4th International Conference for Entrepreneurship, Innovation and Regional Development

H.E. Dr. Gjorge Ivanov
President of the Republic of Macedonia

Dear participants,

It is my great pleasure to welcome you in the Macedonian and Balkan pearl, our spiritual and cultural centre, the city of Ohrid.

I am pleased that the regional initiative started in 2008 in Macedonia as an International Conference for Entrepreneurship, Innovation and Regional Development continuously confirms its international character. The success of this venture is further affirmed by this 4th Conference which offers an excellent opportunity to participants from more than 30 countries to share best practices and experiences, to gain insight in the cutting-edge knowledge and to learn the latest achievements.

At a time when the world still recovers from the global economic and financial crises, it is more than obvious that the only manner in which we can successfully overcome the crisis and create sustainable economy based on free market, competitiveness and quality, is to encourage the successful work of small and medium enterprises (SMEs), which are the driver of economic development of every prosperous country. The promotion of innovations and the

dedication to entrepreneurship are the prerequisites for creation, development and promotion of the SME sector. Hence, I believe that the business environment encourages the exchange of knowledge and experience and is essential for the success of every national economy, while opening the doors to regional collaboration and development.

The 4th International Conference for Entrepreneurship, Innovation and Regional Development represents a platform for such exchange and triggers the synergy among the scientists, the policy-makers and the business practitioners, on national and regional levels. It also encourages innovation as one of the most profitable investments. These efforts surely contribute to the fulfilment of the vision of Innovation Europe and symbolize the dedication of the Republic of Macedonia to the European and Euro-Atlantic integrations.

Therefore, I wish the participants of this important international conference successful work and fruitful cooperation.

Dr. Gjorge Ivanov

4th International Conference for Entrepreneurship, Innovation and Regional Development

Dear ICEIRD 2011 participants,

It is my privilege and honour to welcome you to the historic town of Ohrid, Macedonia for the 4th International Conference for Entrepreneurship, Innovations and Regional Development.

ICEIRD network was initiated in 2008 in Macedonia, together with our Greek partners and a few enthusiasts from Serbia and Bulgaria, with the aim of showing that, through the cultivation and growth of innovation and entrepreneurship, we can foster regional collaboration and bridge any political dilemmas in a peaceful and productive manner. The second conference was held in Thessaloniki, Greece. ICEIRD 2010 was in Novi Sad, Serbia. ICEIRD 2012 will be in Sofia, Bulgaria.

The primary objectives of ICEIRD conferences are to bring together the decision makers, (government, ministries and state agencies), innovation experts (universities, research and development centres, technology transfer centres, and business start-up centres), and practitioners (business incubators, business support organisations, small and medium size enterprises/SMEs), and then generate discussions in which these highly-intelligent and creative people can exchange ideas that work to promote entrepreneurship and increase the levels of innovation, with the overall aim of seeing enterprises compete and succeed nationally and regionally.

ICEIRD 2011 draws together more than 350 authors and participants from 42 countries.

The organising committee would like to express its sincere gratitude to His Excellency Prof. Dr. Gorge Ivanov, the President of the Republic of Macedonia, for his willingness to support and participate in ICEIRD2011.

Special appreciation also goes out to the conference patrons:

- European Academy of Sciences and Arts,
- Macedonian Academy of Sciences and Arts, and
- European Council for Small Business and Entrepreneurship.

The National Center for Development of Innovation and Entrepreneurial Learning in the last several years was supported financially by the Austrian Development Agency (www.adv.gv.at), and this agency also supported ICEIRD 2011. The organising committee would like to express its deepest gratitude for this continued support!

The Central European Initiative (www.ceinet.org) also gave financial support to the conference and the ICEIRD team would like to express their gratitude and appreciation for this important support.

4th International Conference for Entrepreneurship, Innovation and Regional Development

Many other domestic and international institutions also supported the conference and to all of them we express our genuine and heartfelt thanks:

²Faculty of Business and Economics, South East European University, Tetovo, Macedonia, h.cipunsheva@seeu.edu.mk

The aim of this paper is to investigate the evolution of ownership, innovation activities and productivity using the Privatization and post-Privatization Enterprise Survey firm-level data of Macedonian Privatized Firms, in 2010. Studies that have considered the issue of privatisation are usually restricted to the ownership – performance relationship, whereas the novelty of this paper is based on the idea of studying the evolution of ownership and its impact on performance so that we can express the adjustments that arise from ownership change on innovation activities.

Empirical evidence of the relationship between ownership, innovation and performance is given. Further some economic background of the country for the transition period is elaborated. Various statistical measures are implemented on the original survey to test whether the change in ownership has lead to more innovative activities. Studies that investigate the relationship between the ownership and innovation undertaken by firm (Munari and Sobrero, 2002[1]; Munari and Oriani, 2002[2]; Domadenik et al., 2003[3]) emphasise that the amount of shares being sold to private shareholders, the level of technological opportunities and the degree of market competition of the industry seem to affect significantly innovation activities within privatized companies.

Based on the survey we find evidence that companies introduced new or improved goods (71.79%) and services (52.38%) since privatization. They developed these innovations mainly by the entity itself (80%) or together with other enterprises and institutes in the sector (16%). These innovative goods and services were new to their enterprise and to the domestic market. In addition, the enterprises introduced new methods of manufacturing and producing (65.71%), new or significantly improved logistics (61.76%), delivery or distribution methods for the inputs, goods or services (73.53 %), and new or significantly improved supporting activities for the processes (73.53%).

Innovation Activities and R&D, Ownership Evolution, Performance, Privatised Enterprises

1. Introduction

In today's world, the role of innovation is attracting massive attention. It is evidenced in the literature that US as a leader in innovation activities experiences higher labour productivity. European Union significantly lags behind US in both innovation activities and productivity. Therefore, EU has implemented an ambitious target of increasing R&D expenditures to 3 per cent of GDP by 2010 in order to move into the "knowledge-based economy" and to catch up with US.

Far behind on the list of innovative regions are the transition countries. Having in mind their historical background and transformation from socialist system to market economy, it is expected that these

countries will face a time gap prior to involve in innovation activities. There are several empirical and theoretical literature that have attempted to identify factors that prevent south-east European countries from catching up with more developed ones. Many studies show that changes in ownership from state to private have improved performance. However, some research has found differences in performance among different types of private firms. On the other hand, the transition countries in the last two decades seem to be an attractive place for the foreign investors. First the ownership change followed by the privatisation process and then the evolution of ownership to foreign owners accompanied with the innovation activities is expected to further improve firm performance in TEs.

The process of privatisation of state-owned enterprises started in Great Britain, in 1979 and it was transferred to other European governments and later to a number of developing countries as well. By the end of 1980s privatisation was spread to the former socialist countries. Being part of the SFR Yugoslavia the privatisation in the Republic of Macedonia was initially introduced in 1989 with the Law on Social Capital of the Former Yugoslav Federation. This Law was based on the concept of privatisation through which internal shares were issued to all employees of socially owned enterprises. Immediately after proclaiming the independence of the Republic of Macedonia, the Parliament rejected the Law on Social Capital and expressed its intention to enact new, Macedonian Law on Privatisation. The process was intensified in 90s after the Macedonian Law on Transformation of Enterprises with Social Capital has been enacted in June 1993.

This paper is structured as follows: after the introductory part and the section on theoretical framework we continue with empirical evidence on the relationship between ownership evolution, innovation activities and firm performance. Then what follows is some background information of the Macedonian economy and its privatisation process. Further the statistical analysis based on the enterprise survey data 2010 is elaborated. Finally we give the conclusions of the study.

2. Theoretical Framework and Empirical Evidence

2.1 Theoretical Framework on ownership and innovation

While under social ownership the incentive for innovation and dynamism was absent, private ownership, together with competitive pressure, are expected to generate strong incentives for innovation and technical change. The theoretical framework is crucial for understanding the debate on the public versus private sector performance.

Martin and Parker (1997)[4] consider the principal-agent relationship in the public sector as more complex, because the ultimate owners of state assets, the principals, are the public, and between them and the managers of the assets exist layers of other agency relationships, which provide more scope for 'noise' to distort the information flow. An immediate consequence of privatisation will be a shift in the objectives of principals thus it is expected that a change in ownership involves a new principal-agent relationship with new forms of information and incentive regimes, which bind agents to the principals' goals, in a world of incomplete contracts (Martin & Parker, 1997, p. 6[4]; Vickers, J. and Yarrow, G., 1988, p. 7[5]). When incomplete contracts are introduced, ownership and governance structure are shown to matter more, as they dramatically alter incentives with important consequences for company performance (Bortolotti, 2004[6]).

According to the property rights theory, private ownership is superior to public ownership because it provides effective managerial incentives and more effective monitoring schemes, (Vickers & Yarrow, 1988: p.44[5]). Based on the property rights tradition one can conclude that self-interested owners of capital have more incentives to aim for profit maximization and at the same time undertake innovation activities. The public choice theory, because of differences in their objectives and constrains state owned and privately owned firms will differ in actual behaviour and performance (Martin & Parker, 1997: p 10[4]). The Austrian school of economics in the presence of market discipline stresses the role of the entrepreneurial factor in the market, and relaxation of barriers to entry is believed to improve the entrepreneurs' performance.

The last theory can be related with the Schumpeterian view. After the first view about the relation between market structure and dynamic market performance, Schumpeter Mark I of *The Theory of economic Development*, according to which it was the new (often small) firm that carry out innovation, comes the second fundamentally different view, the Schumpeter Mark II of *Capitalism, Socialism, and Democracy*, according to which it is the established (large) firm that generates technological progress. In relation to this he notes that large firms are more responsible and have to do with creating the standard of living and to innovate rather than the ones that work under conditions of competition. The

well known economist Schumpeter (1939, 1942)[7][8] developed the ideas on which most of the theoretical and empirical analysis of the economics of innovation and research and development are based.

When analysing innovation and their effect on firm performance, it is a primary objective of the empirical studies to find appropriate measures of innovation activities and its role to technological progress. A good starting point is the definition and the taxonomy of innovations following Joseph Schumpeter, who defined innovation in a broad sense, saying (1934, p.66): *“the carrying out of new combinations” that include “the introduction of new goods (...), new methods of production (...), the opening of new markets (...), the conquest of new sources of supply (...) and the carrying out of a new organization of any industry”*.

Having discussed the theories such as the principal agent, the property right and public choice, and the Austrian school of economics which are all giving supporting arguments for better performance of private ownership, and further the Schumpeterian theories on innovation, we will now look at the empirical work done on the relationship between ownership structure, innovation and performance to support the theoretical argument.

