 0.21% of its GDP on R&D. This is very low by international standards, the World average R&D expenditures in 2007 was 2.21% of GDP and the average for the European Union was 1.98% in the same year. It is recommended that Macedonia set a target of 1.0% of its GDP for investments in R&D by the year 2020.

Increasing High-Technology Exports: In 2007, Macedonia exported only 1% of its manufactured exports as high-technology products. This is a very low ratio compared with a World average of 17% and the European Union average of 14% in the same year. The potential impact of increasing investments in STI and increasing high-technology exports from Macedonia will enable Macedonia to move faster towards a knowledge-based economy, which will increase economic growth and improve the well-being of the society. It is recommended that Macedonia make a concerted effort to increase its high-technology exports.

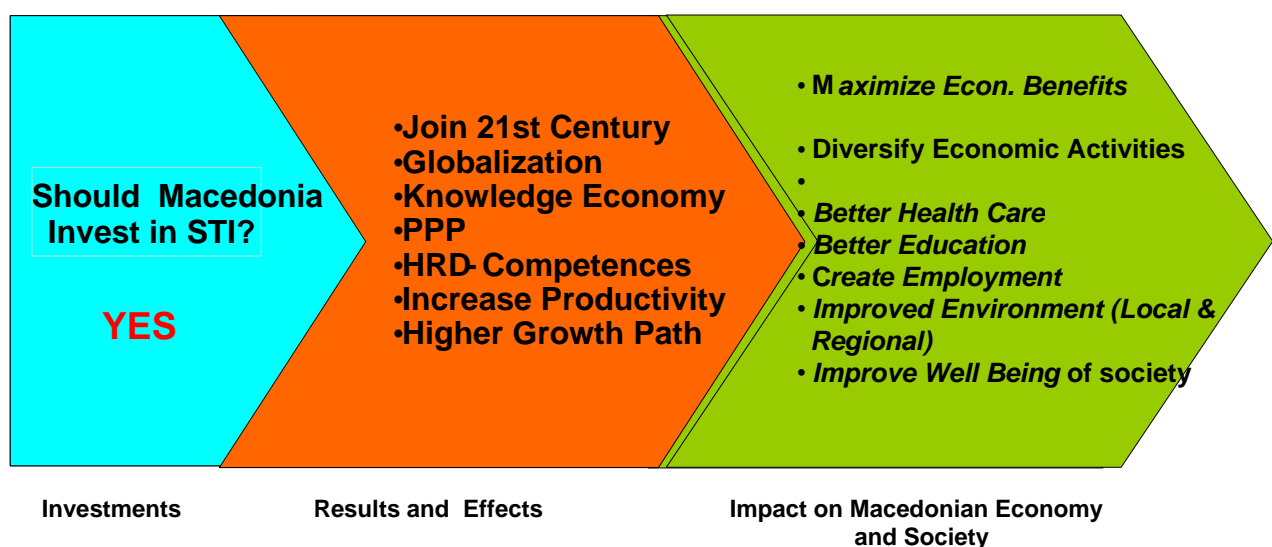

Strategic Alliances and Increasing Collaborative Research: Collaborative research will not only increase source of funding R&D but more importantly it increases interaction with regional and international scientists, which is important to build up the capacity of researchers and scientists in Macedonia. It is recommended that Macedonia establishes Strategic Alliances with reputable research institutions and increase collaborative research at the regional and international levels.

Commercialization and Venture Capital: In OECD countries about 0.07% of OECD GDP were allocated for early phase development and about 0.27% of GDP for expansion phase. In the USA these allocations were about 0.12% and 0.29% respectively. It is also recommended that specific allocations for venture capital investments for the commercialization of proven technologies should be allocated for early phase and expansion phase developments in Macedonia.

Increasing the private sector funding for R&D is also recommended.

Establish an Annual Presidential Prize: The proposed prize will encourage researchers to conduct high quality research for commercialization, which will contribute to higher economic growth and create jobs for the people of Macedonia. It is recommended that HE the President of Macedonia establishes an annual Prize for high quality research and innovation in areas of strategic importance to Macedonia.

Should Macedonia Invest in Science, Technology and Innovation?

The above diagram is based on the National Technology Agency of Finland (Tekes) and summarizes the reasons why Macedonia should continue to invest and increase its investments in Science, Technology and Innovation (STI).

Macedonian Entrepreneurs and Their Efficient and Effective Time and Stress Management Skills

Angelina Taneva-Veshoska¹, Ljubomir Drakulevski²

¹FON University, Skopje, Macedonia, angelina.tanevaveshoska@fon.edu.mk

²Faculty of Economics, Ss. Cyril and Methodius University, Skopje, Macedonia, drakul@eccf.ukim.edu.mk

Purpose – The purpose of this paper is to examine the relationships between time and stress management skills and their personality type among Macedonian entrepreneurs. **Design/methodology/approach** –It is argued here that Macedonian entrepreneurs have efficient and effective time and stress management, which is related to their own personality type. **Findings** –Results show that personality type is significantly related to time management and coping responses entrepreneurs use. **Research limitations/implications** – Limitations of this research include narrow sample, not the best representative of the population. **Practical implications** – This research provides implications for practice in several areas: development and sustainment of entrepreneurs with excellent time management skills and development and sustainment of entrepreneurs with excellent coping response strategies. **Originality/value** – This research contributes to the field by offering support and new findings. This study adds to the body of literature in what is considered a relatively new area of study. The survey conducted among Macedonian entrepreneurs contributes a lot for the knowledge about entrepreneurship in Macedonia.

Keywords

Coping Response Strategies, Entrepreneur, Personality type A and B, Stress Management, Time Management

1. Introduction

Managing time and stress is one of the crucial management skills in a competent entrepreneur's repertoire. A review of the surveys conducted on time and stress management and its relation with human health illustrates the wide-ranging and devastating effects of stress. The National Institute of Occupational Safety estimated that almost half of all adults suffer adverse health effects due to stress. An estimated one million workers are absent on an average working day because of stress-related complaints and approximately 555 million workdays are lost each year due to stress. In one major corporation, more than 60 percent of absence was found to be stress related. And about 40 percent of worker turnover is due to job stress. It is estimated that business in the United States alone will spend more than \$12 billion on stress and time management training. [1]

Time is usually the greatest source of stress for entrepreneurs. Even though there are hundreds of books on time management, organizers, consultants, still entrepreneurs are increasingly stressed by a perceived absence of time. Time stress is escalating because the rapidity of change and the overwhelming amounts of information that entrepreneurs encounter on their job. Most of them are moving pretty fast just to keep up, but still feel inadequate because they find it impossible to completely keep up. The Hilton Time Value Survey found that 77 percent of people identified their top goal in the coming decade as "spending more time with family and friends". Two-thirds of the respondents indicated a desire to put more emphasis on "having free time". The trouble is that the average entrepreneur was required to engage in between 237 and 1073 separate incidents a day. More than a third of entrepreneurs indicated that they don't accomplish what they set out to do each day and time stress results. [2]

2. Stress and time management

Almost everyone suffers now and then from a pervasive feeling of time stress. Along with the information age has come an increasing sense that each of us is falling behind. For example, this week more books will be published in the United States or any other modern country, than any entrepreneur can read in the remainder of his life. Consequently, we all have the feeling that we just can't quite keep up. Somehow, no matter how much time is available, it seems to get filled up and squeezed out. Currently, the most common prescribed solutions for attacking problems of time stress are to use calendars and planners, to generate to-do lists and to learn to say "no". Although these tactics are sometimes useful, still they are more examples of an efficiency approach to time management, rather than an effectiveness approach. In eliminating time stressors, efficiency without effectiveness is fruitless.

Two sets of skills are important for effectively managing time and for eliminating time stressors. One set focuses on efficiently using time each day. The other set focuses on effectively using time over the long term. Managing time with an effectiveness approach means that:

- individuals spend their time on important matters, not just urgent matters;
- people are able to distinguish clearly between what they view as important versus what they view as urgent;
- results rather than methods are the focus of time management strategies;
- people have no reason not to feel guilty when they must say "no".

A number of time management experts have pointed out the usefulness of a "time management matrix" in which activities are categorized in terms of their relative importance and urgency. [3] Important activities are those that produce a desired result. They accomplish a valued end, or they achieve a meaningful purpose. Urgent activities are those that demand immediate attention. They are associated with a need expressed by someone else, or they relate to an uncomfortable problem or situation that requires a solution as soon as possible. Activities such as handling employee crises or customer complaints are both urgent and important. A ringing telephone, the arrival of the mail or unscheduled interruptions might be examples of urgent but potentially unimportant activities. Important but non urgent activities include developmental opportunities, innovating, planning and so on. Unimportant and non urgent activities are escapes and routines that people may pursue but which produce little valuable payoff: for example, small talk, daydreaming, shuffling paper or arguing.

Table 1 Types of activities that determine Time Use

		Urgency	
		High	Low
Importance	High	Crises, Customer complaints	Developmental opportunities, planning, innovating
	Low	Mail, telephone	Escapes, routines

Usually in the lives of entrepreneurs dominate activities that are important and urgent. They are seen as "have to" activities that demand immediate attention. Attending a meeting, responding to a call or request, interacting with a customer or completing a report might all legitimately be defined as important and urgent activities. The trouble with spending all one's time on activities like this is that they all require the manager to react. They are usually controlled by someone else, and they may or may not lead to a result the manager wants to achieve.

The problem is even worse when it comes to unimportant and urgent activities. Demands by others that may meet their needs but that serve only as deflections or interruptions to the entrepreneur's agenda only escalate a sense of time stress. Because they may not achieve results that are meaningful, purposeful, and valued-in other words, important-feelings of time stress will never be overcome. Experiencing overload and loss of control can be guaranteed. Entrepreneurs are merely reactive in these situations. Moreover, when these time stressors are experienced over an extended period of time, people generally try to escape into performing activities that are non important and non urgent to relieve the stress. They escape, shut out the world or put everything on hold. Although feelings of stress may be temporarily relieved, no long term solutions are implemented, so time stress is never permanently reduced. That means lives are spent battling crises 95 percent of the time and escaping 5 percent of the time. A better alternative is to focus on activities that are important and non urgent, which may label opportunities instead of problems. They are oriented toward accomplishing high-priority results. They prevent problems from occurring or build processes that eliminate problems

rather than just reacting to them. Preparation, preventive maintenance, planning, building resiliency and organizing are all “non-have-to” activities that are crucial for long term success. But, because they are not urgent, they are driven out of entrepreneurs’ time schedules.

Important moderator of the effects of stress is an individual’s psychological resiliency. Individuals with certain psychological characteristics or personality types tend to handle stress better than others. Type A personality relates to a personality pattern many individuals develop as they enter the competitive worlds of advanced education and of management. For more than five decades, scientists have been aware of a link between certain personality attributes and stress-related behavioral, psychological and physiological problems such as anxiety, deteriorating relationships and heart disease. [4] Subsequent research has found that in America about 70 percent of men and 50 percent of women exhibit Type A personality traits, such as extreme competitiveness, strong desires for achievement, haste, impatience, restlessness, hyper alertness, explosiveness of speech, tenseness of facial muscles, free-floating hostility and so on. Most Type A individuals believe it is their Type A personality that has led to their success. Many are unwilling to give up that orientation because hard driving, intense, persistent action is generally admired and valued among entrepreneurs.

2.1. Time and stress management skills among Macedonian entrepreneurs

The purpose of this paper is to explore the research questions: How well are Macedonian entrepreneurs using their time and stress management skills? Is there a correlation between type of personality of the entrepreneur and the way he copes stress and his time management strategies among Macedonian entrepreneurs? Are they using their time management skills efficiently and effectively? Do entrepreneurs spend more time doing important and urgent matters or they can’t say “no” and spend time doing things that are urgent but not important?

Based on the research problem and theory the following *hypothesis* is formulated: There is a correlation between the personality type of entrepreneurs with the coping strategies and time management skills among Macedonian entrepreneurs. Also it was expected to find positive correlation between time management skills and coping strategies, as well as positive correlation between the coping strategies Macedonian entrepreneurs use.

2.2 Methods

2.2.1 Sample

The sample group consisted 82 entrepreneurs working in SME in Macedonia. Because of incomplete data 10 entrepreneurs were not included in the final analyzes of the results, which induced the sample to 72 entrepreneurs. The sample group consisted 47 males (65,3 percent) and 25 females (34,7 percent). Entrepreneurs in this sample group had different education: high school diploma, college diploma, university diploma, MA and PhD (Table 2).

Table 2 Manager’s formal education

high school	college	university	MA	PhD
11	6	50	1	4
15,3 %	8,3 %	69,4 %	1,4 %	5,6 %

According to the marital status 53 entrepreneurs were married (73 percent), while 19 entrepreneurs (26 percent) were single or divorced. Their age was between 20 and 52 years, and the average age was 31 for all entrepreneurs, or the average age of the female in the sample was 29 years, while the mean age for the males was 33 years.

2.2.2 Data collection

An introductory email was sent to the sample population, explaining the study and inviting their participation. Following this introduction, we emailed the population to explain the study in greater detail and the method of participation. Three reminder email notices were subsequently sent to those who had not previously responded.

2.2.3 Measurement of variables

Independent variable: Type A and type B personality type that describes a pattern of behaviors that were once considered to be a risk factor for coronary heart disease. Type A individuals can be described as impatient, excessively time-conscious, insecure about their status, highly competitive, over-ambitious, business-like, hostile, aggressive, incapable of relaxation in taking the smallest issues too seriously; and are somewhat disliked for the way that they're always rushing and demanding other people to serve to their standards of satisfaction. They are often high and over-achieving workaholics who multi-task, drive themselves with deadlines, and are unhappy about the smallest of delays. Because of these characteristics, Type A individuals are often described as "stress junkies." Type B individuals, in contrast, are described as patient, relaxed, and easy-going. [5] The personality types were assessed through the Type A and B Personality Inventory, designed by Friedman and Rosenman. The Inventory is composed of a series of behavioral indicators based on their theory. Respondents were asked to complete each item on a frequency scale ranging from "not typical for me" to "very typical for me". The scores described the person by 4 dimensions: competitiveness, impatience free-floating hostility and urgency.

We've chosen a questionnaire because it structured and we wanted all the respondents to be treated equally, answered the same questions, so that we can easily assess the answers later. Also this questionnaire was developed and used in lot of other research studies before; it has a good validity and reliability. Here are some questions that we ask the entrepreneurs to find out which personality type they are:

1. My greatest satisfaction comes from doing things better than others.
2. I move, walk, and eat rapidly.
3. I feel as though I can accomplish more than others.
4. I feel guilty when I relax or do nothing for several hours or days.
5. I hurry the speech of others by saying "Uh huh", "Yes, yes", or by finishing their sentences for them.
6. To do something well, you have to concentrate on it alone and screen out all distractions.
7. I find it intolerable to watch others perform tasks I know I can do faster.
8. Getting ahead in my job is major personal goal.
9. I simply don't have enough time to lead a well-balanced life.
10. I frequently try to do two or more things simultaneously.
11. I tend to fill up my spare time with thoughts and activities related to my work.
12. I find it anguishing to wait in line.

All these questions are very well chosen to clearly define the personality type and all its characteristics. For example, people with type A personality want to spend their time working, competing with others, setting goals that demand a lot of work in a very short period of time, they can't relaxed and that's why they are often stressed out or even burn out. But the way they manage their life also helps them to manage their time better, but the main question is are they efficient and effective? Asking these questions we wanted to find out how Macedonian entrepreneurs manage their time, work and life in general.

2.2.4 Dependent variables: stress management strategies and time management

Stress management strategies can be strategies to approach stress situations and strategies to avoid stress situations. The stress management strategies were measured with Coping Response Inventory (CRI) by Rudolf Moos.[6] The CRI assesses an individual's approach and avoidance coping skills in response to stressful life circumstances and other challenges. The CRI also allows clinicians to develop more complete case descriptions and to evaluate treatment outcomes. Approach coping responses are: 1. logical analysis, 2. positive reappraisal, 3. seeking guidance and support, 4. problem solving. The first two are cognitive responses, and the second two are behavioral responses. Avoidance coping responses are: 1. cognitive avoidance, 2. acceptance or resignation, 3. seeking alternative rewards, 4. emotional discharge. Coping is a complex process. It is variously described as a situational and as a trait-like response, as a response to stress and as a disposition to respond to change. It is generally considered to be a stress-specific pattern by which an individual's perceptions, emotions, and behaviors prepare for adapting and changing. The more narrow view of coping is described here as "coping style" and represents a more observable but general style of interacting. Our expectations were that stress management strategies are relevant to the subject and we can get to know the entrepreneurs even better this way. It was important to see how Macedonian

entrepreneurs react and what strategies they use when they are under stress. All the respondents are entrepreneurs, so it is expected to have a stressful job. With this questionnaire we can see if the Macedonian entrepreneurs use approach coping responses or avoidance coping responses. Here are some of the questions that we asked: When faced with a problem did you:

- Had time to prepare?
- Thought of problem as a threat?
- Thought of way to resolve the problem?
- Thought of a problem as a challenge?
- Talked with your spouse or relative?
- Made plan of action?
- Tried to forget the whole thing?
- Felt angry, defeated, scared?

Time management is the second dependent variable. The inventory used to measure time management was developed by Whetten and Cameron and consists two parts, the first one which measures time management in every day life and the second part, which measures time management at work. The respondents were asked to complete each item on a frequency scale ranging from "never" to "always". The final score they have is between 0 and 160.[7]

Here are some of the questions that were asked:

1. I make a list of tasks to accomplish each day.
2. I divide large projects into smaller, separate stages.
3. I have some time during each say when I can work uninterrupted.
4. I set deadlines for myself.
5. I have clearly defined long-term objectives toward which I am working.
6. I continually try to find little ways to use my time more efficiently.
7. I finish at least one thing every day.
8. I concentrate on only one important task at a time, but I do multiple trivial tasks at once (such as signing letters while talking on the phone).
9. I don't procrastinate. I do today what needs to be done.
10. I do something productive whenever I am waiting.

This questionnaire offers lots of questions and measures how well people manage their time. But, also answering these questions entrepreneurs are telling how efficiently and effectively manage their time, especially the ways they use. [8] One of our goals is to see how Macedonian entrepreneurs deal with things that are important, but not urgent, or with things that are urgent, but not important. Having asked these questions we can found out are they using their time management skills efficiently and effectively? Do entrepreneurs spend more time doing important and urgent matters or they can't say "no" and spend time doing things that are urgent but not important?

2.2.5 Data analysis

The hypotheses were tested using Spearman's rank correlation coefficient or Spearman's rho. The hypothesis suggested that is positive correlation between the personality type of the individuals and their coping mechanisms, as well as correlation between the personality type and time management skills. For all the variables descriptive statistics (means, standard deviations) were also calculated.

2.3 Results

The descriptive statistics are reported in following tables. In Table 3 are reported means and standard deviations of all variables. If we compare the theoretical value of the independent variable (48) with the found one (47,29) we can conclude that there are entrepreneurs with both type A and type B personality behavior. According to the result on time management we can say that Macedonian entrepreneurs are very good time entrepreneurs. The descriptive statistics show that the most commonly used strategies among Macedonian entrepreneurs are: logical analysis, positive reappraisal and problem solving, which also mean that Macedonian entrepreneurs approach the stress situations. Sometimes they use strategies like: cognitive avoidance or seeking alternative rewards, which are avoidance coping responses.

Table 3 Descriptive statistics

Variable	M	σ
Personality Type A or B	47,2917	7,5142
Time management	103,5556	14,7169
Logical Analysis	12,6389	3,5734
Positive Reappraisal	12,3611	3,4896
Seeking Guidance and Support	9,9722	3,9645
Problem Solving	12,9306	4,0985
Cognitive Avoidance	8,6528	3,9438
Acceptance or Resignation	6,3611	3,9193
Seeking Alternative Rewards	10,1111	3,6446
Emotional Discharge	3,7639	3,1778

Correlation between personality type and time management is 0,36 ($p < 0,01$). The level of significance for this correlation is very high and statistically valid.

On Table 4 are presented the correlations between personality type and approach coping responses. There is high correlation between the personality type and Problem solving response. The same analysis is made for avoidance coping responses, shown on Table 5.

Table 4 Correlations between personality type and approach coping responses

Variables	Logical analysis	Positive reappraisal	Seeking guidance and support	Problem solving
Personality type	0,124	0,204	0,215	0,326**

Notes: * $p < 0,05$; ** $p < 0,01$; $n = 72$

The results show positive correlation between these variables, especially between personality type and cognitive avoidance, seeking alternative rewards and emotional discharge.

Table 5 Correlations between personality type and avoidance coping responses

Variables	Cognitive avoidance	Acceptance or resignation	Seeking alternative rewards	Emotional discharge
Personality type	0,352**	0,022	0,237*	0,485**

Notes: * $p < 0,05$; ** $p < 0,01$; $n = 72$

Also, correlations are calculated for all coping responses (shown on Table 6). As expected, we found correlations between almost every coping response. There are high positive correlations between all approach coping response.

The same way correlations are calculated for avoidance coping response (shown on Table 7).

Table 6 Correlations between approach coping responses

Variables	Logical analysis	Positive reappraisal	Seeking guidance and support	Problem solving
Logical analysis	1,000	0,564**	0,230	0,467**
Positive reappraisal	0,564**	1,000	0,528**	0,489**
Seeking guidance and support	0,230	0,528**	1,000	0,449**
Problem solving	0,467**	0,489**	0,449**	1,000

Notes: * $p < 0,05$; ** $p < 0,01$; $n = 72$

Table 7 Correlations between avoidance coping responses

Variables	Cognitive avoidance	Acceptance or resignation	Seeking alternative rewards	Emotional discharge
Cognitive avoidance	1,000	0,565**	0,202	0,401**
Acceptance or resignation	0,565**	1,000	0,250	0,232*
Seeking alternative rewards	0,202	0,250	1,000	0,170
Emotional discharge	0,401**	0,232*	0,170	1,000

Notes: * $p < 0,05$; ** $p < 0,01$; $n = 72$

Statistical analysis is made for the dependent variables and their correlations were calculated. The results are shown in the next tables.

Table 8 Correlations between time management and approach coping responses

Variables	Logical analysis	Positive reappraisal	Seeking guidance and support	Problem solving
Time management	0,153	0,212	0,147	0,340**

Notes: * $p < 0,05$; ** $p < 0,01$; $n = 72$

Table 9 Correlations between time management and avoidance coping responses

Variables	Cognitive avoidance	Acceptance or resignation	Seeking alternative rewards	Emotional discharge
Time management	0,007	-0,267*	0,346**	0,062

Notes: * $p < 0,05$; ** $p < 0,01$; $n = 72$

Time management was positively correlated with problem solving, and with seeking alternative rewards. Also, time management was negatively correlated with acceptance or resignation.

3. Conclusions

The results of this survey showed that the hypothesis was supported, because of the positive correlation found between the variables, time management, and personality type and coping responses. The positive correlation between personality type and time management means that entrepreneurs who are type A personality are better at managing time, than entrepreneurs who are type B personality. Entrepreneurs with type A personality set more short term goals. They also do things very rapidly, and are always in a hurry. They also have tendency to evaluate all activities in terms of measurable results. The determination to win every situation they have, made them learning skills which are important for better ways of managing time. [9]

Results showed that there is positive correlation between the personality type and approach coping responses. One of the approach coping response was problem solving, which points out that it is more expected from the type A personality entrepreneurs to have fast action and reactions toward the problem situations. These entrepreneurs are also prone to use some of the avoidance coping responses, like cognitive avoidance, seeking alternative rewards and emotional discharge. These strategies are behavioral, which also means that they use lot emotions too. Entrepreneurs, who are calmer, like entrepreneur with type B personality, more likely think a lot before they act or avoid the stress situation. The results from this sample group of entrepreneurs point out that Macedonian entrepreneur tend to use approach coping response more frequently than avoidance coping response. Macedonian entrepreneurs use logical analysis and positive reappraisal before acting. This fact conforms that the respondents use cognitive strategies when faced with a stressful situation, which leads to greater results and more problems solved. In addition to this, Macedonian entrepreneurs very often tend to use action in problem situations, supported with lots of information and appraisal from their colleagues. The active use of cognitive and behavioral strategies gives the entrepreneur power to restore his capacity and strengths in every stress situation, maintaining the individual balance.

The interview with Macedonian entrepreneurs showed that they have typical patterns of using time, not very different from the other population in the world. They often do the activities they like, before the activities they don't like. Also, they perform the things they know how to do faster, things that are easier, or require little time. Entrepreneurs stated that they have schedules and are planning things in

advance, setting dead lines on every goal. Still, they admit that sometimes, they respond to demands of others, before their own demands, and very often they respond to crises and things that are urgent, but not important. The good thing is that these entrepreneurs are aware of their ways of using time and are searching for techniques to improve their own time management skills.

From the questions we asked and behavior we can observe, we can say that these entrepreneurs have typical patterns of time use:

1. They do what they like to do before they do what they don't like to do.
2. They do things they know how to do faster than the things they do not know how to do.
3. They do the things that are easiest before things that are difficult.
4. They do things that require a little time before things that require a lot of time.
5. They do things for which the resources are available.
6. They do things that are scheduled (e.g. meetings) before nonscheduled things.
7. They sometimes do things that are planned before things that are unplanned.
8. They respond to demands from others before demands from us.
9. They do things that are urgent before things that are important.
10. They readily respond to crises and to emergencies.
11. They do interesting things before uninteresting things.
12. They do things that advance our personal objectives or that are politically expedient.
13. They wait until a deadline before they really get moving.
14. They do things that provide the most immediate closure.
15. They respond on the basis of the consequences to us of doing or not doing something.
16. They tackle small jobs before large jobs.
17. They work on things in the order of arrival.

In our proposal we expressed that we're interested to find out how many of the Macedonian entrepreneurs spend time to increase their management knowledge and to develop better management skills. For what we found is that Macedonian entrepreneurs sometime go to workshops to develop better management skills, but they do this very rarely. Our opinion is that Macedonian entrepreneurs have lack of management knowledge and need more theoretical knowledge, as well as practical.

Implications for future theory and research. This research provided an initial examination of the relationship between personality type and time and stress management skills. This research has sparked numerous additional questions to be addressed by future research. Research like this is rare in Macedonia, and it would be the best to replicate the same study on other entrepreneurs to provide more data about Macedonian entrepreneurs and their time and stress management skills. Further surveys will probably enhance the organizations and the educational system to take bigger steps in educating the entrepreneurs in these topics and create greater awareness of the skills they use and methods for improving them.

Implications for practice. The implications of the findings presented in this study are also important for practice. Information that will help organizations improve performance and have better employees is always desired. This research provides implications for practice in several areas: development and sustainment of entrepreneurs with excellent time management skills and development and sustainment of entrepreneurs with excellent coping response strategies.

Green Innovations within the Framework of International Cooperation: New Challenges for New Days

Alexander Tanichev¹

¹Faculty of International Industrial Management, Baltic State Technical University, Saint-Petersburg, Russia, tanichev_alex@mail.ru

In a learning economy, which indeed also is a knowledge-based economy argues that in our contemporary economy knowledge is the critical resource and learning the most important process, innovation should basically be understood as an interactive learning process, which is socially and territorially embedded and culturally and institutionally contextualized. This implies that competitive advantage is based on exploitation of unique competencies and resources, i.e. a firm or a region/nation competes on the basis of what they have which is unique in relation to their competitors. Unique regional capabilities rooted in particular patterns of inter-firm networking and inter-personal connections cannot easily be transferred over space [1] 'it can only be built up over time' [2]. Thus, a strategic perspective in the contemporary global economy is how to develop such unique competencies and resources in order to foster competitiveness based on competitive advantage.

However, research has revealed that the regional level is neither always nor even normally sufficient for firms to stay innovative and competitive. Moreover it points at the additional importance of extra-local (national and international) linkages and connections to create a sustainable competitive advantage. In an ongoing discourse on knowledge and globalization some authors argue, that as a result of globalization and codification processes originally tacit knowledge becomes increasingly ubiquitous, which implies that the competitive advantage of high-cost regions and nations runs the risk of being steadily undermined [3]. Other authors argue that much strategic knowledge remains 'sticky' and that important parts of learning processes continue to be localized as a result of the enabling role of geographical proximity (e.g. through face-to-face contact) and local institutions (e.g. regulation, conventions, informal rules and habits that coordinate economic actors under conditions of uncertainty), constituting region-specific assets that stimulate interactive learning.

In the perspective of innovation as culturally and institutionally contextualized, strategic parts of learning processes emerge as highly localized, as opposed to placeless. Thus, local contexts can represent important parts of the knowledge base and knowledge infrastructure of firms and regions, underscoring the role of historical trajectories. Governments and agencies at all spatial levels have increasingly become involved in seeking to stimulate innovation, and, consequently, innovation policy is put at the centre of policies for promoting regional and national economic development. At the regional level regional innovation systems and learning regions have been looked upon as a policy framework or model for implementation of long-term, development strategies initiating learning-based processes of innovation, change and improvement.

Innovation, international cooperation, globalization, partnership, R&D

1. Introduction

In the light of the need for sustained economic growth in the world (and in Europe), a new direction must be given to European leadership on energy and climate security. The risks of energy or climate disruptions are as great, if not greater than ever. Smart, green growth is the way forward, but to achieve this, European policies must shift to an innovation-centered approach in partnership with consumers and the progressive business community.

The European and international debate must be about opportunities and strategies for a better life in all countries. Innovation to drive “green growth” must be at the heart of this strategy. Europe can lead in innovation and investments which offer solutions which are effective, sustainable, multi-purpose and carry the support of key businesses and communities in the world. We therefore need a new approach for a partnership between business, legislators, civil society and Governments, each contributing to transformation in their own way.

It is essential to encourage and enable the business and investment communities to accelerate investments in innovations for three areas of transformational change:

Smart green growth is firstly about energy efficiency. Most of the reductions in European emissions by 2020 will come from improvements in efficiencies. Technologies for radical improvements exist, but are not widely enough used. Their potential goes beyond incremental improvements in the efficiencies of existing products and services. IT and electronic communications offer radical changes in the way services are provided; in new business models and services that substitute for traditional ways of doing things, and in making more intelligent use of energy in homes, offices and cities. The ICT sector is the motor of innovation capacities and has over 2 billion customers worldwide. It is also spinning-off more efficient lighting systems, solar energy and smart-grid technologies that can help meet our needs more efficiently. Enormous new investments are needed to exploit new opportunities in all societies, but can now be a key role in accelerating recovery from the current economic and financial crisis.

The opportunities for ICT-based green growth have been addressed by an EPC Task Force, from which the report is now published. The Task Force urges new action to put three critical infrastructures in place:

- A carbon accounting infrastructure to make energy use and carbon emissions visible to all;
- A smart electrical power grid system to accommodate new demands for renewable energy, energy efficiency and consumer empowerment, and
- High speed broadband access to the Internet to support a new range of efficient on-line services.

This will require sustained investment, and Governments must create the regulatory frameworks and partnerships within which such investments are secure. In addition, the Task Force suggests mobilizing ICT-based innovations in transport and logistics: smart buildings and smart green cities, and also stresses that the numerous dispersed initiatives for smart, green growth must be brought together in a coherent and synergetic framework.

In this paper the author present a sub-set of the findings from the systematic review and consider the *general* evidence base that has explored the relationship between innovation and networking across countries and sectors. In the following section I would like to outline the specific methodology I adopted to conduct this particular review.

2. Globalization as a Driver of Cooperation

Driven by more complex innovation projects and ever shorter innovation and product-life cycles, firms are faced with a demand for knowledge they cannot satisfy with their internal resources alone. “Tapping external sources of knowhow becomes a must” [4]. Firms thus have to look for partners for their innovation projects, which has led to an increase in the number innovation cooperations, documented among others by Hagedoorn [5].

The globalization of firms’ activities has contributed to the pressure to become more innovative and to conduct R&D and innovation activities on a global scale, leading to an increase in both domestic and international collaborative activities. With this increase, the type and structure of collaborations and partnerships between domestic and foreign partners has changed. While, in the past, international R&D and innovation alliances were mostly equity-based alliances, like joint-ventures, looser forms of collaboration between partners from different countries have emerged in recent years. Actually, most of the growth in international collaborative activities can be attributed to these looser and more flexible forms of collaboration between partners from different countries [6].

The increasing collaborative activities of firms and the exchange and flows of knowledge associated with them have attracted the interest of policymakers. Some national and European-level financing

institutions have established cooperation, and, in particular, international cooperation, as an essential condition for giving support to firms in the area of innovation and research and development in order to foster the flow of knowledge between national innovation systems [7]; [8].

The growth in international collaborative activities in innovation and R&D has led researchers from different areas to investigate the underlying motives for these kinds of agreements. Main contributions come from the international management literature, which is concerned with the strategic aspects of international innovation collaboration, and from economics, which looks at the growth of different forms of international alliances and their underlying motives. This paper is closely related to the second of these two strands of literature. I look at the factors and firm characteristics that influence firms' decisions to collaborate with foreign partners on their innovation and R&D activities. The paper contributes to the existing literature in two ways. First, we use a large scale survey to tackle the question at hand and not a case study approach. Additionally, the data we have also allow us to take the looser forms of collaboration into account and focus not only on equity joint-ventures.

3. Cooperation activities and R&D

The increased complexity of knowledge processes, which are the backbone of the creation of new technologies, leads firms to search for valuable knowledge and skills externally in order to complement their own capabilities [9]. Since the 1980s, the increasing instability of the competitive environment, with shorter product and technological life cycles, has forced firms to reconsider their innovation strategy in order to widen their technology base [10]. In this context, cooperation has gained an important role in the innovation process at the firm level, given that innovation cooperation activities are considered an efficient means of industrial organization of complex R&D and innovation processes. As described by Rosenfeld [11] and Hagedoorn et al.[12], not only multinationals firms but also small and medium-sized firms are engaging in more and tighter relationships with other companies to achieve greater economies of scale, market strength, or exploit new opportunities. These joint activities can take several forms, both formal and informal, such as co-marketing, co-production, shared resources, or joint development [13]. As far as innovation activities are concerned, the boundaries of innovation are shifting from a situation where firms perform R&D activities mainly internally [14] to a reality where corporate partnering, collaboration and external sourcing in R&D are used. In this new context, internal and external sourcing of innovation inputs, as R&D, are not seen as substitutes, but as complements, since internal innovation activities are not incompatible (and can be synergetic) with agreements with other firms, research agreements with universities, investments in the capital stock of new firms, and acquisition of small firms [15], [16].

Cooperation activities with other firms or institutions are seen by firms as an opportunities to access complementary technological resources (as skill sharing), for faster development of innovations, to improve market access, to realize economies of scale and scope, and to share costs and spread risk (see, for example, [17], [18], [6], [16], [19], [20]). Cooperation activities are usually characterised by intensive knowledge exchange and mutual learning, basically by combining complementary assets and building synergies [21], [9]. In other words, since innovation-related cooperative agreements favor knowledge accumulation that might be converted into new technological and organizational innovations, the firms' decision to cooperate opens up the range of their technological options [14], [22]. As argued by Gomes-Cassares et al. [23], firms enrolled in cooperation activities or alliances are involved in denser knowledge flows than non-allied firms.

The classic perspective for analyzing the decision to cooperate is to see it as an equilibrium between achieving a high level of knowledge flow and the protection of internal knowledge from leaking out, ie the internalization of spillovers (see, for example, [24], [25], [26], [27], [16]). Only firms that can protect their vital information are willing to engage in cooperative agreements, an issue which may be less present in cooperative agreements with research institutes and universities than in cooperation with other firms [28]. In other words, cooperation in innovation activities can be analyzed as a trade-off between spillovers: firms generate and receive spillovers to and from their cooperation partners. Therefore, firms must manage the external information flows in order to maximize the incoming spillovers from partners and non-partners while, at the same time, control the spillovers to non-partners.

A crucial role in that respect is played by a firm's absorptive capacity, ie its ability to "identify, assimilate and exploit knowledge from the environment" [29]. Firms can try to increase the extent of incoming spillovers both within cooperative agreements and from the environment in general by investing in "absorptive capacity". The higher a firm's absorptive capacity, the more able it should be to access and implement a larger amount of external knowledge [29]. Put differently, as argued by

[30], external knowledge is more effective for the innovation process when the firm engages in its own R&D.

The capacity of firms to take advantage of knowledge generated elsewhere has a positive effect on the probability of being a successful innovator and is positively associated with the decision to undertake formal research collaboration with other firms and institutions [31], [32]. *Perse* the effect on the cooperation decision is unclear, however, since higher absorptive capacity can make a firm less likely to cooperate because it can obtain access to external knowledge without cooperating.

Other factors that have been argued to influence a firm's cooperation decision include

- Public support [31], [33], [34]
- export activities [21], [34]
- size [35], [36], [37]
- Industry [38], [39]

4. International cooperation and Innovation

Globalization has contributed to a growing number of international R&D and innovation partnerships (see, for example, [40]). Luo [41] states that the growth of international competition and cooperation is a natural outcome of the expansion of firms into new markets and countries since this process makes firms face new realities and challenges. Some of the high costs of managing international projects [42] have been reduced by the availability and wide diffusion of new information technologies [43]. Associated reductions in communication costs and increases in the potential to coordinate activities across countries have certainly contributed to the boom of international R&D cooperation. The motives for cooperating on innovation in general are also potential motives for international R&D and innovation cooperation. However, there are also some specific motives for entering into international cooperative agreements. Glaister and Buckley [18] analyze UK firms' international cooperation behavior (in general and not just related to R&D) and show that motives related to technology development, like sharing of R&D costs and exchange of complementary technology, are more important for cooperation with domestic partners than for cooperation with international partners. The opposite is true of market development motives, such as faster entry into markets, conforming to foreign government policies or facilitating international expansion. Glaister and Buckley's [18] show that R&D cooperation motives are similar for international and national partners.

Von Zedtwitz and Gassmann [42] take a similar approach to analyzing international cooperative agreements. Using a database of 81 companies representing 1,021 R&D sites, they stress the significance of two main internationalization drivers in R&D: access to local science and technology sources, and access to local markets and customers. Von Zedtwitz and Gassmann's [42] findings that technology-intensive firms are trying to exploit location-specific innovation advantages through the internationalization of their R&D activities and are thus able to cope with the increasingly globalised environment, can serve as an explanation for Glaister and Buckley's [18] result. Firms no longer look for partners, say, to share R&D costs within their country only, they also consider firms outside of their country, leading to the observation that the motives for both types of R&D cooperation are similar.

Palmberg and Pajarinen [40] focus on the benefits of foreign R&D cooperation comparing non-equity international partnerships with FDI and equity-based international partnerships. They find that non-equity international partnerships are a mean for firms "to simultaneously be present, source knowledge and compete in multiple countries and regions without the liabilities associated with FDI or joint ventures" (p. 3). Similarly, von Zedtwitz and Gassmann [42] conclude that complete integration of globally dispersed R&D activities can produce high coordination and social costs, which drive firms to invest in local product adaptation and in foreign science clusters, usually through looser forms of innovation cooperation.

Another benefit of setting up international cooperative agreements is a potential increase in the competitiveness of the firm. Some empirical evidence stresses that dispersed R&D activities may contribute to firms' competitiveness when compared with centralized R&D operations since it is an opportunity to take advantage of host-country scientific inputs and reduce the uncertainty in unfamiliar business environments [43].

A different explanation for the growing number of international cooperation agreements has been presented by Narula and Hagedoorn [6]. They argue that the fact that few firms have resources to duplicate value chains in different locations has led to more cooperations.

Finally, the involvement of public authorities through support systems can be expected to have an impact on the willingness of firms to engage in R&D cooperation across borders [44]. In the European Union, for example, many funding schemes explicitly require firms to cooperate in order to gain access to funds for R&D and innovation projects.

In summary, access to complementary foreign knowledge and markets and a reduction or sharing of R&D costs seem to be the main drivers of international cooperation.

5. Conclusions

This paper analyses the decision of firms to cooperate with foreign partners on innovation projects. The main conclusion of this analysis is that the determinants of cooperating with a foreign partner on innovation activities are similar in all countries. In other words, the typical international cooperative firm of a small and less developed economy has the same characteristics as the international cooperative firm of a large and more developed economy: above-average absorptive capacities, receiving public funding, higher level of outgoing spillovers and above-average number of employees. It looks as though firms have the same needs and must own similar capabilities to be able to engage in international innovation networks. Supporting investments in absorptive capacities, the growth of firms and the production of knowledge, could thus be policies that promote innovation and internationalisation.

Future research should complement this study. One possible line of development could be deepening the analysis of the different types of partners, trying to scrutinize whether firms choose similar or different types of international partners (eg competitors, suppliers or research institutes) to develop innovation collaborations. In addition, the comprehensive analysis could provide further insight into the mechanisms behind international cooperation on innovation activities. Further research is necessary to compare the effects of domestic collaboration and international collaboration on various microeconomic as well as macroeconomic outputs.