2.2 Empirical evidence on ownership structure, innovation activities and firm performance

There is a large body of literature on the effects of changes in ownership structure in TEs but the evidence is rather inconclusive. Megginson and Netters' (2001)[9], Djankov and Murrells' (2002)[10] and the latest Estrin et al.s' (2009)[11] review of the empirical literature done on privatisation in TEs leads them to diverse results, either within different countries or on the effect of different factors. Megginson and Netter (2001)[9] summarize the cross-sectional and time series evidence on the relative efficiency of public and private ownership. They conclude that performance of firms under private ownership in TEs is better than continued state ownership. According to them most studies document that if firms are privatised to new managers (outside owners) then the performance improves more than when the original managers (inside owners) are retained. Their general conclusion is that that privatisation around the world tends to improve firm performance. Djankov and Murrell (2002)[10] conclude that the impact of privatisation on company performance has been positive and significant, though not in all circumstances. For example in the CIS countries the effect of privatisation is statistically insignificant. More specifically privatisation to outsiders is found to have the largest positive effects on enterprise restructuring, both in Eastern Europe and in the CIS. Increased competition is associated with positive results in Eastern Europe but not in the CIS. The most recent empirical survey realized on transition economies for the effects of privatisation and ownership is Estrin et al.'s (2009)[11]. They conclude that the performance effect of privatisation to domestic owners has been less impressive than privatisation to foreign owners which results in considerably improved performance of firms. Furthermore, they conclude that concentrated (especially foreign) private ownership has a stronger positive effect on performance than dispersed ownership in CEE and CIS.

Foreign investments are also shown as important vehicle for the transfer of technology. The transition countries in the last two decades seem to be an attractive place for the foreign investors. The Transition Report 2005 confirms that apart from the business environment ownership and management decisions have a significant influence on the performance of firms and their competitiveness in international markets. Foreign-owned firms, which usually acquire better performing firms and can draw on the technical and management know-how of their parent companies, tend to be more efficient than domestic. Furthermore, according to this report the most important factor that impact firms' performance is the extent of competition, which it prompts firms to improve their levels of efficiency more quickly but it does not have an impact on the overall efficiency.

There are few studies that investigate the relationship between the ownership change and innovation activities undertaken by firm (Munari and Sobrero, 2002[1]; Munari and Oriani, 2002[2]; Domadenik et al., 2003[3], Brown et al., 2009[12]) emphasising that the amount of shares being sold to private shareholders, the level of technological opportunities and the degree of market competition of the industry seem to affect significantly R&D commitment within privatized companies. Ownership structure is shown to influence productivity both directly and indirectly, through innovation activities (Hill and Snell, 1989[13]). Carlin et al. (2001)[14] find significant effect of privatisation on new product restructuring. Moreover new product directly increases sales and productivity growth, implying an indirect effect of ownership on enterprise growth. On the other hand, Dachs and Ebersberger

(2009)[15] study for Austria, testing if foreign ownership influences the innovative behaviour and performance, find that this relationship appears neutral.

The number of studies that have studied the ownership changes in Macedonia is numerous, but there are very few studies that have related the change in ownership with the innovation activities and firm performance. Studies written on the 2000s are characterised with empirical evidence on the effects of privatisation, such as: Prasnikar et al. (2002)[16], Domadenik et al. (2003)[3], Zaludendo (2003)[17], Koman and Markovska (2007)[18]. Their major finding is that foreign ownership improve performance. Koman and Markovska (2007)[18] find evidence that internally-owned firms (where majority owners are insiders) chose defensive restructuring, meaning that they created the same revenue by substantially reducing the employment; whereas externally-owned firms (where majority owners are outsiders) chose strategic restructuring, where the revenues increased with a modest reduction in employment.

3. Economic Background

The Republic of Macedonia is a small country in Europe situated in the midst of the Balkan Peninsula and covers 25,713 square km. It is inhabited by approximately 2 million people and the 2002 census showed that ethnic Macedonians constituted 64% of the population and ethnic Albanians 25% whilst Turks, Roma and 3 other sub-groups constituted a further 10% of the population. On the 8th of September 2010 Macedonia celebrated its 19th anniversary of her independence, that also correspond to the years in which the transition from planned to a liberal market economy has taken place. The differences among the former Yugoslav republics before their independence are shown in Table 1.

Table 1 GDP per capita of the former Yugoslav republics in 1987

Republics	GDP per capita – Index*
SFR Yugoslavia	100
Slovenia	226.2
Croatia	128.2
Serbia	87.5
Montenegro	73.9
Bosnia and Herzegovina	70.5
Macedonia	62.4
Kosovo	49.3

Source: Statistical Yearbook of Yugoslavia, 1987

*The index measurement is given as a relation of the GDP of the republics to the GDP of the federation as a whole.

As it can be seen from Table 1, before its independence Macedonia was one of the least developed parts of Yugoslavia, thus after 1991 the reform process started in a very unfriendly environment. Apart from belonging to a region impacted by wars, Macedonia inherited from the former Yugoslavia a considerable external debt and an economic structure that needed urgent restructuring.

Table 2 shows some economic indicators, which give a clear picture of the unfavourable economic trends followed immediately after the independence such as negative GDP growth, high inflation, high unemployment, low levels of export, etc.

Table 2 Economic indicators of Macedonia from 1991 – 2009

Economic Indicators	GDP growth (annual %)	GDP per capita growth (annual %)	Inflation, GDP deflator (annual %)	Unemployment	Net Export-Import (% of GDP)	FDI, net inflows (% of GDP)	External debt stocks (% of GNI)

Source: World Bank Development Indicators

In the early years of transition the economic situation was not very favourable, thus economic reforms were needed. After implementing the reforms the situation improved (GDP started to rise, inflation dropped to 2.87% in 1996) except for the unemployment which continued to remain high throughout the transition period. Privatisation of the Macedonian economy was one of the reforms that needed to be undertaken.

In June 1993, two-years after Macedonia's independence a new law, The Law on Transformation of Enterprises with Social Capital.. The Government chose the 'case by case' method of privatisation, the principle privatisation for revenues (Klusev et al., 2002)[19]. As referred to article 6 of this law: *"The privatisation of state capital of enterprises is decided upon by the Government of the Republic of Macedonia, on a case by case basis. Privatisation is undertaken in accordance with a Program, which shall be adopted by the Government of the Republic of Macedonia for a period of 6 months"*. They believed that this method will foster the privatisation process, which would bring to an end the difficulties that the enterprises were facing. The drawbacks of the chosen method were that it did not help develop the capital market and the participation of the Albanian population in the privatisation process became limited. However, it was a strategic decision of Macedonian Government not to use a mass privatisation scheme, because it was believed that such a privatisation method would only postpone the main objective of the privatisation, which is the appearance of real and effective owners – who would have the incentive and means to increase the efficiency of enterprises.

There is no such a study that has analysed the privatised enterprises from the innovation aspect. With the questionnaire survey conducted in 47 companies in Macedonia in 2010 we came up to some findings that might change the belief that has been circulating with the literature during the last two decades. The following section elaborates the methodology and the results of the enterprise survey 2010.

4. Enterprise Survey 2010

The enterprise survey 2010 was conducted in Macedonian privatised firms through a questionnaire constructed by the authors, in order to get primary data to determine whether privatised firms have gone through changes in ownership during the transition period and weather the changes have significant role in the performance of these firms. A total of 50 privatised firms in Macedonia were randomly selected to comprise the sample. The managers of the selected firms answered a survey questionnaire with a face-to-face interview. The data gathered from this research instrument present information on a wide range of firms' characteristics and are computed for interpretation. The questionnaire consisted on 7 parts covering the following segments of the company's performance: the ownership structure and governance, production and investments, labour force, production management, marketing and competition, innovations of products and processes, and financial performance. Having in mind the cautiousness that we had for surveying the top management (general directors, managers or owners) of the firms, one can be ensured on the credibility of the data. In addition to this, the dataset is unique, since there is no available firm-level data for the privatisation process, especially not for such a long period. In the next section we continue with the statistical analysis of the data to explain the relationship between ownership structure, innovation activities and firm performance.

4.1 Findings

The survey results show that the biggest part of the surveyed companies that were privatized during the process of transformation of the economy are transformed as shareholding companies whose shares are now traded in the stock market (46.81%). There is unfavourable representation of female considering the leading positions in the privatized companies, since the survey results show that only 8.5% of females are in the highest management structure of the companies. The educational distribution of the general managers shows that 41% are engineers, 26% graduate economists, and 17% lawyers, just 2% of them have secondary education. There is also a significant change in the ethnical affiliation structure of the owners from the moment of privatization till today. The distribution is as follows: Macedonian – 50% in the moment of privatisation, 30% today; Albanian 10% in the moment of privatisation, 30% today, Mixed 30% in the moment of privatisation, 20% today; and Foreign – 0 in the moment of privatisation, 20% today. Considering the production and investments, the majority of the surveyed companies reported that they do not have a production sector outside the headquarters (location) of the company.

The majority of the companies stated that they are / were seeking cooperation with foreign investors; because they have great opportunities for increased capital (46.15%) and they have access to new technology (23.08%), as well as access to export markets (23.08%). This is in line with the government policy for attracting foreign investments to Macedonian market and taking measures to reduce the administrative barriers and improve the judicial sector, in order to help investors to invest their capital in Macedonian companies.

What is in the particular interest of this paper is the development of human capital in Macedonian companies that passed the process of transition, since it is one of the major factors for introducing innovations. Considering the labour force policy of surveyed companies, the results show that after the huge release of workers, which was a common practice after the process of privatization (81.8% of them reported that they have released employees during these decades), the labour regulation and inadequately educated workforce are still barriers to their current operations. It seems that not just the physical, but also the human capital development are still not over-passed obstacles and influence on their successful performance today. If we relate the data for the labour force characteristics and marketing and innovation activities, we can see that the level of development of the Macedonian privatized companies even 20 years after privatization is not enviable – just 15.56% of employees advanced their qualifications, 5.7% advanced their educational level, 27.87% use computer and internet, 17.58% followed training. In the era of knowledge economy and lifelong learning, just 67% of the surveyed companies offer trainings for their employees.

Even that the human factor was stressed as one of the main obstacles for development and improved performance of the companies, in the era of globalization and increased competition, the data concerning innovation activities are mainly significant and positive. The surveyed companies introduced new or improved goods (71.79%) and services (52.38%) since privatization. They developed these innovations mainly by the entity itself (80%) or together with other enterprises and institutes in the sector (16%). These innovative goods and services were new to their enterprise and to the domestic market. In addition, the enterprises introduced new methods of manufacturing and producing (65.71%), new or significantly improved logistics (61.76%), delivery or distribution methods for the inputs, goods or services (73.53%), and new or significantly improved supporting activities for the processes (73.53%), such as maintenance systems or operations for purchasing, accounting, or computing. The companies reported that 36.36% of them have innovation activities to develop product or process that were abandoned by these years or still ongoing by the end of 2009.

The investments in innovations are influenced by many factors, such as highly noticeable economic risks, high direct innovation costs, financial costs and availability of finance, organizational limitations, lack of qualified personnel, lack of information for technologies, lack of information for markets, lack of responsibility of the customers for new products and services, impact of regulations and standards, increased assortment of goods and services, etc. As the following figure shows, after the process of privatisation, the significant part of the surveyed companies invested in innovation activities.