² Senior Expert , General Directorate for Regional Development and Structural Adjustment , State Planning Organization , T.R. Prime Ministry, meozsan@dpt.gov.tr

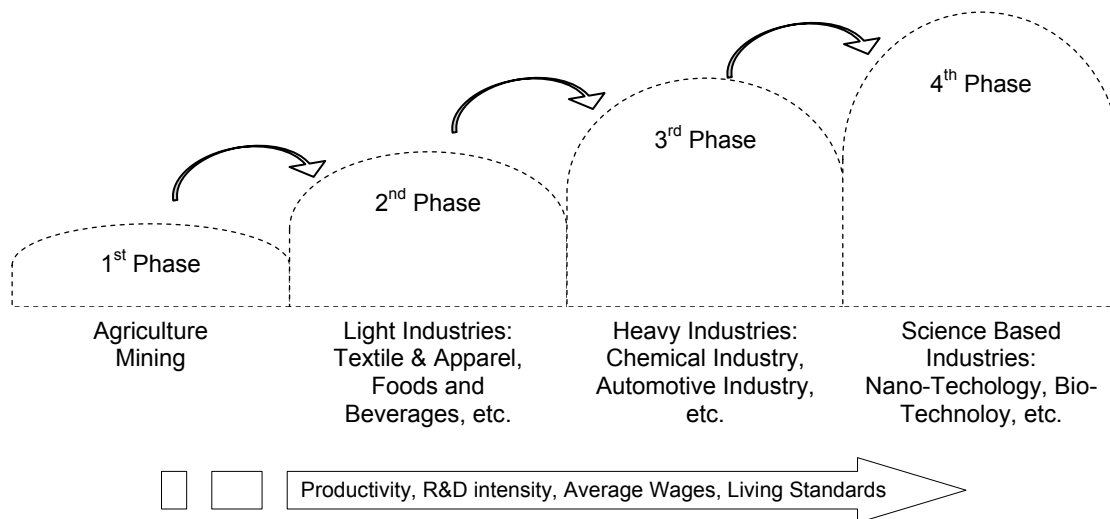

After the elections of 2002 the new governments followed the same fiscal tightening policy offered by IMF as well as export-led strategy for real sector. However, one of the most serious problems of Turkish is widening current account deficit despite higher growth rate. One of the major reasons of current account deficit is technology gap between exporting and importing industries. As Turkey exports low-tech goods more, imports medium-high tech and high-tech goods more. Therefore, the technology gap incurs heavy cost as current account deficit. This situation shows that there are some structural problems in Turkish manufacturing industry and regional economies. We assume that it stems from lack of innovativeness and technological capability of Turkish regions. In this paper, we try to identify technological levels of 26 NUTS 2-level regions according to OECD's classification. Then, we develop an innovation and competitiveness index (ICI) for Turkey by employing Principal Component Analysis. In conclusion, we formulate some workable policy solutions and suggestions for regional economies in Turkey. According to index results, Istanbul is the most innovative and competitive region in Turkey. Ankara is becoming regional knowledge cluster thanks to its strong R&D infrastructure and high-qualified researchers.

Technology Level, Innovation and Competitiveness Index, Turkey, Turkish Regions

1. Introduction

All countries necessarily pass through a gradual development phase. Some of them are endowed with natural resources that trigger their development while other countries possess highly educated human capital, and potentially having higher productivity levels. Developing countries (DCs) have a long history of traditional agricultural production. In general, agricultural is considered domestic work and technology's interference was minuscule. This situation prevented higher savings which were needed for investments. Agriculture and mining sectors were dominant in the overall economic structure. Low productivity levels limit the competitive power of DCs in international markets as well. Western countries industrialization began in 19th century and agricultural production was performed as part of the industry. Early industrialization ensured capital accumulation and consequently a financial system that could provide necessary capital for heavy industry. As science based industries were growing, chemical, electrical machinery and automotive industries were diverted through DCs. This happened because industrialized countries were able to produce higher value added products with relatively less environmental problems, thanks to the advantages of early industrialization and division/specialization of labour. The following figure illustrates the general technology phases of industrial development stages in a country.

Source: TASCI (2009)

Figure 1 Technology Phases of Industrial Development in a Country

As DCs started to benefit from the learning process by increasing trade volume with Western partners, they also received direct foreign investments and financial capital to produce capital intensive technologies. Governments of newly industrialized countries (NICs) like Taiwan, South Korea and Singapore combined import substitution and export promotion policies with the subsidization of high-tech industries. These countries succeeded in exporting higher value added goods and their GDP per capita got closer to that of the high-income countries. Within this framework, we will try to examine development levels of Turkish regions in terms of technology phases of manufacturing industries. Then, it will be developed Innovation and Competitiveness Index for Turkish regions by using these findings and other indicators.

2. Technology Development Levels of Turkish Regions

Although Turkey started off industrialization efforts in 1930s, it could not achieve much in the past 70 years. Turkey implemented import substitution policy until the 1980s but high level of agriculture employment and insufficient capital accumulation stood as hurdles for success. Trade liberalization in 1980s helped Turkey's international integration and Customs Agreement with European Union in the middle of 1990s. This enhanced competitiveness in the industrial sector. Export revenues increased dramatically in the last decade after the financial crisis of 2001. However, trade deficit also tremendously increased due to higher import expenditures. The share of high-tech export within the manufacturing sector is under 10 percent level which is one of the lowest one among OECD countries. Medium low-tech exports have been increasing during the period while medium high-tech import expenditures have risen since 2003. This fact illustrates the underlying reason for growing gap between export and imports. The regional development pattern of Turkey followed a pattern in line with the international trade scheme of the country. Import substitution policies caused high migration flow from eastern regions to certain cities including Istanbul, Ankara and Izmir. Industry localized around these demand centres since the economy was not yet open to the international markets. Increasing trade volumes in the last two decades ensured a more dispersed industrial location due to lower wages and land rents in other cities. Bursa, Kocaeli, Gaziantep, Kayseri, Denizli are those significant industry centres benefiting from industrial dispersion. Approximately 90 percent of international trade activities happened within the triangle of Istanbul, Ankara and Izmir. It is important to note that Istanbul NUTS II Region produces more than half the sum of exports and imports in Turkey. It is followed by TR41 and TR31 NUTS II Regions. Istanbul and its peripheral cities is absolutely the trading hub of Turkey. It is interesting to note that exporting regions create positive externalities for neighbouring regions. For example, Gaziantep is an important industry and export centre in South-East part of Turkey and contributes to the development of near cities, K. Maras, Sanliurfa and Adiyaman. In this very direction, government should combine regional and international trade policies to create strategic growth poles in the underdeveloped regions. Border regions seem promising in terms of future trade outlook.

2.1. Methodology and Data

A country's integration to world economy is a measure of its international trade in goods and services. In terms of GDP, small countries are usually more integrated as they have a tendency to specialize in a limited number of sectors and these countries need to import and export more goods and services than larger countries as domestic demand must also be satisfied. However, GDP of a country is not the one and only factor that determines the level of its integration with world economy.

Although international trade in goods and services has been seen as the sole path of economic integration, other forms and transactions are becoming more relevant and prevalent since the last 20 years (e.g. foreign direct investment, portfolio investment). Scientific or technological development and globalization can be quoted as those two terrific courses which are driving the world's economy in the last two decades.

Table 1 Classification of Technology Intensity in Manufacturing Industries by OECD

Technology Level	ISIC Revision 3 Industry Classification
High-technology industries	Aircraft and spacecraft
	Pharmaceuticals
	Office, accounting and computing machinery
	Radio, TV and communications equipment
	Medical, precision and optical instruments
Medium-high-technology industries	Electrical machinery and apparatus
	Motor vehicles, trailers and semi-trailers
	Chemicals excluding pharmaceuticals.
	Railroad equipment and transport equipment
	Machinery and equipment,
Medium-low-technology industries	Building and repairing of ships and boats
	Rubber and plastics products
	Coke, refined petroleum products and nuclear fuel
	Other non-metallic mineral products
	Basic metals and fabricated metal products
Low-technology industries	Manufacturing, n.e.c.; Recycling
	Wood, pulp, paper, paper products, printing and publishing
	Food products, beverages and tobacco
	Textiles, textile products, leather and footwear

Source: (OECD, 2007)

In this section, we focus on Turkey's manufacturing industries with a technological perspective to identify the vulnerability of the industrial structure in the country, and also to contribute to the industrial policy-making process. To do this, we will consider OECD's classification of technology intensity in manufacturing industry. Taxonomy of the trade data for manufacturing industries is achieved according to the intensity of technology using the ISIC Rev. 3 breakdown of activity. Formerly, technology classification based on ISIC Rev. 2 industry classifications was what was mostly accepted. That methodology is based on three indicators of technology intensity which categorically reflect, "technology producer" and "technology-user" aspects to different degrees: 1) R&D expenditure/production 2) R&D expenditure/ value added 3) (R&D expenditure + technology involved in intermediate and investment goods) / production (OECD, 2007).

The classification of manufacturing industries into high-technology, medium-high-technology, medium-low-technology and low-technology groups was accomplished after ranking industries with respect to their average from the period of (1991-99) against the aggregate OECD R&D intensities. Industries that fell into higher categories have a higher average intensity for both indicators than industries in the lower categories. The low-technology group owes much to the limited, detailed R&D expenditure data across countries and consists of relatively aggregate sectors. In some exceptional cases, R&D intensities are available for more detailed (2-digit) breakdowns and predicate the classification of these industries into low technology (OECD, 2007).

2.2. Findings

Above mentioned OECD methodology has been applied to Turkish manufacturing industry. Related data employed in the study were obtained from the Turkey's Labour Statistics released by Turkish Statistical Unit, annually. The last available data for manufacturing industry is for 2008 and five different data will be used to determine technology development level of manufacturing industry. These are; number of firms, employment, wages, revenues and investments of manufacturing industries. Medium high-tech (MHT) and high-tech (HT) data consolidated and 26 NUTS II Regions are classified under three categories with respect to their share of medium high-tech and high-tech production within the country. Revenues obtained from medium high-tech and high-tech activities are used as the main criteria for determining technology development levels of regions.

First group NUTS II regions are composed of six regions and have the biggest share in revenues gained from MHT and HT activities. It should be noted that all of them are situated at the north-western part of Turkey and 43 percent of total population resides in these regions. Annual population growth rate and population density per km. are higher in these regions. It illustrates that technology diffusion has a positive impact on population movements. In other words, as the technology development level of regions increase, they attract population from other regions.

Table 2 MHT and HT Development Level of First Group NUTS II Regions (2008)

	Number of Firms	Employment	Wages	Revenue	Investments
TR10 İstanbul	34,7	33,8	37,5	37,2	31,0
TR33 Manisa, Afyon, Kütahya, Uşak	1,9	8,4	7,9	16,9	17,9
TR51 Ankara	18,2	18,0	20,6	11,2	9,5
TR42 Kocaeli, Sakarya, Düzce, Bolu, Yalova	2,2	7,1	9,2	9,7	10,8
TR41 Bursa, Eskişehir, Bilecik	5,7	8,4	9,0	8,8	9,7
TR31 İzmir	5,5	6,9	5,7	4,9	5,9

The above table shows that İstanbul has the highest scores for MHT and HT firms, people employed in these sectors, wages earned by employees and revenues gained by MHT-HT firms and investments made by them. Around 1/3 of all high level technological activities are performed by İstanbul. When the population size of İstanbul which is 18 percent of total Turkish population is taken into account, it can be considered that industry sector in İstanbul twice as productive as the rest of the country. Although TR33 (Manisa, Afyon, Kütahya, Uşak) NUTS II Region has not a big share in the number of firms, it produces a big amount of revenue and has the second biggest share in MHT and HT investments. TR33 region hosts one of the biggest producers of consumer electronics, IT, digital technologies, and household appliances with €3.7 billion turnover. The company account for 21 percent of TV market in Europe. Another important point is that TR51 (Ankara) NUTS II region has comparably higher firm and employee numbers in MHT and HT sectors and 21 percent of wages earned there. Ankara suffers from revenue production and lower investment rates to technology. It mainly stems from small scale of technology firms most of which are located in METU and Bilkent Techno parks. Those firms are in a disadvantageous position in fund raising for new investments. On the other hand, Ankara is the leading region in human capital. In one thousand population, 150 people have university degree, 14,5 have graduate and 5.6 phd degree in Ankara. Further efforts are needed for Ankara region to employ qualified human capital in more innovative and technology intensive sectors.

Table 3 MHT and HT Development Level of Second Group NUTS II Regions (2008)

	Number of Firms	Employment	Wages	Revenue	Investments
TR62 (Adana, Mersin)	5,0	1,7	1,4	1,5	1,1
TR21 (Tekirdağ, Edirne, Kırklareli)	0,8	1,2	1,7	1,0	0,4
TR32 (Aydın, Denizli, Muğla)	1,8	1,0	0,5	0,8	1,0
TR72 (Kayseri, Sivas, Yozgat)	3,0	2,3	1,0	0,7	1,0
TR52 (Konya, Karaman)	3,3	1,6	0,7	0,7	0,5

The first group NUTS II regions earn almost 90 percent of wages and revenues of MHT and HT sectors. Second group NUTS II regions left with only around five percent wages and revenues

obtained from technology intensive sectors. 17 percent of total national population lives in these five regions. TR62 (Adana, Mersin) NUTS II region has the highest share in the number of firms and revenues in the group. Adana province has the highest unemployment rate in Turkey. TR62 NUTS II region is a destination point for immigrants who migrate from eastern regions where illiteracy rate is high and qualified workforce is scarce. TR21 (Tekirdağ, Edirne, Kırklareli) NUTS II region is another important destination point for internal migrants. The region benefits from positive spillover effects originating from Istanbul region where firms search for new investment places due to the higher rent and labour costs in Istanbul. The economy of TR32 (Aydın, Denizli, Muğla) NUTS II region is more concentrated on service sectors, mainly tourism. According to the statistics of Ministry of Culture and Tourism (2008), Mugla is the second in the number of tourism facilities and third in international flights. Denizli province is a historically textile and apparel industry centre of Turkey. It is among four centres in this sector. The city suffers much from low level technology intensive production in textile and apparel industry and loses its competitive power against China because of the lower production costs.

Table 4 MHT and HT Development Level of Third Group NUTS II Regions (2008)

	Number of Firms	Employment	Wages	Revenue	Investments
TR61 Antalya, Isparta, Burdur	5,7	1,9	0,9	0,6	0,2
TR22 Balıkesir, Çanakkale	1,1	0,4	0,3	0,4	0,6
TR83 Samsun, Tokat, Çorum, Amasya	2,1	1,5	0,8	0,4	0,3
TRB1 Malatya, Elazığ, Bingöl, Tunceli	1,5	0,9	0,3	0,2	0,0
TR63 Hatay, Kahramanmaraş, Osmaniye	0,5	0,3	0,1	0,2	0,1
TR71 Kırıkkale, Aksaray, Niğde, Nevşehir, Kırşehir	0,6	0,7	1,0	0,1	0,1
TRC1 Gaziantep, Adıyaman, Kilis	2,4	0,4	0,1	0,1	0,0
TR90 Trabzon, Ordu, Giresun, Rize, Artvin	0,8	0,3	0,1	0,1	0,1
TRC2 Şanlıurfa, Diyarbakır	0,9	0,5	0,3	0,1	0,0
TR81 Zonguldak, Karabük, Bartın	0,4	0,5	0,2	0,1	0,1
TR82 Kastamonu, Çankırı, Sinop	0,2	0,2	0,2	0,1	0,0
TRA1 Erzurum, Erzincan, Bayburt	0,8	0,1	0,0	0,0	0,0
TRB2 Van, Muş, Bitlis, Hakkari	0,6	0,3	0,1	0,0	0,0
TRA2 Ağrı, Kars, Iğdır, Ardahan	0,3	0,1	0,0	0,0	0,0
TRC3 Mardin, Batman, Şırnak, Siirt	0,2	0,0	0,0	0,0	0,0

15 NUTS II regions are the ones that have the lowest technological development levels in manufacturing industries. Except TR22 and TR61 NUTS II regions, all of them are located in the eastern part of TR42, TR51 and TR62 NUTS II hypothetical border. 40 percent of total population lives in these 15 regions, while they produce just 2.3 percent of national MHT and HT revenues which amount only 1/7 of TR33 (Manisa, Afyon, Kütahya, Uşak) region's revenue. It is interesting to see that the least developed NUTS II regions of Turkey are also at the bottom in terms of technological production. 56 provinces, most of which are among third group NUTS II regions, have less than 10 patent applications in 2010, according to the Turkish Patent Institute statistics. 42 percent of patent applications originate from TR10 (Istanbul) NUTS II region which is followed by Ankara with 10 percent share. The situation holds for trademark registrations, as well. 52.6 percent of total trademark registrations came from Istanbul and eight percent from Ankara in 2009.

3. Innovation and Competitiveness Index for Turkish Regions (ICI4TR)

3.1 Methodology and Data

Competitiveness of private sector is one of the major determiners of competitiveness of regions in both domestic-national and global market. Before taking initiative at policy field, observing and identifying the innovation and competitiveness performance of regions would be first action. A kind of Factor analysis, Principal Component Analysis is widely accepted tool to create composite indexes. Creating the ICI4TR, we will benefit from the statistical analysis method. Principal Component Analysis (PCA) Because of the page limitation, we could not be able to explain how Principal Component Analysis (PCA) works in detail (For detailed information, please see Vogelvang 2005). In order to create Innovation and Competitiveness Index for Turkish Regions (ICI4TR), the following variables have been used.

Table 5 Variables

Variable	Name	Year	Source
Medium-High Tech and High-Tech Manufacturing Companies Share(%)	TECHCOMP	2008	TURKSTAT
Medium-High Tech and High-Tech Manufacturing Employment Share(%)	TECHEMP	2008	TURKSTAT
Urbanization Rate (%)	URBRATE	2010	TURKSTAT
Masters and PhD Degree Ratio within +15 Age Population (%)	MSPHD	2009	TURKSTAT
The Number of Patent Applications	PATENT	2009	TURKSTAT
The Number of Trademark Application	TRADEMARK	2009	TURKSTAT
Total Export Per Capita (US \$)	EXPORT	2009	TURKSTAT
Banking Credit Ratio (%)	BANKCREDIT	2009	The Union of Turkish Banks
GSM Subscription Ratio Per Head	GSPENTR	2008	ICT Authority
Broadband Penetration Ratio (ADSL/Household)	BROADBAND	2008	ICT Authority

In the above table, the first and second variables indicate technological level of manufacturing industries of Turkey. Medium high-tech and high-tech manufacturing industry companies and employment are directly related to productivity of country. We assume that the innovative capacity and competitiveness of regions increase as the regions reach scale. Therefore, urbanization rate variable would be expressive. According to OECD and EU classifications, full-time equivalent researchers should have at least master's degree, and high qualified human resources are the heart of knowledge based economy transformation. Hence, we used "Masters and PhD Degree Ration within +15 Age Population (%)" variable in order to measure capacity of human resources across the Turkish regions. The number of patent applications and trademark applications are the best known innovation indicators. Total export per capita is a useful indicator of competitiveness level of a region. Banking credit ration variable refers economic vitality of regions. The last two indicators of our model are related to e-readiness of Turkish regions. Regarding all above variables, the most recent available data has been used in our model.

3.2 Findings

PCA is a data elimination technique and indicates how many varieties are crucial to explain the observed variance in the data. The following table shows which principal component how much explains uncorrelated data. As explained variance increases, the principal component would be more explanatory for our index.

Table 6 Principle Components for Selected Variables

Principal Components	Eigen Value	Explained Variance %	Cumulative Proportion
1	7,55571	75,56%	75,56%
2	1,01123	10,11%	85,67%
3	0,73630	7,36%	93,03%
4	0,28953	2,90%	95,93%
5	0,26049	2,60%	98,53%
6	0,07077	0,71%	99,24%
7	0,05476	0,55%	99,79%
8	0,01259	0,13%	99,91%
9	0,00753	0,08%	99,99%
10	0,00109	0,01%	100,00%

As seen from above table, the first principal component is good enough to explain model since it has 75.56% explained variance. Each component creates weights of variables which indicate which variable is more important at final index.

Table 7 The Weights of Principal Component 1

Variable	PC1 Share%
Medium-High Tech and High-Tech Manufacturing Companies Share (%)	35,61%
Medium-High Tech and High-Tech Manufacturing Employment Share (%)	35,38%
Banking Credit Ratio (%)	35,18%
The Number of Patent Applications	34,85%
The Number of Trademark Application	34,33%
Total Export Per Capita (US \$)	34,21%
Broadband Penetration Ratio (ADSL/Household)	32,08%
Masters and PhD Degree Ratio within +15 Age Population (%)	28,15%
Urbanization Rate (%)	26,99%
GSM Subscription Ratio Per Head	11,39%

The following table shows innovation and competitiveness index rankings for Turkish NUTS-2 regions. According to index results, the regions have been categorized into 7 sub-groups that are respectively, globally competitive innovation center, regional knowledge cluster, regional competitive innovation center, emerging innovation center, take off stage regions, promising regions and lagged regions.

Table 8 Innovation and Competitiveness Index for Turkish Regions (ICI4TR)

NUTS-2 REGIONS	INDEX VALUE	CLASSIFICATION
TR10 İstanbul	12,015	<i>Globally Competitive Innovation Center</i>
TR51-Ankara	4,473	<i>Regional Knowledge Cluster</i>
TR31-İzmir	2,443	
TR41-Bursa, Eskişehir, Bilecik	1,352	<i>Regional Competitive Innovation Centers</i>
TR42-Kocaeli, Sakarya, Düzce, Bolu, Yalova	0,205	
TR52-Konya, Karaman	-0,122	
TR62-Adana, Mersin	-0,148	
TR33-Manisa, Afyonkarahisar, Kütahya, Uşak	-0,405	
TR61-Antalya, Isparta, Burdur	-0,417	<i>Emerging Innovation Centers</i>
TR21 Tekirdağ, Edirne, Kırklareli	-0,575	
TRC1-Gaziantep, Adıyaman, Kilis	-0,594	
TR72-Kayseri, Sivas, Yozgat	-0,643	
TR32-Aydın, Denizli, Muğla	-0,852	
TR22-Balıkesir, Çanakkale	-0,941	
TR83-Samsun, Tokat, Çorum, Amasya	-1,071	
TRC2-Şanlıurfa, Diyarbakır	-1,094	<i>Take off Stage Regions</i>
TR81-Zonguldak, Karabük, Bartın	-1,101	
TRB1-Malatya, Elazığ, Bingöl, Tunceli	-1,184	
TRA1-Erzurum, Erzincan, Bayburt	-1,190	
TR63-Hatay, Kahramanmaraş, Osmaniye	-1,297	<i>Promising Regions</i>
TR90-Trabzon, Ordu, Giresun, Rize, Artvin, Gümüşhane	-1,352	
TR71-Kırıkkale, Aksaray, Niğde, Nevşehir, Kırşehir	-1,415	
TRA2-Ağrı, Kars, Iğdır, Ardahan	-1,459	
TRC3-Mardin, Batman, Şırnak, Siirt	-1,503	<i>Lagged Regions</i>
TR82-Kastamonu, Çankırı, Sinop	-1,563	
TRB2-Van, Muş, Bitlis, Hakkari	-1,563	

ICI4TR indicates that TR 10 İstanbul is the only one globally competitive innovative center in Turkey. By 2009, the city creates approximately 140 billion US \$ Gross Regional Product which accounts for 21% of national GDP, holds 165 billion US \$ export and import volume which accounts for 55% of total foreign trade of the country. With more than 13 million population and 44 universities, İstanbul is not only competitive economy in Eurasia but also globally competitive innovation center in the world. The

capital of Turkey, TR51 Ankara region is the leader in terms of R&D activities and innovation, and the city has 6 technology development zones of 39, as Ankara Silicon Valley. In 1981-2006, Ankara produced 61,458 scientific publications while Istanbul had only 40,006. By 2009, there were 69,987 people who had masters and PhD degrees in Ankara. As seen from the below figure 2, Ankara is the best place to work for high-tech labour in terms of wages and high-tech labour force has been continuously choosing the city. As result, we may identify Ankara as Regional Knowledge Cluster.

Figure 2 Wages for High-Tech Employment (2003-2008)

TR31 İzmir, TR41 Bursa and TR41 Kocaeli regions are industrialized economies in Turkey. They are significant share of production and foreign trade of the country. While TR41 Bursa is the leading region in automotive industry with producing 622.000 cars which accounts for %65 total automotive production of Turkey by 2010, Kocaeli is the leading region in chemical and shipbuilding industry. Therefore, we call these regions as Regional Competitive Innovation Centers. Emerging Innovation Centers have newly established their research centers and been raised researchers. 8 regions of Turkey can be in this classification. 5 eastern regions of Turkey have been industrializing in recent years. So, we may call them as take off stage regions. There are 4 promising regions which are in a learning process. Government incentives has been re-designed for the regions and new universities founded in order to boost innovative capacity and competitiveness of these economies.

4. Conclusion

Istanbul has the highest scores for medium high-tech and high-tech firms, people employed in these sectors, wages earned by employees and revenues gained by MHT-HT firms and investments made by them. Around 1/3 of all high level technological activities are performed by Istanbul. When the population size of Istanbul which is 18 percent of total Turkish population is taken into account, it can be considered that industry sector in Istanbul twice as productive as the rest of the country. TR51 (Ankara) NUTS II region has comparably higher firm and employee numbers in MHT and HT sectors and 21 percent of wages earned there. Ankara suffers from revenue production and lower investment rates to technology. It mainly stems from small scale of technology firms most of which are located in METU and Bilkent Techno parks. Those firms are in a disadvantageous position in fund raising for new investments. On the other hand, Ankara is the leading region in human capital. In conclusion, there are deep technology gap among Turkish regions. Only 5 regions of the country have positive index values and internationally competitive. TR41 Bursa and TR42 Kocaeli regions have problems to pass next technology phase.

This paper focuses on innovative performances of South East European countries. It analyzes innovative performances of countries from South East Europe, benchmark their innovative performances with EU and innovation leaders; and provide insights about the strengths and weaknesses in innovation-related policies and practices. The findings presented here are based on studies on global innovation performances of countries in last four years. All presented studies suggest the same – SEE countries are not good at innovation. However, good news is that they have grown at a faster pace than the EU27 in the last year, showing the overall fastest rate of improvement in innovation performance. Finally, we highlighted three building blocks needed in order to enable SEE countries to fully capture the benefits of innovation and leapfrog to higher stages of economic and social development.

Keywords

Competitiveness, Governmental and regional policies on entrepreneurship, innovation and R&D Innovation measurement, South East Europe

1. Introduction

In a globalised, knowledge based world where markets, products, technology, competitors, regulations, and even societies change rapidly, innovation is becoming increasingly important for companies and countries. Tangible assets and natural resources such as minerals, coal, and oil no longer determine the fortunes of economies. In such a world, continuous innovation, together with the knowledge that enables it, has become an important source of the competitive advantage. Clearly, if economies are to grow, they need an innovative environment. Therefore, innovation is considered as a key policy instrument to accelerate economic growth, enhance job creation, promote development and improve quality of life [1].

Being a key enabler of progress and competitiveness in the knowledge based economy innovation has attracted attention in many countries. Innovation readiness at the national level has achieved top status on the public policy agendas'. Main stakeholders are involved in creating an enabling environment to support the adoption of innovation and spread their benefits across all sectors of society. On the one hand, companies and entrepreneurs regard it as a vital weapon in holding their corporate competitors off. On the other, it is recognised by governments that countries generating innovation create new technologies and encourage the adoption of these new technologies, grow

faster than those that do not. Furthermore, capacity of innovation is accepted as driver of growth, facilitator of countries' recovery, and a way in sustaining national competitiveness in the medium to long term [2]. Therefore, it is important to policymakers to measure innovation against certain benchmarked global standards and to evaluate the progress of innovation readiness in countries, highlighting the obstacles that prevent governments, businesses, and individuals from fully capturing the benefits of innovation.

Reflecting the importance of this topic, numerous studies on innovation performances of countries are conducted. The traditional approach to measure innovation has been to look at parameters like patents and publication of scientific journals per million of population or research and development (R&D) expenditure. However, the understanding of innovation has evolved over the last ten years. More holistic approach is currently used and the models are based on tens of parameters, including: political and macroeconomic stability, regulatory environment, human capacity, general and ICT infrastructure, openness of national economy to foreign investment, access to investment finance, protection of intellectual property, market and business sophistication. Using this framework, the world's economies are ranked on their innovation capabilities.

Clearly, some parts of the world are more innovation-friendly than others. Majority of studies focus on the world's best-performing economies or regions, showing low level of interest for less developed areas or countries. This is partly consequence of the conventional wisdom that innovation is most likely to drive growth in the highly developed countries, while poor and middle-income countries can import technology from abroad and therefore need not bother to innovate domestically. However, recent study [3] showed that for low- and middle-income countries, innovation yields a higher impact on economic growth than for high-income countries. This finding also reflects the fact that for low- and middle-income countries, domestic innovation activity tends to facilitate the more efficient and rapid absorption of imported technology. Thus, they benefit from their internal innovativeness as well as from the spillover effect of foreign innovations. This would tend to increase the catch-up prospects of the more innovative middle-income countries.

Following these arguments the purpose of this paper is to analyze innovative performances of middle-income countries from South East Europe, benchmark their innovative performances with EU and innovation leaders; and provide insights about the strengths and weaknesses in innovation-related policies and practices. We use data from different studies on innovation performances of countries conducted in last four years and focus on the following countries: Turkey, Greece, Bulgaria, Albania, Macedonia, Serbia, Bosnia and Herzegovina, Montenegro and Croatia.

The paper begins with overview of studies on innovation performances of countries. After a general discussion about innovation trends and brief description of innovation leaders, the paper goes on to analyze innovative performances of SEE countries and compare them with EU and innovation leaders. We examined innovation-related strengths and weaknesses of each country and of the whole region in order to detect and suggest measures for enabling these countries to leapfrog to higher stages of economic and social development. The paper ends with some conclusions and implications for policymakers in the Region designed to help to fully capture the benefits of innovation.

2. Global innovativeness

In the last few years a number of studies have assessed countries' global innovativeness. Table 1 summarise the most important features some of these studies. The Global Innovation Index (GII) [4] was developed by INSEAD in 2007. It is based on a mixture of hard data and survey data conducted annually by the World Economic Forum. The index is based on 60 variables and weighs the innovativeness of 132 economies in 2010. The Innovation union scoreboard [5] (previously known as European innovation scoreboard) is a comparative assessment of the performance of the European Union (EU) member states and a few select countries. The report is an initiative of the European Commission under the Lisbon Strategy. It divides nations into four categories - innovation leaders, innovation followers, moderate and modest innovators, to match up countries based on their performance in the innovation score. Global competitiveness report (GCR) [2] is published every year by World Economic Forum (WEF). Although it is in essence a report on competitiveness, it includes critical components of innovation. This report is based on 117 variables and weighed the competitiveness of 133 economies in 2010. The Innovation imperative in manufacturing [6], US centric innovativeness report investigates the current status of innovation in US companies, and position of the country on the world's innovation map. The report based on 24 indicators, ranks 110 countries and 50 states in the US. Furthermore, the Economist Intelligence Unit [3] conducted an online survey of

485 senior global executives on their opinions regarding innovation in order to understand the basic drivers of innovation. They ranked 82 countries on their innovativeness. Finally, the Atlantic century report [7] ranked a total of 36 nations and the four regions. It uses a total of 16 variables under six broad categories to understand how countries are performing in terms of global competitiveness and innovation.

It is clear that no one study is perfect or the best one. However, from them we can make several conclusions. First, countries like Switzerland, Iceland, Sweden, Denmark, Finland, Norway, Hong Kong, Singapore, South Korea, Taiwan, Netherlands, Germany, USA, Canada, Japan and UK are leaders in innovation regardless metrics used. These countries have a strong knowledge based economy founded on high level of business and governmental commitment to innovation. Excellent infrastructure, strong R&D sector with good international linkages, a number of global companies, strong base of talented work force and IT investments are just few representative features of these economies. Finally, bulk of the investments in R&D in the countries is by industries, followed by universities and then by public research institutes and industrial research institutes.

Table 1 Countries' innovativeness – Summary of reports.

Report parameters	Global Innovation Index Report 2009-2010 [4]	Innovation Union Scoreboard (2011) [5]	Global Competitiveness Report 2010 – 2011 [2]	The Economist Intelligence Unit (2007) [3]	The Innovation Imperative in Manufacturing (2009) [6]	The Atlantic Century Report (2009) [7]
Countries covered	132 countries	34 countries	133 countries	82 countries	110 countries	36 countries and 4 regions
No of Variables	60 variables	29 variables	117 variables	4 variable	24 variables	16 variables
Top fifteen ranking countries in descending order	1. Iceland 2. Sweden 3. Hong Kong 4. Switzerland 5. Denmark 6. Finland 7. Singapore 8. Netherlands 9. New Zealand 10. Norway 11. USA 12. Canada 13. Japan 14. UK 15. Luxembourg	1. Switzerland 2. Sweden 3. Denmark 4. Finland 5. Germany 6. UK 7. Belgium 8. Austria 9. Netherlands 10. Ireland 11. Luxemburg 12. France 13. Cyprus 14. Iceland 15. Slovenia	1. Switzerland 2. Sweden 3. Singapore 4. United States 5. Germany 6. Japan 7. Finland 8. Netherlands 9. Denmark 10. Canada 11. Hong Kong 12. UK 13. Taiwan, 14. Norway 15. France	1. Japan 2. Switzerland 3. USA 4. Sweden 5. Finland 6. Germany 7. Denmark 8. Taiwan 9. Netherlands 10. Israel 11. Austria 12. France 13. Canada 14. Belgium 15. South Korea	1. Singapore 2. South Korea 3. Switzerland 4. Iceland 5. Ireland 6. Hong Kong 7. Finland 8. US 9. Japan 10. Sweden 11. Denmark 12. Netherlands 13. Luxembourg 14. Canada 15. UK	1. Singapore 2. Sweden 3. Luxembourg 4. Denmark 5. South Korea 6. US 7. Finland 8. UK 9. Japan 10. Netherlands 11. France 12. Ireland 13. Belgium 14. Germany 15. Canada
Top ranking SEE countries in descending order	45. Croatia 46. Greece 49. Bulgaria 59. Montenegro 67. Turkey 77. Macedonia 81. Albania 101. Serbia 116. Bosnia	22. Greece 25. Croatia 29. Serbia 30. Macedonia 32. Bulgaria 33. Turkey	49. Montenegro 61. Turkey 71. Bulgaria 77. Croatia 79. Macedonia 83. Greece 88. Albania 96. Serbia 102. Bosnia	30. Croatia 32. Greece 42. Bulgaria 56. Turkey 67. Serbia	42. Greece 48. Croatia 53. Bulgaria 67. Albania 76. Macedonia	37. Greece

Second, successful countries today are not geographically large or rich with natural resources. They are ones that have managed to expand opportunities for their populations through the full exploitation of the opportunities afforded by the world economy through international trade, foreign investment, and the adoption of new technologies [4]. Majority of named countries are relatively small with each having less than 0.5 per cent of the world population. These countries benefit from easier networking, efficient enforcement of economic and legislative policies, better management of resources and effectiveness of social benefits systems.

Finally, innovation is and will be global and technology based phenomenon. The current global trends indicate that innovation will be distributed globally rather than being a prerogative of the western world. On the other hand, our civilisation is technology based. Its sustainability, economic development and

growth are highly dependent on technological development. In order to maximise benefits from existing technology our society is adapting its organisational form to the permanent changes of technology. In such a world, technology-intensive industries play an increasingly important role and innovation is key process for long-run economic growth.

3. Innovation and South East Europe

The region of South East Europe (SEE) is also referred to as the Balkans. In geographical terms it includes all the countries on the Balkan Peninsula, territory south of the rivers Sava and Danube. In this paper we recognize the following countries as parts of SEE: Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Turkey, Macedonia, Montenegro and Serbia. SEE has long been associated with political instability. Currently, it is the most complex region of Europe. Its complexity is result of historical legacies as well as the developments that occurred in the 1990s. During the Cold War era this area was divided region where neighbouring countries did not communicate either economically or politically. After the fall of the Berlin Wall in 1989, at a time when the countries of central Europe were becoming European Union (EU) members, this area was held back by civil war in SFR Yugoslavia.

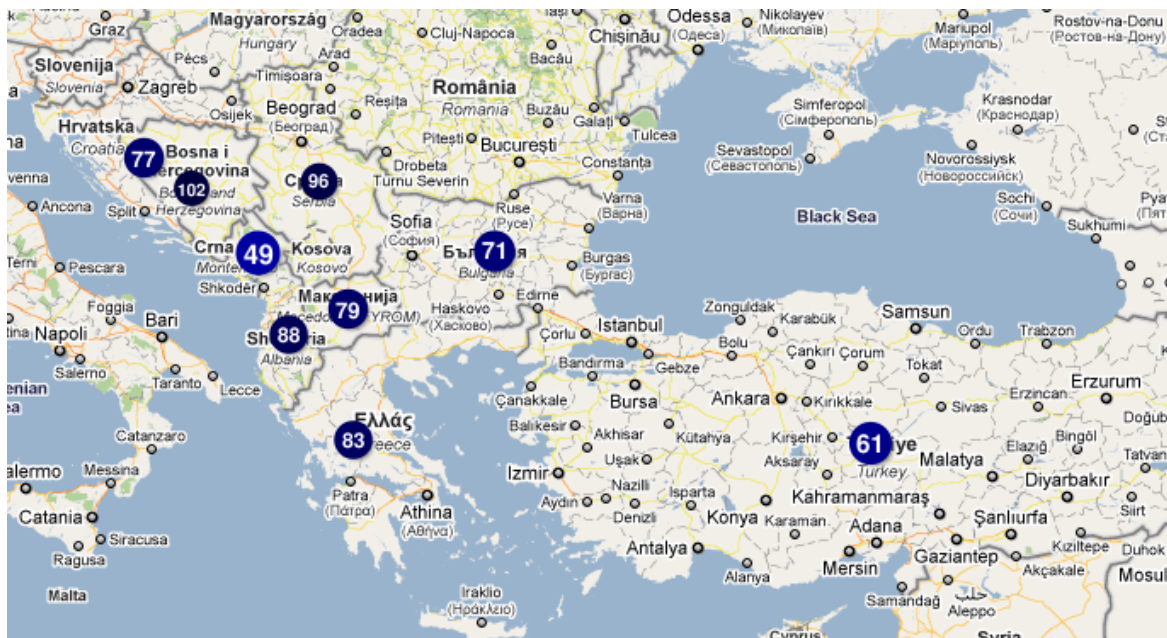

Figure 1 Competiveness of SEE countries [2]

Even today, serious problems are present: uncertainty regarding the status of Kosovo, the very complex institutional system in Bosnia and Herzegovina, big financial crises in Greece, corruption in Bulgaria and ethnical problems in Macedonia. Therefore, European integration represents the only viable project and objective to ensure social and political coherence of the region. Even for the SEE countries that are EU members (Greece and Bulgaria), prosperous neighbours are the best guarantors of stability and economic growth.

The economies in Southeast Europe are small and under developed. They are faced with many economic and social problems, including the rise in poverty, low wages, high inflation pressure, persistent trade deficits, large and untransformed industries [8]. However, these countries have potential to achieve economic growth. Their greatest economic potential is highly skilled cheap labour force, geostrategic position in Europe and in Euroasia generally, good natural raw materials and great skilfulness. But they lack a good system of organization to connect all these factors together and to generate growth [8].

Nowadays these countries are in the process of economic and political transition. They build a market economy and strive to create a new structure of the economy that is more in accordance with world and European market demands [9]. Although countries in the region of SEE share many common characteristics, they are heterogeneous. The SEE countries are at different stages of transition to a market economy, at different phases of EU integration, and consequently at different levels of

development (Figure 1). Nevertheless, SEE countries have some common features and face some similar challenges. One of the most important is the fact that innovation and technological readiness are among the worst dimensions of their competitiveness (Figure 2) [2].

Figure 2 Innovation performances vs. global competitiveness of SEE countries [2]

All presented studies suggest the same – SEE countries are not good at innovation. Although, it is common place in all reports, Global Innovation Index report assesses all SEE countries and offers the best position to comment on countries performances. Table 2 and Table 3 show selected results from this report, including SEE countries. The SEE countries, as a group are well below EU27 average [4]. The gap between two groups is substantial. It is almost 1 point on 5 points scale, while the difference between the SEE and worst performing country (Syria) is 0.87 [4]. However, there is diversity in regional innovation performances. Croatia, Greece and Bulgaria in all studies perform better than other countries in the region. On the other hand, Serbia and Bosnia have the lowest levels of performance. Looking at SEE countries, it seems that there is strong correlation between innovation performance and the level of EU integration.

Similar results are reported by Innovation Union Scoreboard, where Macedonia, Bulgaria, Turkey and Serbia are grouped as modest innovators (the last one), while Croatia and Greece are one step ahead as a moderate innovators. However, good news is that all SEE countries have grown at a faster pace than the EU27, showing the overall fastest rate of improvement in innovation performance [5].

The results of Global Innovation Index [4] show that countries have different strengths and weaknesses. All countries from selected region have problem with the efficiency of legal system, but especially in area of intellectual property protection. Foreign direct investments are an extremely important channel for integration of innovations, new processes and technologies in SEE. Furthermore, companies' spending on R&D is very low, financial market is not developed and venture capital is not available. Finally, intensity of local competition is very low and university-industry collaboration in R&D is not developed. Political stability is marked as a problem in Turkey, Serbia and Bosnia. On the other hand, Albania and Bosnia perform very low in human resources aspects, innovative culture and capacity for innovation. It seems that main strengths of the region (except Albania and Bosnia) are good human resources with relatively large numbers of researchers, scientists and engineers, a well organised education framework and scientific output.

Table 2 Selected innovators [4]

Country	Global innovation index	Ranking
Iceland	4,86	1
Sweden	4,85	2
Hong Kong, China	4,83	3
Switzerland	4,82	4
United States	4,57	11
Japan	4,50	13
UK	4,42	14

Table 3 SEE countries [4]

Country	Global innovation index	Ranking
Croatia	3,28	45
Greece	3,28	46
Bulgaria	3,26	49
Montenegro	3,08	59
Turkey	2,99	67
Macedonia FYR	2,89	77
Albania	2,86	81
Serbia	2,68	101
Bosnia	2,58	116
SEE countries	2,99	~70
EU27	3,89	~26

Two points should be additionally emphasised. First, the role of the business enterprise sector in funding and performing R&D is very limited in SEE [4, 10]. There is no country in SEE in which business sector plays a dominant role in terms of both funding and performance of research. Only in Croatia and Turkey companies are important in terms of funding, while in all other countries funding and performance of R&D is dominated by the government sector. This means that R&D in SEE is performed for industry, while R&D in OECD member countries is performed in industry.

**Figure 3** Innovative performances of SEE countries [4]

Second, SEE economies are not able to employ their innovation capacities effectively [10]. They have a noticeable innovation demand gap. This may be due to several factors, including low level businesses processes, which do not exploit new technologies, and inappropriate structure or quality of R&D capacities, industry structure, which is dominated by small firms in traditional industries. Whatever the reason is, it can result in high brain drain, with significant consequences for innovativeness of the region.

4. Conclusions

This paper is our effort to contribute and to improve overall understanding about innovation performances of SEE countries. In particular, we were interested in question: "How innovative South East Europe is?". To better understand problem we have first reviewed reports on global innovativeness, innovation trends and described innovation leaders. After that we analyzed innovation

performances of SEE countries and compared them with EU. We examined innovation-related strengths and weaknesses of each country and of the whole region.

In this section, as a conclusion, we are suggesting direction and possible measures in order to enable these countries to fully capture the benefits of innovation and leapfrog to higher stages of economic and social development.

The SEE countries have achieved a large amount of progress in recent years, but clearly there is a lot more that could be done. Lisbon Strategy [11] sets out a vision of Europe as 'the most competitive and dynamic knowledge-based economy in the world capable of sustainable economic growth with more and better jobs and greater social cohesion'. The SEE countries have a chance to contribute to this goal and become valued members of the community only if improve their competitiveness and innovativeness. In opposite they will continue to be the backward periphery [10].

We want to highlight three building blocks needed for improvement of innovative performances in the SEE countries: 1. long-term commitment to innovation; 2. entrepreneurial university; and 3. international and regional partnerships

Long – term commitment to innovation is crucial for economic development of each country. The frequent changes in direction and policy orientation, institutional set-up, and in the responsibilities of different public agents are very risky and hinder innovative potentials of country [12]. Therefore, it is essential for the SEE countries to promote commitment to innovation as a 'non-political issue' and to isolate it from the daily politics [3]. National innovation policies need to be designed to raise public awareness about the knowledge-based economy and the key role of innovation and technological progress for economic growth. It imperative is to be coherent with other relevant policies and accompanied by a high level of coordination in terms of policies and different ministries and public agencies [12].

The long – term commitment and coherence in innovation policy at the national level should positively result in numerous ways, closing the existing gap with more developed countries [12]. First, it will be easier to create private-public partnerships that bring together the better performing segments of the public and industrial sector and which result in new ventures, high productivity and more jobs. Second, it will end in supportive infrastructure (new laws, technology transfer offices at universities, business plan competitions, innovation funds and science enterprise centres) facilitating the collaboration, networking and entrepreneurship. Finally, it should make available more capital for start-ups and growing businesses through venture capital and credit guarantee schemes.

Being a primary source of new knowledge production and innovation in SEE countries [13], universities and research institutes are crucial element for technological change in vital segments of economy. However, this is only possible if universities develop in the direction of entrepreneurial institutions which are able to become innovation hubs and cornerstones of knowledge regions. One of good examples can be the region of knowledge that emerges in Serbia around University of Novi Sad [13]. SEE Universities should take more prominent role, develop entrepreneurial spirit, promote innovations, creativity and open the door to the sector of small and medium sized enterprises. In this way, universities will become not only a source of new ideas for existing firms, but also, a source of new firm formation, especially in advanced areas of science and technology [14]. Developing entrepreneurial climate and effective cooperation with business sector the universities will be able to contribute to key innovation-based strengths, such as ability to apply new technology, to develop new products, to access new markets successfully, to incorporate best practice in the management, and to develop skill across the full spectrum of the labour force [15]. Enterprises have become increasingly dependent on external sources of knowledge and technology, and the need of constant technology renewal and innovation motivates them to become an intrinsic part of the innovative networks which include universities.

Additionally, to enhance the business skills of potential new technology based firms founders, SEE universities should provide courses, accessible to both staff and students, in entrepreneurship and new business development. That effort should be especially made to combine the empirical skills of scientists and engineers with the managerial skills of others who have experience in the private sector. Only in this way SEE can create an ecosystem that can offer local opportunities and drive down brain drain, which is among the highest in the world, particularly in Bulgaria, Montenegro, Albania, Bosnia, Macedonia and Serbia. However, the equally important role of these universities is to provide high quality human resources according to emerging knowledge and skills needs related to industrial development at global and local level.

Finally, coordination, regional and international cooperation is crucial for innovative performances of the region. One of a specific SEE response to enhance local research and innovation capabilities in globalised world is partnerships among universities and R&D institutes through consortia. Europeanization of innovation policies is inevitable. This process brings a large number of benefits to

SEE. The most important is increased R&D funding through Framework Programs and similar actions. However, governance reform, best practice transfer and infrastructure building are also important. Weak and fragmented R&D points have a chance with EU assistance to improve innovativeness of the region.

Purpose: In the knowledge-based global economy, it becomes increasingly difficult to manage knowledge, and the importance of higher education becomes more prominent. IPR-related issues have become gradually relevant and important for Europe Union (EU) members as they should provide to the society an optimum environment for future innovations. Products and services provided by Intellectual Property (IP)-based industries are the main driver in facilitating innovation and social and economic growth. Higher Education Institutions (HEI) play a key role in this process. **Design/ methodology/ approach:** The research methodology included mainly ethnographic research and narrative inquiry, together with a thorough review of the related literature on Intellectual Property Rights (IPR) policy in EU member states. **Findings:** Making university students' IPR a priority in HE, potentially leads to several benefits including increased trust, better rank, and greater business and social value, and a prospect for revealing innovation potential of students. Widely implemented in industry is IPR issues to be covered through contracts, in conformity with the law. Following good practices for IPR management in HEIs through law and contract, despite assorted implementation of EU Copyright Directive (EUCD) in EU members regarding HEI, would be much beneficial for the society to apply similar basic concepts. The description of a pattern of good practices in IPR management offers a strategic tool for HE institutions. **Research limitations:** Limitations in the implementation and adaptation of the pattern are related to social environment and national legislation. Specifically, limited duration in the case of copyright and patents; language-specific, and technology-specific limitations, regarding dissemination; limitation in IPR management in so called "sandwich" education program, compared to that education program at one HEI. **Practical Implications:** The patterns approach described in this paper can help HEI managers take more informed and structured decisions, and enhance the process of IPR policy development. **Originality/ value:** Developing and implementing a strategy for IPR management in HEIs, is expensive and much time consuming project. The paper offers a pattern with reusable solution for dealing with students' IPR in any HEI. The pattern / solution could be used and reused in different countries. **Paper type:** Applied Pattern

Pattern, Innovation, Knowledge Management, Intellectual Property Rights in Higher Education, Governmental and regional policies on entrepreneurship, IPR Strategy

1. Introduction

Until recently some countries ignored IPR management as an issue. However, in an era of globalization it has become unsustainable to be isolated from the global IPR system. Higher education and research institutions in EU members demonstrate a key case in this respect.

UK High Court Patents Judge Sir Hugh Laddie in the report of the Commission on Intellectual Property Rights states:

“Whether IPRs are a good or bad thing, the developed world has come to an accommodation with them over a long period. ... For too long IPRs have been regarded as food for the rich countries and poison for poor countries. ... The Commission suggests that the appropriate diet for each developing country needs to be decided on the basis of what is best for its development, and that the international community and governments in all countries should take decisions with that in mind”[3].

The foundation of the current information era was built during last century. The existing knowledge society highlighted emerging challenges in education, research and knowledge transfer. The priority of i2010 and Lisbon Strategy goals focused on the EU’s research and development instruments and sets priorities for cooperation with the private sector to promote innovation and technological leadership. A lot of challenges for policy makers, regulators and organizations in the EU were raised, and set new trends in the on-going activities in education and research. [4]

Today technology evolution and innovations enrich the knowledge society. Digital media and the internet have become a part of everyday life in education. Digital Rights Management (DRM) is an important tool for IPR strategy. DRM focuses not only on the management of ‘traditional’ IPRs such as copyright, but also on the management of technology and its use, on legal and social rights, and on policy and culture, where rights are determined through law and contracts (Figure 1).

To date EU countries’ national legislations are in line with EU Commission policy, and have implemented the EU Copyright Directive [5]. According to many EU members’ national legislations, the first owner of the IPR is the author, if it is not stated otherwise in the employee contract. In addition, the employer (depending of the specific national legislation) has normally the rights to deal with the product without asking for permission and without specific payment to the author (current or former employee). In countries where the copyright of employees’ work belongs to the employer the HE institutions normally reassign the ownership of copyright of the employees’ work to the author (with the purpose of publications), with an exemption for example of copyright in course materials, copyright in software programs, etc.[6].

In many EU countries HEIs have developed and implemented their own internal policies, dealing with these sensitive issues as for example HEIs in UK. However, development and implementation of such internal policies is a long term project, and expensive as well.

Therefore in this paper authors try to generalise their expertise together with observed and analysed good practices among the European HEI, and to suggest a strategic solution in a form of a pattern. The proposed solution serves better as a general frame, and decision makers should pursue their own legal and professional advice in related law issues relevant to their own socio-economic-political environment.

The pattern presented here is mainly intended for those developing and implementing IPR strategies and policies. This group includes, but is not limited to: current and future managers in HE and research institutions, academic staff, as well as entrepreneurs. It is also directed to scientists, researchers, and HE students.

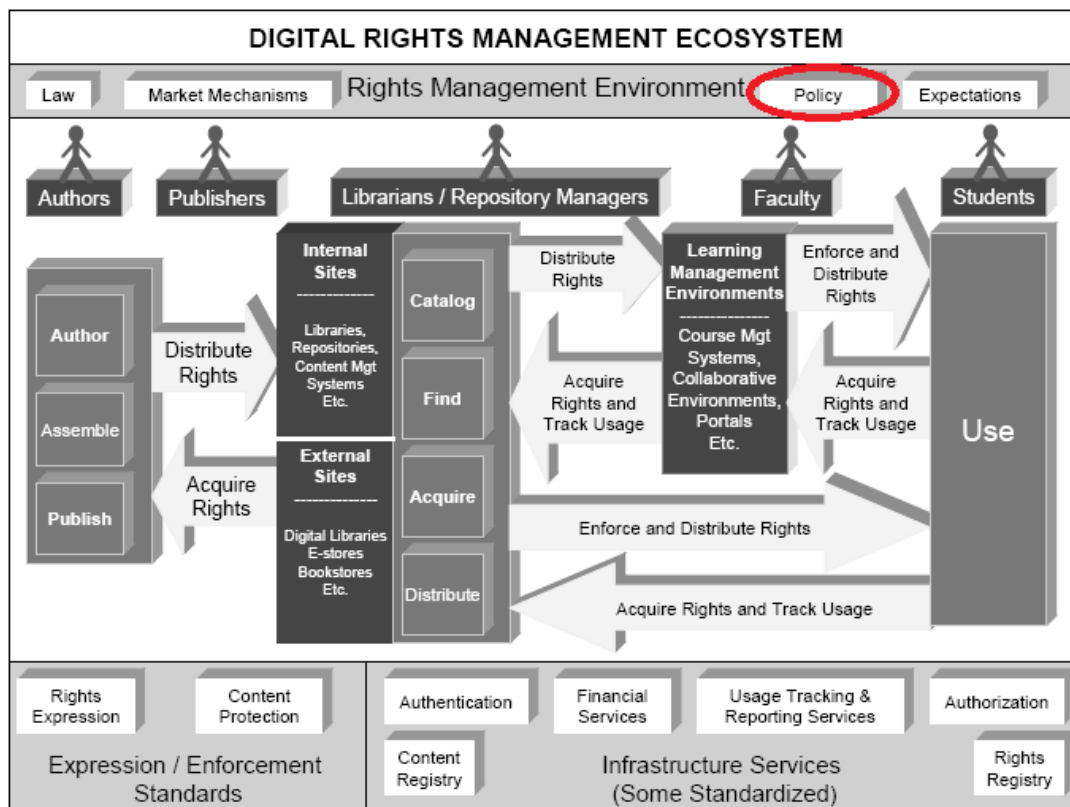

Figure 1: Adopted DRM Ecosystem Model for Education Community [7]

2. The Patterns

As a most likely “father” of the patterns is considered Christopher Alexander, Emeritus Professor of Architecture at the University of California, Berkeley. In his book “A Pattern Language”[8], he describes patterns as follows

“Each pattern describes a problem which occurs over and over again in our environment and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over without ever doing it the same way twice.” [8]

Shortly, a pattern could be described as a solution to one problem in a certain context. However, patterns are not magic solutions. Rather, they just describe simple, basic norms, and suggest solutions. [9]

Since the early 1990’s patterns have been widely used to document software development practise IBM’s pattern database is very popular [10]. Later some pattern writers crossed beyond the technical aspects, and used patterns to discuss organisation structure topics [11].

A lot of pattern books and articles have been published. The majority of them concern IT issues. Business, education, and social area deal in most of the cases with intangibles, and therefore is difficult to write a pattern for it. An example of such valuable patterns are in “Strategies for Leading through Times of Change” by Manns and Rising which contains patterns for introducing change into organisations, and “Customer Interaction Patterns” [12]. The paper adopts an Alexandrian style of pattern writing with the main parts Context, Problem, Forces, word “Therefore ...” as connecting element to Solution, Consequences, Variations, and Example.

3. Students’ IPR

Dealing with intellectual property rights in Higher education institutions is extremely difficult in today’s knowledge society. Describing a pattern for this complex area is even more difficult and challenging.

The next figure (figure 1) presents map for IPR patterns in HE.

The HEI should recognise that students in the process of fulfilling their students’ plans could contribute to the generation of intellectual property, and even generate such, and as a result they have their own IPR. Although by law HEI don’t claim ownership of intellectual property generated by students at the

time of studentship, the institution could develop a policy to arrange IPR matter for example in the case where there is a financial support to student by the institution or where the student decides on his/her sole discretion to assign ownership to the institution. [6]

A HEI should preferably assign a Committee responsible for IPR. These IPRs normally accumulate to the institution (university, college, etc.) from research, discoveries and inventions, made by staff and students. A good practice is IPR policies in HEI to provide possibilities for the mutual benefit and commercialization to the author of the intellectual property and the HEI. [6]

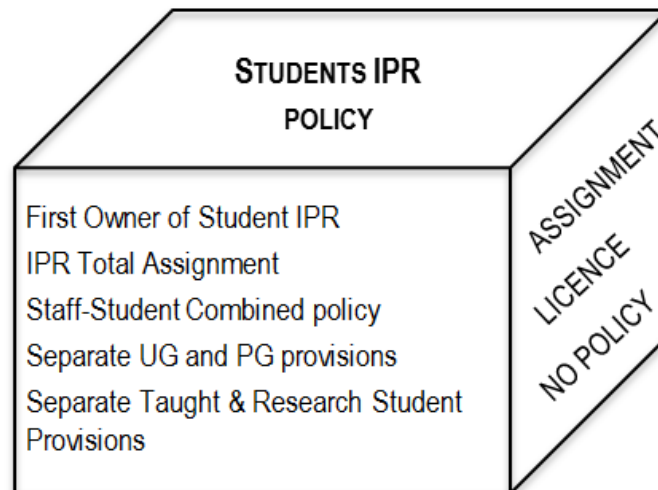

Figure 1 Map for IPR patterns in HEI[1]

3.1 Context

In the field of science, in higher education institution as well as in research institutions, there is still room for designing and implementing appropriate for the society policies. On the one hand, students, scientists and researchers should be free to do their work, to innovate, and to bind and transfer knowledge blending the national borders. On the other hand, they should also feel protected, and in this sense free, to produce knowledge and innovations, despite difficulties in cross-border transfer of knowledge caused by national legislation. Despite the varieties in the national legislations, EU countries and EEA countries are in line with EU commissions' policies.

Dealing with freedom and protection in the area of knowledge and IPR, the society should care especially after its young generation. There is still lack of policy dealing with IPR in higher education institutions, especially for students. In this sense and for the purpose of the paper, the term students means full time students, part time, undergraduate, postgraduate, PhD students, students which are also staff of the HEI, etc. In some countries undergraduate students are still not adult in the sense of the code of law, especially on the time of enrollment. In addition to the law perspective, the social perspective reveals variety priorities for undergraduate students. Therefore the society and the HEIs should be involved in the process of care after not only their own IPRs but also for students IPRs.

3.2 Problem

How can higher education institutions claim ownership of intellectual property generated by students at the time of their studentship, while being social responsible institutions and caring after intellectual property rights of the students itself?

3.3 Forces

In the process of knowledge transfer from HEI to students, a lot of uncertainties appear. Some students receive financial support from Institution in which they are enrolled in view of scholarship. Should it be the same IP policies for students receiving financial support, and for students not

receiving such financial support? In business, for example, it is not normal changing the IP policy according to raising the remuneration after regular attestation of employee's work.

Working on external or internal for HEI project, students, researchers and staff contribute to the generation of IP. They all they normally receive financial support for their work on external projects. In some cases the institution should transfer IP to the external organisation, and there is a need of clarifying the copyright issues, generated by involved staff and students. In this case is there a need of different policy for staff and students? Additionally there is a need of clarifying the necessity of specific policy for external project and internal one.

A well-known fact is that students, whether undergraduate or postgraduate, are not employees and HEI is not an employer for them. HEI as a social responsible body for future society should care after the IPR of their students and should also pay extra attention to and offer support and protection to its students and young researchers.

Normally students are not able to grant rights in third party material used in their work, hence the institution is responsible for the development of procedures for respecting the third party rights in reuse of the students work.

Therefore ...

3.4 Solution

The HEI should develop and implement a contract between the institution and the student and IPR policies should be included in the contract.

HEI should assign a committee responsible for the development and implementation of IPR policy.

HEI without IPR policy should develop and implement an IPR policy.

Institutions with an existing IPR policy should review regularly the clauses to guarantee rational balance and compliance with national legislation.

Institutions should make available their IPR policy freely for the society and in this way give an opportunity to prospective students to acquaint themselves to IPR issues prior to committing to study at that institution.

HEI should develop and implement contract between institution and student. The contract should be signed prior to the students' enrolment.

A statement regarding the ownership of IPR should be included in one of the documents in a package (e.g. research proposal form, or equivalent)

3.5 Consequences

Learning to deal with IPR, students will be inspired to work in a creative way and to generate original ideas and often to make innovations. They will learn how to be aware of their own IP, and how to deal with respect to others' IPR. They will fill themselves protected by the institution regarding their IPR and applying it via the institution's project they could also have a fresh start and new opportunities of their ideas.

From the perspective of the institution, if IPR policies are applied, the institution could more easily and lawfully monetize IPR. When Institution controls the entire educational and research process, including IPR, it can give talented students and researchers special attention to address their needs and concerns. Institution can decide which IP is worth pursuing and spending time on, and to make business and promote innovations with it in external projects. Beneficiaries of this approach are both sides. In case of suitable and adequate IPR Management, the reputation of the institution could raise up, along with the reputation of its students, researchers and staff.

3.6 Variations

Variations shall be expected when different paths in developing IPRs are pursued. In the process for developing IPR policy patterns such as ASSIGNMENT[2], LICENCE, OR NO POLICY (AN ASSIGNMENT OF RIGHTS BY THE STUDENT TO THE INSTITUTION, a LICENCE OF RIGHTS BY THE STUDENT TO THE INSTITUTION, OR NO ASSIGNMENT NOR LICENCE OF RIGHTS) could be selected. There are a lot of questions which the institution should answer and decide on. Just to name a few: Who is the First Owner of Student IPR?

Does HEI possess total assignment or license? Is there separate policy for staff, for researchers and for students? Are there separate provisions for undergraduate and for postgraduate students? Are there provisions for undergraduate in general? How are regulated reward provisions? Etc.

Depending of the approach and institution's strategic goals variations shall be expected when IPR policy are developed and implemented.[13]

3.7 Example

Digging in details, in next table could be seen different approaches in development of IPR in some of world class HEIs.

Table 1: Analysis of institutional intellectual property rights policies [14]

Institution	First Owner of Student IPR	Total Assignment	Staff-Student Combined policy	Separate UG and PG provisions	Separate Taught Student & Research Student Provisions	Discipline Specific	Reward Sharing Provision
University of Aberdeen	Student	Yes (1)	No	No	No	No	Yes

University of York	Student (9)	No	Yes	No	No	No	Yes

4. Conclusions

Research shows that the majority of EU further education institutions lack evidence of relevant IP policies. As for HEI, some of EU countries have relevant policies, and some doesn't have evidence for that. Despite the geo-political situation for European countries, researchers, students, faculties and institutions are not only authors, but also publishers of learning materials and knowledge with all the rights and the responsibilities this brings, and they should be utilising existing copyright exceptions freedoms accessible to them.

Clusters as a Driver of Regional Development

Nikolina Trajanoska¹

¹Ministry of economy of the Republic of Macedonia, nikolina.trajanoska@economy.gov.mk

The key weakness that all existing clusters in the Republic of Macedonia share is lack of capabilities in the area creating economies of scale in purchasing, gathering, applying and expanding knowledge and creating innovative solutions to business challenges.

Area that clusters have to improve are: trust, strong social capital, rapid tacit information flows and the development of collaborative knowledge based of an abundance of eyeballing (rather than emailing); co-specialization amongst local firms; the merits of a demanding local market; an ongoing exploration of new opportunities at the cluster's periphery; close alignment amongst public agencies around the cluster's priorities and aggressive leadership coming especially from the private sector.

In upgrading regional competitiveness through clustering approach scientists particularly identifies:

- Close and frequent personal contacts between the senior players in the cluster, covering business, academia, and local politicians;
- Excellence in research and education in the appropriate discipline;
- A tight focus on a specialization;
- A tight geography ... at the most 30 km radius;
- A technological infrastructure that attract customers, creative talent and new start-ups and
- A cultural / lifestyle infrastructure.

In this paper, we present the current state and the level of development of the clusters in the Republic of Macedonia.

Keywords

Cluster strategy, Evaluation of clusters, Knowledge industry, Networking, Supply chain.

1. Introduction

Governments are showing great interests – and some are spending considerable amounts of money in developing research clusters that they hope will benefit their local and national economies. We have seen every day an increasing interest in evaluating the effectiveness of such policies. In spite of a rapid increase in the number of cluster policies and programs, and thousands of local cluster initiatives around the world, we see very little evidence of serious cluster evaluation in our data. Today, regional clusters of related industries are the source of jobs, income, and export growth, and evaluation must come to the forefront in the construction and reconstruction of clusters across the world.

Porter defines a cluster as a geographically proximate group of interconnected companies and associated institutions in a particular field, linked by commonalities and complementariness where, the 'value of the system ...as a whole is greater than the sum of its parts'. [1]

Figure 1 Cluster structure

Natural comparative advantage is no longer sustainable and the source of competitive advantage often lies outside a given company or even outside its industry, residing instead in the locations of its business units. The nature of competition and competitiveness now emphasizes *'think global, act local'* as a way of doing business and succeeding in the international marketplace.

Over the past ten years, the concept of regional clustering has gained much popularity in business, government and academic world. Geographically concentrated cooperation is viewed as an organizational survival strategy in today's competitive business environment. Nowadays, firms have to cooperate in order to remain competitive.

Regional clusters often emerge in the market spontaneously without much government intervention. Local government can influence the supply of premises, the quality of local transport services, and can assist the creation of a business support infrastructure. In addition, they can influence the quality of education and the supply of skills.

The two competing tendencies, of the globalization of economic activities and the localization of industries have created policy challenges for national and local governments around the world. As a result, in the last decade we have seen a proliferation of development policies based on clusters or firms and industries. Such policies have focused on various aspects of growth such as regional development, SME development, overall economic development, domestic capability building, national systems and growth of 'knowledge' industries.

2. Importance of Clustering

In 1990, Michael Porter introduced the so-called "diamond" as an analytical tool to assess business environments. The diamond includes the four elements factor conditions (e.g., physical infrastructure, skills, etc.), demand conditions (e.g., sophistication of local customers, product and consumer regulation), the context for strategy and rivalry (e.g. taxation structure, competition laws, and the strategies of competing local companies), and the presence of related and supporting industries (e.g., the breadth and depth of the cluster). These elements interact in their impact on specific companies and clusters; they exhibit system-effects where the weakest element often tends to have the strongest impact on the overall quality.

The diamond can be used to analyze the general quality of the business environment at the national or regional level. However, it can also be applied at the regional cluster level, looking at the specific conditions relevant for the cluster in the four categories defined.

Many types of firms and organizations constitute the set of actors on the cluster "stage". Here, we have identified six main types: firms, financial actors, public actors, universities, organizations for collaboration and media (see Figure 2). [2]

Figure 2 Actors on the Cluster Stage

Government policy has an impact on all elements of the cluster-specific diamond. It often has responsibilities for large parts of the infrastructure, it sets key rules and regulations affecting competition and demand, and it affects the cluster presence through, for example, recruiting companies from other locations to make investments.

More recent research emphasized the need to look at government policies in a more differentiated way, separating the role of government at different geographic levels - from the cross national, to the national and local.

Other recent research has also stressed the importance of different types of “institutions for collaboration”, [3] that create specialized platforms for interaction among cluster participants. Because the performance of a cluster depends on the strength of interaction among its constituents, the presence of such institutions that allow knowledge to flow more easily and enable the cluster to organize collective actions has a significant impact on how the available assets in the cluster are being deployed. This research develops earlier work that had stressed the strength of networks and open collaboration within different regions as a key factor for economic success. [4]

2.1 Approaches for Evaluation of the Clusters

The first and most important step in developing clusters is to assess capacities, resources, and opportunities. Given the importance of planning, the tools are surprisingly weak. No one tried-and-true acid test for cluster capacity or potential exists. A number of methods have been used-ranging from ad hoc formalized consulting and opinion formation, to valuing or analyzing cluster capacity through descriptive or institutional analyses, to empirical, statistical analyses of detailed industrial data-but no truly the potential efficacy of a cluster likely requires a blend of quantitative and qualitative approach, understand or evaluate.

Given that clusters are to some extent self-defining, one approach often used is to convene an industrial, expert, or community forum to identify common interests and opportunities. While useful for identifying actors, or at least companies that would willingly participate, these processes are simply a start-up point. In the first instance, they likely determine whether the necessary number of interested/engaged actors can foster effort to develop a cluster. The processes can also be valuable for identifying scale and scope of current traded or untraded interdependencies, as well as for planning future development that may either require or generate greater connections in a community. However, they often run the risk of becoming either subject to groupthink (where everyone goes along with the most important or loudest participant) or to end as unfocused debates about what is, is not, could be, or should be happening locally. Every process needs to move beyond rhetoric. Depending on local capacities, two main approaches have been tried.

One common analytical approach is to look at the institutional composition and leadership of the industry, supply chain, technology, or market. Generally speaking, clusters always represent a high

concentration of people and activity within a particular region. Thus, qualitative analyses of clusters would measure that reflect those concentrations relative to benchmarks or other regions. A foundational theory that underlines any number of quantitative approaches is central place theory, a geographical theory that seeks to explain the size and spacing of human populations. The theory relies on the notion that the centralization is a natural principle of human order and that the nested hierarchies of people and institutions will follow this principle. [5]. In the context of that theory, many communities will seek to identify the community's array of industry (for example, leading companies and suppliers), supply chain (that linked suppliers ranging from input industries through production to transportation, wholesale, and retail trade), and functional actors (finance, marketing research, and labour services).

2.2 Methods of Evaluation

To evaluate clusters and clusters programs is a complex proposition. As a part of preparing this paper, we conducted a simple survey of cluster evaluation. Data was gathered through a questionnaire sent by e-mail to the existing cluster organizations. The questionnaire covered ten questions regarding the evaluation of cluster programs and initiatives. Some of the questions were based on a five-step Likert scale (ranging from 1, "strongly disagree" to 5, "strongly agree"). [6] Out of 12 clusters, 8 participated in the study; four stated that they had not done any form of evaluation. The fact that only three organizations had conducted formal evaluation with an external evaluator is an indication that evaluation indeed is a rare task among cluster organizations.

External factors that were identified in this analysis and were shown to affect business growth include:

- Funding (Financial capital) – including levels of investment and time and cost to commercialization
- Skills and recruitment (Human capital) – number and type of graduate numbers, occupational level and salary average.
- Networks (Social capital) – growth of networks, study of industry organizations and inter-organization joint working.
- Global market position (Market capital) – success or failure information on foreign investment and exporting levels.

Further, more, some clusters are affected by several policy instruments in parallel, including regional policies, science and innovation policies and so on, and thus it is difficult to separate out of the effects from a particular cluster instrument. Evaluations tend to be carried out within to three to five years, and then few if any major effects on the cluster should be detectable, especially if the cluster is an emerging one.

3. Macedonian's Clusters Assessment

Several cluster initiatives are already operating in Macedonia: textile cluster, information technology cluster, wine cluster, tourism cluster, agricultural mechanization, automotive components, wood processing, food-processing cluster, fashion design cluster etc. These clusters are at various stages of development and as such need specific support to further accelerate their development.

The key weakness that all Macedonian existing clusters share is a lack of potential for innovation, new products and services development to compete better in the global markets. Existing clusters have mainly been created with the purpose of "grouping of small enterprises" to better sell on the markets and have done much less in the area of sharing and creating economies of scale in purchasing, applicable research and development and innovation. Big companies are generally not active members of Macedonian clusters. Analysis of successful clusters around the world shows that successful clusters gather, apply and expand knowledge and create innovative solutions to business challenges. These qualities of clustering still need to evolve in Macedonia. [7]

In assessing Macedonia's current position, we could conclude that government is focused on three of the dimensions of the diamond so far. Namely:

- Open-up the economy to global competition (through tariff reductions and introducing national competition policy)
- Microeconomic reform and restructuring of major inputs (electricity, transport, telecommunications, finance, and the regulatory framework)

- Supporting public sector research infrastructure and providing a strong education system (as a result both the government, and the Macedonian consumers).

From case study comparison, three properties are common to all successful clusters. These properties are:

- Formal and informal networking, allowing for effective transfer of technology and other organizational capabilities;
- Close user-producer collaboration allowing for production flexibility and joint development;
- Mobility and flexibility in the local labour market, allowing low redundancy costs and easy adaptation to changes in products and processes.

The benefits for Macedonian clusters from clustering process include:

- The availability of specific natural resources – many clusters have traditionally formed around natural resources (textile cluster, cluster for agro-equipment, wine cluster).
- Supplies of special labour– specialized labour pools develop around clusters, flexibility and efficiencies for firms seeking specialists’ skills in the market and facilitates the technology transfer.
- The economies of scale in production – some industries can support a number of efficient-scale plants in a given region (Tikvesh region)
- Superior access to information – informal, unplanned, face-to-face, oral communication is a critical to the innovation process. Clusters facilitate this type of communication. The geographic concentration of firms, suppliers, and buyers in the cluster provides short feedback loops for ideas and innovations. Clusters provide the opportunity to access the specialized information embedded in personal, community and business relationships, about markets, technology ad competitive strategies.
- Institutional support – clusters often have mutually supportive relationship with local universities, standards agencies, research laboratories, training providers, trade associations, and financial institutions.
- Obtaining critical mass, the clustering of firms reduces the unit costs of technical services provided to members of the cluster. By operating in close proximity, firms also more easily subcontract to competitors those orders that exceed their own capacities (especially the textile cluster).

Looking forward, we also asked respondents in an open-ended question what they viewed as the biggest threats to clusters organizations (see Figure 3). The largest threats indicated were: insufficient financing, poor economic situation and lack of new ideas and commercialization.

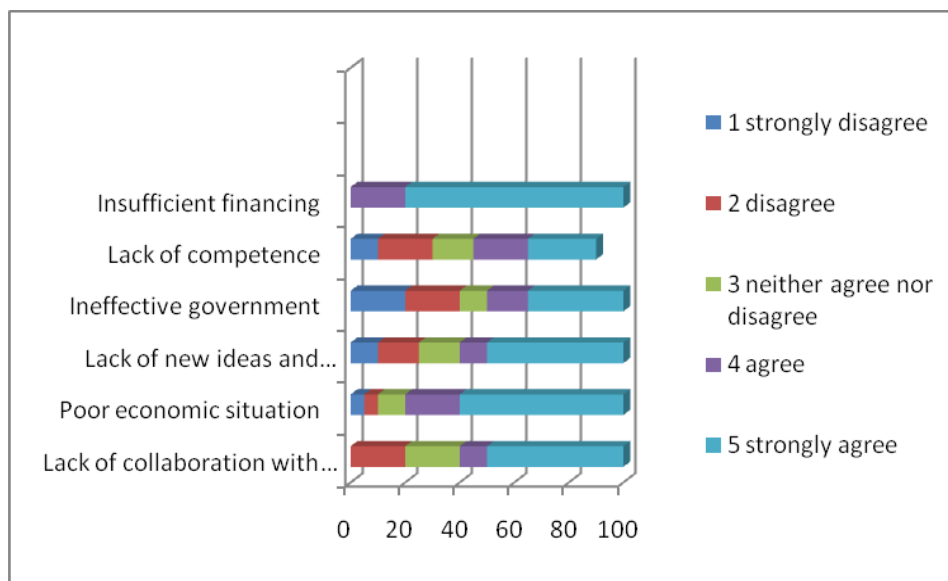

Figure 3 Biggest threats to clusters

3.1 Cluster development programme

In place of a uniform measure for encouraging the development of clusters, Ministry of Economy designed a wider package of measures for encouraging cooperation's and networking. The implementation of Cluster program has been conceived in three phases. The first phase entailed the identification of potential clusters, the second the definition of cluster policy, and the third the implementation of the cluster policy in practice. The original concept was, on the basis of the clusters identified, to promote the development of those clusters that were of strategic importance to Macedonia in terms of the number of companies, the proportion of employment, the existing advantages, development potential, and market share in Macedonia and on foreign markets.

Cluster development policy in Macedonia pursues three objectives. The first is to encourage cooperation and networking between companies in order to strengthen individual and joint abilities to develop partnerships in different areas of business and to intensify cooperation between companies and research and development institutions in order to strengthen the common capabilities required for promoting innovation and technological development. Here The Ministry of Economy co-financed joint projects carried out by at least three companies and at least one R&D institution in the areas of technological improvements, product development, specialization, supplier chains, joint production and marketing. The second objective is to promote the development of clusters through increased investments in support infrastructure. This primarily entails investment in strengthening the know-how, skills and expertise required by actors of cluster development (people and institutions) for promoting the development and functioning of clusters. A training program was designed to improve of cluster development, and to develop a network of cluster promoters, coordinators and potential cluster managers. The third objective is to initiate the formation of clusters in practice.

4. Conclusion

In summary, our findings clearly indicate the importance of evaluating cluster initiative. Cluster thinking and cluster strategies have the potential to accelerate regional economic growth and assist with the nation's needed economic restructuring, but they are more a paradigm than a single program. In that sense, the opportunities that a cluster policy framework provides for delivering impact, clarifying economic priorities, and coordinating disparate programmatic efforts will only grow more important in the coming era of intensified competitive pressures and tightened resources.

Evaluation of clusters should be made in real time, on a regular basis and by an external party.

In any event, globalization, increased competitor-state policy activism, and the current economic crisis are all helping to make clusters an important framework for working out a pro-market, pro-productivity stance that avoids old-style "industrial policy," but it gives government an active role in fostering competitiveness. After all, through the natural and fostered emergence of diverse, locally-embedded clusters of excellence the nation can compete aggressively without slipping into directly "picking winners." Likewise, through the bottom-up development of strong, place-based clusters that nation stands a better chance to build unique new industries that will be harder to off-shore.

Regional leaders should identify cluster challenges and coordinate cluster actors. Regional intermediaries should work to identify and describe local clusters, identify their binding constraints, and facilitate regional joint action to implement needed exchanges and initiatives.

Local policymakers should bring to tools to influence on-the-ground implementation of cluster-oriented economic development. They should manage zoning and permitting issues to benefit the physical infrastructure in which clusters exist, and they should keep an eye out for the broader demographic and social context in which new industry clusters might form and to which existing ones must adjust.

The combination of three-dimensional (3D) modeling and Web technologies supports the development of adaptive learning environments. These environments enable learners to interact and behave in a natural manner. In this paper modeling and implementation of Virtual Classroom for Graphic Technology (VirCGT) is presented. VirCGT enables learning through exploration and collaboration in order to understand the basic concept of graphics technology. VirCGT with smart tutorial has been developed using Web3D technologies. We evaluated our system quantitatively, and qualitatively, using formal performance assessment, a pilot project, and syllabus.

1. Introduction

Virtual Reality (VR) is a computer simulated environment regardless of the fact that environment is a simulation of the real world or an imaginary one. VR allows user to interact with virtual environment (VE). VE could be visual experience shown on the screen, with which it could be possible to interact using standard input devices, such as keyboard and mouse systems or by using various multi-modal devices, with tactile feedback.

The combination of synchronous learning tools, Web technology, social networks and video games, haptics and tracking devices creates rich 3D learning environments. These environments enable learners to interact and learn the way not possible outside of virtual worlds. Achieving high level of immersion could provide better distant communication, interaction, and collaboration. Conventional input devices such as the mouse and keyboard lack in intuitiveness when it comes to 3D manipulation tasks.

In practice, there are not yet fully integrated systems to support 3D model of e-learning. The result of this work is a VirCGT classroom that enables interaction between the on-site and distant students and teachers using educational resources through integrated virtual and real classrooms.

The key features of VirCGT are: communication using chat; collaboration characteristics with manipulation of shared 3D objects, using the same space by concurrent users, and predefined and saved models.

Section one introduces the concept of virtual environments, being motivated by pedagogical approach, and educational contexts in which environments can be used; section two gives an overview of published works; section three illustrates virtual classroom for graphic technology; section four describes offset technology process; section presents evaluation of educational applications of graphics technology; section six ends with contribution, conclusion and future work.

2. Related Work

Multi-user 3D environments have seen tremendous growth. Not only they affect large number of participants [1], or hosts big number of VE [2] but the emphasis on interpersonal communication, participation in the joint construction, and development of 3D content is also important.

There are lot of examples from papers and locations [3] [4] [5] [6] [7] [8] of environments which provide facilities to enable modeling, displaying and collaboration. They are created in order to display external media such as video, audio, graphics, and web pages. It could be a classroom for educational purposes or room for design and development. Virtual printing is a simulation of real printing using "woodblocks", "a paper sheet", "a BAREN (Japanese squeegee)", and "inks" in a virtual 3D space [9] [10].

The integration of multimedia content with virtual environment is common in the development of VR applications. There are many technologies that enable presentation of 3D data on the Internet. X3D (royalty-free open standards file format and run-time architecture to represent and communicate 3D scenes and objects using XML) enables the visualization of applications in VR and augmented reality through integration of interactive real time 3D technology [11].

3. VirCGT description

There are many X3D content-creation tools [11]. In this paper, X3D-Edit is used for the environment creation. X3D-Edit is a graphics file editor enabling simple error-free editing, authoring and validation of X3D scene-graph files. Base model, named "VD-30", is virtual representation of real classroom "D-30" as one of many classrooms intended for practical exercises in computer science (fig. 1).

Figure 1 Virtual classroom VD-30

The existence of such classrooms enables real time teaching to be run (fig 2). Interaction between teacher and student is achieved by using various educational resources through the integration of virtual and real classrooms. Dynamically adaptive system is used to student's and teacher's requests. Time and spatial concurrent work is enabled. Elements are loaded from the library, different browsers are used, interaction is enabled through access to the same elements (at the same time), and external applications and services are integrated.

Figure 2 Complete integration of real and virtual environment

The interface of this system includes X3D model display area and communication area (fig. 3). The users could operate directly the X3D model, performing usual actions such as navigation, exploration, moving objects, and communicating with teacher or student. A teacher or student can add and move objects in the floor plan, making their own schedule. A chat panel is responsible for the chat communication, either text or video, between online users.

Figure 3 Description of graphic user interface

4. Description of the offset technology process

The workflow process of printing technology that we use in this virtual model is shown in figure 4. The process starts by entry of the material that is used in printing process and customer's demand to create a certain product. The first phase of this process is the design of the graphic product and computer realization of typeface so that the product can be developed further on. During this phase a need arises for description of computer resources, both hardware and software that is being used through this phase of realization in this technology.

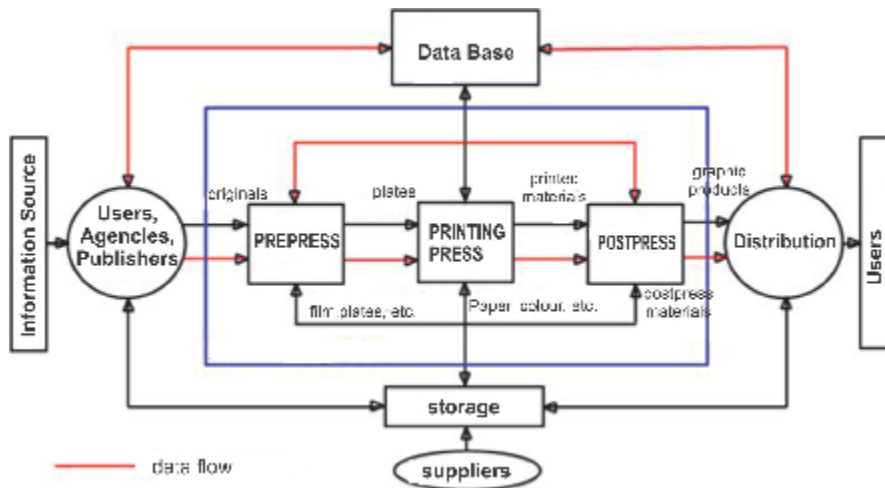

Figure 4 The workflow of printing technology process

After this phase, technological technical prepress follows. It consists of preparation of the material that will be used during the printing phase (cutting paper to the dimension of printing sheet, selection of plates etc.) In this phase, binding of sheets is also being done, proof printing and film or offset plate exposure are realized (fig. 5).

Figure 5 Technological technical prepress

After choosing the material and plate exposure we are ready for the next phase which is printing of sheets. During this phase we describe printing machines and their functioning as well as the way of proof creation. It is also necessary to describe the quality control of proof which is essential for quality printing.

In offset printing we differentiate two basic choices of machines, the sheet-fed press (that prints on individual sheets of paper) and rotation printing machine roll to roll and roll to sheet. The choice depends on print run and purpose of product, and of the quality we wish to achieve. Having finished sheet printing, we move on to post press phase or the final realization of product. Apart from printed sheets, some specific materials such as various kinds of adhesives, foils, cardboard, wire, thread etc. belong to this phase. During this phase, all kinds of binding sheets into final product are being conducted, sheet folding, sheet binding, sheet lamination, cutting and perforation of sheets as well as folding boxes and gluing sheets into a final product, and other operations currently not mentioned. Part of this phase is cutting certain products into their final size (books, magazines, catalogues etc.) and their packaging. The last phase of printing process is storing final products and distributing them to end-users.

5. Evaluation

System efficiency is measured by comparing the final results of students in the third year at the Faculty of Informatics and Computing who accessed that classroom through the virtual and physical interface. As most objective abilities to analyze the efficiency of virtual classroom in practical use were identified by comparing results of students who used real and virtual classroom. Results of final exam are compared. Exam was conducted in controlled environment and 40 students (20 students that used physical and 20 that used virtual environment).