Figure 1 Investments in innovation activities

5. Conclusions

Even though the economical background, as discussed in section 3, gives evidence of not very favourable conditions for the Macedonian economy, the results of enterprise survey that we conducted in a representative sample of privatise firms proved the opposite. 80% of the companies developed innovation activities by the entity itself. 71.79% introduced new or improved goods since privatization. This shows that during the transition period, with the ownership change and the reforms undertaken in the Macedonian economy, there are high performing firms that face the competition and thus fight with it by developing new products or processes.

The undertaken activities with respect to the introduced new methods of manufacturing and producing (65.71%), show that these firms have introduced also new machinery and technology, which is highly related with the improvement of their performance. Also companies have positively reported for being engaged in the new or significantly improved logistics, delivery or distribution methods for the inputs, goods or services, and new or significantly improved supporting activities for the processes, such as maintenance systems or operations for purchasing, accounting, or computing.

The results might seem as opposite to the common belief of the people for the performance of the privatised enterprises. But one should notice that we came to evidence that is in accordance with the theory, that ownership change, competitive markets and foreign owners improve the performance of the enterprises and are positively related with the innovation activities of the firms.

Finally, one can say that the trends of the economic reforms should continue so that they can enforce increased competition, a larger flow of foreign investments and enabling the companies to cope with the foreign markets. The visa liberalisation to EU and further steps to become EU members should be one of the advantages that the Macedonian economy should make use of in the following years to come. There still some space for the future research, to tackle the issue of de-novo enterprises by getting a broader sample of firms, so that their trend for innovation activities is followed, or compared to the old existing ones

How to get out of crises:

Crises management and Change management

*Ruth Alas*¹

¹*Estonian Business School, Tallinn, Estonia, ruth.alas@ebs.ee*

Successful change management could help to avoid crises. Crises management is needed if change management efforts fail. There are the common features of crises management and change management and there are the differences as well. At the same time different elements should be emphasised during these two processes. In this article the triangular model of crises is compared with triangular model of organizational changes. Implications for managers are developed.

Keywords

Change, crises, organization

1. Introduction

Organizational change is planned movement from stage A to stage B. Crisis is a low probability, high consequence event that is capable of threatening organizational legitimacy, profitability and viability [1]. At the same time, crisis could be taken as the first step in the organizational change management process: 'establishing the need for change' according to Galpin [2]. At the same time crisis-driven changes tend not to last [3]. The research question here is how to make such changes last. The Estonian economy has been in a transition process since 1991 [4]. There are several studies of organizational change in Estonia [5], and of crisis management in Estonian companies [6]. This paper aims to compare change management and of crises management.

2. Change Management Theories

Dopson and Neumann [7] have perceived change as a necessary evil for survival in the context of uncertainty. In this article an organization is defined as a complex system that produces outputs in the context of an environment, an available set of resources and a history [8]. Armenakis and Bedeian [9] have divided research on organizational change into (1) content research, (2) contextual research, (3) process research and (4) criterion research. Nutt [10] combines structure and process. The author of this article refers to the first component as 'types of change' and the second component as the 'process of change'. Every organization has forces for change and forces for stability [11]. There is also a third crucial factor – a readiness to change in the particular organization. Struckman and Yammarino [12] combine types of change with the readiness to change, but they do not take process into account. Author connected these four types - content research, process research, contextual research and readiness research – into triangular model of organizational change.

2.1 Types of changes

Changes are most often classified according to scope and the way the changes are initiated. Also the duration of change is important in understanding change. **Types of change in terms of scope.** In content research most theorists divide change into two types according to scope: change taking place within the given system and change aiming to modify the system itself. First order change provides a method for managing stability. It helps one to manage current strategy more effectively and efficiently [13]. A first order change cannot produce transformation because it lacks the creativity to discover new

strategic ideas [14]. Second order change calls for innovation in order to lead the change. Second order change is difficult to carry out because information gathering in an organization will tend to reify the rules, culture, strategy and core processes that make up its current paradigm [15]. Ackerman [16] has described three types of organisational change: (1) developmental change, (2) transitional change, and (3) transformational change. Burke and Litwin [17] have developed a model for making a distinction between transactional and transformational change. **Type of change in terms of initiative.** Unplanned change is usually spontaneous and random [18]. It can be beneficial or disruptive, but, more often than not, unplanned changes are disruptive. Planned change is a rationally controlled, orderly process [19]. It is usually triggered by the failure of people to create continuously adaptive change [20]. The need for planned change can come from external or internal sources or both. Dirks, Cummings, and Pierce [21] have made a difference between self-initiated and imposed changes. A self-initiated change means that the individual makes a change as a result of her own initiative and volition. An imposed change is change initiated by others so that the individual is forced to act. Management-driven change is typically executed by managers. Participatory change is based on the premise that there is a genuine sharing of power and responsibility for change between employees and management [22]. **Duration of change.** In a change event categorization scheme, Struckman and Yammarino [12] differentiate between short-term and long-term change, where both could provide radical or continuous improvement.

2.2 Process of change

Descriptive research that only assesses the structure may fail to see underlying causes, whereas analyzing the dynamics of the process appears to provide powerful prescriptive insights [10]. Depending on the context there exist at least ten different definitions for the word process [23]. The process of change could be seen as an individual activity or connected activities or sub processes bringing about the processing of a task [23]; or as a sequence of dependent events [24]; or a logical, related, sequential (connected) set of activities [25]. Pettigrew and Whipp [26] have viewed change management as an analytical, educational (learning) and political process. The basic model developed by Lewin [27] consists of three steps: unfreezing, moving, and refreezing. Lewin's model is often quoted, but sometimes without the warning that freezing at the new level should be a deliberate planned objective. Merely reaching a new level is no guarantee of its permanency, even in the short term [28]. As change management has been considered as a business process like any other that a company carries out [29], the author applies process management using a triangular model. The author points out the reason for the change as the trigger event, which gives an impulse to start the process of change. The steps and activities during implementation are divided into core processes and support processes.

Trigger events. It is usually changes in the external environment that trigger a process to start. Events represent the changing state of the world [30]. A trigger event is an event whose occurrence starts a task or a workflow [23]. **Core process.** A major process is a process that usually involves more than one function within the organizational structure and its operation has a significant impact on the way the organization functions [25]. Core processes are strategically important business processes [31]. These processes form the sequential steps — the steps have some order — one should be started before the next. For example, before vision creation the need for change should be determined. **Support processes** take place during almost the whole change process and are inevitable for the implementation process as a whole. Support processes provide inputs that allow the core activities to take place. For example, in order to implement changes successfully, several support processes are needed to identify resistance as an obstacle to overcome [9]. Three elements – information, communication and training – have been pointed out as part of a definition of change management by [32]. People have to be informed about changes, then their feedback is required and intense communication starts. Finally, people have to be trained to be successful in the new business process environment [33]. The change drivers are activities or behaviors facilitating the implementation of change – leadership and participation [34]. As changes in organizational structures bring with them a redistribution of power and influence in regard to decision making, groups and individuals that are negatively affected by a reorganization, in the sense that their impact on decision making is reduced, typically are opposed to the change [35]. Handling power issues helps to remove obstacles in the implementation process. By mobilizing, the dynamic for change is created; by catalyzing, the structure of the project is created and run; by steering, actions are kept on course [36].

2.3 Readiness to change

When analyzing employee behavior in organizations implementing change, three factors should be taken into consideration – employee attitudes towards change, organizational culture, and organizational learning.

Employee attitudes. Attitudes are considered an indicator of the future success of an organization [14]. Attitude strength depends on the extent to which these attitudes are related to each person's own deeply held philosophical and political values and are of concern to the person's social group [38].

Organizational culture. Cameron and Quinn [38] stated that to sustain success, firms have less to do with market forces than with company values. Schein [39] sees organizational culture as a deep-rooted phenomenon, which cannot be changed easily — a pattern of basic assumptions that a given group has invented, discovered, or developed in learning to cope with its problems of external adaptation and internal integration. In a stable environment, it is safe to be completely task oriented, but in a turbulent environment with high interdependence, relationships need to be valued in order to achieve the level of trust and communication that will make joint problem solving and solution implementation possible [39].

Organizational learning. Learning, both institutional and individual, and the ensuing corporate changes are seen as a prerequisite for the success and survival of organizations irrespective of their size and sector [40]. A learning organization is the antithesis of the traditional bureaucratic organization [41]. The barriers to learning may stem from the culture of the organization [42] or from the past organizational experiences of the members of the organization. Organizational learning emphasizes a socially constructed process, which proceeds through sharing interpretations of events and through reflection on these interpretations [43]. Creating lasting organizational change is inextricably linked with culture change [44], which includes attitude change. Author connected 4 main elements and 9 sub-elements into one model – the triangular model of organizational change.

3. Crisis management theories

Crisis is a low probability, high consequence event that is capable of threatening organizational legitimacy, profitability and viability [1]. Most similar to crisis is transformational change. The consequences of crises are more serious than consequences of organizational change effort. Therefore consequences should be one element of the crises 'types' triangle. The other two elements of 'types' triangle are source of crises and scope of crises (Table 1).

Table 1 Types of change and types of crises

Type of change	Type of crises
Initiator of change	Source of crisis
Scope of change	Scope of impact
Duration of change	Character of crisis

In order to handle consequences external help is needed. This gives special importance to shareholders. As in crises situation quick actions are required, rules should be established beforehand. Primary and secondary shareholders should form one triangle together with values and ethical principles. This triangle could be called 'partnership' triangle and this could replace 'readiness' triangle in triangular model for crises management (Table 2).

Table 2 Readiness to change and partnership during crises

Readiness to change	Partnership during crises
Employee attitudes	Key partners
Organizational culture	Shared values and ethics
Organizational learning	Network

Readiness to crises should be viewed as the part of 'process' triangle. This triangle includes crises management strategy, with strong emphasis on pre-crisis activities. Two support processes – leadership and communication – have crucial importance during crises. These should be other two elements of 'process' triangle (Table 3).

Table 3 Processes of change and crises management

Process of change	Process of crises
The trigger event	Strategy
Core process	Leadership
Support processes	Communication

To conclude, there are common elements in change and crises management. At the same time different elements should be emphasised during these two processes. Therefore there are also differences in conceptual models of crises and change management. Therefore the basic triangle consists of three main elements that characterize every crisis: crisis type, process, and partnership.

3.1 Types of crisis

Crisis management scholars have turned a lot of attention to developing classification systems of crisis types. These systems help to reduce uncertainty when crises occurs [45]. Crises differ according to **scope of impact**. Some crises affect community as a whole, others directly threaten only a few people [46]. The crises have different **character**: Hwang and Lichtenthal [47] distinguish between abrupt and cumulative crisis. An abrupt crisis strikes suddenly and catches the management off-guard; the latter accumulates stressors and eventually erupts. Crises are **triggered** in variety of ways: by natural forces and by the deliberate acts of 'others' inside or outside that society [46]. Perrow [48] in his disasters research makes difference between natural, industrial and terrorist disasters. Lewis [49] distinguishes between the crises made by single person or group of people on one hand and natural disasters and infrastructure disruption on the other hand. He considers also organizational transition as crisis. Therefore the crises could be classified according to **sources of crises**. Coombs [50] first points out attacks on organizations, which harm organizations reputationally and financially. There are also differences in causes of public crises: mismanaged crises are characterised by failures within governmental machines and agenda setting crises expose wider social vulnerabilities and fears [51]. To summarize, the crises differ according to scope, impact and character. These are the main elements of type of crises triangle.

3.2. Partnership

Stakeholders are internal or external groups that can have an impact on the organization [45]. Stakeholders can also be segmented as dependent, impacted, unknown, supporting and intractable stakeholders [53]. The partnership triangle consists of relationships with key partners and the whole network. It is important to determine who may be helpful during different types of crises and in different phases of the crisis management process. Resources are always limited; therefore, few **key partners** should be pointed out. But all parties involved should be identified and included in the **network**. Relationships rely on values and ethics. As was seen from the analysis section of this paper, developing values and principles is not enough on its own – **shared values and ethics** are also needed.

3.3 The process

Crisis may begin with something very simple such as a crudely written flyer in high school or the much more complex multilevel disaster such as Hurricane Katrina in 2005 [54]. In the crisis management process, Curtin [53] suggest taking three areas into consideration: people, physical assets and systems. People may have low morale, physical assets may be damaged and systems may cause a communications breakdown. The implementation of change in a crisis situation often fails because senior executives abdicate their responsibility for the tough decisions to nonperforming employees or 'sacred cows' that are paralyzing the organization [3]. The crisis management process could be divided into 3 stages: pre-crisis period, the crisis itself and post-crisis. The processes of crisis management described by different authors are summarized in Table 4.

Table 4 Theories about the process of crisis management

Author	Pre-crisis	Crisis	Post-crisis
Mitroff [52]	1. Signal detection 2. Preparation and prevention	3. Damage containment	4. Business recovery 5. No-fault learning 6. Redesign
Penrose, Rasberry and Myers [55]	1. Hidden crisis 2. Pre-crisis	1. Full crisis	1. Post crisis
Turner [56]	1. Normal operations 2. Crisis incubation 3. Precipitating event	1. Onset of crisis	1. Rescue and salvage 2. Readjustment of belief system
Aba-Bulgu and Islam [57]			1. Assessment of incident 2. Crisis management planning 3. Temporary resumption of operations 4. Replacement and reconstruction of tangible assets 5. Marketing and promotion 6. Permanent resumption of operations
Rike [58]			1. Assess the damage 2. Stabilize the environment 3. Activate the in-house recovery team 4. Restore the area

To summarize the table, the first three theories could be considered proactive or preventive, because these also include elements in the period before the actual crisis. The last three are reactive since the crisis management process only starts after the damage has been done. As prevention can save lives, money and reputations [59], the first three models could be considered more advanced. There are different **leadership** styles during crisis. Connection has been found between leadership style and leaders power needs: leaders with high power need practice personal involvement and control and rarely delegate important decision tasks [60]. Decision-making during crises is also impacted by leader's general sensitivity to context and need for information: sensitive leaders gather more information and are also more willing to hear bad information [61]. The leadership style during preventive crisis management is more consultative and involves more people in the decision-making stage than the leadership style during a crisis. During a real crisis, the leader is more directive and there is less time to consult people. Also, the **communication** style before and during a crisis is normally different. During a crisis, because of the lack of information everyone is listening to announcements very carefully, trying to get more information than is actually being provided. Also, people try to read something from the behaviour of their managers; they try to read their thoughts. Therefore, their tone of voice, facial expressions, the way they carry themselves and so on are all of critical importance. In Table 5 author compares main elements of change management triangle and crisis management triangle.

Table 5 Triangles of change, crisis and innovation management

Success of Change	Crisis Management	Innovation management
Type of change	Type of crisis	Type of innovation
Process of change	Process of crisis	Process of innovation
Readiness to change	Partnership	Innovation climate

The whole triangular model of crisis management has been constructed by connecting all the previous triangles. The model for crisis management in organizations consists of 4 main elements and 9 sub-elements.

5. Conclusions

Comparison indicates similarities and differences in change and crisis management. Following part summarizes shortly the main differences. The consequences of crises are more serious than consequences of organizational change effort. Therefore consequences should be one element of the crises 'types' triangle. The other two elements of 'types' triangle are source of crises and scope of crises. Most similar to crisis is transformational change. In order to handle consequences external help is needed. This gives special importance to shareholders. As in crises situation quick actions are required, rules should be established beforehand. Primary and secondary shareholders should form one triangle together with values and ethical principles. This triangle could be called 'partnership' triangle and this could replace 'readiness' triangle in triangular model for crises management. Readiness to crises should be viewed as the part of 'strategy' triangle. This triangle replaces 'process' triangle in change management model. 'Strategy' triangle includes crises management process, with strong emphasis on pre-crisis activities. Two support processes – leadership and communication – have crucial importance during crises.

To conclude, there are common elements in change management and crises management. At the same time different elements should be emphasised during these processes. Successful change management could help to avoid crises.

Entrepreneurship in Developing Countries: Opportunities and Challenges: The Case of Jordan

Fuad N. Al-Shaikh¹

¹Professor Business Administration Gulf University for Science and Technology, Kuwait.
In Sabbatical leave from Yarmouk university, Irbid, Jordan, alshaikhfuad@yahoo.com

The main purpose of the present research was to identify the obstacles that small firms encounter in a developing country, Jordan. It also aimed at exploring whether people in charge of small firms get any kind of entrepreneurial training before they start their businesses and the skills they would like to acquire.

The research is based on review of the literature about the topic. In addition, a survey was designed to collect data from people in charge of small firms. Results indicate that one quarter of the small firms are less than 5 years, which point out to the importance of providing support to these firms as the first years of any project life are for critical for success or failure. The most important challenges that face small firms are lack of financing, raw materials prices and inflation respectively. Only 10% of the entrepreneurs received training before starting their businesses. As for the skills that entrepreneurs wish to acquire, financing came on the top of the list followed by marketing and building their business plans respectively. Finally some recommendations were made based on the results of the study.

Keywords:

Entrepreneurs, Jordan, obstacles, opportunities, social and economic development

1. Introduction

Entrepreneurs play a pivotal role in the world economy. The prominent economist Schumpeter has long recognized how entrepreneurs create what he calls creative destruction by coming up with new business ideas and changing the nature of the demand. Therefore, revitalizing the economy and giving more impetus to innovation, growth and economic development.

Entrepreneurial firms provide employment opportunities for a wide array of people, and support big firms by providing services to customers that big firms may not be able or willing to provide. Therefore, boosting the economic and social welfare of societies in which they operate.

Promotion of small and entrepreneurial firms has increasingly been recognized by many governments and economic and social development scholars as one of the means by which the dual problem of poverty and unemployment can be alleviated. As for Jordan, which is the main concern of this study rates of unemployment are much higher than many other countries. The formal statistics of unemployment in Jordan was estimated at 12.9% in 2009. The informal statistics claim that the real figures are much higher and they may go up to 25% or even higher. As for poverty level, statistics show that the percentage of people below poverty line was 14.2% in 2009 [1].

2. Why entrepreneurship and small businesses

In line with the drive for globalization and liberalization of economic policies Jordan has been concerned more than ever before about liberalization of its economic policies and promoting the role of the private sector in the economic development of the country. Therefore, entrepreneurship is emphasized. Many scholars argue that it is entrepreneurs not politicians, or economists who make the difference. The leading scholar of entrepreneurship and innovation, McClelland concurs by saying

“There is no best way to give momentum to economic development in any society better than increasing and promoting entrepreneurs” [2].

In line with the above argument, Gibb stresses that small and micro firms has the most important role in the development and economic growth of China which has been achieving impressive rates of growth over the past two decades[3]. The author of the present research is of the view that if small firms are to be supported and developed in order to contribute to the country economic and social development, understanding the reality of these firms, their features, and the challenges they face become extremely important issues to investigate.

3. Objectives of the research

This study aims at answering the following questions:

1. What are the main features of small firms in Jordan?
2. What obstacles do these firms face?
3. Do entrepreneurs have training before they start their businesses?
4. What skills do entrepreneurs in Jordan wish to acquire?
5. How small firms in Jordan can be supported?

4. Small business defined

At the outset it must be stated that there is no universal definition for small business. The definition may vary from one country to another. Also more than one definition may be adopted in the same country. Some of the criteria used to define small business are capital, volume of sales, technology, and number of employees. Probably number of employees is the most popular one. However, no consensus about the cutoff point regarding number of employees as an indicator of size. This can be attributed to different factors such as size of the economy, purpose of the definition, and nature of the business. For instance, in the USA small business is defined as the one that hires 100 employees or less [4].

As for Jordan there is also no consensus about the definition of small business. However, some attempts are made by organizations that are concerned about small businesses. For instance, the Ministry of Trade and Commerce suggests that firms that have 19 employees or less to be the cutoff point between small and medium firms. The present study will adopt this definition.

5. Previous studies

This part of the research sheds light on the previous studies. It is worth mentioning that most previous studies address small and entrepreneurial firms as one topic. This study will follow the same approach.

Alshaikh [5] in a study aimed at identifying the obstacles that face small businesses in Jordan based on a survey conducted on small industrial firms in 1995 indicated that the most important problems arranged in order of their intensity are high taxes, high interest rates, high prices of raw materials, government regulations and economic conditions. In another study by Alshaikh [6] about factors that cause small business failures in developing countries with particular reference to Jordan it was found that the most important factors are: poor planning, lack of finance, poor management, competition from big firms, and lack of experience.

Alsahlawi [7] shed light on the impact of some factors on the spread of small and medium enterprises in Saudi Arabia and found a positive relationship between spread of these firms and availability of finance.

Haddad and Alkhateeb [8] study surveyed previous studies and publications about small and medium enterprises. They classified the difficulties that face these firms into financial, managerial, marketing, and organizational difficulties.

Mahrouq and Magableh [9] also shed light on the problems that face small and medium enterprises in Jordan based on review of previous studies. They concluded that the most important problems are: high cost of capital, inflation, competition from large firms, financing difficulties due to lack of warranties, government procedures and bureaucracies, high taxes and scarcity of raw materials.

Another stream of research emphasized the role of entrepreneurial and small firms in economic and social development. Kroon et al [10] emphasized the vitality of coordination between educational institutions and business firms. They stressed the importance of incorporating entrepreneurship in the curriculum of schools in South Africa. They also highlighted the importance of being aware about entrepreneurship and self-employment which is likely to have positive impact on the economic development of the country.