Results of this statistical analysis were expected and are very important for our further work. Absence of statistically important difference in results of control and treated groups, when using confidence interval of 95 percents, proves usability of this concept.

6. Conclusion and Future Work

This paper presents the results of a one-year experiment in incorporating 3D modeling educational environment in Computer Graphics courses which are part of the Programming and Design engineering degree. The results of our initial experiments are promising enough to encourage further integration of VirCGT model with sensors and 3D searching.

Global Entrepreneurship Index for Western Balkan countries and Slovenia participants in the GEM 2009 project

Bahrija Umihanić¹, Mirela Arifović²

¹*Faculty of Economics, University of Tuzla, Tuzla, Bosnia and Herzegovina, bahrija.umihanic@untz.ba*

²*Entrepreneurship Development Centre, Tuzla, Bosnia and Herzegovina, mirela_a@bih.net.ba*

Focus of this paper are entrepreneurial performances of Bosnia and Herzegovina, Serbia, Croatia and Slovenia, that will be analyzed through construction of Global Entrepreneurship Index (GEINDEX), which is created with aim of unique measurement of entrepreneurship between countries and during the time. Global Entrepreneurship Index captures essence of contextual characteristics of entrepreneurship and fills the gap in measurement of entrepreneurship and development within certain country. This index captures contextual characteristics of entrepreneurship by focusing on entrepreneurial attitudes, entrepreneurial activity and entrepreneurial aspirations. It has been developed by researchers gathered within the project Global Entrepreneurship Monitor (GEM) and the basis for its creation are GEM variables created from research results of the countries that participate in the project. Western Balkan countries, Bosnia and Herzegovina, Serbia and Croatia, as well as Slovenia participate in the project Global Entrepreneurship Monitor (GEM), so it is possible to calculate and analyze Global Entrepreneurship Index for these countries. First part of the paper contains basic information on the project Global Entrepreneurship Monitor (GEM), since GEM variables are basis for creation of the Global Entrepreneurship Index. Then, methodology of building the Global Entrepreneurship Index will be shortly presented. Final part of the paper contains calculated Global Entrepreneurship Index for Bosnia and Herzegovina, Serbia, Croatia, and mutual comparison of calculated GEINDEX of these countries. The aim of this paper is to analyze and compare entrepreneurial performances of Bosnia and Herzegovina, Serbia, Croatia and Slovenia, countries that participated in the project Global Entrepreneurship Monitor 2009, through construction of Global Entrepreneurship Index, and to promote a new way of unique measurement of entrepreneurship.

Keywords

Economic development, Entrepreneurial performances, Entrepreneurship, Global Entrepreneurship Index, Global Entrepreneurship Monitor.

1. Introduction

It is widely acknowledged that entrepreneurship has the key importance for understanding the economic development. Dynamics of the entrepreneurship process can vary depending on the institutional context and the development level of certain country. This is the reason for accepting the notion that in order to understand entrepreneurship within one or within several countries, it is needed to review wide spectrum and relation between entrepreneurship, economic development and institutions. Connection between entrepreneurship, institutions and economic development helps in understanding why relative contribution of entrepreneurship varies between certain countries and regions. In accordance with this, in previous period great level of importance is given to role that

institutions have in economic development of certain country. In order to get better insight and understanding of the role of entrepreneurship, scientist are searching for the measure with which comparison of the entrepreneurship performances of the countries will be enabled. Those attempts were more intense during the last decades. Taking in consideration the advantages and lacks of previous researches on entrepreneurship, two respectable researchers Zoltán J. Ács (School of Public Policy, George Mason University, VA, USA and Max Planck Institute of Economics, Jena, Germany) and. László Szerb (Faculty of Business and Economics, University of Pécs, Pécs, Hungary) defined the basic preconditions for building of the one integral entrepreneurship index which should be sufficiently complex in order to capture multifunctional characteristics of entrepreneurship, besides the quantity to be the indicator which refers to differences related to the quality and to incorporate variables of the individual level as well as the institutional variables. Taking in consideration presented preconditions for building of the one integral entrepreneurship index with a will to contribute to better understanding of economic development through building of entrepreneurship index, previously mentioned researchers have developed the Global Entrepreneurship Index - GEINDEX that incorporates the essence of the contextual characteristics of entrepreneurs and fills the gap in measuring of entrepreneurship and development.

The Global Entrepreneurship Index (GEINDEX) captures the contextual characteristics of entrepreneurship by focusing on entrepreneurial attitudes, entrepreneurial activity and entrepreneurial aspirations. Construction of the Global Entrepreneurship Index involves 31 variables, 17 from the Global Entrepreneurship Monitor and 14 from other data sources, from which 14 pillars, three sub-indexes and one "super index" is built. The Global Entrepreneurship Index can have value from 0 to 1. The most of the variables used for creation of indicators are from master data sets of the GEM annual adult population surveys, and since Bosnia and Herzegovina, Serbia and Croatia, as well as Slovenia participate in the project Global Entrepreneurship Monitor (GEM), it is possible to calculate and analyze Global Entrepreneurship Index for these countries.

Data for Croatia, Serbia and Slovenia are from the 2006-2007 years survey while for Bosnia and Herzegovina are from the 2008 survey. Amongst those countries that participated in both years original yearly data are averaged, while single year data is applied if certain country participated only in one year. GEM has a lack of necessary institutional weighting variables so the authors of GEINDEX substituted the index with certain widely used relevant data from World Bank, UNESCO, United Nations and similar. In cases, where certain variable was missing, the authors of the GEINDEX estimated the data by estimation conducted by the by expert estimation technique.

2. Global Entrepreneurship Monitor (GEM)

The Global Entrepreneurship Monitor (GEM) is a not-for-profit academic research consortium that has as its goal creation of high quality international research data on entrepreneurial activity which are available and understandable to wide audience. GEM is the largest single study on entrepreneurial activity in the world. The Global Entrepreneurship Monitor research program is the annual estimation of entrepreneurial activity in a national level. Since 1999, number of countries – participants in the GEM project has been increasing, so the GEM research is expanded from 10 countries in 1999. to 21 countries in 2000., 29 countries in 2001., 37 countries in 2002., to 54 countries in 2009.

The GEM research has three main objectives:

- To measure differences in the level of early stage entrepreneurial activity between countries;
- To uncover factors which determine the levels of entrepreneurial activity;
- To identify the policies that may enhance the level of entrepreneurial activity.

This research is based on data collected through three research sources:

- Data collected through Adult Population Survey (APS);
- Data collected through National Experts Survey (NES);
- Data collected through Standardized cross-national datasets.

Unique and the most important dataset in the GEM project is got from the Adult Population Survey. Every participating national team complete the Adult Population Survey in its country. The APS surveys provide harmonized estimations of the level of entrepreneurial activity in the country. Each national team must survey at least 2000 adults in their country, so the sample of surveyed people is in most cases 2,000 adult persons (18 to 64 years old), but this sample can be higher. Adult Population Survey presents the harmonized measure of the prevalence of entrepreneurial activity in the country.

The second relevant data source for the research on entrepreneurial activity are the attitudes and opinions of experts, collected through standardized questionnaire consisted of several groups of questions which refer to entrepreneurial environment. These data are collected within the National Experts Survey, which is a survey of experts conducted by GEM national teams each year. The main objective of this survey is to provide information about the entrepreneurial framework conditions in each nation. National Expert Survey also provides experts' opinions on abilities of population, their knowledge and skills to start up, perceptions about opportunities to start up, women support to start up, high growth support and other topics of interest. NES questionnaire can also have questions on special topics. Every GEM national team is responsible to conduct an interview with 36 experts from their country. Through interview, experts estimate the entrepreneurial conditions in their country by using the elements of the Licert Scale.

Standardized national data are gathered from international data sources such as the International Monetary Fund, the World Bank, and the United Nations. These data are used for establishing the link between macroeconomic conditions and national levels of entrepreneurial activity, as well as the impact of the state of national conditions which are required for establishment of this link.

3. Global Entrepreneurship Index (GEINDEX)

Methodology of creation of the GEINDEX was developed by two respectable researchers Zoltán J. Ács (School of Public Policy, George Mason University, VA, USA and Max Planck Institute of Economics, Jena, Germany) and László Szerb (Faculty of Business and Economics, University of Pécs, Pécs, Hungary) who were led by the principle that for creation of the Global Entrepreneurship Index it is needed to include individual level as well as environmental, institutional variables and that proper weights should be used. One of the novelties of this methodology is that the institutional variables are considered as interaction variables, not as independent indicators.

The construction of the Global Entrepreneurship Index includes 31 variables, 17 from the Global Entrepreneurship Monitor and 14 from other data sources, from which 14 pillars, three sub-indexes and one "super index" is built. The Global Entrepreneurship Index can have value from 0 to 1. The criteria for selection of certain institutional variable is that it is an environmental variable where exist the logical link of the certain entrepreneurship variable and the interpretation and the possibility of explanation of the selected variable.

When creating the Global Entrepreneurship index it is started with the definition of entrepreneurship that it is a dynamic interaction of entrepreneurial attitudes, entrepreneurial activity, and entrepreneurial aspiration that vary across stages of economic development. There are four steps of index building: selection of variables and weights; indicators; sub-indexes and the super-index.

The GEM Adult Population Survey is the basis for creation of the Global Entrepreneurship Index. The starting variables which are all individual level variables directly come from the original APS data sources for each country included in the analysis. The institutional variables are gathered from various sources, by using the selection criteria previously described. All the indicators are calculated from the variables, and the indicators are the fundamental building blocks of the sub-indexes. The super-index, the Global Entrepreneurship Index, is the average of the three sub-indexes.

Sub-indexes include number of indicators so they can be interpreted as building blocks of the Global Entrepreneurship Index. Those sub-indexes are: entrepreneurial attitudes, entrepreneurial activity and entrepreneurial aspirations.

Entrepreneurial attitudes are defined as general national attitude towards opportunity recognition, personal knowing entrepreneurs, referring high status to entrepreneurs, taking risks related to business start up and possessing necessary skills for successful business start up.

Entrepreneurial activity is defined as rate of starting up a new ventures adjusted to effect of business discontinuation initiated by educated entrepreneurs.

Entrepreneurial aspirations can be defined as the efforts of the early-stage entrepreneurs to introduce new products/services, develop new processes of production processes, enter at new markets, increase the number of employees etc.

In order to address the dynamism of the index and to normalize created indicators the authors of the GEINDEX used special developed approach called "penalizing for bottleneck" (PFB) which will not be presented in this paper, since the topic of the paper is to analyze the Global Entrepreneurship Index for Western Balkan Countries who participated in the GEM 2009 project and Slovenia. For more detailed explanation of the methodology and "penalizing for bottleneck" (PFB) approach please refer to Ács Z.J. and Szerb L. (2009) „The Global Entrepreneurship Index (GEINDEX)“ Foundations and Trends® in Entrepreneurship Vol. 5, No 5, 341-435.

3.1. The Entrepreneurial Attitudes Sub-index (ATT)

The purpose of the Entrepreneurial Attitudes Sub-index is to identify the entrepreneurial attitudes of the population in certain country related to entrepreneurship. One of the aspects of entrepreneurial attitudes is the opportunity perception. This aspect is important and it shows whether the population in certain country sees good opportunities for business start-up. Additional aspects are perceptions regarding skills for business start up and possibilities to network, which is one of the basic conditions for successful use of the business opportunity. On the other hand, no matter if the population see good opportunities for business start up, have positive attitudes towards own skills and possibilities to network for purpose of business start-up, if the fear of failure is present, it can prevent those people with positive previously mentioned aspects of entrepreneurial attitudes, to start the business. This is the description of the individual level variables that are used for creation of the Entrepreneurial Attitudes Sub-index. As institutional aspects that affect the entrepreneurial attitudes, and which are used for creation of the Entrepreneurial Attitudes Sub-index, selected are market size, education, the riskiness of a country in general, the usage rate of the Internet in the country, and culture.

The Entrepreneurial Attitudes Sub-index contains five indicators: “*opportunity perception*”, “*start-up skills*”, “*nonfear of failure*”, “*networking*” and “*cultural support*”. All of the mentioned indicators are combination of individual and environmental variables.

Table 1 contains data on GDP per capita (in analyzed period) and the calculated Entrepreneurial Attitudes Sub-index for Bosnia and Herzegovina, Croatia, Serbia and Slovenia.

Table 1 The Entrepreneurial Attitudes Sub-index and the GDP per capita (in analyzed period) for Bosnia and Herzegovina, Croatia, Serbia and Slovenia

Country	GDP per capita (\$)	ATTINDEX
Slovenia	24172	0.62
Croatia	14040	0.39
Serbia	5351	0.29
Bosnia and Herzegovina	7048	0.22

GEM groups the economies into factor-driven, efficiency-driven, and innovation-driven economies based on the World Economic Forum’s (WEF) Global Competitiveness Report that identifies three phases of economic development based on GDP per capita and the share of exports comprising primary goods. According to that Croatia, Serbia and Bosnia and Herzegovina are classified as efficiency driven economies, while Slovenia is classified at the group of innovation-driven economies.

Slovenia is one of the most developed countries in the Balkans, and most developed country among the countries that are included in the analysis for the purpose of creation of this paper. All of the included countries were part of the Yugoslavia and have similar economic and political background. Slovenia is a member state of European Union, its economy is innovation-driven, with GDP per capita over 20.000 \$. If we look at the Slovenian results for the Entrepreneurial Attitudes Sub-index, it is the highest among countries included in the analysis. Croatia, Serbia and Bosnia and Herzegovina has significantly lower result for the Entrepreneurial Attitudes Sub-index, especially Bosnia and Herzegovina, which results is 0.22. This implies that in Croatia, Serbia and Bosnia and Herzegovina should be worked on improvement of attitudes towards entrepreneurship, since this aspect is very important for entrepreneurship development in countries. Entrepreneurial environment should be improved in order that people enter at entrepreneurial activity not just because they are “pushed” into it and because they did not have other opportunity to work, but because they see good opportunities for that. Economies should enable to people to start the businesses when it is necessary, but it is also needed to work on decrease of fear of failure and encouragement of those who are attracted to entrepreneurship by opportunity.

3.2. The Entrepreneurial Activity Sub-index (ACT)

New firms have the important role for economy of certain country, but in the past low importance was given to mentioned role of new firms. Global Entrepreneurship Monitor takes a comprehensive approach and includes in the analysis and considers the level of involvement in entrepreneurial activity of population in certain country, as well as different types and phases of entrepreneurship.

Entrepreneurial activity can have different forms, but one important aspect according to GEM is the extent to which population in certain country creates new business activity, in absolute terms as well as relative to other economic activities including discontinuation of business. GEM also considers the entrepreneurial activity as a process rather than an event, and measures entrepreneurial intentions, nascent, new, and established business activity, as well as business discontinuation activity.

The Entrepreneurial Activity Sub-index mainly involves and is dedicated to measurement of start-up activity with potential for high growth. Entrepreneurship creates new businesses with greater potential for high growth than non-entrepreneurial subjects. Measures included within this sub-index are opportunity motives for start-up, business operations in technology intensive sector, the educational level of population and the uniqueness of the offered product or service. The institutional variables used, include the ease of doing business, the availability of the latest technology, the level of human development, and the freedom of business operation. The Entrepreneurial Activity Sub-index contains four indicators: “*opportunity startup*”, “*tech sector*”, “*quality of human resources*” and “*competition*”.

Table 2 contains data on GDP per capita (in analyzed period) and the Entrepreneurial Activity Sub-index for Bosnia and Herzegovina, Croatia, Serbia and Slovenia.

Table 2 The Entrepreneurial Activity Sub-index and the GDP per capita (in analyzed period) for Bosnia and Herzegovina, Croatia, Serbia and Slovenia

Country	GDP per capita	ACTINDEX
Slovenia	24172	0.58
Croatia	14040	0.30
Serbia	5351	0.26
Bosnia and Herzegovina	7048	0.19

As for the Entrepreneurial Attitudes Sub-index, Slovenia has the highest score for the Entrepreneurial Activity Sub-index, among the countries included in the analysis. Bosnia and Herzegovina, at the other hand, has extremely low result for the Entrepreneurial Activity Sub-index. Croatian and Serbian result is not satisfactory, and scores 0.30 that is 0.26. Taking in consideration that the Entrepreneurial Activity Sub-index measures the average quality of startups rather than the quantity of business, the low results of this index is related to low quality of start up businesses in given country, and the governments should contribute to improvement of aspects that refer to the quality of start up businesses.

3.3. The Entrepreneurial Aspiration Sub-index (ASP)

Entrepreneurial aspirations are related to the qualitative side of entrepreneurial activity, including aspirations of entrepreneurs to introduce new products and production processes, to enter the foreign markets, to use new technology, to develop a significant organization, and to fund growth with external capital. Realized entrepreneurial aspirations can contribute to the important economic impact of entrepreneurial activities.

Individual level variables included in this sub-index are related to the newness of the product and of technology, internationalization, high growth ambitions and finance variables. The institutional variables of this sub-index are related to the R&D potential, the sophistication of business and of innovation, the level of globalization, and the availability of risk capital. So, the Entrepreneurial Aspiration Sub-index (ASP) contains five indicators: “*new product*”, “*new tech*”, “*high growth*”, “*internationalization*” and “*risk capital*”.

Table 3 contains data on GDP per capita (in analyzed period) and the Entrepreneurial Aspiration Sub-index for Bosnia and Herzegovina, Croatia, Serbia and Slovenia.

Table 3 The Entrepreneurial Aspiration Sub-index and the GDP per capita (in analyzed period) for Bosnia and Herzegovina, Croatia, Serbia and Slovenia

Country	GDP per capita	ASPINDEX
Slovenia	24172	0.41
Croatia	14040	0.39
Bosnia and Herzegovina	7048	0.23
Serbia	5351	0.16

Among all presented sub-indexes for Bosnia and Herzegovina the Entrepreneurial Aspiration Sub-index is the highest, although the score of this index is also low, and not encouraging. Serbia has extremely low result for the Entrepreneurial Aspiration Sub-index, while this sub-index is the lowest among three presented ones for Slovenia. Entrepreneurial aspirations are important for development of entrepreneurship, because, as it was already mentioned, they are referred to the qualitative side of entrepreneurial activity and tendencies of entrepreneurs to improve their businesses and ensure their growth, which is important for sustainability of businesses and their capability to compete at the market. Aspirations of entrepreneurs to ensure the growth of the enterprise and implemented activities related to it, have effect on development of qualitative side of entrepreneurship in the country. When analyzing the three entrepreneurial sub-indexes it should be considered that all these sub-indexes does not have the same level of importance. In relation to entrepreneurship development in the country, aspirations sub-index is probably more important than either the attitudes sub-index or the activity sub-index. Of course this depends on level of development of the country and other specific contexts in the country.

4. The Global Entrepreneurship Index (GEINDEX) for Bosnia and Herzegovina, Croatia, Serbia and Slovenia

The Global Entrepreneurship Index is calculated as the average of the three sub-indexes, that is the Entrepreneurial Attitudes Sub-index (ASP), The Entrepreneurial Activity Sub-index (ASP) and The Entrepreneurial Aspiration Sub-index (ASP). The GEINDEX correlates strongly with the level of economic development and its advantage is that it links entrepreneurship and the entrepreneurial environment to economic development.

Table 4 contains data on GDP per capita (in analyzed period) and the values of GEINDEX for Bosnia and Herzegovina, Croatia, Serbia and Slovenia.

Table 4 The GEINDEX and the GDP per capita (in analyzed period) for Bosnia and Herzegovina, Croatia, Serbia and Slovenia

Country	GDP per capita	GEINDEX
Slovenia	24172	0.54
Croatia	14040	0.36
Serbia	5351	0.24
Bosnia and Herzegovina	7048	0.21

Slovenia is ranked at the highest place of GEINDEX among all other countries included in the analysis. Although Croatia is ranked second, and stands better than Serbia and Bosnia and Herzegovina, the result is not satisfactory and the entrepreneurial aspects and other aspects related to the components of the GEINDEX should be improved in this country. Serbia has extremely low score of the Entrepreneurial Aspiration Sub-index, so the weak performance in this area should be handled, and activities aimed at this aspect should firstly be implemented because it can have the negative effect on all the other features of entrepreneurship. Bosnia and Herzegovina has the lowest score for GEINDEX among countries analyzed in this paper. This country has also low scores for all three sub-indexes which resulted in low GEINDEX. Bosnia and Herzegovina is still struggling to revive its economy. The political and administrative structure of the country is complicated and has many levels. New entrepreneurial activities are mostly based on necessity, and entrepreneurial environment is not supportive to business start ups, so this score of GEINDEX for Bosnia and Herzegovina is not surprising. Policy makers in Bosnia and Herzegovina, as well as in Croatia and Serbia should consider all three aspects, that is entrepreneurial attitudes, entrepreneurial activity and entrepreneurial aspirations and adopt policies and implement programs to foster entrepreneurship in their countries. Policy makers in all countries included can use the GEINDEX and its components, to see how their country ranks, and which are the weak aspects that should be strengthened, and work on their improvement.

3. Conclusions

During the last decade there were many attempts for construction of entrepreneurship index, which will be theoretically grounded and empirically proven, but those attempts did not have much success. However in 2009, two respectable researchers Zoltán J. Ács (School of Public Policy, George Mason University, VA, USA and Max Planck Institute of Economics, Jena, Germany) and László Szerb (Faculty of Business and Economics, University of Pécs, Pécs, Hungary) defined the Global Entrepreneurship Index which captures the contextual characteristics of entrepreneurship by focusing on entrepreneurial attitudes, entrepreneurial activity and entrepreneurial aspirations.

The authors of the GEINDEX are researchers gathered in the Global Entrepreneurship Monitor and the most of the variables used for creation of indicators that are part of the sub-indexes are from master data sets of the GEM annual adult population surveys. Bosnia and Herzegovina, Croatia, Serbia and Slovenia participate in the Global Entrepreneurship Monitor and it is possible to construct and analyze the GEINDEX of mentioned countries.

Slovenia has the highest scores for all three sub-indexes which are the components of the GEINDEX. Other included countries have the low scores, but among Western Balkan countries Croatia stands the best. Serbia has the weakest performance in the Entrepreneurial Aspiration Sub-index, and for other two sub-indexes is third among four countries included in the analysis. Among three presented sub-indexes for Bosnia and Herzegovina, this country has the best score for the Entrepreneurial Aspiration Sub-index, although it is a low score, and not encouraging. Since, the GEINDEX correlates strongly with the level of economic development, the ranks of analyzed countries at the GEINDEX are not surprising. Slovenia is ranked at the highest place of GEINDEX among all other countries included in the analysis, while scores of Croatia, Serbia and Bosnia and Herzegovina, are not satisfactory and the entrepreneurial aspects related to components of the GEINDEX should be improved in these countries.

Global Entrepreneurship Index can provide important insights in entrepreneurial performances of the country, and it can help in understanding entrepreneurship and its components as well as their role in economic development of the country. GEM national teams could use the Global Entrepreneurship Index to estimate and present the weak and strong aspects of entrepreneurship in their country to policy makers and other relevant subjects from the field of entrepreneurship, which is a great contribution to understanding the entrepreneurship, entrepreneurial environment and its components.

In the first part of this paper the description of the halal products market is presented. The halal market of the regions, of the EC and the world was observed. This market is growing every day and the interested producers of food should adjust their production to halal standard in the aim of taking advantage of this market.

In the second part of this paper the term “halal” in Islam is explained and the bases of this standard and the standard for the system of managing food safety – HACCP and ISO 22000 are described; before the implementation of halal standard, the standard for food safety management systems should be implemented. Presently there are an increasing number of requirements for proving the halal status of food products. According to the Islamic rules halal food is the one permitted to be consumed. In order to acquire halal status, the products should not contain forbidden raw materials and additives, such as: pork, alcohol, blood and other components.

In the final part of the paper the experience of the firms in Serbia having implemented the above mentioned standards is explained.

Keywords

Food, Halal, haram. standardization,

1. Introduction

The consumers require the producers of food to respect the customs and habits of various groups of the population. Everyday the consumers are selecting the products whose characteristics of quality they consider most appropriate, opting not only according to its brand, but also to its kind and the composition of its basic components. The alimentation of different population groups is often part of their religious obligations. Accordingly, the consumption of halal food is a part of the Muslim religious obligations. According to estimates, the Muslims present a fourth part of the world population. Generally, the Muslim countries are not producing enough food, thus being obliged to its importing. Due to a large demand for halal products on the market and a growing mass trade with those products, the producers of food intending to place their products on those markets, should present proofs about their halal status. Accordingly, the UN institutions recognized the need of protecting the interest of those consumers, and set the standards and instructions on using the term “halal” [1].

In Islam the rules of alimentation are prescribed as well as the provisions classifying the permitted and forbidden food. Some rules are strictly concrete (banning pork meat, alcohol, carcass, blood, etc.), while others are defined in an indirect way. For example, each food product with a potential or proved damage to the brain, body, or spirit is haram and its consumption is forbidden. Halal is the Arabic word meaning permitted, i.e. food appropriate according to the Islamic rules. The rules referring to food in Islam are based on the Koran and Sunet (Muslim religious law), the base of the Islamic law – the Sheriyat. According the rules, the prescribed food, as well as the additives, can have the status: Halal – permitted, Haram – forbidden and Meshbuh –suspicious. [1]

2. Halal Products Market

The halal products market can be divided according to several criteria, but most practical is to observe its size, i.e. the number of consumers and their concentration in a given area. According to those criteria, the market may be divided into: the regional, the EU and the world one.

The regional halal market covers somewhat more than 5 million members of the Islamic religion in the area of the former Yugoslavia. This market is developing every day, and there is a growing interest to certificate halal products and services. In the aim of a further development of this market, the highest possible diversity of halal products should be provided. In this area halal quality is controlled by the Islamic community or an authorized Agency for Certification, authorized by that community. In this area halal standard is registered only in Bosnia and Herzegovina in the Institute for Standardization of Bosnia and Herzegovina, as a national standard entitled "Halal Food – requirements and Measures", BAS 1049:2007 (new version – BAS 1049:2010).

The EU Halal Market: The halal market of the EC can be most prospective to the producers of alimentary products in our country and those in the region, since the members of the Islamic religion are nearby, and their purchasing power is at a very high level. In Europe there are more than 52 million Muslims, and according to estimates the halal market in the European Community amounts to 66 billion dollars. In France there are about 7 million Muslims, in Great Britain over 3 million final consumers of halal food, in Germany 3,3 million [2]. In France the annual increase of the consumption of halal meat increases for 7 to 10%, although the total consumption of meat is decreasing for 2 to 3% [3]. The unique report entitled 'The Halal meat market: Specialist supply chain structures and consumer purchase and consumption profiles in England', gives an overview of the Halal market in the UK. While the Muslim community in the UK represents only 3% of the population, they consume 20% of all the lamb sold in England, together with an increasing amount of beef. The Halal meat sector is a multi-million pound contributor to the British economy. [4]

The World Halal Market is certainly interesting to our businessmen for its proximity and the traditionally positive economic relations. According to estimates one of the best ways of Serbia's facing its foreign trade deficit and a very small scope of export is to restore the neglected positive business relations and trade exchange with the countries of the near and Middle East and Northern Africa. There are several reasons in favor of such a statement [5]:

1. The compatibility of the economies of Serbia and all the countries in the Near East and Northern Africa is highly prominent. The unfavorable geographic conditions prevent those countries to develop agriculture, and a number of industries, due to the lack of water. On the contrary, Serbia disposes of exceptionally favorable conditions for the development of agriculture and tithe production of a wide range of alimentary products, and has a prominent production of a number of industries not existing in those countries.
2. The traditional trade connections should be used. In comparison to the former Yugoslavia, with very good relations with the Muslim countries resulted in large export, now those markets are covered by foreign multinational companies, and Serbia's economic cooperation is not significant.
3. Those countries, exporters of oil, were not fully protected from the global economic crisis. Still, when compared to the major European trade partners of Serbia, they underwent the consequences of the World economic crisis in a far less dramatic way

The above mentioned arguments are clearly in favor of the thesis that in those markets, or at least in a number of them, Serbia can expect considerable opportunities for export, and should redefine its export strategy and examine more thoroughly the possibility of increasing the scope of its foreign trade with those countries. The total value of importing food in the countries with the majority of the Muslim population amounted to over 120 billion USD in 2008 (Table 1). According to the data of the World Trade Organization, the import of food in some of those countries amounted to one fifth of the total import of commodities. Now the largest exporters of halal food are the non-Muslim countries like Australia, New Zealand, Thailand and Brazil, meaning that the supply of qualitative food is of crucial importance.

Table 1. Import of Food in Some Islamic Countries [6]

Country	Value (Million dollars)					Share in economy's total merchandise imports %

3. Halal Standards for Food Safety Management

From World War II up to the end of the 20th century, the total production of food in the world was based on the permanently growing consumption, so the producers were more oriented towards satisfying the demand in quantity. The new model of the food market is oriented to quality, and not to quantity. In other words, according to this model, quality becomes more important than quantity. [7].

According to the market and contemporary provisions, the producers should manufacture primarily the products safe for health. Presently, there is a number of standards in the world, whose implementation and certification by the authorized bodies contribute to proving the safety of the products to the consumers. In that aim numerous standards are set in managing food safety: HACCP, ISO 22000, the French standard IFS, the British standard BRC, GLOBALGAP, etc. They define the systems for managing food safety; they contribute to identify and follow up the concrete dangers possible to be present in the food products (biological, chemical or physical characteristics of the product), and exert a negative influence to the safety of food products. In those standards the subject having the final responsibility for providing its produced food safety is clearly defined. The organization is required to analyze its processes in the aim of identifying the critical points of control, to define the critical limits and the processes of their follow-up.

The international rules establish, on the global level, the regulations of importance for the health correctness of food. The states establish also their own national regulations, which should as a rule be in accordance to the international rules. The application of the standards for managing food safety is most frequently a legislative obligation. In its intention to advance the existing system of food safety, Serbia passed the law predicting the application of the HACCP-concept in all the plants of food production.

The halal standard is one of the increasingly present requirements in the alimentary production. In contrast to HACCP, halal standard is not obligatory in our country; it is applied by the organizations on a voluntary basis. The organizations implement this standard primarily in the aim of expanding their markets. This standard is based on the preventive, proactive method and is compatible to other international standards managing the qualitative food production (ISO, HACCP and others). Before the implementation of the requirements of halal standard the organization is advised to set HACCP or the standard ISO 22000. The following documents were used as a basis for making halal standard [8]:

1. CAC/GL 24-1997, General Guidelines for Use of the Term “Halal”,
2. CAC/RCP 11-1993, Codex Recommendation for Fresh Meat,
3. BAS ISO 22000: 2006, Food Safety Management Systems – Requirements for Any Organization on the Food Chain,
4. BAS ISO 9000:2001, Quality Management Systems – Fundamentals for Vocabulary
5. Sheryat Principles – Koran and Hadis

The halal quality may be confirmed only by the Islamic community or an authorized Agency for Certification possessing the permission of the Islamic community. In Serbia and in the neighboring countries the Islamic community applies the halal standard registered in the Institute for Standardization of Bosnia and Herzegovina as a national standard entitled “Halal Food – Requirements and Measures”, BAS 1049:2010. This is a reference document used by the Expert Group for Standards of the Organization of the Islamic Conference for the production and introduction of a unique international halal standard. [9]

4. Requirements for Halal Food

The producer needs to introduce the system which can guarantee that the products placed on the market by certain producer are halal and that there is no possibility of mistake or commission during the production which would lead to the production of not “halal” but a “haram” product. The system is called HAS (Halal Assurance System). Accordingly, the application of HAS can be formulated as a tendency towards an ideal situation, according to the so called concept of “3 zeros”, i.e.

1. Haram substances cannot be present in the production (zero limit),
2. No haram products can be produced (zero products) an
3. No possibility for risk during the implementation of the system (zero risk). [10]

Therefore the halal standard was introduced as a document clearly setting the procedures of halal certification. The following is established by halal standard:

- what is permitted or forbidden to the Moslems,
- how to certify and check the application of the provisions of halal standard,
- how to perform halal butchery of animals,
- how halal products are labeled,
- which additives are halal and which are not.

The halal product is the one satisfying all the rules on the health correctness, both hygienic and sanitary, and containing not a single ingredient forbidden for the Moslems. In the process of manufacturing halal products the producer respects the requirements of halal standard and cannot use the forbidden raw materials.

Founded on the Basic Instructions for using the term “*halal*” (CAC/GL 24-19971) [9], issued by the Secretariat of the Joint FAO/GL Program of the Alimentary Products (1999), halal food is defined as permitted according to the Islamic laws and should meet the following requirements:

- should not contain any ingredient forbidden by Islamic rules,
- should not be prepared, processed, transported or stored by using any installations or means containing anything forbidden by Islamic rules,
- should not be in contact with any alimentary products not meeting the conditions 1 and 2 in the process of preparation, production, transport and storage.

The forbidden food for Moslems can be of animal or plant origin. The food from the following animals is forbidden:

- pigs and wild boars,
- dogs, snakes and monkeys,
- carnivorous animals with claws and canine teeth, like lions, tigers, bears and similar animals,
- birds of prey with claws, like eagles, vultures, etc.,
- pests, like rats, centipedes, etc.,
- animals not permitted to kill according to Islamic laws, like ants, bees and woodpeckers,
- animals considered as “disgusting”, like worms, flies, beetles, etc.,
- animals living on land and in water, like frogs, crocodiles, etc.,
- mules and donkeys,

- poisonous and dangerous sea animals,
- meat from any of the permitted animals if it was not butchered according to Islamic rules,
- blood (of any animal).

Food of plant origin from toxic and narcotic plants is forbidden, except where harmful components are eliminated during the process of production. Alcohol and other narcotic beverages (drinks) harmful to health are forbidden to the Moslems, regardless to their name.

Also, the standard regulates halal butchery of animals whose meat is appropriate for consumption to the Moslems. The animal should be healthy and alive or at least show the signs of life before butchery. The person performing the butchery should be a Moslem, mentally sane and trained for such an activity. The animal should be treated in a human way, the words "Bismillah" (in the name of Allah) should be pronounced before the butchery. The meat of the animals that perished, but were not slaughtered or hunted, is strictly forbidden. Fish and other sea animals are excepted and their meat may be consumed although they were not butchered. [11]

Halal bans the use of additives made from any haram component.

Additional requirements: Besides strictly defined raw materials and the conditions of butchery, halal product requires also an appropriate processing, preparation, packaging, labeling, storage and transport. This primarily means the prohibition of using the plants not meeting the requirements for halal products, and the prohibition of using hygienic or other means of origin or in contact with forbidden, haram products.

In some cases, when the production of halal products and those not being halal is impossible to be completely separated, the use of separate lines of production and separate storage in the same space is allowed, under condition of undertaking all the measures necessary to prevent their contact.

In exceptional cases, it is permitted to carry out the processing, preparation, storage and transport of halal products in the plants and spaces previously used for food not meeting halal requirements, if they are thoroughly cleaned in an appropriate way before use. The recommendation for cleaning and the permission for using the space may be issued only by the Agency for Certification of Halal Quality, after inspection. [8]

Labeling of halal products is one of the tasks that should be met by the producers. Labeling is performed in the aim of an easier identification of halal products by the consumers. Halal product should be labeled according to the valid legislation and the sign of halal quality.

The trademark of halal quality is applied on the products in different forms and sizes (Figure 1). [8]

Figure 1. Different forms of halal signs

4.1. The Procedure for Halal Standard Certification

The process of the certification of halal standard is carried out through the procedure set by the Agency for the Certification of Halal Quality. For acquiring the certificate, the HACCP system should be established (critical points of controlling haram), meaning the analysis of additional risks and steps where the control should be applied and documented, in order to prevent the possibility of halal products to "become haram". A supervising agency or a body for certification should also be engaged, authorized or nominated by the Agency for Certification of Halal Products to set, verify and check the products meeting the requirements in quality. [8]

The Agency for Certification of Halal Products carries out the process of certification on the basis of the halal certification procedure, equal for all the organizations deciding to make their products appropriate to halal quality and thus permitted for consumption to the Moslems. The procedure of halal certification is an integral part of halal standard. [9]

The procedure of halal certification consists of the following steps:

1. The firm presents the requirement for certification and submits to the Agency its documentation, as a proof about its business operation being in accordance to the law and possible to satisfy the requirements of halal quality.

2. The Agency checks the submitted documentation.
3. The Agency and the firm sign a contract on certification.
4. The Agency points to the staff in the organization what should be undertaken for the products to be halal.
5. The organization prepares the documentation containing the description of all the production procedures and checking of all raw materials and components used in their production.
6. The Agency checks whether the organization has met the conditions for acquiring the certificate.
7. The Agency submits all the documentation to the Committee for verification which checks whether the certification has been performed in a proper way.
8. The Managing Board decides about granting the certificate.
9. The Agency grants halal certificate to the firm.

After granting halal certificate, the Agency follows-up and controls the products and installations in the firms, through announced and unannounced audits and laboratory analyses. According to the Book of Regulations and other acts for halal quality certification, the laboratory analyses are carried out as a way of validation halal certified product.

The laboratory analyses are carried out so that the products are sampled and analyzed for the ingredients not permitted to Moslems, primarily pork meat and alcohol. It is performed as follows: a product from a supermarket or a shop is taken for analysis in some of the authorized laboratories. Halal standard clearly defines that halal certified products should not contain forbidden ingredients even in shops. The meat products and manufactures products are analyzed for the presence of proteins or raw materials of pork origin. Soft drinks are analyzed for the presence of alcohol, since very often they may contain some percentage of alcohol [8].

Besides the alimentary products for human use, the Agency also carries out the analysis of cattle fodder, since often the farmers add raw materials of animal origin into fodder and premixes, and accordingly such food becomes forbidden.

The development of industry considerably made difficult the process of approving the products halal status. Today the firms use a large number of ingredients in the process of making the alimentary products, and knowing that a number of them has no clearly defined origin of raw materials, they are obliged to apply also to the suppliers for the certificate for halal origin of raw materials, for example: various plant and animal products used as additives may contain lard as an additive. The producers are not obliged to declare these characteristics on label; therefore the information presented on the label does not guarantee that this food staff is halal. [10] Therefore the process of implementing halal products is not simple, but very demanding.

5. Examples of the Companies from Serbia

After realizing the importance of halal standard for the companies dealing with food production, the Ministry of Agriculture of the Republic of Serbia invested in 2009 and 2010 stimulating funds for their implementation. The state subsidized the producers having opted for the implementation of halal standard in their production by donating 50% of the value of the implementation expenses. The Agency for Foreign Investments and Export Promotion of the Republic of Serbia SIEPA, from 2006 provides free financial assistance to the domestic economic societies in the activity of the implementation and certification of halal standard. The agency USAID and the project *Agrobiznis* joined this process providing a support to selected companies for the production of food according to halal standards, and prepared them to present their products on halal market. According to estimates, about thirty, mainly large firms in Serbia, implemented halal standard up to the end of 2010. [12]

During the last year a number of firms from Serbia started their export to halal markets. Primarily owing to the certified standards for managing food safety (HACCP and ISO 22000), those firms have very rapidly applied the requirements of halal standard, thus meeting the basic condition for exporting their products to halal markets.

The slaughterhouse *Turković* from Sjenica signed in September 2010 a contract on the export of 600 tons of baby beef meat in the Republic of Turkey. The first tranches of 100 tons were delivered to Turkey during October and November by special flights from the airport "Nikola Tesla" in Belgrade.

The firm *Iradia* from Sremska Kamenica through its application of the internationally recognized standards, provided the preconditions for exporting a day old chicken from Serbia to the Arabic Republic of Egypt and after a long time realized its return to this large and demanding market. From Serbia up to now a million chickens were exported to Egypt, and that country is ready to purchase also larger quantities of lamb from our producers. The first export was realized in June 2010, and up to the end of that year a million chicken were exported. [13]

The dairy shop from Šabac exported at the end of 2010 the first quantities of “Šabac feta” (cheese) and “Ala kajmak” (milk product) in Libya, Azerbaijan and Egypt. This company used the HALAL certificate as an entrance to the markets of the Islamic countries. In the following year the turnover is expected to amount to 60 million Euros, and 40% of the production will be exported. [14]

The company *Zlatiborac* from Mačkat started to export the first quantities of halal products to the market of Azerbaijan. The export of 100 tons of meat products annually was contracted. This business is important since not only the market of Azerbaijan is in question, but also nine countries in the area, with approximately 200 million inhabitants, mainly participants of the Islamic world. The market of Azerbaijan is interesting also for other companies from our country, intending to do business with this part of the world. [15]

The Halal Agency of the Islamic Community of Serbia, assisted by the agency USAID organized a presentation of the Serbian food at the MIHAS (Fair in Malaysia) in June 2010. The companies which participated at the fair announced the deliveries of their products amounting to 1.1 million US dollars. The participants are very satisfied with their results, since the alimentary halal products from Serbia are almost unknown on this market. [16]

6. Conclusion

In the international trade, standards represent a common “language” or reference basis alleviating the introduction of better relations among the producers, buyers and suppliers. The importance of introducing halal standard is resulting in increased export as well as in the future business arrangements and joint ventures in the food industry with the foreign partners as well. The standardization allows the firms to expand their production and to provide a higher added value, influencing the trade balance and profitability of our firms.

The firms possessing HALAL certificate are certain in disposing such a quality of their products possible to meet the needs of the targeted market. The consumers, believers in the Islamic faith get the product of the expected quality also meeting their religious obligation, and in manufacturing such a product the companies provide a better market position.

The food industry of Serbia still did not benefit of the possibility to place its products on the markets of the Islamic countries, and accordingly the number of companies with halal certificate should be increased. By providing such a certificate the doors of halal markets become open to those companies.

The overall research theme in this paper is social entrepreneurship. This is related to and motivated by the growing attention this phenomenon. The first part of the study deal with social entrepreneurship in cocept, the second – understanding of technology-based entreprenurship evelopmet processes ans preconditions. The third part initiates discussion on the role of technology transfer in social entrepreneurship in as the precondition of sustainable development pursuit.