Gibb [11] also addressed the role of small firms in alleviating poverty and unemployment and leveraging the economic development. He refers to China to support his argument. He compared between the level of economic development that China achieved over the past years and level of development in the Tigers countries. Gibb also elaborated on this point by emphasizing that China did not use the Western countries model but it used a model that suits the Chinese culture. According to Gibb, this policy not only helped improving the economic well-being of Chinese people but was also successful to stabilize population in rural areas which represent 70% of the population of China.

Djankov et al [12] attempted to identify the differences between Chinese entrepreneurs and nonentrepreneurs. A sample of 414 entrepreneurs and 561 nonentrepreneurs was selected. The main findings of the study are (1) entrepreneurs are more motivated and work is central thing in their lives more than nonentrepreneurs (2) most entrepreneurs have three times more entrepreneurs in their families than nonentrepreneurs.

Edminston [13] highlighted the contribution of small firms compared to large firms in economic development with special reference to the case of the United States of America. He stressed the idea that small firms are more innovative than large firms in some industries such as the small computer industry. He also emphasized the role that small firms play in employment.

Venkataraman [14] emphasizes the importance of what he calls the intangible infrastructure for promoting entrepreneurship. He believes that this type of infrastructure is overlooked. Venkataraman provide some examples about the intangible infrastructure that should be promoted. Chief among these are: generating ideas that are relevant to the region as some ideas generated in some regions may not necessarily be relevant for other regions, promotion of informal entrepreneurship forums, providing encouragement for entrepreneurs who try new ideas even if they fail. This can be done as seen by Venkatarmaran by providing jobs.

Tambunan (2007) distinguishes between 3 types of problems that face entrepreneurial firms in Indonesia which she believes to be universal problems. She classifies these problems into three main types: infrastructure problems, problems related to availability of agencies/organizations that support entrepreneurial firms and economic problems.

Joshi and Ganapathi [16] highlighted the importance of changing attitudes and future orientations of people in South and Southeast Asia towards social and economic problems. They consider this change to be the key for development and economic growth in this part of the world.

Is entrepreneurship born or can be acquired through training? Laxmana and Eshwara [17] tried to answer this question. They followed up training programs that were conducted for potential entrepreneurs in India. They found that 77% of the trainees established their own businesses after completing the training. Women were even more motivated to start their own businesses than men. 80% of women trainees launched businesses after the training programs.

A careful reading of the above literature can lead to the following conclusions: 1. There is consensus among scholars and agents interested in small and entrepreneurial firms about the vitality of these firms and their significant influence on economic and social development 2. If small businesses are to be effective and successful support must be provided to these firms. This support should not be restricted only to the public sector but other sectors should also be involved 3. More emphasis is needed to be put on rural areas to boost its development and social welfare 4. Some of the studies reviewed above depended mainly on statistics and previous studies to reach to conclusions. In other words, they relied on the use of secondary data rather than primary data.

6. Methodology

Based on the census by the Department of Statistics in Jordan the vast majority of firms in Jordan are small firms. The firms that hire 19 workers or less represent 98% of the total firms. Most of these firms are concentrated in three governorates: Amman, Zarka and Irbid. Business firms in these three governorates represent 78% of all firms in Jordan [18].

Unfortunately, there is no list that contains all small firms in Jordan or in any governorate. Therefore, this study depended on a convenient sample of firms. Sixty small firms were contacted and requested to fill the questionnaire designed for data collection. The achieved sample was 50 responses. Three of the returned questionnaire were unusable and were excluded.

The questionnaire was designed by the researcher based on review of previous studies and experience and observation of the researcher about obstacles that face small firms. The questionnaire was piloted on 10 business owners who were not included in the analysis. Based on the piloted sample some modifications were made in the phrasing and structure of the questionnaire.

7. Results

First of all it is worth providing an idea about ages of small businesses. It can be seen that ages of these firms ranges between 1 and 19 years. Twenty six percent of the firms are below 5 years old. Firms between 5 and less than 10 years represent 22%, whereas those that are 10 years to less than 15 years were 34% of the sample. Finally, small firms that are more than 15 years represented 18%. It can be seen from these results that ages of small firms is relatively low. One fourth of the sample (25%) is less than 5 years. This category of firms especially the ones that have been established recently need more support. Studies indicate that newly established firms tend to be more vulnerable to failure and problems than older firms.

Table 1 Age of Small Firms

Age Category	Number	Percentage %
Less than 5 years	12	25
5-less than 10	10	22
10-less than 15	17	36
15 and above	8	17
Total	47	100

Table 2 Challenges Facing Small Firms*

Lack of finance	4.13
Raw materials prices	3.82
Inflation	3.81
High Oil prices	3.73
Currency fluctuations	3.69
Lack of qualified employees	3.21
High wages	3.20
High interest rate	3.10
Product poor quality	1.71
Lack of political stability	1.65

The higher the mean the more serious is the challenge

Table 2 shows the main Challenges that face small firms. These obstacles were measured on a scale from one to five. The higher the score the higher would be the challenge that face these firms. Lack of finance is the most important challenge with a mean score of 4.13 followed by high prices of raw materials with an average mean of 3.82. Inflation, high oil prices, currency fluctuations followed with means of 3.81, 3.73, and 3.59 respectively. As for the least important obstacles, poor quality of product and lack of political stability were the last obstacles on the list with means of 1.65 and 1.71 respectively.

Respondents were asked about whether they have received any kind of training related to entrepreneurship and small businesses before starting their businesses. Table 3 indicates that the vast majority responded in the negative. Therefore, owners or those in charge of small firms started their businesses without any kind of training. The author is inclined to raise a question here: had those entrepreneurs taken any kind of training would that make them less vulnerable to problems? Unfortunately, it would be difficult to address this question without empirical evidence. However, common sense as well as studies in other countries suggest that training has significant influence not only on improving management of the firm but also on increasing motivation of the trainees to start their own businesses [19].

Table 3 Level of Training

Did you have training?	Number	Percentage %
Yes	5	10
No	42	40

As for the skills that the respondents want to obtain, finance-related skills were the most important. Almost half of the sample (45%) as can be seen from table 4 stressed their need to develop these skills. The desire to develop marketing skills came next (26%) followed by the desire to acquire how business plans are built and human resource management skills with 17% and 12% respectively. These results are consistent with previous results which show that financing problems is on the top of the list of problems that small firms face in Jordan.

Table 4 Skills Needed by the Respondents

Type of skill	Number	Percentage %
Finance	21	45
Marketing	12	26
Building business plans	8	17
Human resource management	6	12
Total	47	100

How small firms can be supported? Twenty nine percent of the respondents believe that this can be achieved by providing government support to domestic industries. Reducing taxes was considered by 21% of the sample as an effective means to support small firms. Providing subsidies in the startup process were highlighted by 14% of the sample. Finally, 7% of the respondents stress the need to reduce bureaucracy and government procedures and avoid concentrating new projects only in some areas such as Amman. Doing so will reduce pressures on Amman (the capital of Jordan) public

services and encourage residents of small cities and rural areas to stay where they are, therefore, enhancing the economic and social welfare of rural areas.

Table 5 How small firms can be supported?

Means of support	Number	Percentage %
Support local industry	14	29
Reducing taxes	10	21
Support startup firms	7	14
Don't concentrate projects in some areas only	3	7
Reduce bureaucracy and procedures	3	7
Other means	10	22

Table 5 shows that a substantial percentage of the respondents urge the government to take actions in the form of providing support for domestic industries and reducing taxes. Such results trigger a question related to the willingness of the government to take actions like these. In other words, are these suggestions realistic given the fact that the government in Jordan has been less involved in the economic activities?

8. Recommendations

Based on the results, the following recommendations can be made:

1. Training of entrepreneurs and small business owners is extremely important. The results show that only 10% of the respondents had training before starting their new firms. Special emphasis should be placed on financing and marketing skills. Government agencies, universities, civil societies, and nongovernment sectors can pull their efforts together in that direction.
2. Improve awareness of small business owners and potential entrepreneurs about financing resources. The researcher was able to conclude based on the interviews with the respondents that some of them don't have sufficient knowledge about sources of financing.
3. Improve awareness of those in charge of small firms about the significant role that can be played by small firms-supporting organizations. Chief among these are chambers of industry and trade, nongovernment organizations, and universities.
4. Urge small and entrepreneurial firms-supporting organizations to put more efforts to develop and support small firms.
5. Revise curricula of educational institutions by incorporating entrepreneurship, initiative and creative thinking as important skills that should be instilled in students attending these institutions.

Transferability of entrepreneurship educational programmes: Finland, Sweden and Norway

*Bjørn Willy Åmo*¹

¹*Bodø Graduate School of Business, Bodø, Norway, bwa@uin.no*

This paper compares conditions for and manifestations of entrepreneurship in Finland, Sweden and Norway. It does so as educational programs and syllabuses often are transferred between countries and implemented without a theoretically based framework for considerations regarding local adjustments. This paper then discusses the need for such adjustments and proposes a framework for local adjustments. The paper presents an outline of antecedent, process and output when discussing conditions and perceptions leading to entrepreneurial behaviour. The paper utilizes data from the Global Entrepreneurship Monitor research program in order to compare the conditions the potential entrepreneur faces, the actions of entrepreneurs and the outcome of these entrepreneurial actions. The paper then discusses how entrepreneurship programs at university level have to be adjusted to the different settings for entrepreneurship in the local countries as the entrepreneurs' experience it to be, and the entrepreneurs corresponding entrepreneurial actions.

Keywords

Entrepreneurship conditions, entrepreneurial results, transferability of entrepreneurship education programs, university level entrepreneurship programs.

1. Introduction

Entrepreneurship is considered to be an important mechanism for economic development through employment, innovation and welfare effect [1:2]. This understanding has led to a growing appreciation of the relevance of entrepreneurship education as a tool to gain such benefits [3]. In the search for educational programs serving the students' needs for entrepreneurship skills and the societies' need for entrepreneurs, universities look for best practice in entrepreneurship education at other universities to copy from. The presumption of translating good practice is that what works for one is working for the other. It is well known in innovation research that there is always a bit of invention in the adoption of innovations [4]. An innovation has to be adjusted to the local situation in order to be successful, and the more insightful this adjustment is done, the better results the adoption delivers. When an innovation, as an educational program in entrepreneurship, is to be copied by an institution, some adjustments have to be done. The adjustments needed depend on the purpose of the adoption, the complexity of the innovation, the complexity of the adopting organization and how the environment differs for the copied and the copying institution.

The study presents an antecedent, process and output outline when discussing conditions and perceptions leading to entrepreneurial behaviour. Antecedents consist of the environment as the entrepreneur faces it, the process represents the tools that the government has in hand and how they utilize it and the outcome is the entrepreneurial result. This paper addresses the need for adjustments in educational programs regarding entrepreneurship when universities inspire each other. The paper investigates the conditions for entrepreneurship in Finland, Sweden and Norway. It also reveals differences between the countries in entrepreneurship activity and their corresponding entrepreneurial results. The paper links to current research streams when it discusses how these differences influence the need for entrepreneurship education and how this entrepreneurship education should be shaped to fit the unique challenges the three countries face [5].