Keywords

Social, entrepreneurship, technology, sustainable, development

1. Introduction

The term “social entrepreneurship”, it seems, more or less has a rather appropriate definition and merges mission and money filled with distaste. Unless a nonprofit organization is generating earned revenue from its activities, it is not acting in an entrepreneurial manner. It may be doing good and wonderful things, creating new and vibrant programs: but it is innovative, not entrepreneurial. Only earned income will ever allow a nonprofit to become sustainable or self-sufficient. It's one thing to design, develop and implement a new program - and quite another to sustain it without depending on charitable contributions and public sector subsidies. The accumulated tacit knowledge and culture of the entrepreneur are the resources essential to create wealth from research commercialization leading to technological innovation. New, technologically-based firms have had, in the aggregate, substantial economic impact but the biggest challenges actively developing forms of technology transfer that will directly benefit the people that need it mostly, as practice shows, highly at the regional level. However, looking from the perspective of sustainable social entrepreneurship, technology creation and transfer is the process by which technical knowledge moves within or between institutions and is applied in address key challenges faced mostly by developing countries. Despite years of investment by developing countries in technology transfer are testament to the importance of aligning the priorities of the nourished with decision-making over which technologies to import and promote. However, local communities' knowledge and skills go unrecognized and they are given little or no role in choosing, controlling and assessing the impacts of the import technologies [3]. The purpose of this paper is to construct the comprehensive approach and present the theoretical insights of the interaction between the correlative and at the same time distictive phenomenons: the promotion of social entrepreneurship through technology based development processes, through the introduction of the methodological framework of the diagnosis the succes factors of the phenomena fostering. Methodology – this article utilizes existing knowledge on this topic introducing the systemic theoretical analysis, practical construction method of theoretical perspective. To solve the described problem the interpretative – constructive methodological approach was chosen, which enabled to reveal the estimation of the subjective phenomena and to develop the researcher's attitude to the researched problems.

2. Technology- Based Entrepreneurship as a Catalyst of Economic Development

The 1960s began an unprecedented period of science and technology development, which has continued throughout the remainder of the 20th century [4] perhaps with the rise of research-based new ventures emerging from Silicon Valley and the Boston Area companies [5]. Technology based entrepreneurship is a phenomenon that become increasingly important during the last decades. One of the most important reasons for this is the role played for industrial renewal and economic growth. While nature and traditional industrial sectors have witnessed a declining importance, new technology and other knowledge-based sectors have been expanding rapidly [2]. The academic studies also witness, that the transformation from industry and manufacturing to creative knowledge-based activities arguing it to be the great industrial revolution. The academic research from early 1969 extensively analyzing successful US, Swedish firms allowed to jump to the conclusion that today technological development has a major role in international trade and economic development [1], [2] despite the fact that technology-based entrepreneurship was mainly conducted in the US. Europe the subject has gained in importance during the last 20 years. Although academic interest in technology entrepreneurship appears to have growth alongside the economic importance of the phenomenon, scholars have understood entrepreneurs as efficiency-inducing change agents in the economy [5]. However, is important to state, that in the social context it might be necessary to have a lot of experimentation in business ventures to discover the right ones as well as organizational failure in such a system may be enhanced by entrepreneurial experimentation efficient socially [5], [6]. It is also believed that technology entrepreneurship distinguished from other forms of entrepreneurial entry by being innovation-based, which may be constructed as a barrier to entry. Anyway, because of the limited amount of the paper, top elements not only characterizing the *technology-based entrepreneurship*, but also significant in the context of social entrepreneurship maintenance are presented below:

- It is a style of business leadership based on the process of identifying high-potential, technology-intensive business opportunities, gathering resources. An attractive business opportunity consists of a great value proposition, technically feasible products, strong intellectual property, a sustainable competitive advantage, a large potential market, and a proven business model. It can be based on either a revolutionary breakthrough in technology or an evolutionary advancement; and it can target an existing market or create an entirely new one;
- involves identifying and reducing four major types of risks over time: people, technology, market, and financial. This is accomplished by the right combination of vision, strategy and execution. Although a compelling vision (e.g., core values and mission) and a set of strategies (e.g., product and market) are important, it is often execution that differentiates great companies from good ones. An A+ team and adaptable leadership can guide a venture through its challenging journey of growth and adversity where everyone works diligently on clear goals;
- positioning forces a hightech entrepreneur to clearly identify what the product or service is, who the customers are, what benefit it delivers, and how it differs from the competition. Great entrepreneurs use every asset (e.g., vision and intellectual property) to create mutually beneficial social networks;
- sources available include traditional venture capital, angel investors, corporations, incubators, bank loans, personal funds, cash is a critical resource for reaching each funding milestone, which is defined by the reduction of some particular set of risks. Great startups always spend their cash wisely on the current "white hot risk". It gives stability and strategic flexibility to a venture as opportunities and problems arise. For startups, financing events are strategic and require substantial discipline, effort, and foresight;
- successful innovation is a function of both creativity and teamwork. Developing an outstanding team requires setting a coherent and compelling vision, hiring and retaining people better than oneself, using proper recognition and compensation strategies (e.g., cash, stock options, and other rewards), enabling proper autonomy and delegation, and creating a culture where success is recognized and failure is allowed;
- the ability to gain the support of many different types of stakeholders (e.g., revenue and endorsements from real customers) is important for building momentum. Basic negotiation, influence and persuasion skills are critical;

- is not all about personal financial gain. It concerns crafting a lifelong plan to make a positive impact on society. Character does matter. Failure is OK; unethical behavior is not. True wealth requires the creation of enduring value, which requires integrity and ethics [7].

Technology transfer begins with an idea for applying an existing technology in new ways (supply push), or with an idea for improving the features and functions of an existing product by acquiring an existing technology (demand pull). It ends with a new or improved product available in the marketplace. This process spans a wide range of activity, with much of the initial and final stages thoroughly studied. However the crux of the matter—the transformation from technology invention to product innovation—is not well documented or understood. What is technology transfer? Despite the dearth of rigorous analysis and the absence of consensus on a single definition, one can readily focus discussion by identifying the unique value of “technology transfer” that differentiates it from related activities and initially prompted coining the phrase [5]. In the management literature, technology transfer is usually considered within or across firms, such as the dissemination of information through transfers of employees from one division or country to another. Anyway, technology transfer does and should continue to represent a value-added process that encompasses a continuum of related activities from laboratory innovation through market consumption. The phrase “technology-base” is operationally defined here as:

- **(what)** the novel application of existing technologies or prototype devices,
- **(who)** by members of multiple stakeholder groups,
- **(where)** operating through research and development facilities,
- **(when)** collectively viewing transfer as a feasible, attractive option,
- **(why)** to commercialize an innovation,
- **(how)** through the synergistic matching of capabilities to needs [5].

All kinds of external forces impact entrepreneurship and reinforce the need to understand the entrepreneurial process. For instance, economic cycles can fluctuate dramatically, fostering periods of extreme optimism as well as those of deep concern and fear. And in some industries, political and government influences are the primary market drivers. A venture’s location also plays a role, as attitudes toward entrepreneurship are different everywhere. Places like Silicon Valley, for example, offer infrastructure, networks, and talent in an environment that accepts failure in the pursuit of innovation. Other factors influencing the creation of new technology-based firms, are generalized in Table 1.

Table 1 Complex of factors of technology-based entrepreneurship development
(authors own representation, basing on [5],[7])

Factor	Author
University	Casstells and Hall
People with ideas	Florida and Gates
Capital	Florida and Gates
Source availability	Miller, Porter
Balance between the countercyclical high technology and more cyclical manufacturing sector	Thomson
Availability of venture funding, experienced entrepreneurs, skilled labor, supplier’s access, market access, supportive government policies, logistics, receptive population, support services and living conditions.	Bruno and Tyebjee

As the tehatod above testimony, not all money has the same intrinsic value. For example, professionally managed venture capital contributes both strategic counseling and a network of contacts in addition to cash. Another key point is that valuation an subsequent dilution are not the only important issues. Understanding the venture finance process requires fully appreciating such concepts as multi-stage financing, valuation criteria, risk reduction, employee stock pools, deal structure and terms, corporate governance and control, and the role of liquidity events for stakeholders such as

IPOs and M&A transactions. The IPO is foremost a financing event (albeit one with special characteristics) and certainly not the final destination for a startup.

Findings in the economic research show that the number of technology-based new firms corresponds to a small share of general entrepreneurship. Technology-based entrepreneurship is a highly regional phenomenon, where local large firms are important for the training and breeding of future entrepreneurs. Spin-off processes are likely to enhance regional knowledge development and learning processes because it involves the diffusion and sharing of technological and managerial expertise [4] despite the fact that it offers a “win-win” situation for the participants. By implementing an already developed (and already financed) technology in a new and novel application, the originators gain returns from a new market and the appliers meet a need while avoiding the cost of development [5], [8], [9], [10]. Technology developers in Federal, corporate and university laboratories—as well as those working in their garages and basements—are working toward an explicit goal. Whether they succeed or fail in attaining their goal, the process of discovery and invention yields new technologies offering novel capabilities.

3. Social Entrepreneurship as a Phenomenon

The idea of “social entrepreneurship” has struck a responsive chord. It is a phrase well suited to our times. It combines the passion of a social mission with an image of business-like discipline, innovation. The time is certainly ripe for entrepreneurial approaches to social problems. Many governmental and philanthropic efforts have fallen far short of our expectations. Major social sector institutions are often viewed as inefficient, ineffective, and unresponsive. Social entrepreneurs are needed to develop new models for a new century [9]. Defining what social entrepreneurship is not an easy task. This is in part because the concept is complex, and in part because *the literature in the area is rather new* that little consensus has emerged on the topic [9], [10], [11], [12]. The word “social” simply modifies entrepreneurship. If entrepreneurship doesn’t have a clear meaning, then modifying it with social won’t accomplish much, either [4]. Contemporary writers in management and business have presented a wide range of theories of entrepreneurship [3], [4]. But the common among them is that *entrepreneurs have a mind-set that sees the possibilities rather than the problems created by change*. As most authors notice, We should build our understanding of social entrepreneurship on this strong tradition of entrepreneurship theory and research. *Social entrepreneurs are one species in the genus entrepreneur*. They are entrepreneurs *with a social mission*. However, because of this mission, they face some distinctive challenges and any definition ought to reflect this. One argument for this is that only founders of socially beneficial organizations that primarily rely on earned *income from paying consumers are social entrepreneurs: ‘problem-solving nature’ of social entrepreneurship is prominent, and the corresponding emphasis on developing and implementing initiatives that produce measurable results in the form of changed social outcomes and/or impacts*.

With its emphasis on problem-solving and social innovation, *socially entrepreneurial activities*

- tackle major social issues, from increasing the college enrolment rate of low-income students to fighting poverty in developing countries;
- operate in all kinds of organizations: innovative nonprofits, social purpose ventures such as for-profit community development banks, and hybrid organizations that mix elements of non-profit and for-profit organizations;
- generate social value-not wealth-is the central criterion of a successful social entrepreneur. While wealth creation may be part of the process, it is not an end in itself. Promoting systemic social change is the real objective.
- see and act upon what others miss: opportunities to improve systems, create solutions and invent new approaches that create social value. And like the best business entrepreneurs, social entrepreneurs are intensely focused and hard-driving-even relentless-in their pursuit of a social vision [4];
- change agents in the social sector: they attack the underlying causes of problems, rather than simply treating symptoms;
- recognize and relentlessly pursuing new opportunities: the key element is persistence combined with a willingness to make adjustments as one goes. Rather than giving up when an obstacle is encountered;
- engage in a process of continuous innovation, adaptation, and learning: Entrepreneurs are innovative: they break new ground, develop new models, and pioneer new approaches. Innovation can take many forms. It does not require inventing something wholly new; it can simply

involve applying an existing idea in a new way or to a new situation. Entrepreneurs need not be inventors. They simply need to be creative in applying what others have invented [3].

Summarizing it is concluded that social entrepreneurship is exercised where some person or group: (1) aim(s) at creating social value, either exclusively or at least in some prominent way; (2) show(s) a capacity to recognize and take advantage of opportunities to create that value ("envision"); (3) employ(s) innovation, ranging from outright invention to adapting someone else's novelty, in creating and/or distributing social value; (4) is/are willing to accept an above-average degree of risk in creating and disseminating social value; and (5) is/are unusually resourceful in being relatively undaunted by scarce assets in pursuing their social venture [9]. The single most important of these criteria is the first in that it serves, conceptually, to distinguish social entrepreneurship from other forms. There is no exact way of fixing the border below which the importance of social goals fails to qualify something as social entrepreneurship. It is a commitment to providing social value that marks the divide between social and their forms of entrepreneur. As in the case of the social aspect of the target concept, this list represents a catalogue from which particular users of the notion will choose somewhat selectively both as to what they include and how they weight the factors. All these characteristics preserve the distinctive status of social entrepreneurs whom we need to help us find new avenues toward social improvement as we enter the next century. However, these new avenues might be easier found and driven not only by single technologically innovative leaders, but also these ideas admitting actors.

4. Sustaining in Technology-Based Economic development: Is There a Niche for Social Entrepreneurship?

The term "sustainable development" was first mentioned at the United Nations Conference on the Human Environment in 1972. Later it was gained prominence by way of a report to the United Nations by the World Commission on Environment and Development chaired by Norwegian Prime Minister Gro Harlem Brundtland (henceforth referred to as The Brundtland Report). In this 1987-th the definition emphasized the dynamic aspect of sustainability and emerged from The Brundtland Report: "Sustainable development is development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs". Review of socioeconomic literature has shown that there is believed, that in order to sustain something it may well be necessary to integrate ecological, social and economic issues, but this is not what sustainability is "about". These pragmatic requirements are not the focus of the concept. The point is that that it is not possible to **achieve** a desired level of ecological **or** social **or** economic sustainability (separately) without achieving at least a **basic** level of all three forms of sustainability (Figure 1).

Figure 1 Forms of sustainability (authors' own presentation)

It means maintaining a balance between the human need to improve lifestyles that means -feeling of well-being. Secondly, preserving natural resources and ecosystems– develop sustaining (Figure 2).

Figure 2 Principal understanding of sustainable development (adopted from www.gdrc.org/sustdev/definitions.html)

The term refers to achieving economic and social development in ways that do not exhaust a country's natural resources. The essence of this form of development is a stable relationship between human activities and the natural world, which does not diminish the prospects for future generations to enjoy a

quality of life. Social entrepreneurship corresponds in most of the goals. It is seen as a field of experimentation and innovation, has the potential to contribute new insights to the discipline of entrepreneurship, and also to the wider social sector. The interfaces between corporations, universities and public institutions offer great potential for discovering new forms of collaborative value creation in support of sustainable development [3] and creation of social value. The outcomes of social entrepreneurship are social value creation. The implications of social value creation are that while a for-profit enterprise operating in aged care would be able to identify its total outcome as superior value creation. However, the authors assume that entrepreneurs working in high technology environment are by definition driven by self-interested profit-seeking motives. That means that entrepreneurs can *be motivated to contribute to sustainable development by making it profitable to do so, despite the fact that most motives and principles of social and technology based entrepreneurship do coincide, however, there some aspects that separate the development of these two phenomenon (Figure 3):*

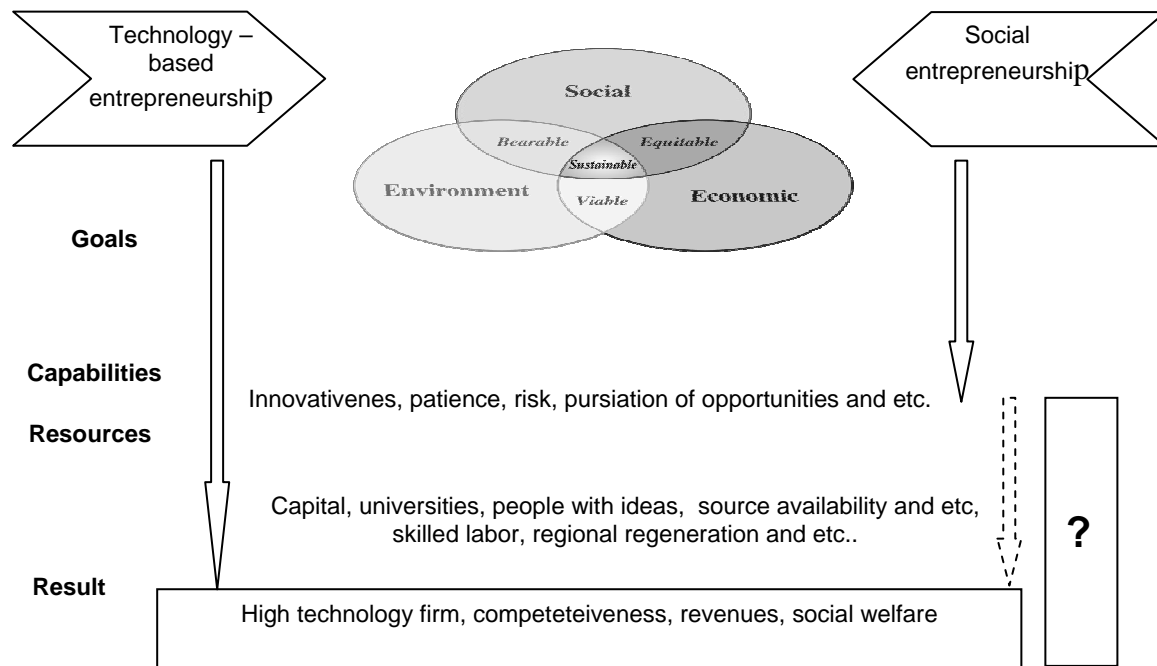

Figure 3 The divide between two forms of entrepreneurship (authors' own representation)

There is, therefore, a need for researchers to recognize that the above discussed principles are more of theoretical than practical manner. Theoretic, analysing resource-based theory entrepreneurial economic development state, focus not only on “founders” unique awareness of opportunities and ability to acquire resources needed to exploit the opportunity. The are tended to think that a communities economic development effort has a similar relationship to the development of sustainable competitive strategy. Despite the fact that most mentioned above factors and resources fostering technology-based entrepreneurship may have value to the community only as far as they can be mobilized in such a manner that new ventures find them more attractive than those found in another competing community. Thus communities compete for new business development relative to other communities by leveraging theirs resources. We suggest that the same question regarding how unique resources enable new firms to come into being can also be asked about how new sustainable entrepreneurs come into being. The creation of heterogeneous resources in communities in combination with the imperfect mobility, and substitutability of their resource positions can lead some communities to be more successful than other[5]. Extending this point we do conclude that a higher level of technology based start-up activity will also require new types of legal and accounting services that address their unique needs. With a higher level of start-ups activity **human resource dimension take on added significance**. Communities must assist in this process by sponsoring educational programs, such as Fast'Trac'Tech to help individuals learn more about starting a technology-based business. If a research university does not exist nearby, communities might consider leveraging the presence of existing technology firms and workers to establish strategic research partnerships. Finally, local authorities in Incipient communities must work with local real estate developers to create flexibility in physical workspaces. Entrepreneurial hot spots will develop unless the usual staple of

formal financial and infrastructure elements are supplemented by the development of informal resources in order to attach creativity class that characterizes technology workers. The question here is whether social entrepreneurship is able to induce the preconditions? The active fighters for the technology transfer will only help eradicate poverty when the realities of the poor inform decision-making and investment. Poor people's basic technological needs are generally overlooked in this process. Local communities' knowledge and skills go unrecognised, and they are given little or no role in choosing, controlling and assessing the impacts of imported technologies [3]. Seeking to overcome the aforementioned obstacles for technology transfer the author also concludes [3], that:

- Decision-makers should be identifying the most vulnerable groups of society, and determining how their existing knowledge could be strategically used to overcome poverty-related challenges;
- they should also be assessing how such individuals will be affected by the introduction of technologies, and how they can use these citizens' creative abilities to contribute to technology transfer decision-making and monitoring processes;
- but most decision-makers do not harmonise technology choices with their commitments to poverty eradication - technology is not an area where the poor's involvement is desired or expected. They are seen as passive recipients rather than as active and competent stakeholders able to analyse and choose the technology they want and need. Rather, technology transfer remains the professionals and technicians' prerogative - consideration of its sustainability and impact takes second stage.
- despite evidence from decades of development work worldwide that top-down approaches do not lead to sustainable solutions and can create dependency on external resources, most technology transfer targeted at the poor is still centrally managed through government or academic extension services; In this way, decision makers can favour the interests of more powerful stakeholders involved in distributing and promoting technologies over strengthening poor people's livelihoods ensuring ecosystem resilience and agricultural biodiversity. Instead of contributing to the public good, technology then becomes a commodity for those who can afford it.

The perception of technology transfer as being an exchange of hardware or knowledge only between specialists must be altered to also include recognition and strengthening of the poor's knowledge and skills to produce relevant products and services. This will be a challenging, but not impossible, task. Decision-makers' lack of understanding about poverty dynamics often results in little support for research agendas and technologies that respond to vulnerable communities' most pressing needs. But by building alliances between communities, development practitioners and researchers, they could bring diverse levels of expertise and knowledge together to create platforms for dialogue and decision-making that ensure viability, ownership and sustainability. The expertise developed in participatory processes can provide a solid base for developing pro-poor technology transfer and should be seriously considered in technology transfer agendas or discussions.

4. Discussion

In this paper, it was drawn the corruption, economic development, and entrepreneurship and innovation literatures to advance the hypothesis that better involvement of technology based business making in social entrepreneurship would allow to obtain so pursued goals of sustainable development and regeneration. It gives the managers of global corporations a unique opportunity to learn and create new collaborative efforts that are in the corporations' own economic interest, while at the same time creating social value for those who need it most. But experts of entrepreneurship believe that there are broad array of resources that must exist in communities that might establish technology-based competitive ventures. The academic research has shown that many communities even those undernourished may be only marginally successful in their efforts to combine these two strains of entrepreneurship. Despite the fact that activist of social entrepreneurship deeply believe in the ability of wide public of finding inerrable groups of society, and determining how their existing knowledge could be strategically used to overcome poverty-related challenges. It is also believed that decision makers can favour the interests of more powerful stakeholders involved in distributing and promoting technologies over strengthening poor people's livelihoods ensuring ecosystem resilience committing the technology as a commodity for those who can afford it. However, the question of developing unique bundles over time and that the development of these bundles in a particular even sustainable growing geographic areas in neither linear nor easily replicable what allows the statements concerning the merge of social and technological entrepreneurship treat to be of a open ground discussion.

Entrepreneurial Alertness: Turning Innovation into Economic Benefit

Dave Valliere¹

¹ Ted Rogers School of Management, Ryerson University, Toronto, Canada,
valliere@ryerson.ca

This article is an investigation into Kirzner's concept of entrepreneurial alertness and its causes. Entrepreneurial alertness is the important link between innovation and economic benefits. Without alert entrepreneurs to discover potential applications and market needs, innovations can contribute very little to the economic benefit of regions and nations. Reaping full benefit from investments in innovation and R&D requires both that there be sufficient numbers of prospective entrepreneurs to commercialize the innovations and, more importantly, that these entrepreneurs be alert to the market potential of innovations as they emerge. By drawing from the decision theory of Simon and the schema theory from the cognitive psychology literature, a model is developed to show how the effects of innovations are mediated by entrepreneurial alertness to be recognized by entrepreneurs as opportunities for new businesses. Entrepreneurial alertness is seen to be the application of unique cognitive schemata that allow the entrepreneur to see potential in innovations that would not be seen by other managers. This entrepreneurial ability to see the market potential of innovations arises from differences in schematic richness, schematic association, and schematic priming. These three antecedents may therefore form a basis on which enhanced entrepreneurial alertness can be developed. From this it is argued that an important strategy for regional development must be the provision of regional programs that teach prospective entrepreneurs to develop different schemata. Recommendations for such programs are provided, based on the literature of schematic learning.

Keywords:

Entrepreneurial alertness; Entrepreneurship education; Innovation; Opportunity spotting;

1. Introduction

Innovation is widely believed to be the path to the improved economic development of nations. As a result many countries invest large portions of their economic and human capital into fostering greater innovation. Collectively, these investments result in the creation of a knowledge infrastructure that supports innovation and creates new growth opportunities [1]. But innovation alone is insufficient to achieve significant economic benefits; many countries obtain little return on their investments as ideas sit unused or are exploited by other countries. The necessary second ingredient for growth of a nation is the presence of alert and motivated entrepreneurs, individuals who recognize the economic potential of the innovations and take action to turn this potential into market realities [2].

Individual people can differ widely in their ability to see new business opportunities within a given environmental situation. The social and economic impact of these differences is enormous, as the economic actions taken by entrepreneurs can have wide-ranging effects. These many benefits are contingent upon an individual entrepreneur noticing changes in the environment and discerning an opportunity for profit. Our current best understanding of this discernment is "entrepreneurial alertness". According to Kirzner, entrepreneurial alertness refers to "a sense of what might be 'around the corner', i.e., the sense to notice that *which has hitherto not been suspected of existing at all*" [5 pg. 12]. While arguing persuasively that entrepreneurial alertness is the critical economic driver of a dynamic and competitive entrepreneurial process, Kirzner did not attempt to explore the determinants of this alertness. He explicitly indicates that the antecedents of entrepreneurial alertness remain

unclear, although the prospect of profits is assumed to be the underlying motivation for alertness [5]. Early investigations into possible determinants of entrepreneurial alertness have suggested individual cognitive or psychological aspects of the entrepreneur, such as locus of control [6], psychological disposition [7], personality traits [4], and self efficacy [8]. But to-date there has been little work done towards a theoretical foundation for the antecedents of entrepreneurial alertness [9]. This gap in our understanding is important precisely because the effects of entrepreneurial alertness are so large. The primary contribution of this article will therefore be to suggest a theory for entrepreneurial alertness and to use this to identify determinants and educational approaches. The article will first discuss cognitive and structural influences on the attention of entrepreneurs and their ability to interpret changes in the environment, and then introduce schema theory as an explanation for the differences in their ability to notice environmental changes. Finally, it will use this theoretical basis to identify specific antecedents and educational strategies.

2. Alertness and Attention

The alertness perspective on entrepreneurial behaviour begins with the occurrence of changes in the environment, such as technological or economic shifts that have potential to change the value of products and resources in some market [5]. Some of these changes are of sufficient magnitude or salience to be noticed by individuals who are paying attention and are immersed in the corresponding knowledge corridors [10]. These individuals are able to discover opportunities within these changes, and to pursue these opportunities through entrepreneurial business actions.

The key role that is played by individual attention suggests an approach based on the psychology of strategic management, and particularly Herbert Simon's [11] view that the challenge of matching of problems, solutions, and actors within an organization is constrained by the limited attention capacity of individual decision-makers, and that organizations therefore allocate and channel environmental stimuli to the attention of individual decision-makers. While this view was developed in the context of strategic management in large organizations, it is also the essence of the challenge faced by entrepreneurs trying to evaluate new opportunities [12, 13] and to match available means with market ends [14].

This allocation is constrained both by limitations in cognitive capacity and by structural influences. Of these, the role of cognitive-capacity constraints is relatively well-understood. The allocation of attention is primarily constrained by bounded rationality and the routines of individual actors [15]. In a social context, the allocation of attention is also influenced by enactment of social scripts [16] and the loose coupling of the "garbage can" model of organized anarchy [17].

2.1 Structural Constraints to Attention

In contrast to the cognitive-capacity constraints of decision-makers, structural constraints are much less well-understood. Ocasio [18] presents an initial argument wherein structural influence follows three steps: (1) the existing allocation rules of the organization (both formal and informal) influence the distribution of the attention of actors among potential channels, (2) this organizational allocation combines with contextual factors to instantiate a "situated" attention, and (3) this results in a specific focus of attention for each actor, ready to notice and respond to environmental changes. Employing a more precise terminology, Barnett [19] then improves upon this model by revising the steps: (1) contextual structures (e.g., culture and informal rules) influence whether opportunities are enacted, (2) these enacted opportunities are then processed through concrete structures (e.g., business processes and tools) which allocate the opportunities to specific attention channels, and (3) actors within those channels use their situated attention to evaluate the opportunities and determine the appropriate organizational response. Figure 1 provides the representation of a combined Ocasio-Barnett perspective on structural influence.

Figure 1 Structural influence

The enactment of situated attention is the key organizational requirement for noticing environmental change; the organization is dependent on a situated or contextualized attention to bring the environmental change forward for evaluation by the constrained cognitive capacity of the decision-makers. It is at this point that attention provides the foundation necessary to recognize any opportunities latent in the change [20, 21]. Thus, it must be at this point that entrepreneurial alertness somehow comes into play. But this approach does not yet clarify the exact nature of this entrepreneurial alertness, nor the mechanism by which it mediates the relationship between environmental change and the attention of decision-makers. For this, we turn to the theory of schema.

3. Schema Theory

Human beings use a variety of strategies for dealing with the volume and complexity of sensory information streaming in from the world. One powerful technique is the use of rules, scripts, and categorizations (called "schemata") to interpret incoming information and make sense of it [22]. These interpretations are combined with task requirements to create the mental models that we use to solve problems. A schema is a mental framework with "slots" to represent some set of real characteristics and relationships of a situation, which shapes or directs our interpretation of sensory phenomena. The invoked schema causes us to apply a particular mental image or model that ascribes meaning to what is happening, which we can then use to guide our subsequent reactions or behaviours.

When faced with a novel situation in the world, we invoke schemata to make meaning and understand relationships among the various sensory stimuli. For example if a stranger is strolling in a park with a furry mid-sized animal on a leash, these characteristics are sufficient to invoke a "dog-walking" schema – we recognize the animal must be a dog even if it is of some exotic breed that we've never encountered before. We can then use schemata to make predictions about future behaviours, as we can expect this novel dog to wag its tail and give us a sniff or to react in very predictable ways if we extend our hand towards it. The invoked schema stipulates the relationships among its elements (it is the person who is responsible for the well-being of the dog, and not the reverse) and the range of actions that can be expected (we know that the owner will likely be pleased if we pet the dog, but not if we free it from its leash). These schemata are particularly useful to us because they reduce the attentional burden of making sense of the world, as this sense-making and prediction of future behaviour can happen automatically without conscious effort [22, 23].

Different people may interpret and react quite differently to the same situation, depending on their surrounding contexts and on the content of the schema they apply to the situation. For example, your schema and mine may differ significantly based on our own prior experiences with dogs, so our actions might also differ. If you happen to have been a dog breeder or trainer before, your schema is also likely to be more complex and developed than my naive pet-owner version, making you aware of a greater range of relationships and possible actions. We might also differ in how a given set of observable characteristics invokes one particular schema and not another. The approaching dog in the park might invoke in me a schema in which I am likely to pet the dog and compliment it to the owner. But if you have recently been victim of a dog attack, the approaching dog might invoke a self-defence schema in which your action is to flee. The invocation of a "threat" schema, rather than "pet the dog", has been primed by your experience.

Our schemata are constantly being updated in the face of new information about the world. In particular, when some phenomenon does not accord with our existing schema we must make some changes to incorporate this new reality, the extent of which depends on how fundamentally the new phenomenon disagrees with our existing schemata [22]. If the change is very minor, it can be assimilated through simple accretion of new attributes of a schema (if, on meeting a new dog in the park, I am surprised that this one has no tail to wag I adjust my schema to indicate that "tail" is a frequent yet merely optional attribute of a dog). If the change is more substantial it may be necessary to make a more substantial accommodation or tuning of schemata (perhaps it is a "working" dog assisting a disabled person, such that the relationship of who is looking after whom is no longer simply unidirectional, and their appearance in the park cannot be assumed to be simply recreational). And if the change goes to the root of my schema a complete restructuring of it and related schemata might be necessary (perhaps something bizarre occurs, like the human is wearing the collar and leash and is being "walked" by the dog, which forces me to completely re-examine many of my preconceptions about the behaviours of humans, the capabilities of dogs, and the different possible relationships between them).

Because schemata are subject to this constant updating and refinement as we learn new things, they broadly reflect the prior knowledge, experience, and culture of individuals. In the case of

entrepreneurs, this may dispose them to schemata that differ from other people. This potential for schematic difference may be viewed as a significant example of entrepreneurial information asymmetry [24] and may explain the influence of their being embedded into specific information corridors [14].

3.1 Schemata and Entrepreneurial Alertness

Kirzner's theory of the alert entrepreneur attempts to explain how it is that some individuals are able to see and exploit entrepreneurial opportunities. But it is silent on exactly how these entrepreneurial individuals are able to make the leap from a noticed change in environment to a recognized opportunity for present or future arbitrage. This is the gap that schema theory is able to fill. Since individuals can differ in the schemata they employ and they can differ in the context and priming effects of specific environmental stimuli they may encounter, they can therefore impute very different meanings to the same observed phenomena. For example, two people both observe a long queue of people waiting for the cashiers at a grocery store. One invokes a customer-service schema and interprets the situation as a retailer who does not care enough about customer service to pay the cost of providing additional cashiers. The other, however, invokes a problem-solving schema and interprets the situation as a non-optimal resource dependency in the business. The second individual therefore is more likely to recognize the latent opportunity in this phenomenon, and therefore to see it as evidence of a market opportunity for alternative retail payment resources (e.g., self-serve technology). Schemata do not sit passively in the mind; they actively influence the filtering and detection of sensory stimuli – the selection of which changes in the environment become noticed, and what magnitude of change is required to be noticeable. For example, two individuals driving past a neighbourhood street sale may see people walking past the displayed goods without buying anything after checking pockets/purses and discovering that they are not carrying any cash. The first observer, lacking a schema for retail selling, may not consciously be aware the situation at all. But the second, having a finely developed retailing schema, is more likely to notice the passers-by as being lost sales, and to interpret the situation as a need for alternative payment mechanisms (such as an ability for homeowners to rent wireless credit-card POS terminals for the day). This means that individuals having different schemata will notice different environmental changes, and will be alert to different things. From this perspective, variation in entrepreneurial alertness is a manifestation of individuals having different schemata.

Figure 2 presents a model of how the application of schemata combines with the structural influences of the Ocasio-Barnett view to create a situated attention that is alert to entrepreneurial opportunities. The alert entrepreneur, having formed a contextualized intent to seek new opportunities, and by participating in concrete activities such as gathering market intelligence or assessing available resources, presents a situated attention ready to investigate and evaluate the opportunity potential of any phenomena that are brought to it. The alert entrepreneur also, by virtue of prior knowledge and the priming effects of experience, possesses schemata that relate various types of environmental changes to various types of potential opportunity. The alert entrepreneur is thus able to form mental images of the environment that are rich in potential opportunities. When these mental images are brought to the situated attention their latent opportunities are recognized and can then become the basis for entrepreneurial actions.

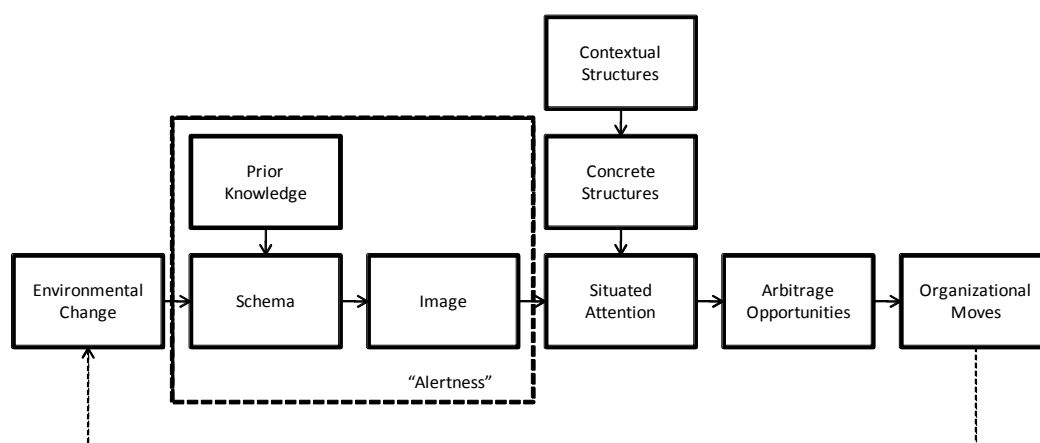

Figure 2 How entrepreneurial alertness supports opportunity spotting

4. Discussion

The model presented above is an attempt to provide a theoretical mechanism for the effects long attributed to entrepreneurial alertness, and to thereby suggest some antecedents for heightened entrepreneurial alertness. It provides a much more detailed and specific description of the cognitive nature of entrepreneurial alertness and its relationship to the attention-channelling of Simon and others, one which integrates prior theoretical perspectives of entrepreneurship, prior knowledge, experience, environmental scanning, and entrepreneurial cognition. From this model three potential antecedents of entrepreneurial alertness can now be identified:

Schematic Richness. A single schema can differ between individuals by having representation of more attributes or more complex relationships, and in particular by whether it includes representation for business opportunities that are commonly associated. This difference is sometimes used to explain the differences in how experts and novices perceive situations [e.g., 25, 26]. If a schema for “malfunctioning business process” has representation for “weakest link” then the individual will be specifically attuned to notice the weak link and to consider whether replacing it constitutes an opportunity. But if the schema lacks such an attribute, then that individual will fail to notice the weak link and any associated opportunity. Similarly, an individual is more likely to see opportunity in a new social fad if their schema for fads includes representation for how money was typically made from previous fads. As a result, two individuals exposed to the same environmental change and ascribing the same meaning to it may still differ dramatically in the opportunities they perceive and in the subsequent actions they take.

Schematic Association. Individuals can differ in the schemata that they possess and how those schemata are associated with external stimuli such as environmental changes. It is therefore possible that a shared stimulus will invoke a different schema in one individual than in another. Moreover, a schema that is habitually used may become automated to the degree that it is activated without choice by the individual, in response to key attributes of the environmental situation [27]. In the earlier example of a grocery store with long cashier queues, the two observers differ in the degree to which they possess schemata associated with retail payments. These two individuals, on being exposed to the same environmental change, differ in the meaning they ascribe to it and the actions they could take in response.

Schematic Priming. Individuals can also differ in the availability and ease of activation of the various schemata they possess. Two people may be walking in a shopping mall and entering into the food court area. Although they possess identical schemata, their responses may be very different. A hungry person will be acutely aware of this environmental change and may perceive it as an opportunity to satisfy their hunger, while a person who is not hungry but is desperately searching for a replacement mobile phone will notice only that this part of the shopping mall is annoyingly devoid of telephone stores. The two people differ in which schema has been primed for activation and so, in response to the same environmental stimulus, one smiles while the other scowls. Such differences are sometimes referred to as keeping your “antennae” tuned [12 pg. 483, 28], or looking at world through “opportunity-spotting glasses” – both of which underline the deliberate nature of this priming by the entrepreneur.

4.1 Implications for Entrepreneurship Education

The foregoing understanding of entrepreneurial alertness as the application of richer, more diverse and primed schemata, may have significant educational implications for the development of alertness and the resulting spotting of opportunities. As noted earlier, schemata are not static for an individual entrepreneur, but are subject to accretion, accommodation, or restructuring the face of new non-conforming information from the world. An individual schema can be expanded or changed based on the individual’s experience with the application of that schema (e.g., new attributes can be added, exception cases can be noted). And sets of related schemata can also be changed through experience (e.g., boundaries among schemata can be redefined, and relationships such as generalization/specialization can be modified). In particular, an entrepreneur can learn to develop and apply schemata that are richer in their attributes and connections, or can learn to associate and habitually invoke new and different schemata in response to environmental stimuli, or can deliberately take steps to prime particular schemata for activation.

On all three antecedent dimensions, it appears possible for the entrepreneur to learn, develop, and enhance entrepreneurial alertness through strategies of schema modification. The objective of the modifications is to make the shift from the schema of the novice to the schema of the expert – a mental shift that is well-understood in cognitive science [29]. The schemata of experts can differ

substantially from that of novices, by being more complex, more parsimonious, or more abstracted (and certainly the schemata of experts have more accurate data). It is the goal of entrepreneurship education therefore to assist novices in changing their schemata to be more like those of expert entrepreneurs.

But herein lies the paradox for entrepreneurship educators. Learning to accommodate new information generally involves applying an existing schema and making accommodations or adjustments where new facts do not fit the existing framework – so the learner must have some pre-existing schema that can be reasonably be applied to the situation. But new entrepreneurs face the tasks of seeing opportunities and potential of *things that do not yet exist*, for which there may be no applicable schemata. So, teaching alertness and opportunity-spotting to prospective entrepreneurs has the unique challenge of trying to impart information to students when those students may not have any applicable schema on which to anchor it. As Carey [30 pg. 1123] explains it, the paradox is “that to understand something, one must integrate it with already existing knowledge schemata... [and yet] to impart new schemata to replace the student’s extant ideas, which differ from the scientific theories being taught”.

Research in educational psychology can suggest several methods of approaching and resolving this paradox, based on exposing students to analogies and inductive reasoning that encourages them first, to acquire new and relevant schemata, and second, to automate the invocation of these schemata in new entrepreneurial situations [31]. Following this approach, students would be exposed to several diverse examples of entrepreneurial problem solving (e.g., case studies of successful opportunity spotting) and explicitly told that the examples share underlying similarities. This approach enables them to transfer learning in one case to other cases, and thereby to begin to abstract a generalized new schema [32-34]. Testing and validation of this approach to schema acquisition has yielded some useful guidelines that may be adopted by entrepreneurship educators [31]. First, the process of induction and transfer, by which new expert schemata are learned, happens very slowly over a great many examples. So, it may take very much practice before novice entrepreneurs begin to develop the schemata to allow them be significantly more alert to new opportunities. Secondly, the learning of how to appropriately invoke these new schemata happens by repetition and observation of simple cases that do not involve significant cognitive loads. The practical implications for entrepreneurship educators interested in developing greater entrepreneurial alertness in their students may be summarized as follows: *Greater entrepreneurial alertness can be taught through extended repetitive practice of opportunity spotting and through observation of simple cases of opportunity spotting by others.*

Such an approach can be expected to be successful because it facilitates the acquisition and use of new expert schemata. The prospective entrepreneur thereby obtains schemata that are richer (through abstraction across diverse cases), more associated with environmental stimuli and changes (through inductive invocation), and primed for activation (through repetitive practice). These three attributes are the fundamental determinants of increased entrepreneurial alertness.

Financial sector in B-H and microcredit organizations in B-H

Saša Vujić¹, Slobodan Vujić²

¹University "Vitez" Travnik, Bosnia and Herzegovina Školska, sasa.vujic@unvi.edu.ba

²University "Vitez" Travnik, Bosnia and Herzegovina Školska, slobodan.vujic@unvi.edu.ba

The goal of the paper is the analysis of financial and micro-credit industry in B-H. The expansion of micro-credits is evident through an increase in placed micro-credits and the number of micro-credit users. Indicators of the growth in micro-crediting may include: the percentage of new clients per year, percentage of lost clients, percentage of clients who gave up further use of micro-credit, and percentage of clients who announce the repeated use of the credit. Reasons for high-quality ranking of B-H micro-credit organizations derive from the fact that they accomplished the set goals: employment, increase in household income, reduction of poverty, starting business, etc.

The characteristic pictures of economically dismantles systems led to the development of a specific supply of financial services. The key factor of the development of this form of supply has been conceived and designed at the level of international community and WB activity focused on the aid in development. The specific form of resources placement required a specific solution for the issue of the supply beneficiaries. Micro-credit organizations have a significant role in the B-H credit market, and one of the basic reasons for their great share in the overall financial market is the fact that a great number of persons that need such a kind of financial services do not meet credit-rating requirements required by commercial banks. The B-H micro-financial sector with its activities and overall assets is becoming increasingly significant for the development of small and medium-sized businesses that cannot access commercial loans so easily. In his way, the micro-financial sector boosts employment, reduces poverty, and contributes to the development of the entire society.

Primary and secondary research among service users was used for the purpose of the research. Scientific analysis studied the number of clients and the number of credits by years, average term of the credit, average loan amount and the percentage of suspicious and external credits.

Key words

financial sector, microcredit sector, microcredit clients, microcredit organizations

1. Introduction

A more significant development of microcredit organizations and microcrediting in Bosnia and Herzegovina [1] started in 1996. War activities in B-H resulted in huge destruction of industry, appearance of a great number of refugees and disabled war veterans. War activities and additional effects of war activities led to sudden impoverishment of almost all population categories in B-H. The fact that a great number of community members was left jobless and thus without permanent income significantly contributed to this situation. All these had a strong effect on the development of poverty.

Microcredits are (a form of) financial services created in countries and regions with a high share of poor population, as a rule unemployed and without a permanent source of income. The development of such a form of offer was conceived at a level of international community and WB (World Bank) activities focused on aid in development. It is a mode of creating a system of investing available resources in the form of loans, in an accessible and acceptable way, and thus allowing a multiple use of available funds.

2. Development of microcredit organizations in B-H

The expansion of microcredits is particularly visible through the growth of the number of granted microcredits and the number of microcredit users. For illustration purposes, we will list only data for five microcredit organizations among twelve microcredit organizations that cover 98% microcredit market; thus the sample is representative since it includes data for 42% large microcredit organizations. [2] Data were collected through direct research and primary data collection. Research produced the following results. [3]

In 1996, at the start of microcredit organizations' activities, the number of clients amounted only to 1,350, in order to grow to 102,300 in 2008. Every year the number of clients registered a high growth rate. A similar growth trend was also registered in the growth of the number of credits. From the initial 1,350 credits, as many as 108,000 credits were granted in 2008. The percentage of new clients registers a fairly high growth, between 24% and 63% compared to the previous year. The percentage of lost clients registers a high percentage of clients lost for various reasons (move, disease, death, old age, etc.) and ranges from 16% to 26% in various years. The percentage of clients who gave up using microcredits is also fairly high. It ranges from 17% to 39% in different years. Reasons for giving up

Table 1 Data from 5 MCO

DESCRIPTION	1996	1997	1999	2000	2001	2002	2003	2006	2007	2008
NUMBER OF CREDITS	1,350	6,620	9,100	22,300	38,000	56,100	74,200	95,400	98,000	108,000

Source: Vujic S (2010), own data collection

(based on their own decision) vary, for instance closing business, shift to bank loans, no need for new microcredits etc. However, the percentage of clients who are announcing repeated use of credits is high and ranges from 51% to 66% every year. The percentage of suspicious and disputable claims expressed the volume of clients that are two or more installments overdue. The percentage between

1.5% and 2.5% is fairly low and tolerable, which suggests that clients are regularly paying off their microcredits. The indicator of sued clients is also fairly low and ranges from 1.7% and 2.1% in different years. Based on the collected primary indicators, the percentage of clients who are taking the credit for the second time is very high and ranges between 39% and 59%. The percentage of clients who are taking a credit for the third time is fairly high and ranges from 27% to 35%. Finally, the percentage of clients who are taking a credit for the fourth or more times is comparatively high and ranges between 14% and 21%. The percentages reveal that clients are satisfied and loyal to MCO since they repeat credit cycles. Indicators of the average length of payment of paid-off credits are also interesting for microcredit analysis. Starting from the initial, nine-month period in 1996, the duration of payment period has been increasing. In 2006, it was 23 months, and 20 months in 2008. Clients who move to a new cycle have the possibility to increase the term of payment. The average amount of credit reveals the increase of microcredit amount. From the initial average of 1,400KM in 1996, the average grew to 5,350KM in 2008. The data that the average credit amount constantly increased is interesting, since it related to the increase in term of payment. The average credit amount was 5,350Km, and payment term was 20 months. [4]

3. Financial sector in B-H and microcredit organizations

The financial sector in B-H includes the activities of the microcredit sector. Financial sector in B-H includes activities of banks, investment funds, leasing companies, insurance companies and microcredit organizations. "Financial markets include all the institutions and procedures that link customers and issuers of financial instruments. [5]

Although the structure of B-H financial sector is fairly simple compared to some countries in the region, sources of potential future risks can be identified. Capital connection between different financial market segments is increasing, and it is necessary to shift the focus from banking to the entire financial sector in the future. Leasing companies are most often part of foreign banking groups, and the number of insurance companies that are part of foreign groups which also include commercial banks is also increasing. Besides, commercial banks have separate divisions or legal persons within the group that have the role of intermediary in capital markets. Besides, The growth of bundling products of different parts of financial sector is obvious, most often within the same group (e.g. commercial banks that granted mortgages together with real estate insurance policies with the insurance company that operates within the group).

Same as in previous years, the increase in credit growth is one of the main characteristics of B-H financial sector. [6] Further restructuring and enlargement of banks results in better capitalization, banks that have a larger credit potential and that attempt to increase their market shares in B-H. Banks continue developing and introducing new banking products that better satisfy client needs. Thus clients need to finance their activities and mainly rely upon bank loans which is, among other things, a results of a lack on alternative financing sources. If the demand structure is observed, the greatest part pertains to households (47.5%), private non-financial enterprises (44.2%), while only a small percentage (less than 1%) of demand for loans pertains to the government sector. The largest part of credit growth pertains to two sectors: households and private enterprises. These two sector together make up over 95% of the overall credit growth. It is obvious that commercial banks still consider these two sectors as the most reliable clients, while other sectors have low capacity dor indebtedness. B-H banking sectors includes 30 banks (21 mostly forign-owned, seven mostly locally, privately owned and two mostly state-owned).

B-H microfinancial sector with its activities and overall assets is becoming increasingly important for the development of small and medium-size businesses, which have a difficult access to commercial loans. In this way, the microfinancial sector encourages employment, decreases poverty and helps the development of entire society.

According to the data by Microfinance Information Exchange (MIX) [7], as many as seven B-H microcredit organizations were among the first hundred ranked microcredit organizations in the world. [8] By the number of microcredit organizations, B-H shares the second place with Ecuador, while India is the first ranked, with nine MCOs among the best hundred.

B-H microcredit organizations business has been regulated by law since early 2007, when Entity laws on microcredit organizations [9], came into effect. In 2008, a few additional regulations were passed that regulated MCO business in more detail. Entity laws on microcredit organizations assigned the role of microcredit sector supervisor to the competent Entity Banking Agencies. Pursuant to these laws, microcredit organizations had to conduct the transformation into one of the legally offered forms, non-profit microcredit foundation or a microcredit company, as a form of for-profit organization. Thus, by

the end of 2008, out of 27 licensed B-H microcredit organizations, 23 were registered as microcredit foundations and four as microcredit companies.

MCO sector finished 2010 with lower rates of return on capital and assets compared to previous years. Profitability indicators are still at a higher level than those in banking and other financial sectors. When MCO business indicators are observed and compared to the previous year, microfinancial sector in 2010 was more significantly affected by the global financial crisis. The effect of financial crisis is mainly evident through a more difficult access to foreign capital, Institutions that provide loans to this part of B-H financial sector limited their investments, increased interest rates and shortened terms of payment, and thus MCOs were also forced to start a serious risk control and make stricter conditions for granting credits.

B-H leasing sector [10] - besides a significant increase in the volume of financing through leasing in previous periods, B-H leasing market is still a lower-developed segment of the financial sector. Law on Leasing in RS was passed in November of 2007, and in FB-H, where most leasing companies are based, Law on Leasing was adopted only in late December of 2008. Pursuant to these laws, supervision over the leasing companies' business was assigned to Entity Banking Agencies, while the division of leasing market by Entities creates difficulties for leasing companies that operate across the country. Additional problems in B-H leasing market were created by the unconfirmed other regulations with leasing operations, so that in case of financing through leasing there is double taxation based on the Law on Real Estate and Law on VAT. Besides, the problem resulting from provisions of Law on Road Transport of FB-H has not been resolved yet. In 2010, there were nine leasing companies operating in B-H, seven of which were members of Association of Leasing Companies. Leasing companies have also been affected by the global economic crisis.

The insurance segment as part of the overall financial system has a significant share in the B-H financial market. In 2010, 26 insurance companies were operating in B-H. The new Law on Insurance and established insurance agencies at Entity levels and Insurance Agency of B-H allowed the unique implementation of law in the area of insurance and insurance companies' activities in whole B-H.

4. Conclusion

Microcredit organizations operate in the area of banking services. "Microcredit organizations base their goals on the combination of banking and social causes. [11] The basis of financial services is the sales of money whereby the supplier achieves its goals, particularly profit, through interest, while the customer (user) uses it to perform its entrepreneurial activity and achieve its business goals, including the business profit. Microcredit organizations operate by banking principles: they collect financial resources for their crediting potential, sell credits with interest, insist and achieve payment of credits – principal and interest, and usually achieve a surplus income above all the business costs.

In the B-H credit market, [12] microcredit organizations have a significant place, and one of the basic reasons for their great share in the overall financial market is the fact that a great number of persons who need this type of financial services do not satisfy pre-requisites required by commercial banks.

Result of MCOs as non-profit organizations, after their establishment and initial results, show that they achieve significant results through a very high growth of the number of clients, as well as the value volume of sold microcredits. The goal of microcrediting growth is the achievement of self-employment, starting own small business, which in turn leads to increase in income and reduction of poverty. Discovering, understanding and anticipating changes in the environment must be oriented to recognizing and developing opportunities that vary from obvious to "unthinkable" and should be brought to the surface". [13].

Decision making on Innovation process

Ariana Xhemajli¹, Mersiha Kalac²

²Lecturer Faculty of Applied Sciences in Business in Peja – University of Prishtina

Any process of innovation must define and describe the actions and outcomes that result from the application of specific methods and tools (and the reasons behind these methods and tools). The actions of people following the process take place over time and, therefore, have a time linear nature that, if described strictly by a linear sequence of activities and events, belies one of the most important aspects of the innovation process itself - it is not linear! The process of innovation relies on the non-linear methods of iteration and abstraction. Iteration because that is how we learn things and obtain new knowledge, by going back, refining and maturing what we know to gain insight and understanding of the things we see and learn. Abstraction because that is how we synthesize knowledge, sees patterns and makes connections to new things. Both of these activities, iteration and abstraction, are inherently non-linear, yet must necessarily take place over time as a series of concrete actions by people using a process for innovation.

The process described here is laid out as a sequence of Process stages that unfold over time. These stages can happen, however, at different levels of abstraction or generalization and there are many, many iterative elements within each stage and between stages. These iterative and generalization components are an inherent part of the process and methods employed

Key words

Decision making, Innovation

1. Innovation process

The best approach is to have a comprehensive innovation process management (IPM) structure that treats innovation as a series of cycles that run within a grand, enterprise innovation process cycle. The cycle starts with a problem or goal which needs to be formulated into an innovation challenge. Once this is done, the challenge is presented to the problem solving group. This may be done in the form of a brainstorming event, ideas campaign or other activity. The group problem solving group may be a team, all employees in the firm, the public or any other group of people.

2. Collaboration

In order to maximize the creative potential of the problem solving group, the idea generation activity should be collaborative in nature. This can be accomplished in many ways. Idea management and innovation process management software often provides on-line collaboration tools, while facilitators of brainstorming and other ideation events should promote collaborative idea development.

3. Combination

Because an innovation process cycle starts with a challenge, ideas tend to be interrelated and many are complementary. Hence, before going further, it is best to combine such complementary ideas into larger, more sophisticated ideas so that they can be handled as a single package. This makes the next steps in the cycle more efficient.

4. Scientific Peer Review Evaluation

Here is where a lot of innovation initiatives break down: choosing the best ideas. Many poorly thought out approaches use voting, which is a good way to identify the most popular idea, but an appallingly ineffective method for identifying the most potentially innovative idea. I have also seen organizations put a great deal of effort into idea generation, leaving the final decision to a manager who basically picks out her favorite idea. Assuming the manager has suitable business expertise, such an approach is better than voting – as it is based on expertise rather than popularity – but it is typically far from perfect.

5. Testing and Development

Ideas identified as being potential innovations are now ready to be tested and developed. Here is where typical business tools come in useful. A business case is a useful means of hypothetically implementing an innovative idea and projecting the potential results. Of course it is not perfect, but it indicates possible issues in the implementation of the idea, as well as benefits that may not have been obvious to the original idea developers.

6. Decision making on Innovation process

Prototypes are an excellent means for testing ideas. Not only do they allow you, your colleagues, customers and others to see how an idea would actually look in implementation, but building and playing with a prototype is a good method of further improving upon the core idea. Prototypes are, of course, ideally suited towards material ideas such as new products. But more abstract ideas, such as new services, process improvements and other concepts can often be prototyped through role-play, building structural models and making diagrams.

7. Implementation

Ideas that make it through testing and development are ready to be implemented. Unless the idea is a radical change from your usual activities, you don't need me to tell you how to do this!

8. Review

Once ideas have been implemented, they need to be reviewed, probably against an ongoing series of milestones. If an implementation does not achieve a milestone, it needs to be modified or killed. Moreover, even the most spectacularly effective and profitable breakthrough innovations need to be improved on a regular basis.

9. New Needs and Inspiration

Hence, reviewing the implementation of new ideas should indicate new needs which can be transformed into challenges which, in turn, start a new innovation process cycle. Likewise, implementations can inspire new corporate goals. Again, these can be turned into new challenges and new cycles.

Any process of innovation must define and describe the actions and outcomes that result from the application of specific methods and tools (and the reasons behind these methods and tools). The actions of people following the process take place over time and, therefore, have a time linear nature that, if described strictly by a linear sequence of activities and events, belies one of the most important aspects of the innovation process itself - it is not linear! The process of innovation relies on the non-linear methods of iteration and abstraction. Iteration because that is how we learn things and obtain new knowledge, by going back, refining and maturing what we know to gain insight and understanding of the things we see and learn. Abstractions because that is how we synthesize knowledge, see patterns and make connections to new things. Both of these activities, iteration and abstraction, are

inherently non-linear, yet must necessarily take place over time as a series of concrete actions by people using a process for innovation.

The process described here is laid out as a sequence of Process Stages that unfold over time. These stages can happen, however, at different levels of abstraction or generalization and there are many, many iterative elements within each stage and between stages. These iterative and generalization components are an inherent part of the process and methods employed. The methods used are:

- Iterative Deepening (Iterative development and refinement of knowledge)
- Searching & Exploration (Evidence-based search and discovery)
- Knowledge Synthesis (Pattern Recognition and inductive reasoning)

Mastering these two techniques allows the innovator to gain the necessary knowledge, and to use it in the right ways, to discover those new things that are unknown and valuable.

Innovation, according to Schumpeter (1934), covers:

1. The introduction of a new good or a new quality of the good
2. The introduction of a new method of production
3. The opening of a new market
4. The conquest of a new source of supply
5. The carrying out of the new organization of an industry

The “newness” need not necessarily involve “new” knowledge thereby effectively implying that the “newness” may also concern advancement or modification of existing knowledge. Innovation, according to Rogers (2003), is “an idea, practice, or object that is perceived as new by an individual or other unit of adoption”.

The innovation process encompasses several systematic steps, beginning from problem/requirement analysis to idea generation, idea evaluation, project planning, product development and testing to finally product marketing.

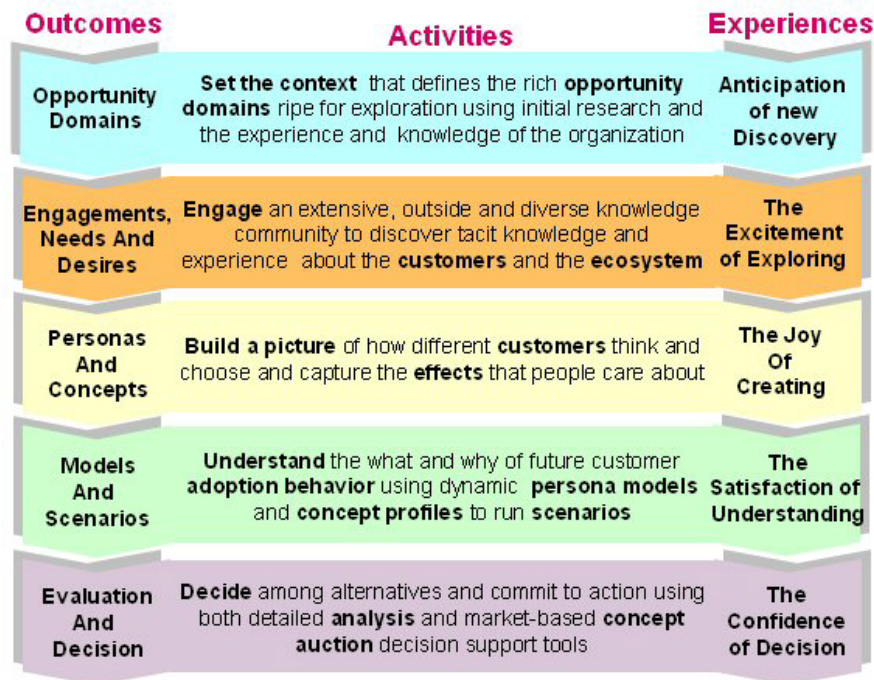

Any process of innovation must define and describe the actions and outcomes that result from the application of specific methods and tools (and the reasons behind these methods and tools). The actions of people following the process take place over time and, therefore, have a time linear nature that, if described strictly by a linear sequence of activities and events, belies one of the most important aspects of the innovation process itself - it is not linear! The process of innovation relies on the non-linear methods of iteration and abstraction. Iteration because that is how we learn things and obtain new knowledge, by going back, refining and maturing what we know to gain insight and understanding of the things we see and learn. Abstraction because that is how we synthesize knowledge, sees patterns and makes connections to new things. Both of these activities, iteration and abstraction, are inherently non-linear, yet must necessarily take place over time as a series of concrete actions by people using a process for innovation.

The process described here is laid out as a sequence of Process Stages that unfold over time. These stages can happen, however, at different levels of abstraction or generalization and there are many, many iterative elements within each stage and between stages. These iterative and generalization components are an inherent part of the process and methods employed. The methods used are:

- Iterative Deepening (Iterative development and refinement of knowledge)
- Searching & Exploration (Evidence-based search and discovery)
- Knowledge Synthesis (Pattern Recognition and inductive reasoning)

Mastering these two techniques allows the innovator to gain the necessary knowledge, and to use it in the right ways, to discover those new things that are unknown and valuable. One of the most important processes in any effort to innovate is to discover new opportunities to go after. This Opportunity Discovery Process focuses on finding specific unmet needs and desires that can be the basis for new and practical solutions. The focus of this process is on people and what they want, rather than on technology and what it can do. Mastering this process results in an on-going, continuous, front-end 'engine' that drives all innovation effort. These are shown in the following diagram which depicts the stages from the perspective of the outcomes, the activities and the experiences of those involved.

Personal values and goals of young entrepreneurs in Macedonia

Marija Zarezankova-Potevska¹, Angelina Taneva-Veshoska²

¹First Private FON University, Skopje, Macedonia, marija.zarezankovapotevska@fon.edu.mk

²First Private FON University, Skopje, Macedonia, angelina.tanevaveshoska@fon.edu.mk

Promoting entrepreneurship is considered one of the most effective ways to address and reduce the problems of joblessness and poverty in developing countries in the world. Each country should develop its own model of entrepreneurship and promote entrepreneurial behaviors as a key factor of the economic development, growth and prosperity. Educational system is one of the most important in building of entrepreneurial society, to enhance the entrepreneurial spirit and culture as a common value. Entrepreneurial learning and life long learning are considered to be most effective ways of promoting creativity and innovations.

We usually assume that entrepreneurial traits are universal. But survey results from all over the world show that there are specific differences between entrepreneur's personality and their personal values.

Therefore, our research looks into psychological values that motivate Macedonian young people to become business owners. We examined the values of Macedonian young entrepreneurs because values drive attitude, which may eventually drive behavior. Thus, knowing the value priorities of business owners will help us know how the choice of establishing their own business is formed. Second, we investigated the linkage between value priorities and firm performance and survival. Our results would help to promote entrepreneurship in R. Macedonia by identifying and investing in aspiring entrepreneurs.

Keywords

Entrepreneur, Entrepreneurship, Entrepreneurial learning, Personal value system, Young people

1. Introduction

Entrepreneurship, as a process of business organization, management and risk-taking, has introduced significant changes in the national and world economy. The entrepreneur has a vision and exercises judgment; the entrepreneur is decisive, motivated, optimistic, courageous, dedicated, willing and skilled to create the optimal combination of production factors in the realization of an idea. Entrepreneurs are small business managers who never rest; they always create and introduce quality, demand and seek changes, innovations and idea realizations. They are competent in sensing the market needs and react quickly upon them, ready to take risk. An entrepreneur realizes ideas; an entrepreneur has a vision and goals to be achieved. Entrepreneurship, as an immeasurable factor of business development, manifests its prime through the growth of small businesses. The small business is oftentimes described as the backbone of entrepreneurship. It constitutes the ideal environment which enables the exposure of the entrepreneurs' real talents and the realization of envisioned ideas. The freedom of self-employment offers an unlimited range of opportunities for economic prosperity and development. An essential factor of successful work – the ability for decision-making to reach a goal – is a vital characteristic of entrepreneurship. The capital and the natural resources remain passive developmental factors and only the active role of the human factor with its creative capability can act as the force towards the creation of new wealth and economic and social welfare. In all successful economies, entrepreneurs are viewed as essential and dynamic factor for

economic growth, as driving factors towards the creation of new jobs, and the advantages of small businesses are by now almost universally accepted". [1]

2. Definition of Entrepreneurship

Entrepreneurship is a process of initial business risk, organization of resources and taking into account future risk and gains. An entrepreneur is a person capable of recognizing and executing sustainable business ideas. Entrepreneurs are idealists but they are also persistent, hard-working and energetic persons. They don't waste time; rather, they use their talent and knowledge, their skills, their time and energy. The term "entrepreneurship" originates from the French verb "entreprendre" which means attempts, takes on; the noun "entrepreneur" denotes a person who attempts, undertakes, an entrepreneur. The phenomenon of entrepreneurship must be nurtured and developed as it creates new values and develops the creativity in people.

Despite the multitude of varying theoretical standpoints in respect to the treatment of entrepreneurs in modern economic theory, a question arises as to whether entrepreneurs are predestined for their business activities or whether their excellent organizational skills and creative and innovative characteristics are a direct result of adequate environments and the solid academic background in management, marketing, IT etc., all of which influence the personality of an entrepreneur. The latest work of Thomas L. Harrison titled "Instinct" [2] suggests the genetic preordainment of entrepreneurs to be creative, active and innovative. We hold this to be very true, but a certain dose of creativity resides in every person and needs stimulation and guidance. The entrepreneur is future-oriented with constantly new ideas and production innovations, which makes entrepreneurship a dynamic development factor, given the strong correlation between the development and entrepreneurial function. With the creation of a favorable business environment for the development of entrepreneurship, with no administrative and legal barriers, through the active operation of marketplace legalities, with the elimination of the monopolistic role of certain large enterprises and commercial groups, and of course with the active policy of support for entrepreneurial activities, the conditions for economic development ripen. Therefore, entrepreneurship stands for the undertaking of business activities, a philosophy of business functions which enable the expression of creativity, innovation, and the creation of new values through the realization of advanced business ideas.

2.1 Types of entrepreneurship

Entrepreneurship, as a philosophy of business activity in the marketplace (given the nature of the marketplace being one of greatest freedom of activity) is characterized by creativity and innovation in all spheres of economic and social life.

Thus, entrepreneurship manifests itself in:

- Large corporations (intrapreneurship) – otherwise known as internal entrepreneurship and employee innovation, specifically in the production function with the invention of new technological solutions and practices by individual entrepreneurs;
- New Technologies Entrepreneurship – which is also called technopreneurship;
- Information Technology Entrepreneurship – also known as infopreneurship;
- Social entrepreneurship – a reflection of the active role of the non-governmental sector and all institutions and individuals who introduce change in the social environment of life and work, in conjunction with the active government policy of social prosperity and wellbeing.

2.2 Characteristics of entrepreneurs

The basic characteristics of entrepreneurs include:

- Self-confidence
- Talent
- Creativity
- Challenge
- Dynamism
- Vision
- Initiative

- Realism
- Optimism
- Ability to take criticism
- Wit
- Persistence
- Risk-taking
- Independence
- Polyvalence
- Need for realization
- Flexibility
- Envisioning
- Energy
- Non-conformity
- Profit-orientation [3]

Without delving into too deep an analysis of whether these characteristics are a result of the psychophysical personality of someone (in other words, genetic) or a direct result of the educational and learning system of continuous education and experience, we can presume that only with a reciprocal correlation (i.e. with constant nurturing, with the knowledge of the brave economic visionaries) can excellent entrepreneurs evolve and jumpstart entrepreneurship.

Other authors accentuate the desire to create large companies, the capacity for large deals and the feeling of moral and legal responsibility to finish what has been started, as main personality traits of entrepreneurship. They are optimists, perfectionists, excellent organizers; they are profit-oriented – not at any cost, but as a direct result of their efforts. Entrepreneurship is of course one of the largest social and economic forces of our days. This force has an incredibly strong influence on all economic activities within a society.

3. Personal values

Rokeach [4] defined a personal value as an enduring belief that a specific mode of conduct or end-state of existence is personally or socially preferable to its opposite. A value system is an enduring organization of beliefs concerning preferred modes of conduct or end-states along an importance continuum. Two kinds of values-instrumental and terminal-were defined as a person's beliefs concerning desirable modes of conduct and desirable end-states of existence respectively.

Grunert and Scherhorn [5] identified five features of personal values. Values were described as:

- concepts or beliefs,
- about desirable behaviors and/or end states,
- that go beyond specific situations,
- guide the selection or evaluation of events and behaviors, and
- are ordered by a certain hierarchical importance.

The conceptualization of personal values in terms of social adaptation theory posited that personal values are the most abstract type of social cognitions that function to facilitate adaptation to one's environment. The concept of regarding personal values as mediators in the social adaptation process implies that value differences between cultures can be traced back to different ethnic background and the social, economic, political, and technological environments.

The original version of the Rokeach Value Survey consisted of 18 instrumental values or ideal modes of conduct and 18 terminal values or ideal end-states of existence that were rank ordered in terms of their importance as guiding principles of the respondent's life. To facilitate the ranking task, each value was contained on a pressure sensitive gummed label and respondents were instructed to re-arrange the labels until the best ordering of the relative importance of each value was achieved.

The major limitations of the original version of the RVS include:

- subjects are forced to rank one value at the expense of another which may actually be equally important to them,
- the presentation of the 36 value items may exceed the respondent's ability to accurately process information and thus distort the ranking procedure,
- the ranking nature of the data precludes the use of a wide variety of useful statistical analysis techniques that might otherwise be used [6]

Terminal Values refer to desirable end-states of existence. These are the goals that a person would like to achieve during his or her lifetime. These values vary among different groups of people in different cultures. The terminal values in RVS are true friendship, mature love, self-respect, happiness, inner harmony, equality, freedom, pleasure, social recognition, wisdom, salvation, family security, national security, a sense of accomplishment, a world of beauty, a world at peace, and a comfortable life and exciting life.

Instrumental Values refer to preferable modes of behavior. These are preferable modes of behavior, or means of achieving the terminal values. The instrumental values are: cheerfulness, ambition, love, cleanliness, self-control, capability, courage, politeness, honesty, imagination, independence, intellect, broad-mindedness, logic, obedience, helpfulness, responsibility and forgiveness. [7]

3.1 Hypotheses Development

We examined the value system of Macedonian entrepreneurs, because values drive attitude, which may eventually drive behavior. Thus, knowing the value priorities of Macedonian entrepreneurs will help us know how the choice of establishing their own business is formed. For further investigation we can explore the linkage between value priorities and firm performance and survival. The results will find will help us to promote entrepreneurship in Macedonia and investing in aspiring entrepreneurs.

Our hypotheses were based on Fagenson's [8] findings of American entrepreneurs using Rokeach's value measure. Surveying 168 owners of small businesses in New York, New Jersey and Connecticut, Fagenson found that American entrepreneurs ranked three terminal values (self-respect, freedom, and a sense of accomplishment) and seven instrumental values (honesty, ambition, being capable, independence, courage, imagination and being logical) as the most important values to them and the ranking was in this particular order. In other words, American entrepreneurs wanted to be free to strive for achieving and actualizing their potential. Americans also valued terminal goals more highly than instrumental techniques. Fagenson attributed her sample's entrepreneurial aspiration to these specific values.

Hypothesis 1. Macedonian entrepreneurs' most important terminal values will reflect both collective and personal orientation.

3.2 Method

1. **Participants.** We utilized a convenience sample of 45 business owners from Macedonia. Typical demographic information of business owners was collected (e.g., gender, age, and education level). In terms of gender, 70% of respondents were male and 30% were female. Their average age was 23.6 (min = 18; max = 35). In terms of educational attainment, the majority of participants held a college degree or higher (65%); some held an associate college degree (15.4%) or a high school diploma (15.4%).
2. **Procedure and Measures.** Data were collected during the summer and fall of 2010. Entrepreneurs were contacted and asked to be interviewed by one of five trained researchers. Macedonian entrepreneurs' personal value system was assessed with the Rokeach's Values Survey. The RVS consists of 18 terminal and 18 instrumental values listed in alphabetical order. Terminal values are concerned with "end states of existence" or the priority of life goals or motives; instrumental values are concerned with "modes of conduct" or behavioral techniques used to execute goals. [8] Examples of terminal values include "a comfortable life (a prosperous life)" and "a world at peace (free of war and conflict)"; examples of instrumental values include "ambitious (hard-working, aspiring)" and "honest (sincere, truthful)". Macedonian entrepreneurs were asked to arrange the terminal values first, then the instrumental values, "in order of importance to *you*, as guiding principles in *your* life".
3. **Results.** Terminal versus Instrumental Values. Hypothesis 1 stated that Macedonian entrepreneurs' most important terminal values would reflect both collective and personal orientation. The results of value rankings were reported in Table 1. As shown in the table, in terms of terminal values, Macedonian entrepreneurs pursued life goals that were somewhat similar to American entrepreneurs' key terminal values (e.g., self-respect, freedom, and a sense of accomplishment). Specifically, Macedonian top five life goals included happiness, a sense of accomplishment, a comfortable life, family security, and national security, values that are both personal and collective in orientation.

Table 1 Mean Rankings for Macedonian Entrepreneurs' Terminal Values

Terminal Value	Ranking
happiness	1
a sense of accomplishment	2
a comfortable life	3
family security	4
national security	5
social recognition	6
wisdom	7
a world at peace	8
freedom	9
self-respect	10
equality	11
true friendship	12
pleasure	13
an exciting life	14
inner harmony	15
mature love	16
a world of beauty	17
salvation	18

Table 2 Mean Rankings for Macedonian Entrepreneurs' Instrumental Values

Instrumental Value	Ranking
intellectual	1
capable	2
responsible	3
self-controlled	4
honest	5
independent	6
ambitious	7
loving	8
courageous	9
helpful	10
broadminded	11
logical	12
polite	13
cheerful	14
forgiving	15
imaginative	16
clean	17
obedient	18

Life goals such as a world of beauty (beauty of nature and the arts), mature love (sexual and spiritual intimacy), inner harmony (freedom from inner conflict), and an exciting life (a stimulating active life) were ranked as the least important, similar to the rankings of the same values by American adults. Taken together, our findings replicated those found by Fagenson to some extent. Therefore, Hypothesis 1 received support.

4. Conclusions

In this survey we found that, to a certain extent, Macedonian entrepreneurs did uphold values similar to those of American counterparts in the literature. The findings provided evidence for the notion that some personal values of entrepreneurs are universal across countries or cultures. For example, whereas our findings in the present study showed only the value of a sense of accomplishment as an exact replication of Fagenson's study, the rankings of happiness and family security values were similar to the rankings of those values by American adults. Further, although not being ranked among the top five terminal values by Macedonian entrepreneurs, freedom and self-respect did receive the ninth and tenth rankings respectively.

Although not studied in the scope of the present research, future investigators may want to extend the findings to examining how values may be managed, socialized and promoted in Macedonia. Regarding entrepreneurial motives of Macedonian entrepreneurs, our content analysis of the information gathered revealed the emergence of a fascinating, multi-dimensional pattern of motives. Besides apparent and popular motives such as the desire for earning a better income than what they had earned in previous jobs, the desire for more meaningful or challenging work, and the desire to meet market demands, some Macedonian entrepreneurs in our sample also went into business because of other non profit-related reasons such as creating jobs for their family and taking care of family business.

However, we felt that our respondents could have been probed for further elaboration of:

- what motives they would prioritize when they reported a range of motives;
- whether such priorities shifted over time, and if yes, how so.

To establish a multi-dimensional conceptual framework of Macedonian entrepreneurial motives, we would need additional in-depth data collection.

Some limitations of this study should be noted. The convenience sample utilized here limits the extent to which the findings can be generalized to other business owners in other cities and/or provinces in Macedonia. However, we would like to say that until Macedonian entrepreneurs are more comfortable with formal research methodology, convenience sampling is the only feasible way to conduct research in the private business sector.

One of the most difficult and complex issues that researchers are faced with is finding the proper definition and meaning of the word “entrepreneurship” and the proper explanation as for which type of activities may be considered as entrepreneurial activity and which are the main characteristics of entrepreneur and entrepreneurship, although there seems to be a consensus between researchers when it comes to treating innovations and readiness to undertake risk as the main features of entrepreneurship.

The purpose of this paper is not just to give an intensive description on entrepreneurship and its creation and emergence as a discipline, but rather to analyse the development and importance of entrepreneurial activity in the Republic of Macedonia. The paper is divided in two parts. The first part contains basic information on entrepreneurship and entrepreneurial developments in different parts of the world. The second part of the paper is dedicated to entrepreneurship in the Republic of Macedonia. The paper is based on descriptive analysis of the main events regarding the development of entrepreneurship in the Republic of Macedonia and the results of an empiric survey on entrepreneurship in the Republic of Macedonia.

Entrepreneurship, entrepreneurial activity, republic of Macedonia

1. A variety of views and definitions on entrepreneurship

One of the most difficult and complex issues that researchers are faced with is finding the proper definition and meaning of the word “entrepreneurship” and the proper explanation as for which type of activities may be considered as entrepreneurial activity and which are the main characteristics of entrepreneur and entrepreneurship, although there seems to be a consensus between researchers when it comes to treating innovations and readiness to undertake risk as the main features of entrepreneurship.

The word “entrepreneur” itself derives from the French word “entreprendre” which was widely used as a designation for an organizer of an entertaining activity. It appears that one of the earliest uses of the term “entrepreneur” in an economic point of a view was Richard Cantillon in the 1700. In fact he is considered to be the first author ever to separate the entrepreneur from the capitalist and the entrepreneurial activity from the capitalist activity. By the end of the 1700s, the French economist Jean-Baptiste Say used the term “entrepreneur” as a description for people that are in permanent search for opportunities to move the factors of production from the point of a lower economic usage to a point of higher economic usage. Even Adam Smith in his book “The Wealth of Nations” talked about the entrepreneur and entrepreneurship, but failed to make a distinctive difference between entrepreneur and capitalist. For many authors and researchers of this field Joseph A. Schumpeter is considered to be the founding father of entrepreneurship. In his book “The theory of economic development” published in 1934 he considers entrepreneurs as people who are in permanent search for finding new combinations, thus the main element of his definition is innovation. In fact he introduced the Five innovations leading to a new production function: The introduction of a new good, the introduction of a new method of production, the opening of a new market, the conquest of a new

source of supply of a raw material and the carrying out of a new organization of an industry. In yet another definition Kirzner remarked that the essence of the entrepreneurial decision consists of grasping the knowledge that might otherwise remain unexploited. Kirzner perceived the entrepreneur as an equilibrating force; he identified and smoothed-out market imperfections by performing creative arbitrage activities. Kirzner's concept of an entrepreneur was an arbitrager who was able to anticipate when the next imperfections and imbalances would occur and take advantage of them by employing his creative imagination. Table 1 shows the earliest usages of the term 'entrepreneurship' in an economic sense.

Table 1 Timetable for Early Economists Using the Term "Entrepreneurship"

Year	Economist	Contribution
1725	Richard Cantillon	Separated activities of capitalist from entrepreneur
1776	Adam Smith	Discussed entrepreneur but associated activities with the capitalist
1803	Jean-Baptiste Say	Defined entrepreneur as improving the state of resources used in production
1871	John Stuart Mill	Associated capitalist and entrepreneur together through risk
1934	Joseph A. Schumpeter	Defined entrepreneurs as sociologically distinct individuals; separated entrepreneurship from the role of the capitalist

Source: McDaniel B.A (2005): *Entrepreneurship and innovation: An Economic Approach*, M.E. Sharpe, New York, 32

Davidson over the years of entrepreneurial research came to the conclusion that although the many definitions on entrepreneurship seem to be very different from each other, still they all address two main phenomena, social issues. "The first of those is the phenomenon that some people, rather than working for somebody else under an employment contract, strike out on their own and become self-employed, or team owner-managers of an independent business. This implies a radically different risk/reward structure with a much wider span of possible financial outcomes, and a more fluid border between work and leisure. Often these new economic entities involve some element of innovation at start-up, and some degree of innovativeness may be needed in order to survive in this capacity over time. However, it is a well-known fact that the majority of independent businesses are relatively stable operations in mature and low to medium value-added industries. Some of those independent businesses will grow in size, which implies that the owners will face different types of management challenges and transitions over time. Often other family members than the original founder are involved in the business, and eventually the transfer of the ownership and management of the business either within or outside the family will become a major issue for the founders. When the concept "entrepreneurship" is used for this social reality, topics like self-employment, small business management, stages-of development models, and family business issues become aspects of entrepreneurship. In short, entrepreneurship is anything that concerns independently owned (and often small) firms and their owner-managers. The second social reality that emerges as a major underlying theme in entrepreneurship definitions is that the development and renewal of any society, economy or organization requires micro-level actors who have the initiative and persistence to make change happen. Institutions as well as market and organizational structures may facilitate or hinder change and development. However, those structures do not create any change—and they certainly do not change themselves—in the absence of human actors. In the end, it is the unique knowledge, perceptions and goals of individuals equipped with the drive to take action accordingly that initiate novelty. In order for those new initiatives to have lasting impact, however, they need to create value or save resources." (Davidsson,2004,4 [1]). Table 2 contains several definitions on entrepreneurship.

Table 2 Definitions on entrepreneurship

Author	Contribution
Gilbraith	An entrepreneur must accept the challenge and should be willing hard to achieve something
Drucker	One who always searches for change, responds to it and exploits it as an opportunity. Innovation is the basic tool of entrepreneurs, the means by which they exploit change as an opportunity for a different business or service.
Weber	Entrepreneurs are a product of particular social condition in which they are brought up and it is the society which shapes individuals as entrepreneurs.

In practice entrepreneurship is closely connected to the creation and functioning of small business. Data research reveals that all over the developed world most companies are small companies with a very limited percentage of them becoming medium or big business. But, having in mind the way how modern national economies function we might say that entrepreneurship is of great importance not only for the creation of wealth at an individual level but also for its contribution to economic growth and development at a national level. This is very obvious having in mind that entrepreneurial activity as a major source for opening new jobs, creation of new technologies and of course finding new approaches towards solving the main problems in contemporary live regarding better usage of limited resources and finding solutions to the increasing environmental problems.

Part of the divide between the economics and business studies approaches to entrepreneurship is attributable to the different definitions of entrepreneurship they utilize. Economists are often content to utilize business owners (in industrial organization and macroeconomics), the self-employed (in labour and microeconomics) and small firms (in industrial organization) as working definitions. All these definitions rely implicitly on residual-claimant and risk-taking aspects of entrepreneurship, and facilitate the analysis of incentives, investments, resource allocation decisions and occupational choices. In contrast, many business studies researchers feel there is nothing entrepreneurial about merely being an owner-manager of a small business. They usually prefer to study behaviours entailed by starting a new business, and speculate about cognitive and perceptual constructs entailed with it. Economists tend to eschew this approach as overly subjective, insisting instead on inferring motives only from actual observed behaviour. This is the so-called 'revealed preference' principle (Parker, 2009, 6 [2]).

Regardless the definition one of the main questions that arises when it comes to entrepreneurship, entrepreneur and entrepreneurial behaviour is: "What are the main characteristics and patterns of behaviour that a successful entrepreneur should have?" Different authors have different points of view when it comes to the answer of this question. But, perhaps one of the approaches that we all must have in mind is the one given by Carsrud and Barannback (as shown in illustration 1).