2. Theoretical perspectives

2.1 Antecedents to entrepreneurship

At the individual level, people act upon cues from the environment as they perceive these to be [6]. Furthermore, Aizen [6] models that the individual take into consideration both how others value the action, how one self value the action and if the individual believes to master the tasks needed for fulfilling the action, when deciding on undertaking an action. This implies that the potential entrepreneur consider how other values entrepreneurship, if entrepreneurship is suitable for him/herself, and how capable he/her is to succeed as an entrepreneur when deciding to or not respond to a perceived business opportunity [7]. In addition to this, an individual does a cost/benefit analysis of an innovation before adopting the innovation [4]. With regard to entrepreneurship, the individual will then evaluate the potential business in order to judge if acting upon the perceived business opportunity is beneficial or not. Such a decision to act could be regarded as an intention to act. Concerning entrepreneurship as a complex and time consuming task, the intention to act may differ from the actual experienced action, this as the individual has to show persistency over a lengthy time for to fulfil its entrepreneurial intentions. During this time the individual interacts with the institutional structures and other actors and may change its intention as a result of this influence [8].

2.2 The entrepreneurial process

Business opportunities have to be perceived before one could act upon it. The business opportunity exists in the nexus of the individual and the environment [9]. Research evidences that different institutional structures influence entrepreneurial differently across countries [10]. Structuration theory provides further cues on how the environment of the entrepreneurial action influences the actors. Sarason et al. [11] offers structuration theory as a lens to comprehend the nexus of opportunities and individuals. Structuration theory puts forward that the actor and the social system co-evolve in an environment where social structures both constrain and enable entrepreneurial activity [12]. The actor is viewed as a reflexive agent engaging in purposeful action. In structuration theory, the agent is viewed as having the ability to chose whether to / not to intervene in the world, and the agent usually has a full range of resources in hand to pursue his/her goal. Structuration theory has led to considerations concerning how cues from the environment may influence the entrepreneur's action and how he/she wants to represent these actions. Furthermore, the entrepreneur with its human capital is both enabled and constrained by the socio-economic context. This as the structural properties of a social system consists of the habitual arrangements and the means that guides people's everyday life [13]. This implies that entrepreneurship education has to fit to the cultural and industry context [5].

2.3 The outcome of entrepreneurship

Entrepreneurship is a socio-economic phenomenon. The Global Entrepreneurship Monitor model [14] links the individual's perception of the opportunity, the conditions for entrepreneurship as provided by the societal structures, the established business structure with the entrepreneurial action. The GEM model assumes that institutional characteristics, demography, entrepreneurial culture, and the degree of economic welfare all shape a country's entrepreneurial landscape. Entrepreneurial activity rates may differ across countries for cultural, institutional, economic and demographic reasons [15]. This study discusses how the social, cultural and political context influences entrepreneurship education and how the entrepreneurial education again influences entrepreneurship activity, attitudes and aspirations. The GEM model allows each country to have its own growth trajectory regarding entrepreneurship. The trajectory depends upon its starting point and how the actors in sum chose to interpret and act upon these cues. Differences in entrepreneurial activity levels may be specific to regional economic, demographic and cultural contexts and may be composed of entrepreneurs who may vary in type and aspiration [14]. The Global Entrepreneurship Monitor defines entrepreneurship as 'Any attempt to create a new business enterprise or to expand an existing business by an individual, a team of individuals, or an established business' [16].

3. The methodology

The Global Entrepreneurship Monitor (GEM) project utilizes three different data sources for its analysis. This is the Adult Population Survey data, (APS), the National Expert Survey (NES) data and third part indicator data. The data used in this paper consists of APS data from 2007, NES data from 2004 and indicator data from 2008. This is the latest data sources available that contains comparable data from Finland, Sweden and Norway. Finland and Norway has conducted APS and NES each year since they joined the research project. Sweden participated last time in GEM in 2007 and the last time NES data was collected in Sweden was in 2004.

The Adult Population Survey (APS) addresses minimum 2000 randomly selected respondents in each country. The APS addresses the adult population aged 18 to 64 and investigates the respondent's relationship to entrepreneurship. Besides asking how the individual perceives the conditions for entrepreneurship to be, GEM asks the respondent if they currently try to start a business, or have started a business during the last 42 months. It also asks whether the respondent owns a business. GEM measures entrepreneurship by different means. A nascent entrepreneur is an individual who is actively in starting a business, owns part of or all of the business, but the business has not yet paid wages to the founder(s). Baby businesses are established businesses that have paid wages to their owners for a shorter period than 3.5 years. Early phase entrepreneurs (TEA) consists of nascent and baby businesses. Established businesses have paid wages to their owners for more than 3.5 years. The APS data from Finland represents 2005 adults aged between 18 and 64; in Sweden it represents 1712 while the Norwegian data represents 1541 adults.

The National Expert Survey (NES) addresses 36-50 experts in entrepreneurship asking them to state how they perceive conditions for entrepreneurship in their country to be. The national experts were asked to give their opinion on a multitude of subjects related to conditions for entrepreneurship. The items were represented by a 5-point Likert scale with the additional option of "don't know" or "don't apply/refuse to answer". Based upon all NES data from all GEM countries, GEM provides a Principal Component Analysis (PCA) combining the items in variables describing certain aspects of the national conditions for entrepreneurship. The numbers in the tables in this study then represent a PCA of the expert's responses to multiple items addressing each entrepreneurial condition. The higher the value on the PCA, the more agree the expert is that the conditions are favourable for entrepreneurship in their home country. Further information on the GEM research project and the methodology could be found in Reynolds et al. [17]. We were able to retrieve the full APS and NES datasets from Finland and Norway. Hence we could compare the values for the Finnish and the Norwegian items using independent samples T-tests. For the Swedish data we were only able to obtain the mean value for the items. This implied a one-sample T-test where we compared the Swedish mean for the given variable with the values from the Finnish or the Norwegian full dataset. The third data source GEM uses is indicators at a national level gathered from multiple official sources. Examples of such could be GDP or demographical data. The data in the tables in this study then represents actual numbers or actual occurrence of a phenomenon per 1000 inhabitants. The data from third data sources are all actual numbers representing the full population. This implies no variation, hence all differences are statistically significant. Whether the difference is meaningful rests on the arguments in the discussion.

4. Findings

The institutional structures represent the national environment for entrepreneurship. The structural factor influencing entrepreneurial activity is among others the size of internal markets in a country. In the long run the government is able to shape some of the structure for entrepreneurship. It could improve its institutional structures for entrepreneurship by put into effect programs supporting entrepreneurship, i.e. finance, infrastructure or education. Another antecedent to entrepreneurship is how suitable the population finds entrepreneurship as a tool for themselves in improving their living conditions or realizing other personal goals. The institutional structure for entrepreneurship manifests itself in conditions for entrepreneurship, as perceived by the potential entrepreneur.

4.1 Antecedents to entrepreneurship

Table 1 describes the antecedents to entrepreneurial activity. The table shows that in the experts' opinion, the governmental emphasis on improving conditions for entrepreneurship is higher in Finland and Norway than in Sweden and that these conditions are evaluated to be most supportive in Finland.

The figures in table 1 based upon APS data informs that there is a bigger share of the population in Finland and Sweden that perceive it to be better conditions to start a business in the area where they live, then in Norway. Likewise, the data indicate that the Swedes are more confident that they possess the necessary knowledge and skills for starting a business than does the Norwegians. Even so, Norwegians and Finns agree more often that entrepreneurship is a good career choice than does Swedes.

Table 1 The antecedents for entrepreneurship in Finland, Sweden and Norway

Entrepreneurial antecedents	FINLAND	SWEDEN	NORWAY	Finland vs Sweden	Finland vs Norway	Sweden vs Norway
Expert data						
Governmental emphasis on improving conditions for entrepreneurship	3.17	1.84	2.15	***	***	n.s.
Adult population survey						
YES: Good conditions to start business next 6 months in area I live, % of population aged 18-64	52.96	50.33	46.29	n.s.	**	**
YES: Has the required knowledge/skills to start business, % of population aged 18-64	39.73	41.65	36.23	n.s.	n.s.	***
YES: People consider starting business as good career choice, % of population aged 18-64	37.48	52.38	54.95	***	***	n.s.

Note: Level of statistical significance: *** indicates $p < 0.01$, ** indicates $p < 0.05$, * indicates $p < 0.10$, n.s. indicates not significant, n.a. indicates significance not applicable.

4.2 The entrepreneurial process

The entrepreneurial process is an enactment of the institutional structures for entrepreneurship. The motivation and the capacity for entrepreneurial deeds among the population is also a sign of how the institutional structures are converted to entrepreneurial activity. The conditions for entrepreneurship are interpreted and acted upon at the individual level. This perception is then translated to motivation and intentions toward entrepreneurship. As there are different conditions for entrepreneurship across countries, the entrepreneurial process are then different. These differences in entrepreneurial action reveals itself as differences in start-up aspirations, number of owners necessary for handling the complexity in the institutional structures, and in purpose and motivation for the entrepreneurial action. Table 2 displays some of the processes the government is in control of and that influence the entrepreneurial climate in a country. Table 2 indicates that in the eye of the experts, the Finnish population is more capable and motivated to engage in entrepreneurial opportunities than are the Norwegian and the Swedish population. The Swedes are less motivated to engage in entrepreneurship. Table 2 further reveals some of the entrepreneurial processes of individuals in Finland, Sweden and Norway. The table shows that 10.4% of the Swedish population expects to start a new business within the next 3 years, and that this interest is lower in Norway (8.9 %) and Finland (8.65 %). Further, the number of expected owners per business start-up is higher in Norway and Sweden than in Finland. Norway has the highest number of owners per start up (2.39), Sweden the second highest (2.26) while Finland has the lowest (1.89). The purpose of establishing the business is also influencing on the survival and growth trajectory of the firm. The Finnish entrepreneurs have more serious intentions with their business than do the Swedish and the Norwegian entrepreneurs, we see that on the percentage of the entrepreneurs that intend to work full time in their business. Moreover, the table displays that the Finnish entrepreneurs start their business because they want more independence more often than do the Swedish and Norwegian counterpart.

Table 2 Entrepreneurship processes in Finland, Sweden and Norway

Entrepreneurship processes	FINLAND	SWEDEN	NORWAY	Finland vs Sweden	Finland vs Norway	Sweden vs Norway
Expert data						
The entrepreneurial capacity of the population	2.85	1.91	2.46	***	**	***
How motivated the population is to engage in entrepreneurial opportunities	3.11	2.49	2.99	***	n.s.	***
Adult population survey						
YES: Expects to start a new business in the next 3 years, in % of the population aged 18-64	8.65	10.36	8.9	***	n.s.	*
Average number of expected owners in the new firm	1.87	2.26	2.39	***	*	***
Among those in process of starting a business or owning a business younger than 3.5 years: Full time involved	58.36	45.8	44.32	***	***	n.s.
Among those in process of starting a business or owning a business younger than 3.5 years: Opportunity Type: Independence	59.66	51.01	43.5	*	**	n.s.

Note: Level of statistical significance: *** indicates $p < 0.01$, ** indicates $p < 0.05$, * indicates $p < 0.10$, n.s. indicates not significant, n.a. indicates significance not applicable

4.3 The outcome of entrepreneurship

The entrepreneurial process provides results both nationally and for the entrepreneur himself. The research and development process may result in patents and a successful patent may lead to royalties. Another entrepreneurial output is the share of the population starting up a new business, owning a business or supporting others businesses. Likewise, the entrepreneurial output in a country is hallmarked by which production process and products the entrepreneur addresses their selected markets with. These entrepreneurial outputs are a result of how the entrepreneur judges the structural arrangements supporting entrepreneurship and his human capital. Table 3 reveals some national level output from entrepreneurial activity among inhabitants in the country. Such an innovative behaviour could be manifest in patents securing the commercial value of the innovation. The table reveals that the inhabitants in Finland are the ones filing most patents in their home country. The early phase entrepreneurial activity (TEA) measure consists of persons that are either nascent or baby business owners. The table tells that there is more early-phase entrepreneurship in Finland and Norway than in Sweden. The TEA rate in Finland is 6.9, Sweden 4.2 and Norway is 6.5 for 2007. TEA is early phase entrepreneurial activity and measures those presently giving effort to starting a new business including those owing a new business not older than 42 months old. The Finnish and the Norwegian entrepreneurs expect more often that the business they start will hire employees during the next five years than does the Swedes. Even so, high growth entrepreneurs as measured as intent to have 20 or more employees in 5 years from start-up are more common in Norway and Sweden than in Finland. The entrepreneurs in Finland, Sweden and Norway are addressing markets differently. The Swedish entrepreneurs in general more often offer products that are new to all costumers, than do entrepreneurs from Finland and Norway. Norwegian entrepreneurs rarely reports to offer products new to the intended customer. Even so, Norwegian entrepreneurs tend to use newer technology than do entrepreneurs in Finland and Sweden. Norwegian entrepreneurs and business owners more often address foreign markets than do Swedes and Finns. The data might indicate that there are more business angles per capita in Norway than in Sweden and Finland. Business angels are those investing in other persons firms.

Table 3 Entrepreneurial output in Finland, Sweden and Norway compared

Entrepreneurial output	FINLAND	SWEDEN	NORWAY	Finland vs Sweden	Finland vs Norway	Sweden vs Norway
National characteristics						
Patent applications filed by residents in 2005, per million aged 18-64.	552,6	452,2	395,8	n.a.	n.a.	n.a.
Adult population survey						
TEA involvement: setting up firm or owner of young firm (SU or BB) , in % of the population aged 18-64	6.91	4.15	6.47	***	n.s.	***
TEA - any jobs now or in 5 years	4.7	3.34	4.32	*	n.s.	*
TEA - expects more than 19 jobs in 5 years	0.41	0.74	0.77	**	**	n.s.
Product new to all customers, in % of those within TEA	12.19	15.57	7.62	n.s.	***	***
Uses very latest technology (only available since last year) , in % of those within TEA	14.17	8.68	25.27	*	**	***
% within TEA, no customers outside country	67.73	65.23	50.9	n.s.	**	***
YES: Provided funds for new business in past 3 years exclusive stocks & funds, in % of the population aged 18-64	3.31	3.74	3.87	n.s.	n.s.	n.s.

Note: Level of statistical significance: *** indicates $p < 0.01$, ** indicates $p < 0.05$, * indicates $p < 0.10$, n.s. indicates not significant, n.a. indicates significance not applicable

5. Conclusions and discussions

The paper presents antecedent, process and output of entrepreneurship and compares institutional structures and individual perceptions leading to entrepreneurial behaviour in Finland, Sweden and Norway. As indicated by previous research [5] and suggested by GEM data, there are differences regarding antecedents to -, the process of -, and the output of entrepreneurship between the three countries; Finland Sweden and Norway. Antecedents much consists of the environment as the entrepreneur face it, the process is the tools that the government has in hand and how they utilize it and the outcome is the entrepreneurial result. As indicated by the data, there are institutional structures regarding antecedents of entrepreneurship that differ between Finland, Sweden and Norway. These differences are influencing how suitable the inhabitants find entrepreneurship as a tool for themselves. According to the national experts are the Finnish government more engaged in improving the conditions for entrepreneurs than are the Norwegian and the Swedish government. Sweden has the largest part of its population agreeing that they feel confident that their knowledge and training is sufficient for starting a firm, while Finns less often believe that entrepreneurship is a suitable career path for them. There are more perceived business opportunities in Finland per capita than in Norway and Sweden. Looking at the entrepreneurship process indicators, Sweden are more focused on research and technology development than are Finland and Norway. Even so, both entrepreneurship motivation and capacity is stronger in Finland than in Norway and Sweden. The data also informs that there are comparatively more Swedes expecting to start a business in the next three years, while the Finnish are more determined to start a full time business than are Swedes and Norwegians. There are remarkable differences in entrepreneurship motivation among the three countries as well. The Finnish are more concerned for achieving independence. Likewise, there are important differences in entrepreneurial outcomes as well. The Swedes and the Finnish are more eager to formalize their research achievements into commercial commodities than do their Norwegian counterparts. The entrepreneurial output differs in several other ways across the three countries as well. The Swedes are less engaged in entrepreneurship than are Norwegians and Finnish. Norwegians are more convinced that their start up effort will result in a big company with many

employees, and the start-up teams are bigger than in the Sweden and the Finland. The Norwegians start up is based upon more recent technology than are the Finnish and the Swedish. Even so the Norwegians are not to the same extent introducing new products to the market, as are the Swedish and the Finnish. The Norwegians are more export oriented than are the Finnish and the Swedes.

6. Implications for entrepreneurship education

In order to be inspired from good practice, good practice has to be recognized as such. A good practice is regarded as a success measured along the goals of the activity. Regarding entrepreneurship education at universities, this implies a discussion of the goals of entrepreneurship education at the specified universities. An educational institution has to relate to the present situation and can only to a certain extent try to change the direction of the established industry. This as the industry is founded upon a growth trajectory based on and evolved out of the local adjustments to the local resource base and the global requirements. Good practice in entrepreneurship education is then serving the needs of the industry while aligning with the institutional structures shaping the entrepreneurial opportunity.

There are many entrepreneurs in Finland, they tend to start full time firms, and they tend to start their firms to achieve independence. Even so, entrepreneurship is not recognised as a good career choice in Finland. Finns does not to the same extent invest in others businesses as business angles. Finns start their firms alone more often than in Sweden and Norway. The GEM data indicate that Finnish entrepreneurs that start in teams, more often than those starting alone succeeds as a business owner. The high TEA rate in Finland indicates a high level of entrepreneurship in Finland. Even so, the data points to some challenges for Finnish entrepreneurs. They tend to start firms with low growth ambitions and they tend to involve fewer people in the start up process. Involving more people in the start up process allows diversity in human capital, such a multitude of human capital could induce higher growth ambitions. Finns tend to see entrepreneurial opportunities but do not trust on their own entrepreneurial capabilities [18]. Finnish universities offering entrepreneurship programs could respond to this challenge in order to ensure more successful entrepreneurs.

In Sweden, the entrepreneurs are fewer than in Norway and Finland. This even as the Swedes perceive there to be good business opportunities and they have adequate skills for responding to these opportunities. There is an untapped potential for entrepreneurship in Sweden, this is evidenced by the GEM data. There are more Swedes expecting to start a firm in the next three years than in Norway and Finland. Even so, the entrepreneurial capacity is lower in Sweden. The Swedish government does not focus on entrepreneurship to the same extent as does the Finnish and the Norwegian government. Even though Swedes see themselves as entrepreneurs, they do not act as entrepreneurs. From the data, it seems like the Swedish challenge is to release the entrepreneurial potential. Entrepreneurship education in Sweden could be directed toward motivating the students to start their own business, and it could be directed toward understanding how the government could strengthen the institutional framework for entrepreneurship in Sweden.

The entrepreneurs in Norway tend to start firms with high growth ambitions using new technology addressing foreign markets with well known products. The challenges for Norwegian entrepreneurs are related to improving their business idea in such a way that the growth ambition is fulfilled. Securing that the circumstances around the new technology is taken in consideration in such a way that the implementation and use of it is successful and at the same time that their well known products are welcomed by the market. Securing the property rights to their technological inventions is also a problem in Norway. Entrepreneurship education in Norway could be directed toward strengthening the business plan process by focusing on the commercialization of technology and market knowledge.

The differences present between Finland, Sweden and Norway regarding entrepreneurship does imply that care has to be taken when copying entrepreneurship education programmes. When searching for educational programs, syllabuses or educational elements to take home from other universities, considerations on the purpose of the education should be made. The suggestions condensed from this research is then for the universities translating good practice within entrepreneurship education to investigate which needs this good practice serves, and compare this needs with the needs the copying university is to serve. When the needs are similar, the chances are that the provided solutions will work also for the copying university. It is also useful to have in mind that different needs may require different projected aims for different audience with different pedagogical matters and forms [5].

Research and innovation have gained special attention world-wide in the last decade. Their impact on economic and societal development, as well as on competitiveness and growth of businesses, is widely acknowledged. Highly-skilled people often referred to as ‘knowledge workers’, are in the centre of several studies and policy actions. The role of researchers as generators of new knowledge and innovative ideas, and agents for knowledge sharing and transfer has essentially grown. The necessary support for their professional career development and mobility has been in the centre of several fora and actions at European and national level. However, results of a recent survey carried out in Bulgaria under the FP7 I-SEEMob project highlight that there are still a number of problems related to intersectoral mobility of researchers, and the collaboration between industry and academic community. A recent study on national environment in Bulgaria provides the remaining barriers for linking industry and universities for joint research and innovation.

researchers’ career, industry-academia collaboration, innovation

1. Introduction

Research, innovation and lifelong learning have gained special attention in the last decade as critical factors in the knowledge economy. Their impact on economic and societal development, as well as on competitiveness and growth of businesses, is widely acknowledged. Highly-skilled people, often referred to as ‘knowledge workers’, are in the centre of several studies and policy actions. The role of researchers as generators of new knowledge and innovative ideas, and agents for knowledge sharing and transfer has essentially grown. Subsequently, several researchers pointed out the importance of mobile people as transmitters of technology and tacit knowledge [1], [2], [3], [4]. For companies, in particular, incoming researchers influence strongly their innovation performance through access to high-value knowledge, and thus provide higher competitive advantages [5].