Figure 1 Strong entrepreneurial characteristics and behaviour

Source: Carsrud A.R., Brannback M. E (2007). *Entrepreneurship*, Greenwood Press, London, 17

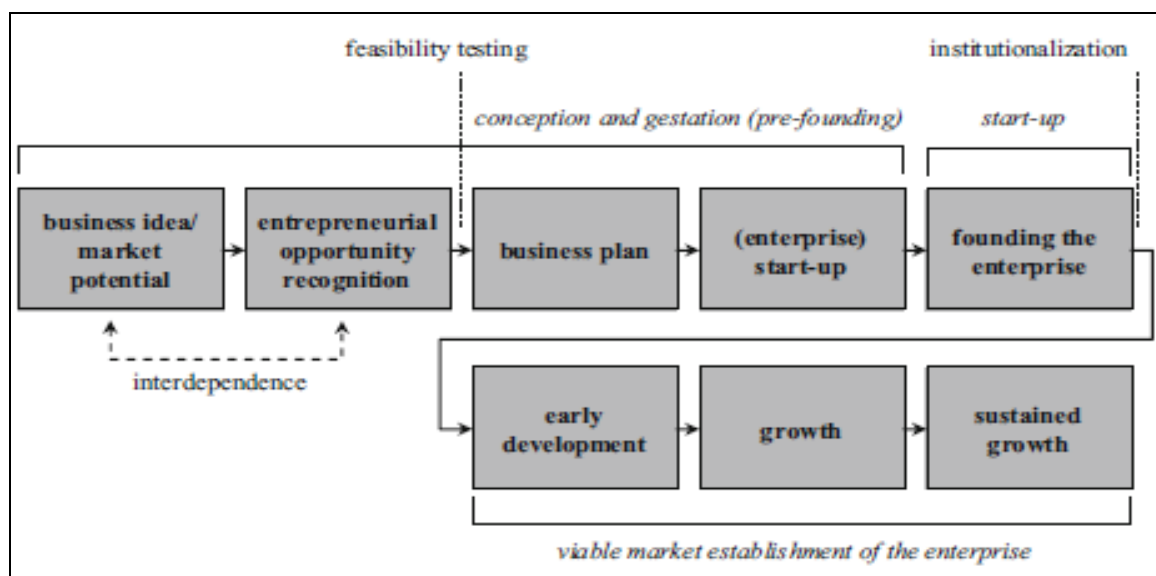

When talking about entrepreneurs and entrepreneurship a distinction between four different types of entrepreneurs should be made (Harvinal, 2009, 102 [3]):

- Innovative entrepreneur: This category of Entrepreneur is characterized by smell of innovativeness. This type of Entrepreneur, sense the opportunities for introduction of new ideas, new technology, discovering of new markets and creating new organizations
- Adoptive or imitative entrepreneur: Such entrepreneurs imitate the existing entrepreneur and set their enterprise in the same manner. Instead of innovation, may just adopt the technology and methods innovated by others.
- Fabian entrepreneurs: Fabian entrepreneurs are characterized by great caution and scepticism, in experimenting any change in their enterprises. They imitate only when it becomes perfectly clear that failure to do so would result in a loss of the relative position in the enterprises.
- Drone entrepreneurs: Such entrepreneurs are conservative or orthodox in outlook. They always feel comfortable with their old fashioned technology of production even though technologies have changed.

Perhaps one of the greatest examples in the entrepreneurship in the USA is Fordism that is Ford's approach in the production of the T-Model, based on Adam Smith's pin factory example and job specialization. The innovations in the automotive industry which occurred parallel ore almost parallel with the great innovations in the steel industry and the oil industry are considered to be the main factors which led to the great economic expansion in the early 1990's. After the great depression, and the Second World War, the very famous "Baby Boom" happened in USA. But at the same time perhaps even a more visible boom occurred, that is the "Innovation Boom" and "Entrepreneurial Boom" which lasted for a few decades and led the American national economy to a position of world economic dominance.

Entrepreneurship and the resulting rapid development of innovations became a worldwide phenomenon in the 1980s as market capitalism became the ideology espoused by Margaret Thatcher, prime minister of England, and Ronald Reagan, president of the United States. This movement was enhanced by the declining acceptance of socialist-based economies worldwide. Exact reasons for the timing and fervour of this movement remain unclear, but in the United States the drive to regain recognition as a world trading power, the downsizing of inefficient plants, opportunities for small start-up firms, and the need for innovations leading to better efficiencies have certainly helped propel this movement. Innovation has become a necessity as well as the hallmark of any quality business venture. (McDaniel, 2002,10 [4]). Many authors talk about the process of entrepreneurship. An example of entrepreneurship process is presented in figure 2.

Figure 2 Entrepreneurial process

2. Entrepreneurship and entrepreneurial activity in the Republic of Macedonia

The Global Entrepreneurship Monitor Macedonia report for 2008 showed that there is a general positive perceptions regarding entrepreneurship in Macedonia. The data presented in the following text are used from this report.

Usually the entrepreneurial activity in Macedonia belongs to the category of necessity-motivated entrepreneurship rather than opportunity-motivated entrepreneurship. In fact the report proved a 1.5 ratio coefficient between these two types of entrepreneurial activity in Macedonia a result that is in full compliance with the economic reality with Macedonia being a country characterised by high unemployment and low economic growth. A comparative analysis of Macedonia and other countries is presented in Figure 3.

Figure 3 Opportunity and necessity motivated entrepreneurship

Source: *Global Entrepreneurship Monitor Macedonia report for 2008*

Data presented in Figure 3 show that Macedonia has the highest degree of necessity motivated entrepreneurship compared to all other countries. In fact it can be noticed that Macedonia has almost twofold higher coefficient of necessity motivated entrepreneurship compared to EU and OECD and almost around five times higher degree of necessity motivated entrepreneurship compared to Slovenia. It's obvious that less developed countries have a higher degree of necessity motivated entrepreneurship compared to more developed countries, but even besides this the fact remains that Macedonia has a relatively low coefficient of the ration between opportunity motivated entrepreneurship and necessity motivated entrepreneurship.

In Macedonia entrepreneurship is more typical for male entrepreneurs compared to female entrepreneurs (Figure 4).

Figure 4 Gender based entrepreneurship in Macedonia

Source: Global Entrepreneurship Monitor Macedonia report for 2008

The report revealed age differences of entrepreneurs in Macedonia compared to other countries as represented in Figure 5.

Figure 5 Entrepreneurs according to age in Macedonia and selected countries

Source: Global Entrepreneurship Monitor Macedonia report for 2008

Data shown in chart 3 reveal that in Macedonia the younger population has a higher positive attitude towards entrepreneurship compared to other countries from the region.

Regarding the influence of education of entrepreneurship the GEM report reveals that people that have a higher level of education have more positive attitudes towards entrepreneurship as can be seen from Figure 6.

Figure 6 Entrepreneurship according to level of education

Source: *Global Entrepreneurship Monitor Macedonia report for 2008*

Data presented in chart 4 reveal that regardless which country is analysed the level of education seems to have a high impact on entrepreneurial activity.

When talking about entrepreneurship in Macedonia a special emphasis should be made for the National Agency for the Promotion of Entrepreneurship in Macedonia which is a state owned institution that deals with measures and activities for the promotion of entrepreneurship and creation of competitiveness of small business in the Republic of Macedonia. Its basic duties include:

- Creating favourable economic environment and legislation
- Creating and developing institutional infrastructure for support and development of entrepreneurship and competitiveness in small business
- Implementation and coordination of state and international support for micro, small and middle businesses
- Promoting entrepreneurship through financial and non-financial forms of support
- Implementing the Program on measurements and activities for support of entrepreneurship and creating competitiveness in the small business of the Republic of Macedonia

3. Conclusions

This paper is based on literature review regarding entrepreneurship with special emphasis on entrepreneurship in the Republic of Macedonia.

In Macedonia, in general, there are positive perceptions on entrepreneurship. 80% consider entrepreneurship to be a good carrier choice and 66% that the media provide appropriate attention to entrepreneurship. Macedonia has the highest entrepreneurial activity from the European countries in which GEM was conducted. In Macedonia the typical entrepreneur is male, at age from 25 to 34, with higher educational level and higher income. The youngest population (18-24) has significantly higher aptitude towards entrepreneurship, compared with the countries in the region.

The Role of Universities in the Triple Helix: A Multi-Country Comparison

Qiantao Zhang¹

¹*Institute for Innovation Studies, University of Wales Global Academy, Cardiff, UK,
q.zhang@wales.ac.uk*

The Triple Helix innovation model (Etzkowitz and Leydesdorff, 1997 [1]) proposes that inter-relations between three spheres – government, university, and industry – are key factors influencing universities' entrepreneurial performance. This paper compares the impact of these inter-relations on universities in three selected countries: the U.S., the UK, and Sweden. A key finding was that the role of government, university mission statements, and industry profiles all impacted differently on the extent of entrepreneurial activity of the universities in each country. In the U.S., government has encouraged interaction between universities and industry and, as a result, many university innovations are further developed by industry. In the UK, although there is quite a strong research base in pure science by international standards, British business is not research intensive and scientific inventions from academia are left underexploited. In Sweden, a dozen companies are responsible for the majority of domestic R&D activities but industrial R&D is generally conducted in-house or through corporate collaboration. Swedish universities, which are funded primarily by government, focus strongly on curiosity-driven research. This study recommends that there is a need to consider a wider context (such as the Triple Helix) when understanding questions like the Swedish Paradox (Edquist, 2010 [2]) and makes recommendations for increasing the entrepreneurial performance of universities.

Keywords

Entrepreneurial University, The Triple Helix, University-Industry linkages

1. Introduction

During the last three decades, significant changes have taken place in universities, especially since the development of the concept of a “knowledge society” or a global “knowledge-based economy” [3]. The increasing importance of knowledge now receives much more attention from government, who see investment in knowledge as a key source of technological innovation and national competitiveness in the global market. Jones-Evans (1998 [4]) has investigated the relationship between rapid technological change and competitive advantages in the markets and found that advances in technology lead to increased industrial output, employment and prosperity.

Universities and other higher education institutions have always been regarded as the most important source of knowledge, as confirmed by their teaching and research activities. Given the new position that knowledge has become a source of industrial competitiveness, one emerging crucial issue is to convert scientific breakthroughs into industrial and commercial success. To achieve this, exchange and absorption of knowledge between industrial firms and universities is critical. Jones-Evans (1998) has examined university-industry linkages in Europe and found that Europe's research and technology base lacked the capacity to make this conversion successfully.

Social changes call for transitions in the roles of universities, from pure research to more applied orientations; from highly autonomous positions to greater connections with other institutions; and from a predominant emphasis on teaching and research to making a significant contribution to economic development. The Triple Helix innovation model, proposed by Etzkowitz and Leydesdorff (2000), has identified these needs and argues that universities are currently undergoing a ‘second revolution’, that is incorporating economic and social developments as part of their missions, while their first academic

revolution was incorporating research as an academic function alongside teaching [5]. Universities well adapted to this transition are regarded as entrepreneurial universities. The model proposes that inter-relations between three spheres – government, university, and industry – are key factors influencing universities' entrepreneurial performance.

However, universities in different countries perform at quite dissimilar levels in terms of being entrepreneurial. In this study, case histories for three countries are compiled and compared: the U.S. (with a large scale higher education sector), the UK (with a medium scale higher education sector) and Sweden (with a small scale higher education sector), and the impacts of government and industry on universities' entrepreneurial performance are analysed. A Triple Helix analysis is applied to each of the three selected countries and recommendations are proposed for policymakers aiming to increase universities' entrepreneurial activities.

2. The U.S. Case

As early as the beginning of the twentieth century, an American method for knowledge commercialisation, based on an entrepreneurial university model, occurred at MIT [6]. This method was later defined as technology transfer through patents and the formation of companies. University-industry linkages, although with a long-standing history, were not the norm prior to the 1940s or even later. Harloe and Perry (2004) found that this trend, first emergent in New England in the 1930s, did not become a national feature until the 1960s and 1970s [7]. The Second World War (WWII) has been identified by many researchers as a turning point for stronger links between the three sectors in the U.S. and this was further reinforced in the context of the Cold War [8][9].

The U.S. higher education sector is the largest in the world and Mowery and Sampat (2005) have described its distinct features as follows:

“The US higher education was significantly larger, included a very heterogeneous collection of institutions (religious and secular, public and private, large and small, etc.), lacked any centralised national administrative control, and encouraged considerable inter-institutional competition for students, faculty, resources, and prestige.”[10]

Mowery and Rosenberg (1998 [11]) have described how the “internationally unique” R&D system in the U.S. developed in the 1940s whereas previously it had only “resembled those of other leading industrial economies of the era, such as the UK, Germany, and France.” It involved a decentralized American university system, based mainly at a State level, with inter-university competition for research funds from both the federal government and industry. This on the one hand gave universities significant autonomy but, on the other hand created a dilemma as they lacked the protection of government support.

The National Science Foundation (NSF) has mapped the changing nature of research and development funding from federal government and industry in the U.S. between 1953 and 2004 [12]. Although the proportion of federal funding decreased from over 50% in the 1950s to just 30% by 2004, the total amount of funding did not fall below that contributed by industry until the late 1970s. More significantly, in the first decade from 1953 federal support increased steadily, achieving a peak at nearly 70% of total funding in R&D. It was therefore not industry, but the expansion of federally funded R&D from the 1940s onwards, that sparked the proliferation of research teams within American academia. This led to the strong need for researchers to organize themselves into teams and formulate a research agenda capable of garnering external funding, which is core to an entrepreneurial university [13]. Gittelman (2006) has remarked that,

“Perhaps the most entrepreneurial feature of the careers of American scientists is the emphasis on raising grants to further one's standing in the scientific community.”[14]

The later increase in industry funding of R&D in universities and colleges in the U.S. may have been due to three reasons: Firstly, a large amount of the federally funded R&D programmes in the post-war years were for primary research, described as ‘research as the motor of progress.’[15] Even as late as the 1990s, universities, and their associated R&D centres, carried out about 60% of all basic research in the U.S. and well over half of this research was funded by federal agencies. In earlier years this percentage was probably even higher. By 1970s, however, the ability of science to deliver social and economic benefit was in question. Gradually, focus shifted to a way in which science could be directly

applied to 'solve' national problems and to foster economic growth. This, in theory, required that universities placed greater emphasis on social responsibility.

Secondly, in part due to the growth of electronics, biotech, software and other high-tech industries, a high demand for R&D developed within companies. Multinational firms strengthened this trend as they developed their businesses worldwide and R&D became a core strategy for creating competitive advantage in the global market. On the one hand, research work in certain industries, such as pharmaceuticals, was already quite advanced and so cooperation with the most abundant research reservoir – universities – became a necessity. On the other hand, the increased pace of technology – due to more participants and input – in turn increased the need for collaboration with other research institutions in order to maintain competitive advantage.

Industry's practical needs contributed only partly, however, to the stronger linkages with universities. Another reason was increased incentives for university researchers to join in commercial activities alongside their teaching and research work due to influential legislation which encouraged, or at least, did not hinder, this. The Bayh-Dole Act of 1980 was the most important legislation in this area as it enabled universities and small businesses to own and manage patentable inventions developed with government funding. Prior to this, federal agencies like the Department of Defence had normally taken intellectual property rights away from the creating organizations and inventors and this decreased incentives for universities in knowledge commercialisation.

The Economist Quarterly (2002) famously stated that,

“Possibly the most inspired piece of legislation to be enacted in America over the past half-century was the Bayh-Dole Act of 1980...”[16]

After the passage of the Act, U.S. university patents made up an increasing proportion of all domestic-assignee U.S. patents. The sharp increase started in the early 1980s with universities increasing their share of patenting from less than 0.3% in 1963 to nearly 4% by 1999 [17]. Prior to the passage of the Act only 10 U.S. universities were engaged in technology transfer activity but this number increased to over 40 within the first decade of the Act. Licensed patents, resulting from government-sponsored research, improved the financial situation of universities as they became able to receive royalty income. In its 2000 Survey, the Association of University Technology Managers (AUTM) showed that 156 U.S. university respondents reported \$1.24 billion in royalty income and cashed-in equity, net of unreimbursed legal fees, meaning the average income per respondent was almost \$8 million [18].

3. The UK Case

The ineffectiveness of the translation of science into business innovation has historically been a problem in the UK. As early as 1919, in his work *Industry and Trade*, Alfred Marshall pointed out that:

“...the small band of British scientific men have made revolutionary discoveries in science; but yet the chief fruits of their work have been reaped by businesses in Germany and other countries, where industry and science have been in close touch with one another.”[19]

However, increasingly universities have been playing a more active role in the economy. The introduction of the 1993 *Realising Our Potential Awards Report* shows an increasing focus by the UK Government on interactions between university and business [20]. Later, in the 1998 White Paper *Our Competitive Future* the government committed to supporting business by encouraging knowledge-based competition and made specific reference to the roles of universities [21].

The comparative international research performance of the UK was described in the report *Funding Research Diversity* in 2003. The report selected a group of G8 member countries (USA, UK, Canada, France, Germany, Japan, Italy and Russia), other European countries with a strong research culture (Switzerland, the Netherlands, Belgium, Denmark, Finland and Sweden) and four Asia-Pacific research economies (China, Singapore, South Korea and Taiwan). Two generally accepted measures of the influence of scientific research – research publications and their citations – were the comparative indices used. Results showed that UK output of publications had increased over a long period but was 'reaching a plateau.' With only 1% of the world's population, the UK typically produces 9% of the world's scientific publications and over 10% of citations. This proves the strong academic science base in the UK and also makes it second only to the USA. However, although the UK's research performance has increased in real terms, the difference between it and various other countries is diminishing, e.g. Germany is now close behind [22].

In contrast to having a leading place in international academic science output, the interaction between university and industry in the UK has been disappointing. Firstly, total research spending in the UK represents only a small percentage of GDP. In the early 1980s, both the UK and the U.S. spent around 2.4% of their GDP in research but by 2007 their paths had diverged sharply with the U.S. percentage increased to 2.68% of GDP, while UK spending had declined to 1.79% [23][24]. Regarding investment in R&D within higher education, the UK again lags behind, ranking only 14th out of 29 OECD countries. In 2007 it input only 0.46% of GDP into higher education R&D [24].

Secondly, UK industry only accounts for a small proportion of university research funding. The *Lambert Review of Business-University Collaboration* listed five main sources of funding in UK universities between 1990 and 2001. The Higher Education Funding Council (HEFCE) and Research Councils UK (RCUK), a strategic partnership of the UK's seven Research Councils, are both government funded and make up the two largest funding streams. Funding from HEFCE is based on the quality of research as measured originally by the Research Assessment Exercise (RAE) and now the Research Excellence Framework (REF). The RCUK supports universities in the form of project grants allocated to particular researchers in response to future research proposals. In 1990-91, UK industry spent £114m on research in UK universities – equivalent to 6% of universities' total research income. This amount went up to £259m in 2000-01 – 7% of total research income [23]. But the percentage decreased gradually again since then to 4.8% in 2006-07 [24].

However it is difficult to apportion blame for this situation. Some argue that universities should do more to attract industry funding for research while others suggest that businesses should take responsibility for the decline in spending on research and development in the UK. The *Lambert Review of Business-University Collaboration* has drawn up a detailed map of the expenditure of major UK industries on R&D between 1987 and 2001. It suggests that part of the expenditure decline is due to a sharp cut in defence R&D spending, which is similar to other developed economies. Yet, in the UK, many other industry sectors such as chemicals also have low investment while other countries show increases. In an OCED comparison, the UK is close to the bottom of the scale in terms of average annual growth in business R&D as measured by 1995 purchasing power parities dollars [25]. A third factor is that, although UK universities have made significant improvements in knowledge commercialisation activities in the last few years, they still lag far behind their US and German counterparts in relative terms. However, amongst European countries, the UK is a pioneer in assigning ownership of intellectual property (IP) rights to academic institutions. Denmark, Germany and France did not pass legislation for such assignment until the late 1990s, whereas the UK enacted this a decade earlier.

The gap in commercialisation activities between the UK and U.S. is highlighted in HEFCE's HE-BCI Survey 2007-08 [26] – see Table below. The data for U.S. universities is collected by the Association of University Technology Managers (AUTM), which has published a dozen annual reports on US universities' commercialisation activities. Although there are many possible explanations for the differences shown in the Table, it is obvious that U.S. universities receive far greater research investment. Other factors may be that U.S. universities have been engaged in third stream activities (revenue-raising activities alongside the more traditional two streams of teaching and research) for a longer period, and have therefore built more experiences in this area, as well as the more established US venture capital market and other specific industry characteristics.

Table 1 Commercialisation activities in the UK and US, 2007-08

	US AUTM Survey	UK HEIs HE-BCI Survey
Number of institutions	157	160
Total research expenditure (£million)	21,623	4,854
IP income including sales of shares in spin-offs (£millions)	1,039	66
IP income as percentage of total research expenditure	4.8%	1.4%
Spin-off companies formed	502	219
Research expenditure per spin-off (£million)	43	22

4. The Swedish Case

The capability of Sweden in transforming R&D investment into innovation has been questioned for a long time. Edquist and McKelvey formulated the idea of the Swedish Paradox, expressed as:

“A relation between high research and development (R&D) expenditures and a low share of high-tech (R&D intensive) products in manufacturing (and exports) as compared to the average of the OECD member countries.”[27]

Sweden is at the top of the OECD rankings in terms of R&D expenditure and the number of people engaged in R&D in relation to the size of its population [28]. Even in international comparisons the country is second only to Israel in R&D when expenditure is expressed as a percentage of GDP. Having undergone a severe banking crisis in the early 1990s, total Swedish R&D expenditure increased rapidly for the next ten years, and this moved it from fourth place to its current top ranking.

In Sweden, a very large share of R&D spending is accounted for by around ten multinational industrial groups, led by Ericsson and AstraZeneca. Swedish SMEs have not shown high investment in R&D and innovation activities. For example, from 1994 to 1996, Danish SMEs spent 4.9% of their turnover on innovation while in Sweden the spend was just 2.7%. However large Swedish companies scored much higher than their Danish counterparts with spends of 8% compared to 4.8%.

The impact of the business sector on total Swedish R&D expenditure is significant. During the early 1980's and in the 1990's, R&D activities grew considerably and in both these expansion periods, the business sector was the sole contributor. University R&D remained at a stable level, while R&D performance in other organisations also remained quite small. One consequence of the high dependence of Swedish R&D activities on a limited number of large companies has been their susceptibility to economic changes. For example, Ericsson and ABB, two of Sweden's leading funders of R&D, made large cuts to their R&D investments when faced with financial problems in 2003. This caused Swedish business sector R&D expenditure to fall from 3.3% in relation to GDP in 2002 to 3.0% in 2003. To change this situation there is an urgent need to expand investment in SMEs, providing support for their research and development and other innovation activities.

Swedish universities, as the second largest sector in R&D expenditure, focus largely on 'blue-sky' curiosity-governed basic research and have only a modest interest in needs-oriented research as compared to their Finnish counterparts. It is considered that Swedish public resources are heavily allocated to research that 'leads to international publications and to academic careers for the researchers.' Although only accounting for 20% of total R&D expenditure, Swedish university R&D finance still represents a high level in relation to GDP by international standards.

Granberg and Jacobsson (2006 [29]) have reviewed studies on the main features of Swedish university research and report that it is generally the researchers themselves, rather than other potential users, who appear to determine the direction of academic research. Swedish universities also have outstanding academic output in terms of publication in international journals. In fact Sweden's worldwide ranking is second only to Switzerland in terms of the number of publications in internationally acknowledged scientific journals in relation to the size of the country's population. During 2000-1 over 1,600 scientific publications were published per million Swedes, which accounted for around 2% of the world total. Measured as the number of articles in relation to GDP, Swedish research is also world-leading [30]. A further finding was a gap between academic research and industry which may be explained in two ways: on the one hand, government policy has been built on the view that universities should be 'the major performers of research and advanced learning in society', while on the other hand university-industry collaboration – although it has achieved some progress in real terms – is still at a low level and industry only provides very moderate funding for university R&D.

Scientific co-operation between firms and universities has been found to be predominantly restricted to large multinational groups. Goldfarb and Henrekson (2003 [31]) also reported that large Swedish firms discourage incentives for researchers' involvement in entrepreneurship and prefer to keep contacts between each other informal. The authors also compared policies towards commercialisation of university intellectual property in the U.S. and Sweden. Whereas in the U.S. universities usually own the IPRs, in Sweden, academics retain the entire rights of their inventions, according to a law passed in 1949. However, this has not translated into incentives for academics to engage in technology transfer due to a lack of support.

5. Discussions and Conclusions

It has been shown that universities in the three countries described vary in terms of their entrepreneurial performance and, more importantly, the Triple Helix inter-relational roles of government, university, and industry for each are completely distinctive.

Firstly, governments have different levels of influence on universities' activities in each country. The U.S. central government has relatively loose control over American universities, partly due to special features of its political system. Heavy governmental funding on defence and basic sciences, during WWII and the next two decades, improved the research capabilities of many universities. Policy changes from the late 1970s led to a strengthening of university-industry linkages and showed the government's intention to increase industrial applications for scientific research.

In the UK, the government has not consistently supported university involvement in third stream activities since the early 1990s and has decreased expenditure on R&D, which has negatively impacted on university research. Furthermore the award of HEFCE funding based on RAE, and now REF, research assessments tends to encourage pure rather than applied research. While in the US the impact of lower governmental research funding was reduced due to increases in industry funding this has not been the case in the UK as industry research funding has not bridged the gap.

In Sweden, government policies have encouraged universities to focus on primary research and academics have high autonomy as well as ownership of IPRs. This has led to outstanding achievements in terms of patents and publications but it has also stifled the commercialisation of academics' findings as universities have no incentives to provide support.

Secondly, the higher education systems of each of the three countries have different histories, traditions and processes. U.S. universities have a long history of working together with companies. With advantages in scale of funding, they are able to attract top-level researchers and scientists from around the world to produce more world-leading scientific advances. Competition for funding (either from the Federal Government or the business sector) provides impetus for universities to conduct research projects that can contribute to society. Positive attitude towards technology transfer in universities is also significant.

British universities have an outstanding history in terms of output of science publications in international journals. However their participation in collaborative projects with industry has been at a relatively low level, partly due to the funding system in the UK and partly due to British industry indifference towards collaboration. Since the 1980s, UK universities have made significant progress in technology transfer activities and spin-off firms but still lag far behind the U.S.

Swedish universities receive a high level of government R&D finance in relation to GDP by international standards but only a modest amount of industry input. As already mentioned, the Swedish Government have set a clear goal for universities to focus on curiosity-governed basic research. Considering this background, it is not hard to understand why the "Swedish Paradox" exists.

Thirdly, industries have different profiles and attitudes towards university-industry collaboration. U.S. industry has a high dependency on university research in a globalised market and fast-changing technology domain. American business culture welcomes risk-taking and entrepreneurial spirit and this has led to a better environment for SMEs, including spin-off firms from universities. The venture capital market is also well developed in America and supports the development of such small firms.

In the UK industry has not been keen to cooperate on research projects with universities and this has contributed to the low levels of R&D expenditure. Furthermore finance, including banking services, are a predominant industry sector in the UK, whereas in the U.S. high-tech industries have a more prominent role. In the UK greater support for high-tech SME's is needed as it is from such businesses that most university spin-offs emerge.

The same could be said for Swedish industry where the sector is controlled by a limited number of large multinationals like Ericsson and Volvo. Industry contributes only a small proportion of university R&D expenditures and large firms also discourage academics from entrepreneurship, preferring to keep contacts informal.

To conclude, the way in which governments set policies for universities, how industry approaches collaboration with universities and how universities have developed historically all have an important influence on universities' entrepreneurial status. Universities cannot simply be criticised for not being entrepreneurial enough or for not transforming fast enough. The wider context has to be considered and a Triple Helix analysis for each country can be used to show advantages and disadvantages in the three sectors as well as their inter-relationships. This may facilitate policymakers trying to encourage university entrepreneurship.

Innovation capabilities of companies depend on a variety of factors, such as R&D expenditure, knowledge management processes, culture, organization structure, management systems etc. In search of new, innovative ideas and solutions the undertakings tend to co-operate more and more often also colleges, universities and other public research institutions, in which research is actually one of their basic missions. If once the purpose and the pinnacle of scientific research work of scientists, employed at the universities and research institutes, was publication of research results in scientific magazines and presentations at the conferences (result of basic research), today the results of research are conveyed through patents, trademarks and other forms of commercial application to a much greater extent. In the research, presented in this paper, our aim was to identify the strongest factors influencing the patent activity of the Slovenian researchers, employed at the universities and research institutes as the organizations of which the fundamental purpose and mission is research and scientific work as the source of innovations. We asked the researchers which factors either as incentive or as obstacle influence most their scientific research work and in this regard the patent activity in different phases of research process. Based on the results obtained through the research we can conclude that the Slovenian universities and research institution have still a lot of work to do in the field of increase of efficiency of the scientific research activity. However obstacles, which we have recorded in the research, are not to be understood and taken only as problems, preventing universities and other research organisation greater commercialisation of the scientific-research achievements and know-how, but also as a new opportunity, which is offered to them in this field.

Keywords

Innovation and R&D, obstacles to innovation, patent activity, university research

1. Introduction

Business performance and innovation are believed to be closely linked. In general there is clear evidence that innovation play a crucial role to long term profitability and growth in firms [1] [2] [3] [4] [5]. Innovation abilities constantly fuel and renew competitive advantage as firms grow and mature [6] [7]. There is little dispute that innovations are important for prosperity of firms, industries and society. Innovation capabilities of companies depend on a variety of factors, such as R&D expenditure, knowledge management processes, culture, organization structure, management systems etc. and on people. People are the main source of innovations within companies and other organizations. Studies show that a large majority of all innovations are created by company employees [8]. Employees' innovation behaviour is therefore crucial for companies, that wish to increase their business

performance and is determined by both the employees' proactivity and organization's desire for employee innovation behaviour [9].

Considering the aforementioned it is of the key essence for the undertakings to establish an appropriate environment within the undertaking in order to encourage innovation or to implement measures increasing innovation of employees. Thereby, they should pay attention to the fact that encouraging innovation and only innovation resulting in inventions, is not sufficient. Innovation in an undertaking has to be such that inventions are also efficiently implemented in the undertaking (e.g. if the invention improves work processes, there should be energy savings or material savings or similar) or commercially utilized. Innovation consists of successfully implementing creative ideas within an organisation [10]. In addition to systems of encouragement and implementation of the innovation within an undertaking, the outsourcing of inventions is becoming more and more important. The undertakings tend to cooperate with colleges, universities and other public research institutions, in which research is actually one of their basic missions.

If once the purpose and the pinnacle of scientific research work of scientists, employed at the universities and research institutes, was publication of research results in scientific magazines and presentations at the conferences (result of basic research), today the results of research are conveyed through patents, trademarks and other forms of commercial application to a much greater extent.

In the research, presented in this paper, our aim was to identify the strongest factors influencing the patent activity of the Slovenian researchers, employed at the universities and research institutes as the organizations of which the fundamental purpose and mission is research and scientific work as the source of innovations.

2. Changed role of universities and research organisations

Traditionally, the research at the universities and other research institutions has been distinctively scientific, i.e. directed toward discovering important scientific achievements and less intended for solving specific issues, which the undertakings, economy and society face in practice. This trend has been changing more and more. The scientific research work has been more and more application focused also at the universities and other research organisation and there is more cooperation with the economy. We can say that the gap between creating a scientific achievement and its applicability in practice is narrowing. Consequently, the number of academic inventions, presenting immediate commercial potential, is growing. Thus, the university know-how presents new source of industrial inventions. However, it is true that the problem of absence of links between the university and economy remains since research results are far more often recorded than the practical use of this knowledge in companies. Nevertheless, the recent researches in the Western World detect changing roles of universities and institutes. The researches at universities are more market-oriented; furthermore, the organisation of universities and institutes has been changing into the direction of »undertaking organisation«.

The changing roles of universities and institutes reflects in the entire research process – from the initial idea to the dissemination and consequently implementation of results. As aforementioned, today the pinnacle and the purpose of scientific research work is no longer only publication of research results, but the universities and institutes are more and more aware of possibilities, importance and opportunities, arising from different forms of commercial application of research results. To certain extent, the researchers attribute these changes to the competitive manner of financing and to some extent to the change of teaching process at universities, i.e. from learning to researching. Some [11] however, state that the adjustment of universities is a consequence of greater and greater competitiveness among universities. It is interesting information that there are more and more research institutions deciding to patent their inventions. In 2001 in Slovenia there were five patents awarded to the Slovenian researchers, registered at the ARRS, while in 2005 they were awarded 69 patents.

3. Research on factors, influencing the patent activity of the Slovenian researchers

For the purpose of our research the patent process has been, first, divided into three separate phases, i.e. phase of discovering knowledge, phase of dissemination of knowledge and phase of application or transfer of knowledge (commercialisation). We have divided the factors, influencing the patent process, into internal (internal satisfaction, acknowledgement of peers, prize money etc.) and external

(state, culture of work, entrepreneur thinking etc.). Internal factors can be further on divided into the factors, influencing the scientist, and factors, influencing field of work or research. Into the first subgroup fall motivators (positive factors) such as internal satisfaction of the scientist, acknowledgment of peers or academic colleagues and prize money. In this group there are also obstacles (negative factors), which obstruct the scientists' way to the desired results, represented by time (spending of own, free time) and costs (own costs), which a research demands. The factors (motivators and obstacles) influencing the field of work and research are more specific and differ materially among professions.

The following step in our research was drafting a questionnaire for the comparison of patent activities of the Slovenian researchers whereby we assisted ourselves with the questionnaire, developed within the questionnaire of a wider European research of patent activity - PATVAL. The questionnaire has been divided into four separate sets according to the content, namely: inventor's process, inventor's benefits, road from an idea to an invention, value and effect of the patent. On the sample of the Slovenian researchers, who have registered at least one patent in the data base COBISS, we have conducted the quality research on scientific research activity in Slovenia with the emphasis on patent inventions and commercialisation of patents.

The invitation for participation in the research has been submitted to 338 researchers, for which it was possible to obtain contact details (there were 476 registered researchers in the data base COBISS, who had at least one patent on 24 February 2010) and 72 valid questionnaires have been returned. The average age of respondents in the research amounted 42.8 years, among which there were 56 men and 16 women.

4. Research results

In order to reach results regarding the impact of certain factors on the patent activity of Slovene researchers, the first part of the questionnaire, as Table 1 illustrates, examined the employment status of the participants in the time of innovation process that concluded with patent application. Almost half of participants were employed in companies (48,6 %), then at university (26,4 %), research institutes (16,7 %) and public entities (4,2 %).

Table 1 Employment status of the participants

		Frequency	Percent	Cumulative %
Valid	Employed in company	35	48,6	48,6
	Employed at university	19	26,4	75,0
	Employed at research institute	12	16,7	91,7
	Employed in public entity	3	4,2	95,8
	Other	2	2,8	98,6
	Self-employed	1	1,4	100,0
Total		72	100,0	

Table 2 below illustrates the patent activity of participants. It indicates that almost half of the participants (45 %) registered one patent and 54 % of participants registered more than one patent. All together, 72 participants filled 180 patent application, meaning that the average of patent applications per scientist is 2.5 application. The comparison of sub-samples, formed based on the criteria of employment, has shown that the average of patent application per employee is half lower at universities and institutes compared to the average of applications of researchers, employed elsewhere. The average patent applications per researcher, employed at universities and institutes, are 3 applications/researcher, while the average of patent application per researcher elsewhere is 6 applications/researcher.

Table 2 Number of patent applications

	Frequency	Percent	Cumulative %
1	33	45,8	45,8
2	10	13,9	59,7
4	8	11,1	70,8
3	6	8,3	79,2
5	5	6,9	86,1
6	2	2,8	88,9
7	2	2,8	91,7
8	1	1,4	93,1
9	2	2,8	95,8
14	1	1,4	97,2
17	1	1,4	98,6
20	1	1,4	100,0
Total	72	100	

From the responses to the question of commercialisation of patents it follows that almost a fifth of respondents (16.7% that is 12 respondents) has not even tried to commercialize their invention, for which they filed a patent application, whereby 34 respondents replied affirmative to the question on the actual applicability of the patent application for commercial or industrial purposes (in the widest sense).

Table 3 The attempts to commercialize the invention

	Frequency	Percent	Valid %	Cumulative %
Valid	0	12	16,7	16,7

The most important part of our research were questions on factors which influence most their work either as a motivation or as obstacles in different phases of research process. In the period of generating the idea and research, "the satisfaction of working what I like" and "curiosity" were on the first place among the motivators. On the other hand, i.e. factors, which hinder the work of researchers to the greatest extent, are reporting manner (on results and means use), constraint and the pressure of the institutions and administrative and bureaucratic support of institution. As motives, which deviate most positively in case of employed at universities and institutes compared to others, the following are expressed: »Possibility of future references«, »Possibility of publication activity« and »Ensuring salary through research projects«. The employed at universities and institutes see a much stronger obstacle compared to others in »technical«, »professional« and »administrative and bureaucratic« support of their home institution.

During the period of patenting and invention the work of researchers has been most motivated by the references, gaining self-value and good connections with the industry; thus, mostly personal factors. The most restrictive factors were: knowledge of writing the patent application, access to capital market and regulation of relations between the innovators and institutions with regard to awards, arising from patents. The employed at universities and institutes state »Restriction of publishing before the publication of the patent« as the greatest obstacle. The results also show that universities and institutes support their researchers essentially worse from the administrative perspective compared to the economy. The employed at universities and institutes differ in a positive way compared to others in the category of »Marking of the patent in Cobiss«, »Gathering points for habilitation« and »References«, which is not surprising.

During the implementation of the patent in practice or its commercialisation the researchers (the entire sample) were most motivated by pleasure to participate and work with the economy and practice, presentation of knowledge and personal work in industry and realisation of own inventions in industry. Among those factors, which were the most hindering, were (besides the small size of the Slovenian market) also: financial pretentiousness, access to capital market and initial capital. Relating to the differences between the employed at universities and institutes and others the least motivating factor among the employed at universities and institutes was »Founding of own company«, »Realisation of knowledge in the form of cooperation with industry«, »Realisation of research capacities«, »Transfer of knowledge between the educational sphere and economy«, »Sale of patents to multinational companies«. The desire to commercialize academic know-how and opportunities for that is obviously much smaller by the researchers at universities and institutes compared to others.

The main reason for patenting (whole sample) is in the order: commercial exploitation (acquisition of exclusive right for economic exploitation of the invention), prevention against imitations (protection of present and future inventions with patenting the »coincidental inventions«) and reputation (patents as element of assessment of successfulness (evaluation) of inventors or research group).

At the end we took a closer look on relation among different motives for patenting an invention. Based on correlation analysis we can conclude two inter-related groups of motives and third independent motive.

In the first group there are significant and strong relations among three variables:

- E5_1 Commercial exploitation (acquisition of exclusive right for economic exploitation of the invention)
- E5_2 Licensing (acquisition of exclusive right for licensing the invention for generating licence income)
- E5_3 Cross licensing (improving own negotiation position in the trading with patent rights with other companies)

In the second group there are significant and strong relations among five variables:

- E5_3 Cross licensing (improving own negotiation position in the trading with patent rights with other companies)
- E5_4 Prevention against imitations (protection of present and future inventions with patenting the »coincidental inventions«)
- E5_6 »Blocking patents« (prevent that others would protect similar inventions)
- E5_7 Preventions to be sued by others for application of the invention, created by us, but patented by others
- E5_9 Time (we have filed the patent application in order to "buy" time for preparing the European patent application or to prepare successful commercialisation)

Third motive represents the variable, which is only weakly related or non-related to other variables:

Reputation (patents as element of assessment of successfulness (evaluation) of inventors or research group).

First group of motives, which lead the Slovenian research toward patenting, is strictly commercial: economic exploitation of results of invention. Second group of motives is also of economic nature, but more indirect – the author does not expect from the patent direct economic benefit, but it should strengthen his "strategic market position" – by blocking competition, decreasing risks, related to intellectual property and gaining time for competitive positioning. Both motives show distinctive »entrepreneur« relation of researchers to results of their work. The last motive – reputation – is, however, related to public service, performed by most of researchers and their role in society: patenting has a greater reputation in this case, visibility among the professional public and last but not least easier access to public means, in case of which previous achievements, including patents,

present one of the criteria for selection. These findings present an interesting basis for a more in-depth research and analysis in the future.

5. Conclusion

Inventiveness is no longer important only in the economy, but presents an important activity also at universities and other research organisations. The pinnacle of scientific research work is no longer only publication of results but also economic exploitation of these results. Innovation and patenting of inventions is becoming more and more important activity of universities and research institutions as such and the income from sold patent license presents more and more important item in their accounting items and financial reports.

In our opinion the results of this research are very important for drafting and applying research politics at universities and other research organisations especially in the part in which we identify factors, that have shown to be most restrictive in the procedures from birth to commercialisation of an invention. Based on recorded obstacles these institutions will be able to direct their policies and measures into removing or lessening these obstacles in the future, which will contribute importantly to a greater effectiveness of scientific research work.

First the result, according to which the average of patent application per employed is half lower at universities compared to average of applications elsewhere employed researchers, has to be stressed. These results can be explained by the fact that research at universities is still primarily focused toward publication of scientific achievements, which are basis for promotion in the academic career and not into commercial exploitation of the academic know-how. The research has shown also other important differences between the researchers, employed at universities, and those employed in other research organisations (in our case these were mostly research institutes).

In the phase of generating the research idea the most hindering factor turned out to be "technical, professional and administrative support of the home institution". The employed at universities and institutes see much greater obstacle compared to others in the reporting manner (on results and means use), constraints and the pressure of the institutions and administrative and bureaucratic support of institution. During the patenting and invention the most restrictive factors turned out to be: writing a patent application, access to capital market and regulation of relations between the inventors and institutions with regard to awards arising from patents. During the period of implementation of a patent in practice the most hindering factor turned out to be financial pretentiousness, access to capital market and initial capital. With regard to the differences between the employed at universities and institutes and others the least motivating factors among the employed at universities and institutes are »Founding own company« and »Realisation of know-how in cooperation with industry «.

Based on results, acquired through the research, we can conclude that the Slovenian universities and research institutions have still a lot of work to do in the field of the increase of scientific research activity. Obstacles, which we have recorded in the research, are not to be understood and taken only as problems, preventing universities and other research organisation greater commercialisation of the scientific-research achievements and know-how, but also as a new opportunity, which is offered to them in this field.

Human capital – a driving force of regional development: challenges and possibilities in Latvia

Daina Znotina¹

¹Faculty of Social Sciences, University of Daugavpils, Daugavpils, Latvia,
Daina.Znotina@inbox.lv

The article deals with the tendencies of human capital development and its effective use in the regions of Latvia, where the greatest attention is paid to Latgale region. The author evaluates and analyses the situation to search for the common and different as regards the use of the human capital in regions having low and high socio-economic development indicators. As positive examples the author mentions several activities, which at the moment are implemented for increasing the value of the human capital, as a result of which the region would become a more attractive place for inhabitants and investors. There have been searched several solutions for the development of regions by using the available human capital for preservation and elimination of the human capital migration in order to attract human capital to regions with lower socio-economic indicators.

Keywords

Human capital, human resources, Latvia regions, regional development.

1. Introduction

The development of a region or a state cannot be explored without effective involvement of human capital. Human capital is a set of individual's skills and abilities affecting one's potential for economic and social activity [1]. It includes person's professional knowledge, social skills, values, attitude, talents, experience, health and many other features. The competitiveness and wealth of industrial society is defined by the means of manufacturing and other tangible values, whereas the main source for wealth and development in society, which is based on knowledge, is human capital. One of the founders of the human resources concept – Gary Becker – describes it in such a manner: "New technological advances clearly are of little value to countries that have very few skilled workers who know how to use them. Economic growth closely depends on the synergies between new knowledge and human capital, which is why large increases in education and training have accompanied major advances in technological knowledge in all countries that have achieved significant economic growth" [2]. This is the reason why economy, based on knowledge and innovations, is a significant indicator in the development of human capital.

Human capital cannot create values *per se*; it cannot ensure social and economic development, i.e., an individual does not act isolated from all the society. The economic value of the human capital of each individual, one's motivation and possibilities for developing and using this capital to make goods, which can be sold, is defined by the demand in the society, state, world. In order to evaluate the human capital it is essential to clarify what skills are demanded in the particular social context.

The aim of the research – to explore the correlation between the human capital and regional development evaluating the challenges and opportunities.

The tasks of the research:

- to explore the socio-economic situation in Latvia regions and its impact on regional development;
- to conduct a research on the Latvia regional development policy in the context of human resources and human capital development;
- to identify challenges and opportunities for the human capital of Latvia regions in the long-run.

Research methods:

- economic analysis;
- content analysis.

2. Research of the socio-economic situation in the regions of Latvia

The territory of the Republic of Latvia is 64 559 km²; according to the information of the Central Bureau of Statistics there have been 2.235 million inhabitants in Latvia on October 1, 2010 [3]. Latvia is divided into 5 regions: Riga, Kurzeme, Zemgale, Vidzeme, and Latgale (see Fig. 1).

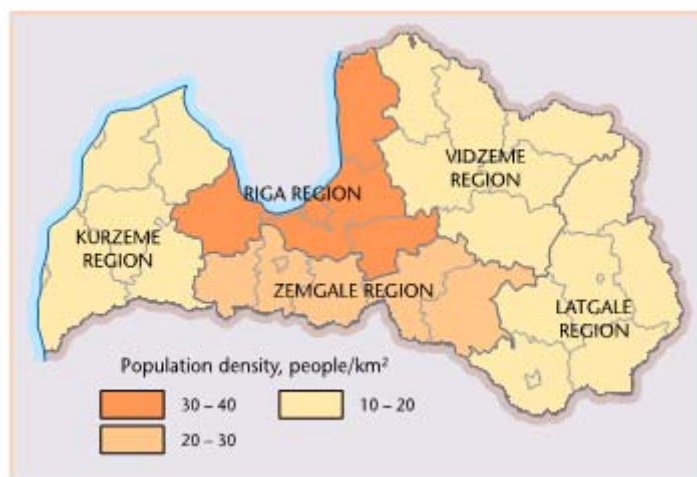

Figure 1 Latvia planning regions territories [4]

As regards the area (see Table 1) Riga region is the smallest one – it covers 16.2% of the total area of Latvia, but as regards the number of population it is the most densely populated one as almost a half (48.6%) of the inhabitants of Latvia live in Riga region; however, as regards the area Vidzeme region is the largest one – 23.6 %, but it has the lowest number of population – 10.4%. Thus, it can be concluded that the regions of Latvia are unequally populated, but the large number of population in Riga region can be explained by the location of the capital city in this region. 31.5% of the inhabitants of Latvia live in the capital city Riga [4;18].

Table 1 Area and number of population in the planning regions in the beginning of 2010
[Data from 4;17 summarized by the author]

Planning region	Area, km ²	Proportion of area, %	Population	Proportion of population, %
Riga region	10 435	16.2	1 099907	48.6
Vidzeme region	15 246	23.6	234 005	10.4
Kurzeme region	13 596	21.1	300 282	13.3
Zemgale region	10 733	16.6	280 494	12.5
Latgale region	14 549	22.5	339 965	15.2
Total in Latvia	64 559	100.0	2 254 653	100.0

Latvia has significant differences in regional development. Considering GDP per capita and assuming that the average indicator in the state is 100% in the period of time from 2003 to 2007 (see Fig. 2), it can be seen that in Riga region it exceeds the average indicator and fluctuates within the range from 138.4% to 143.5%; however, in Latgale region in the respective period this indicator significantly lags behind the average indicator and is in the range from 46.4% to 53.4%.

Due to the economic crisis GDP in Latvia, including regions, significantly reduced; the most crucial changes were observed in such branches as construction (drop by over 30 % in comparison to 2008), trade and manufacturing industry (drop by over 25% in each), transport and communications industry

(drop by over 15%). In the European Union in 2008 GDP increased on average by 0.8% in comparison to 2007 [4;27].

Figure 2 Dynamics of GDP per capita in planning regions in 2003-2007 in actual prices, % in comparison to the average indicator in the state [4;29]

As regards the forms of business, micro enterprises (up to 9 employees) are dominating in Latvia, small enterprises (10 to 49 employees) and medium-sized enterprises (50 to 249 employees), comprising 99.7% [4;33] (2008) of all economically active units. Large enterprises (more than 249 employees) are mostly concentrated in Riga region – 297 enterprises.

The number of individual businessmen and business entities per 1000 inhabitants is used as a significant indicator of territorial development. In 2008 on average in Latvia this indicator was 30.8%, the highest indicator was in Riga region– 43.5%, the lowest indicator was in Latgale region – 15.4% [4;35].

In 2009 in Latvia there were employed 986.7 thousand people (in the age group 15-74), including 504.0 thousand or 51.1% in Riga region, in Latgale – 141.5 thousand or 14.3%, in Kurzeme – 128.4 thousand or 13.0%, in Zemgale – 118.8 thousand or 12.0 % and in Vidzeme region – 94.0 thousand or 9.5% [4;36]. The number of employed people in Latvia is reducing. In the period of time from 2005 to 2009 has decreased by almost 50 thousand.

The main areas providing workplaces in all regions of Latvia are trade and services (in 2008 on average in the state there were employed 63.1%), the second largest area providing employment is industry and energetics (on average 17.6%) and the third largest area is construction (on average 11.4%) [4;36].

One of the basic indicators characterizing the economic development and population activity in the state and planning regions is the level of employment. In the period of time from 2005 to 2008 in all regions the level of employment increased, but in 2009 a rapid decline started. In 2009 the average level of employment in Latvia (it is calculated as a proportion of the employed persons in percent from the total number of populations in the age from 15 to 74) was 55.2% – considerably lower than previous years. Among regions in 2009 the highest employment level was in Riga region – 57.9%, a quite high level in Kurzeme region – 54.6%, the lowest level in Latgale region – 50.8%. Eurostat uses a different age group 15-64 years to calculate a level of employment. According to these calculations in 2008 the level of employment in Latvia was 68.6%, on average in the EU – 65.9%, in 2009 in Latvia – 60.9%, on average in the EU – 64.6% [4;37].

The level of unemployment (proportion of registered unemployed persons from the number of persons having work capacity) is used as a basic indicator characterizing the vivacity of national economy, availability of human resources and social situation in the territories. The level of unemployment in the period of time from 2005 to 2010 can be divided into 2 stages: 1) up to 2008 the level of unemployment decreased on average in the state: in the beginning of 2005 it was 6.2%, in the beginning of 2008 – 3.5%, 2) since 2009 it has rapidly increased from 5.1% in the beginning of 2009 to 12% in the beginning of 2010. In regions the level of unemployment and its fluctuations are close to the average national indicator, except Latgale region, where the level of unemployment has been high fluctuating in the range from 6.6% in the beginning of 2008 to 16% in the beginning of 2010 [4;38].

As regards employment the discrepancies among planning regions slightly decreased till 2008, but since 2009 they have increased again; overall, it can be considered as the main negative social factor

for discrepancies in territorial development. The rapid recession of economy has influenced negative processes in the labor market. According to the labor market development forecast [5] positive tendencies in the increase of the level of employment can be expected later than the economic growth. The forecasts show that the average level of unemployment in the period of time from 2010 to 2015 will remain high 10-13%.

In the period of time from 2003 to 2009 the average salary has changed due to two main reasons: 1) changes in economic activity and 2) demand for labor force. In the beginning of 2009 the average gross salary per month was 659 EUR [4;41], which is 3.9% lower than in 2008. The net average salary per month was 488 EUR was in 2009.

Thus, it can be concluded that there significant differences in the distribution of gross domestic product among the regions of Latvia, number of economically active individual businessmen and business entities, structure of employment, indicators of unemployment as well as number of employees and level of salaries. An individual and his work are the basis of these indicators. As regards all indicators mentioned above the highest results are observed in Riga region, but the lowest – in Latgale region. Such discrepancies should not be present within such small territory as Latvia. It is essential to find solutions to reduce regional differences. Otherwise the human capital flows from regions having lower socio-economic indicators to other regions having a higher level of development. It makes the regions having lower socio-economic indicators become weaker, but the regions having higher indicators – stronger. The government and its policy, including regional development policy, to a large extent are responsible for preservation of human resources in regions, formation of human capital, and its effective use.

3. Research of Latvia regional development policy in the context of human resources and human capital

As regards planning of Latvia development there is worked out a medium level strategic planning document “National Development Plan of Latvia 2007-2013”. It defines the main trends and tasks of development in Latvia to reach the aim of growth – gradual increase of life quality. *Knowledge* is mentioned as the main resource for growth in the National Development Plan of Latvia. The plan emphasizes that neither Latvian natural resources, nor cheap workforce will not be able to serve as the main resource for growth in the long-run. Knowledge and wisdom, their skilful and purposeful use facilitates the quality of labor force, use of capital and development of technologies. Knowledge management, their coordinated and directed creation, accumulation, dissemination and application as a complex process in the state and society are the basis of economy and social life [6].

According to the National Development Plan of Latvia 2007-2013 each planning region has worked out a medium-term regional development program. The author has analyzed regional development programs to identify the role of human capital and human resources in the regional development plans.

Riga Regional Development Program till 2011 [7] defines vision to become a driving force of Latvia development, a competitive European scale metropolitan region having an equally high level of life quality and attractive environment for business and investments in the whole territory. Riga region has put forward 5 aims in its development: 1) high quality and development of human resources, 2) convenient international and local access to the region, 3) competitive national economy, diverse and active business, 4) life environment of high quality, 5) increase of the role and influence of Riga region on the national and international scale. In order to reach the first aim there are put forward the following fields of action: 1) improvement of the demographic situation, 2) development of health, social, education and culture infrastructure and services, 3) better housing provision, 4) creation of favorable pre-conditions for employment, 5) formation of information society, 6) creation of civic society.

Kurzeme Regional Development Strategy till 2013 [8] defines the following regional priorities: 1) to stimulate and diverse regional economy and develop manufacturing, 2) to improve the possibilities provided by regional multimodal transport and infrastructure, 3) to invest in human resources and develop culture of innovations, 4) to create high quality life environment, preserve natural environment and facilitate development of remote areas. Taking into consideration regional priorities to invest in human resources and develop culture of innovations there are put forward the following aims: 1) to improve the quality and diversity of education and training as well as ensure access to lifelong learning, 2) to develop business support infrastructure, stimulate business and facilitate use of innovations, 3) to stimulate employment and increase competitiveness of regional workforce.

Vidzeme Planning Region Development Program 2007-2013 [9] has defined the following strategic priorities: 1) development of infrastructure and services, 2) economic development, increase of competitiveness and orientation to knowledge-based economy, 3) development of human resources and increase of employment, 4) rural development. In order to implement the second and the third priority there are put forward the following fields of action: 1) provision of qualitative education and development of innovations, 2) creation of a direct link between knowledge-based manufacturing and business. The strategic priorities are set taking into consideration the needs of a specific region and balance between industries creating resources and using resources.

Zemgale Planning Region Development Program 2008-2013 [10] has defined a strategic aim – ensuring life quality in Zemgale. The following priorities have been put forward: 1) an educated, creative and competitive individual, 2) development of knowledge-based economy, 3) qualitative life environment. For the first priority there are set the following fields of action: 1) development of human resources, 2) creation of information-based society, 3) creative of active civic society. For the second priority there are set the following fields of action: 1) development of business environment, 2) forming public understanding about the role of innovations for increasing the level of welfare.

Latgale Planning Region Program 2010-2017 [11] has defined the following strategic aims: 1) to facilitate stopping negative demographic and migration processes and preserving at least 320 thousand inhabitants in the region, 2) to increase the proportion of the private sector in creating the added value in the region up to 76% and increase the proportion of a high added value, 3) to increase the income of inhabitants in the region reaching 40% of the EU average gross salary. There are put forward the following priorities: 1) connections – creation of transport and communications infrastructure in Latgale region, 2) skills – support to increase the knowledge and practical skills of individuals, companies and authorities to facilitate economic competitiveness of Latgale region and employment and learn enterprise and initiative, 3) wise management – measures to improve administrative and project capacity of public and municipal authorities, as well as quality and availability of public services, 4) effective companies – actions to increase business and economic activity in the region.

Assessing the strategic aims and priorities put forward in the regional development plans it can be concluded that in all regions human resources and human capital are among the priorities of regional development. It coincides with the standpoint of Latvia National Development Plan 2007-2013 – individual-centered Latvia growth model. In regional development plans of Riga region and Zemgale region as the main strategic aim there are mentioned human resources and human capital, their quality, competitiveness and development. In Kurzeme and Vidzeme regions as the main aim there is put forward the development of the branches of national economy, in Kurzeme region – development of manufacturing, in Vidzeme region – development of services. Investments in human capital have the third place among strategic priorities in these regions. However, in Latgale region preservation of human resources is the main aim put forward. Currently, when the period of implementing these medium-term plans mentioned above is approaching to its end (in 2013), it is envisaged that it is difficult to reach the aims put forward [12] due to the following reasons: 1) emigration of population, 2) aging of society and increase of demographic burden.

4. Challenges and opportunities for human capital of Latvia regions in the long-run

Currently in Latvia the main challenges put forward to the Latvian human capital in the long-run is based on the demographic situation are: 1) natural increase of population, which has been negative since 1991 [13] and 2) negative migration balance as comparatively more individuals emigrate than immigrate. The Sustainable Development Strategy of Latvia till 2030 [14] also envisages that in 2030 the society of Latvia will significantly differ from the one currently living in Latvia. It is envisaged that till 2030 the number of inhabitants will not exceed 2 million. A majority of them will be older than 45, but already in 2020 the number of individuals of pension age will exceed the number of children and youth in the age till 18. Forecasting the number of inhabitants in the long-run, currently there is reason that the situation will change after 2030, vice versa, the aging of the society in Latvia will continue (see Fig.3).

Figure 3 Forecast of the number of inhabitants in Latvia in various age groups in the beginning of 2015-2050 according to the basic version of forecasts [15]

The basic standpoints of national and regional development policies worked out up to now envisaged equal and balanced development of regions; however, in the future it can be difficult to implement. It is foreseen that the number of inhabitants will reduce in the regions of Latvia, except Riga region. The larger the distance from the capital, the more the average age of population will increase. It should be taken into consideration that the aging dynamics of Latvian population is more rapid than on average in the EU states, and at the moment there is already observed decrease of the number of children in several age groups [16]. Aging of society creates new challenges, for example, for the educational system, changes of household consumption, work productivity and changes in the workforce structure. As regards the use of human capital Latvia is one of the leading countries in Central and Eastern Europe. Unfortunately, in case of Latvia high employment does not mean higher productivity of human capital [17].

Solutions to these challenges are also searched in the Sustainable Development Strategy of Latvia till 2030. Essential changes in the educational system are envisaged: reduction of the number of schools, increase of lifelong learning development. Changes are also envisaged in the social sphere: pension system, increase of the number of old people's homes and their maintenance. There must be found solutions how to use effectively the human capital which will be available in remote areas, but it shall be taken into consideration that they will be older people. One of the solutions could be remote employment of these people in e-environment. Thus, there should be foreseen opportunities for population to have active old age and developed health care system.

On the other hand, there is a possibility that regions with rural territories located further from cities will not become underpopulated. In Europe there is observed a tendency that some competitiveness-oriented rural areas attract prosperous pensioners as well as well-paid self-employed people from overpopulated cities [18]. There is observed some 'exchange' of inhabitants – less prosperous rural inhabitants move to adjacent cities, but more affluent inhabitants 'take their place'. Higher demands for life quality and solvency attract better and more expensive services and thus let maintain and develop the existing infrastructure [19].

The researches conducted in other countries as well as modeling show that the negative impact of aging on the pension system can be solved in three ways: increasing the contribution rate, reducing pension-salary substitution rate or increasing contributions of workforce. The first solution makes workforce more expensive, facilitates unemployment and reduces competitiveness of companies. The second solution lowers the life standard in households and promotes poverty. From the point of the sustainability of the labor market the third solution is easier to be accepted in society [19]. The author considers that the third solution would be the most suitable in the situation of Latvia.

Developing medium-term national and municipal development plans these challenges and possible solutions shall be envisaged to make the development policy by using resources effectively and foreseeing possible changes in the long-run – in the educational system, health care system, labor market and social sphere.

5. Conclusions

- The development of a region or a state cannot be explored without effective involvement of human capital. Human capital is a set of individual's skills and abilities affecting one's potential for economic and social activity. An essential factor for development of human capital is economy based on knowledge and innovations.
- The territory of Latvia is divided into 5 planning regions: Riga, Kurzeme, Zemgale, Vidzeme, and Latgale. The regions of Latvia are unequally populated. The large number of population in Riga region can be explained by the location of the capital city in this region.
- In Latvia there are observed discrepancies in regional development. They are observed in the distribution of the gross domestic product among the regions of Latvia, number of economically active individual businessmen and business entities, structure of employment, indicators of unemployment as well as number of employees and level of salaries. An individual and his work are the basis of these indicators. As regards all indicators mentioned above the highest results are observed in Riga region, but the lowest – in Latgale region. Riga region is a driving force of development in Latvia, economy and development of other regions are to a large extent dependant on it.
- If regional discrepancies are observed in the long-run, human capital flows away from regions having lower socio-economic indicators to other regions having a higher level of development. It makes the regions having lower socio-economic indicators become weaker, but the regions having higher indicators – stronger. The government and its policy, including regional development policy, to a large extent are responsible for preservation of human resources in regions, formation of human capital, its effective use.
- Assessing the strategic aims and priorities put forward in the regional development plans it can be concluded that in all regions human resources and human capital are among the priorities of regional development. It coincides with the standpoint of Latvia National Development Plan 2007-2013 – individual-centered Latvia growth model.
- In regional development plans of Riga region and Zemgale region as the main strategic aim there are mentioned human resources and human capital, their quality, competitiveness and development. In Kurzeme and Vidzeme regions as the main aim there is put forward the development of the branches of national economy, in Kurzeme region – development of manufacturing, in Vidzeme region – development of services. Investments in human capital have the third place among strategic priorities in these regions. However, in Latgale region preservation of human resources is the main aim put forward. It is envisaged that it is difficult to reach the aims put forward due to the following reasons: 1) emigration of population, 2) aging of society and increase of demographic burden.
- The main challenges put forward to the Latvian human capital in the long-run is based on the demographic situation are: 1) negative natural increase of population and 2) emigration. It is envisaged that till 2030 the number of inhabitants will not exceed 2 million. A majority of them will be older than 45, but already in 2020 the number of individuals of pension age will exceed the number of children and youth in the age till 18.
- Balanced development of regions in Latvia will be impeded in the long-run because it is foreseen that the number of inhabitants will reduce in the regions of Latvia, except Riga region. The larger the distance from the capital, the more the average age of population will increase.
- Aging of society creates new challenges. Essential changes in the educational system are envisaged: reduction of the number of schools, increase of lifelong learning development. Changes are also envisaged in the social sphere: pension system, increase of the number of old people's homes and their maintenance, household consumption structure.
- Developing medium-term national and municipal development plans these challenges and possible solutions shall be envisaged to make the development policy by using resources effectively and foreseeing possible changes in the long-run – in the educational system, health care system, labor market and social sphere.
- Provision of opportunities for lifelong education and training is an essential precondition for the development of knowledge-based economy in regions. Increasing the quality of education and training the enterprises in regions would get more qualified and competitive workforce having the necessary skills.

Serious games and virtual worlds in the context of entrepreneurial skills development

Albena Antonova¹, Roumen Nikolov²

¹Faculty of Economics and Business Administration, Sofia University, Sofia, Bulgaria, a_antonova@fmi.uni-sofia.bg

² UNIBIT, Sofia, Bulgaria, nroumen@abv.bg

Nowadays business environment is becoming increasingly complex. Globalization, resource scarcity, climate change, demographic issues, and economic crises are expected to become part of the daily agenda for the next generations. In these new realms, entrepreneurial education and training has to build a new set of skills and competences, enhancing future entrepreneurs to run organizations and set goals in even more challenging environment. The present paper aims to research the new opportunities, provided by serious games (SG) and virtual worlds (VW) for development of business and entrepreneurial skills and their added-value for education of future entrepreneurs. In the first part of the paper there will be outlined some of the emerging concepts for development of entrepreneurial and business skills. Then, there will be made a short analyzes of SG and VW characteristics and components for entrepreneurial education and training. In the last part of the paper there will be analyzed some entrepreneurial- and business-SG examples and discussed the key benefits of SG and VW for entrepreneurial training.

Keywords

Entrepreneurship skills, management skills, serious games, virtual worlds.

1. Introduction

Managerial and entrepreneurial skills and competences have been admitted as important not only for professional business experts, but also for wider groups of professionals. The role of entrepreneurship and SMEs for economy ecosystem is recognized for triggering employment, innovations and GDP formation. Entrepreneurship became part of the public priorities and is promoted on various instances. With emergence of new technologies and innovations in communication and business services give opportunity for wider group of people to create companies, lowering start-up and operating costs. Moreover, many professionals become free-lancers, trading with their own knowledge and competences. Thus management and leadership skills and competences should be examined in a broader form, taking into account multiple applications and contexts of entrepreneurship. As a consequence creating and building managerial and leadership skills and competences play increasing role within the knowledge-based society.

While games have been largely used in education since centuries, nowadays computer games propose new challenges and opportunities for high-order training. On the other hand, Game Theory was explored in economics and business as a tool for process optimization and mathematical simulations of models. However, the main purpose of Game theory is to discover and study mathematical models, that mimic real economic situations, finding optimal behaviour and equilibrium between rational players [1].

Serious games and virtual worlds emerged recently as promising new ICT tool for development of complex and soft competences and provide unique opportunity for people to learn in safe and amusing environment. With development of new technologies, hardware applications and visual effects, computer games increasingly gain popularity among different age groups and become complex, immersive and sophisticated entertainment platforms. Moreover, in the last years, computer

games industry become one of the leading entertainment industries, outreaching other medias' popularity as TV, radio, movies and broadcasting industry.

Thus computer games-based learning can become an efficient way to reach new generations and to encourage them to develop new set of complex skills and competences in more appealing form, providing them the opportunity to enrich educational and learning context, with simulated environments beyond physical, geographical and economic limitations, suitable for experiments, interactions, group-work, skills testing, learning-by-doing and explorative research.

The current paper aims to investigate more in details how serious games and virtual worlds can be implemented in the context of development of entrepreneurial skills. The first part of the paper will investigate managerial and leadership skills from various main perspectives, exploring various approaches for identifying key entrepreneurial skills. The second part of the research will identify specific characteristics of serious games and virtual worlds. Finally there will be explored various perspectives how serious games and virtual worlds can contribute for development of new set of business skills and competences.

2. Theoretical overview

In the beginning of the analyses of skillset for future entrepreneurs and business professionals there will be made a short overview of key skills and competences for the new generations. In the last years, taking into account on one side the changing needs of the economy and increasing requirements for high-skilled professionals, different political organizations have identified a new concept of key skills and competences. OECD in 2005 [2] has selected a small set of key competences in its DeSeCo Project, determining that each of them must contribute to some valuable outcome for societies and individuals; to help individuals to meet important demands in a wide variety of contexts; and are important not just for specialists but for all individuals. The outlined key competences can be grouped in 3 main groups: Interact in heterogeneous groups (A. Relate well to others B. Co-operate, work in teams C. Manage and resolve conflicts); Use tools interactively (A. Use language, symbols and texts B. Use knowledge and information interactively; C. Use technology interactively); Act autonomously (A. Act within the big picture; B. Form and conduct life plans and personal projects, C. Defend and assert rights, interests, limits and needs); EU has recently identified a framework for key competences, determining that "Key competences are those which all individuals need for personal fulfilment and development, active citizenship, social inclusion and employment"[3]. These 8 core competences should be in the center of education: communication skills (in mother tongue and in foreign languages), mathematical competence and basic competences in science and technology, digital competence, learning to learn, social and civic competences, sense of initiative and entrepreneurship, cultural awareness and expression. There have been emphasized as well transversal key competencies, such as problem-solving and analytical skills, self-management and communication skills, linguistic skills, and more generally - "non-routine skills".

In parallel, the report of Metiri Foundations [4] based on the expected needs of 21st century workforce in USA, provided a list with 4 main skills and sub-skills as basic for new economy. They include: Interactive Communication (1. Team collaboration, 2. Personal and social responsibility, 3. Interactive communication), Digital Age Literacy (1. Basic, scientific, technological literacies, 2. Visual and information literacy, 3. Cultural literacy and global awareness), Inventive Thinking (1. Adaptability/managing complexity and self-direction, 2. Curiosity, creativity and risk-taking, 3. High-order-thinking and sound reasoning) and Quality, State-of-the-Art Results (1. Prioritizing, planning, and managing for results, and 2. Effective use of real-world tools).

Thus it can be concluded that these three key competence frameworks anticipate that new populations will need strong academic skills, teamwork skills, proficiency of using technology and digital literacy, inventive and high-order thinking, quality and results-orientation.

2.1 Entrepreneurial skills as factor for company success

Various studies highlight the competences and skills of managers and entrepreneurs as main factors for company success. For example, after detailed overview of literature [5] identify 4 key competency domains for SMEs entrepreneurs, analyzing their roles for success of the company (managerial role, entrepreneurial role and functional role). These competency domains include key 7 competences and namely: strategic (set visions), conceptual (innovative thinking), opportunity (recognize chance), organizing (mobilize resources), relationship (deal with people), technical (use tools) and personal (self-confidence, emotional intelligence) competences. According to [6] key business competences

are: initiative, communication, organizing, people management, team working, negotiation skills, ability for problem solving, confidence, creativity and financial acumen as indispensable for entrepreneurship.

2.2 Business education research

Other context for research of business and entrepreneurial skills and competences is provided in business education, where different authors discuss academic approaches for developing skillset for business professionals. Presenting an interdisciplinary cross-modular assignment program in his business school, [7] formulated 13 key skills for business students, including: problem identification and problem solving, oral and written communication, information gathering, information processing, numeracy, analytical, application (of concepts and techniques), creativity, social and inter-personal competences, self-analysis and decision making. [8] propose a framework for building entrepreneurship skills via Simulated Business Enterprise and provide an exhaustive list of business and entrepreneurial skills, including social skills, professional skills, and technological skills. [9] describe 3 main areas of entrepreneurial skills, including *technical skills*: as written and oral communication, technical management and organizing skills, *business management skills*: as planning, decision-making, marketing and accounting skills and personal *entrepreneurial skills*: as inner control, risk taking and innovation.

2.3 Observing managers and leaders

Another approach to identify key managerial and entrepreneurship skills and competences is to observe actual managers and leaders. A recent study of [10] among 3500 executives, identified 5 key skills for innovative and creative entrepreneurs. They include: association skills, observation skills, experimental skills, questioning and networking. Another research of [11] define the leadership skillset based on observations of 500 Canadian CEOs. Moreover, his observations discovered that leadership skillset is developed across 3 main stages, naming them "leader enabler", "leader engager" and "leader artist". The first level leaders aim to "enable" business operations, along three key competences: strong financial, cash-flow and budgeting competences (mastering financial plans and financially quantifying the business), logistics and operations (improving operational efficiency) and understanding economics (understanding complex relationships for forecasting demand). The second stage include leader "engager" aiming to strenghten business through competences for negotiations, communication, media relations and public speaking, dealing with personnel, chairing meetings, performance measurement and analytical approach for problem solving. The last group of competences characterizes leaders "artists" – inspiring and motivating others, and include balance, vision, judgement, leadership (confidence), and integrity. Another survey of [12] identify key business skills for success, rated by recent graduates of business schools. The highest rank of valuable skills for their current job have: interpersonal skills (84%), managing decision-making process (84%), generative thinking (83%), managing strategies and innovations (78%), knowledge of strategic business functions (75%). [13] formed a list with key 6 skills for effective managers in 21st century (out of 14 skills). They are derived after survey and focus groups discussions of both business professionals and business school academics. As result, the following range of skills emerged: communication and interpersonal skills, etical or spiritual orientation (act with integrity), ability to manage change (diversity), ability to motivate, analytic and problem solving skills, being a strategic visionary manager. Additional skills that have been highlighted as important are: persistence in overcoming difficulties, managing knowledge workers, hard work, and finally – be passionate about work.

2.4 Summary of key entrepreneurial skills and competences

After analyzing different approaches used to identify key leadership and managerial skills, they could be summarized in three main streams. The first stream of skills and competences include ability to understand and process information in order to be able to take decisions in the professional business world. Thus entrepreneurs need skills and competences to propose quality value offering on the market, recognizing basic stakeholders and main business processes as business operations, financial, economic and business literacy, marketing and sales, logistics, quality assurance and others. As business environment is fast changing, substantial skills need to be trained as information

gathering, information processing and ability to take decisions, problem-solving and analytical skills, creativity, ability for global vision and long-term visioning, and learning to learn and to fast adapt to evolving business context.

As entrepreneurs and managers are focal point of multiple interactions inside and outside organization, they need to be good communicators: using various communication channels to receive and share information, achieving goals in the process of communication: negotiating and persuading, motivating and inspiring teams, resolving conflicts.

The last stream of entrepreneurship competences include personal confidence and sense of initiative and entrepreneurship: self-direction skills, organizational skills, planning and decision-making skills, self-analysis, global awareness, ethical and spiritual orientation, ability to manage change, strategic and visionary leadership.

3. Serious games and Virtual worlds

In literature there exist many definitions for serious games, often extending the terms of e-learning, edutainment (coming from education and entertainment) and game-based learning [14, 15]. Although slight variances among authors, serious games are commonly described as (digital) games used for purposes other than mere entertainment or fun. Serious games usually refer to games used for training, advertising, simulation, or education that are designed to run on personal computers or video game consoles. [16] sees the sustained imaginative immersion that computer games provide as a way for “the players to invest something of themselves in a game or learning experience as they fully engage with the role”. This ‘personal investment’ is a critical factor in achieving deep learning. [14] distinguish 3 main classes of computer games, including casual games, advergames and serious games. Casual games are developed purely as entertainment activity, and thus the learning outcome is not intentionally foreseen. Serious games are especially designed to improve some learning aspects and players expect the learning process. Advergames are identified as tools designed and delivered as promotion and marketing tool of new coming movie or TV series. [17] overview several classes of computer games - concerning idea (action games, adventure games, fighting games, puzzles, role-playing, simulations, sport games and strategy games), concerning players (individual or multiplayer game), and concerning their development (mainstream, or commercial entertainment games, commercial educational games, and research based educational games). Another classification of [18], propose to distinguish serious games according to their primary market - military games, government games, political games, educational games, corporate games, healthcare games, and political, religious and art games.

Virtual worlds are commonly up-grading the notion of computer games, as they build an open-ended virtual reality. [19] determines virtual worlds as consisting of four components: “Ultimately, real virtual worlds arise from the integration of 3D, Community, Creation and Commerce.” In literature there are used also terms as ‘metaverse’, ‘synthetic world’, MMOG and multi-users virtual environments (MUVE) in place of ‘virtual world’. [20] identified structured and unstructured virtual worlds. Although the recent problems in the field of virtual worlds development, the 3D technologies have promising applications in education, entertainment, reasearch, business and socialization. The most popular virtual worlds are Second Life@, Kaneva@, HabboHotel@ and others. Among the essential elements of a virtual world can be identified:

- The concept of presence in a space
- The notion of interaction in real time with other individuals
- The idea of persistence, environment and objects
- The representation of our online persona via an avatar

While different in nature, serious games and virtual worlds are often confused, and thus its features and elements are overestimated and thus they are not properly adopted for any particular business case.

4. Serious games and Virtual worlds in the context of building entrepreneurial competences;

4.1 Serious games

Serious games are already used in wide application areas, including education, corporate, military, healthcare, government, political games and others. Even traditional entertainment games as strategy games, simulation games, role-playing games and others can facilitate entrepreneurship competence development. However, serious games aim to combine different learning approaches and complex processes to facilitate competence building.

Usually, serious games have prewritten set of actions (scenario) that player must accomplish in order to get some positive result, following preliminary defined rules and constraints. Players can get help and instructions, receive some initial training and guidelines and is virtually "assisted" while playing the games. Moreover, many SGs provide feedback, so player can better understand its results and can improve it. SGs are often displayed in appealing graphical environment and propose a back story, which is amusing for the player and develop a context of his experience. This makes SGs easily integrated in learning process and especially in active learning (focusing on learner needs), for testing competences and skills, developing critical thinking, testing scenarios, profiling, self-learning and others. As negative side, SG cannot integrate theoretical knowledge. Thus SG can be successfully complemented within an e-learning suite or with additional instructional content (Intels@, Yentels@).

There were discovered several categories of serious games used in business (Pixel Learning):

- Business simulation/games - where the learner 'runs' a business to better understand business concepts in finance, marketing, innovation management and others.
- Situational simulations - where learners perform a role in order to gain realistic virtual experience of real world roles such as, for example: auditing; sales; or business planning.
- Role play simulations - face to face or telephone-based conversations with simulated characters e.g. for conflict negotiation or sales training.
- Technical process simulations - which feature custom embedded systems or processes such as, for example, CRM, SAP usage all set within a rich and challenging real world context;

Several examples of serious games that could be used in entrepreneurship training are provided below:

- Innov8@ is the IBM Business Process Management (BPM) simulation game that gives an introduction to BPM, from learning the anatomy of a model, to model optimization. The game explores 3 business applications – traffic, customer service and supply chain.
- Market Place@ business simulation is a platform, delivering wide range of serious games, designed for university courses. There are provided a large number of on-line games focused on different level of marketing, business planning, strategy, e-commerce, supply-chain management, integrated business management and international management.
- TangoNet@ is another business simulation game, designed to enable market focused strategy and building on their company's intangible assets (company image, employee know-how and innovation). It can be combined with learning modules on CRM, Project Management, Human Resource Management, Knowledge Management, Management Accounting and Strategy for knowledge-based companies.
- Project management – [21] presents a project management business game, aiming to improve students' abilities to plan and deal with operational management. The project consist of organization of sport tournament. The game is played for 60 minute and aims to develop skills for Project management.
- Pixel Learning@ suite – Business Game@, Enterprise Game@, Financial Game@ and Sales game@, enable virtual simulations of complete business cases.
- Yentels@ and Intels@ serious games are developed under LLL program, and enhance development of entrepreneurial skills and competences in international trade.

4.2. Virtual worlds

VW applications can situate learning in unusual three-dimensional spaces, facilitating seminar activities, streaming lectures, creating cyber-campus and providing distributed and remotely located learner groups. This may add value to existing educational provision and extend new provision of learning [15]. While structured (i.e., closed) like World of Warcraft®, EverQuest®, Final Fantasy®, and Star Wars Universe® are designed around socialization, fantasy, and role playing, unstructured (i.e., open) MUVs like Second Life® offer these same opportunities plus an active economy where can be trained real entrepreneurial skills. While SG players are motivated by accomplishment of achievements, virtual worlds focus on 3d environment that can be used for different purposes, including socialization and collaboration. Residents are able to explore, build, edit and create objects and services [16]. Studying the motivation of users to take part in VW, [22] summarized the following main reasons, highlighting that human-human interactions are the most interesting and exciting experience:

- achievement – gaining power, understanding “how”, competing against others,
- social – interest in helping and interacting in the community, building relationships, being part of the group;
- immersion – knowing more about others, creating avatar, avoiding thinking of everyday problems.

VWs propose rich interaction, visualization and contextualization, exposure to authentic content and culture, individual and collective identity play, immersion in a 3-D environment, simulation, community presence and content production. Among the examples of applications and benefits of VW in entrepreneurial education can be enumerated as follows:

- Improved participation, collaboration and communication

In contrast to other forms of virtual collaboration such as e-mail, blogs, and webinars, a 3D virtual environment increase participation and improve retention because the addition of avatars and other 3D models helps the user to feel more immersed in learning. VW facilitate group events and activities and role-playing scenarios, facilitating educational exercises such as virtual field trips or experiments [16]. This place new dimensions for effective group work, as it can allow students to interact in 3D spaces, experiment with behaviors that they might be too reluctant or shy to try in the real world. The sense of presence encourages students to explore and engage in informal, self-directed learning, and distance learning become much more feasible and effective [23].

- Simulations and experiments

VW propose unique environment for experimentation, without physical or time constraints. Thus users can participate in complex simulations that would be nearly impossible to construct in real world. This allows lecturers and students to illustrate visually and verbally their ideas and complex systems with minimum effort. As fascinating examples of the potentials of VW for complex simulations can be cited International Spaceflight Museum, the Splash Aquatics Deep Sea Aquarium, and Aimee Weber's real-time weather visualization system in Second Life®.

- Virtual Economy

Open VW as Second Life run a functioning economy that sheds light on questions of where people find real value, even in a virtual world. The virtual economy provides many opportunities for social experiments and business skills development, as observations, marketing studies, innovations, services science and others. One example provided by Craigs University is the opening of a virtual store in Second life for its marketing classes [23].

4.3. Advantages and limitations of using SG and VW for building entrepreneurial competences

SG and VW have many advantages for building complex entrepreneurial skills. They can be successfully applied within the framework of emerging demand of specific managerial competences and skills. Moreover, SG and VW respond on learning preferences of new generations and contribute to:

- Improve understanding of complex business processes and improve vision of usual problems in starting and running business. SG are designed around realistic scenarios, that facilitate future entrepreneurs to take decisions, make forecasts and develop business plans, while executing various business tasks. Thus SG can enhance trainees to develop and test real competences in finance, marketing, business planning, sales, forecast methods and others.

- Improve communication and group work– SG and VW can enhance communication skills, and enable efficient teamwork and knowledge sharing, improve intercultural interactions and limit prejudices and racism. SG and VW successfully create an immersive environment for language learning and help students to overcome foreign language barrier. Moreover, there could be simulated very complex communication situations as for example conflict management, negotiation skills and stakeholder management, social architecture (TARGET EEU FP7 Project @). Role-playing and observing situations from different points of view enhance personal abilities to cooperate with others, to understand different positions, to negotiate better in real-life situations.
- Improve information gathering, complex information processing and better decision making. SG and VW contribute for extending the use of ICT and to master rich media objects within complex learning environments.
- Improve active learning - SG and VW support creative learning activities and experiences, proposing immersive context of knowledge use and area for experimentation and exploration of opportunities.
- Improve self-improvement, planning and forecasting, ability to assess situations, high-order thinking and ability to experiment. Finally SG and VW provide the player with close-to-real experience for taking decisions and coping with complex situations, for testing knowledge and skills and improve his abilities to deal with critical incidents, that can happen in real-life.

Although the high number of advantages for application of SG and VW in entrepreneurship education, there exists as well many limitations for its widespread use. One of the constraints remain the need to adapt educational methodologies with new enhanced ICT methods as SG and simulations. The analysis proves that SG and VW can become powerful tools for educators to change traditional training methodology and to create new forms of learning experiences. However, educators will need to prepare for that change, leaving their role of knowledge providers and transforming to facilitators of complex learning and knowledge management processes, organizing and guiding unique learning experiences. Moreover initial investments for transformation of the educational process in form of money, effort and time are substantial [24]. One other difficulty is the assessment of learning in SG and VW. Traditional grades as collection of quantitative data can not be relevant for specific learning experiences, that are difficult to test, and the soft competences addressed with SG often are not part of the curriculum (collaborative work, visualization skills). Thus application of SG and VW in educational process should be carefully prepared and based on sound educational methodological principles: what is the value of technology use for educational process, what resources are needed for implementing it in class, is it fitting with the goals of the curriculum, and how can be assessed learning usability and outcomes.

5. Conclusions

The present paper provides an overview of entrepreneurial skills and discuss how SG and VW can be applied for entrepreneurship and business training. However, in order SG and VW to become widely accepted educational practice, there should be provided higher number of examples, SG applications and research evidences. The popularity of SG and VW and their wider application in many non-academic and business purposes will contribute as well for their further extension for training and skills building [25].

Entrepreneurship and leadership competences are crucial for development of strong business organizations. Moreover combination of skills and abilities, educational background and professional experience, make business professionals able to lead organizations in challenging times and to transform them to value-adding centers. While in the past, company management was concentrated in the hands of senior professionals with most experience and expertise in the field, nowadays, this practice become obsolete, because of two factors. On first place, flexible and competitive companies need to decentralize its decision-making processes, allowing different management levels to act as entrepreneurs. The second factor is the fast emerging new knowledge domains, requesting fast adaptation and rescoping of company strenghts and opportunities. Thus younger professionals have to make decisions and manage complex organizational relationships with less experience. Thus playing SG and VW can be successfully applied in entrepreneurship education as it propose younger professionals to survive complex practical experiences.