How to convert knowledge into socio-economic benefits, how to facilitate knowledge transfer, and how to enhance European excellence in research and technology development (RTD) – all these issues are discussed at several fora in Europe. In the last few years a number of initiatives have been launched by the EU in order to boost research, innovation and technology uptake in Europe, and to facilitate the career and mobility of researchers [6]. In particular, in its recent Innovation Union flagship initiative[1], EU emphasises the need for:

- ensuring excellence in education and skills development
- overcoming the fragmentation in the European Research Area (ERA)
- supporting the movement towards a ‘fifth freedom’
- supporting open innovation and creativity
- enhancing regional cohesion.

In accordance with ERA objectives and priorities, the main goal of the FP7 funded project I-SEEMob is to contribute to the enhancement of the career development of researchers in ERA by examining the existing legal and research policy gaps hampering the intersectoral mobility of researchers in the South-Eastern European (SEE) Countries participating in the consortium and, accordingly, provide recommendations and guidelines to the respective governments so as to raise the remaining obstacles and to promote intersectoral mobility. Subsequently, some of the project activities focus on mapping the current state of industrial representation on RTD sector in SEE and its respective needs, as well as investigating legislation barriers linked to career development of researchers in SEE with a special focus on industry-academia collaboration.

This paper summarizes the results of the work carried out within the I-SEEMob project in Bulgaria. First, it provides an overview of the research and innovation environment in Bulgaria, present trends, and remaining challenges. Second, the results of a survey carried out recently within the project are presented as.

2. Environment for research and innovation in Bulgaria

A quick look at the position of Bulgarian research and innovation system in Europe provides the European Innovation Scoreboard 2009 (Fig. 1).

Figure 1 Innovativeness of European countries, source [6]

Bulgaria is among the catching up countries and takes the last place according the overall innovation indicators considered (29 indicators in total). This group includes also Romania, Latvia, Croatia, Serbia and Turkey, and it is characterised by a growth trend and catching up of more advanced countries. In fact, all data available show that only Romania is growing at higher rate then Bulgaria. It is interesting to note that Bulgaria shows relatively high growth in production investments, which are unfortunately not giving the expected high economic effects. Namely, the economic effectiveness of innovations and the relationships within the whole system of research, innovation and technology development (RTDI) are placing Bulgaria at one of the last positions in Europe. At the same time, it should be taken into account that the data were taken in the first years of EU membership of the country, and before Bulgaria was severely hit by the global financial crises, and the following sharp decrease of state investments in research and innovation. The European Innovation Scoreboard data further highlight the low increase of human resources in research, where Bulgaria still preserves quite good position in Europe, again severely hit in the last few years by the funding policy of the government [6].

In general, the RTDI system shows serious weaknesses [7], [8].

- First, there is a lack of vision for the development of the system as a whole, and long-term national priorities are missing which link the need of economy and society with the available research results and opportunities. The National Strategy for Scientific Research is in consultation process, while the new law on the academic development staff was stopped in the end of 2010 and next steps for reaching consensus between the Minister of research, Council of Rectors and all other parties concerned are not envisaged.
- Second, the lack of sufficient coordination and collaboration among institutions in charge of RTDI development in Bulgaria reflects not only the horizontal links within the system, but reflects also on its funding opportunities. For example, the Operational programmes available for Bulgaria under the Structural funds support some needs of the RTDI system, however, this is done unstructured, partially and without a clear strategy. Moreover, the state funding of research and higher education continues not to be linked to real merits of the funded organisations, e.g. the created scientific products and new knowledge, as well as does not consider what kind of demands for highly skilled specialists exist on the labour market.

Although these weaknesses are pointed out in several reports in Bulgaria and in Europe, there are no real actions to overcome them [6], [8], [9]. The institutions building the 'knowledge triangle' continue to be separated. The trend for separating research from higher education activities is still dominating the system – the institutes of the Bulgarian Academy of Sciences (BAS) are funded for doing research, while state universities get funding only according to the number of students they are preparing at bachelor and masters level. However, the introduction in the last 2-3 years of a special funding mechanism for support of research projects at the state universities via the National Research Fund could be considered as a positive sign.

It should be pointed out that an effort was made towards the improvement of the research infrastructure in Bulgaria so that to be created poles of excellence in emerging fields of science and also in areas of strategic importance for the country and the region. A Roadmap on the research infrastructures was adopted by the Council of Ministers in 2010. In the same time, Bulgaria still has no defined priorities and reformed public research system.

Considering what has been changed after the accession of Bulgaria into the European Union, emphasis was put on the implementation of several new funding mechanisms for improving the national research system towards more competitive and contemporary environment, adoption of national programmes for doctoral students (PhD) and young researchers and increasing funding under bilateral cooperation. It should be also pointed out that the trends towards integration into the ERA influenced a decision for increasing the percentage of public investments in research up to 1, 5 % from the GDP, however, due to the finances crisis in 2010 the "push" from the integration process was lost. Meanwhile, the work of the Bulgarian Innovation Fund was also blocked due to the lack of enough funding. Subsequently, the private sector which was very hard persuaded to start investing in universities or academia partnerships has been discouraged. Due to these facts, combined with the lack of efficiency and lack of instrument for research-industry collaboration under the Structural Funds, Bulgaria really lost its capacity for supporting innovations and creating an environment for the business investment in competitive research. It should be taken into account also the fact that due to the Innovation Union flagship initiative and the Europe 2020 Strategy, the government started in 2011 some new actions towards increasing the quality of primary and secondary education and improving the children competencies in entrepreneurialship. Calls for set up technology parks and technology transfer offices were also launched recently which could provide eventually new impetus to industry-academia collaboration.

3. I-SEEMob survey results

In the context of changing situation in the SEE countries and the preparation of many of them for joining the EU, the I-SEEMob partners agree that a methodology for elaboration of national reports analyses on industry-academia collaboration and particular for the mobility of researchers between both sectors should be created. In fact, the legal frameworks and national regulations in research and innovation are quite different in each country. The lack of common legal framework for the whole Europe seems to be one of the crucial points for the next programme period and the realisation of the Innovation Europe.

From this point of view, the team of Sofia University embedded almost all relevant factors for independent analysis on the industry-academia collaboration environment starting from the overall characterisation of the research environment in the countries, prioritisation in science and

governmental policy as research and innovation strategies, laws and regulations to the management of RTDI and the necessary management bodies/structures. Important part of the methodology is devoted to the industry working environment for researchers – good practices but also barriers for this collaboration as lack of incentives, transfer of projects and contracts, government support for recruitment of researchers within industry sectors and so on.

The research methodology, proposed for legislation gap analysis related to the inter-sectoral mobility of researchers in SEE, includes a survey among Bulgarian researchers and business organizations. The survey was performed by distributing an on-line questionnaire for collecting data, developed by the Bulgarian university team. The questionnaire comprises 20 questions, some of them open-ended and others multiple-choice questions, focused on various aspects of the existing research environment, the collaboration between academia and industry, and the available opportunities and barriers to inter-sectoral mobility of researchers. The first survey results, presented in this paper, are based on the responses received in December 2010 and January 2011, from about 60 representatives of the academic community, business organisation, NGOs, public administration and media.

The first group of questions is focused on the perception of the research environment in Bulgaria by researchers and business organizations (Fig. 2). In general, the survey shows not very positive assessment of the Bulgarian research environment. The majority of the respondents consider that it is not favourable for competitive development and attracting best researchers in Bulgaria. Besides, for most of the respondents the policy environment for research does not comply to the general European requirements. About 60-70% of them point out that the research infrastructure is usually insufficient, inadequate (not world-class), or not easily accessible. That fact could be almost acceptable for people who are not working in research in Bulgaria, but it could be highlighted that there is comparatively contemporary research infrastructure in almost all important fields of science. Under FP6 and FP7 and with the funding ensured by the National Research Fund (NRF) more than 30 research excellence centres have been supported. Therefore, the percentage of people who believe that there is no favourable infrastructure and/or equipment is pretty confusing. However, these results could be explained by the lack of transparency and proper regulation for providing access to the available infrastructures.

Almost the same percentage of the respondents (60-70%) considers that there is a lack of effective public-private cooperation and partnerships, effective knowledge-sharing between public research and business organisations and the general public, and of well-coordinated research programs and priorities including significant co-planned investments in the public research system. In fact, the prioritization of research turns to be one of the most important factors for industry-driven research as the available funding is usually dispersed into different small projects and initiatives. Moreover, the evaluation of the effectiveness of those funded research actions could hardly lead to any adequate recommendations. The reason is that the fragmentation of the sector can not provide relevant picture of national industry and society needs. Within the National Strategy for Scientific Research is made an attempt for such a prioritisation, but the lack of consensus within the academic society once more diminishes the effect of this attempt. Perhaps the SEE countries, including Bulgaria, have to find out in the context of the Innovation Union which are the priority areas of the economy and society. Otherwise, they will lag behind the modern societies development trying to satisfy all/different interest of researchers, industry, politicians forgetting about the needs of the next generation.

Figure 2 Research Environment Evaluation

The only aspect that is relatively positively evaluated by the survey respondents concerns the competence of researchers. Almost half of them believe that there is an adequate flow of competent researchers in Bulgaria. It could be concluded, therefore, that most of the problems in the Bulgarian research system are due to factors different from the human factor. Despite the severe decline of researchers (due to ageing mostly) in many public research organizations in the last few years, e.g. in BAS, the Agrarian Academy, and several universities, and the overall drop off of the traditional for Eastern Europe excellent research capacity in engineering and natural sciences, the RTDI system is still producing researchers with adequate knowledge and skills. There is a relatively high number of excellent experienced researchers, and a quite high inflow of qualified young researchers. The survey results show that the inflow of competent researches is most intensive in the fields of Mathematics and Informatics (according to 51% of the respondents), and Biology and Medicine (51%). Competent researchers are also available in the areas of Natural Sciences (42%) and Engineering Sciences (30%). The lowest result is achieved for the Social Sciences/Humanities field (4%). These results are easily predictable taking into account the overall misbalance between the society needs and the number of students trained. Moreover, many researchers working in the field of social sciences have not been able to adequately adapt during the last twenty years of economic and societal changes, in order to fit into the European science trends and needs. The general problem is, however, that many young researchers are leaving the Bulgarian RTDI system towards better paid and promising jobs. The unfavourable conditions offered to potential PhD candidates, and the ageing teaching staff, leading to the lack of well trained and motivated young teachers and lecturers (especially in engineering studies, physics, biology, etc.) could further lead to lack of enough PhD students.

Another group of questions focuses on the relations between research and industry. More than half of the survey participants (55%) consider appropriate for industry-academia partnership all tools listed in the questionnaire, e.g. providing internships and/or grants for graduate students and researchers in companies and industry; participation of representatives of industry and other non-government organizations in the research organisations or university management; collaborating in joint research programs and projects; industry realization of intellectual products and services created by academic institutions. A preference is given to the collaboration in research projects and programs (26% of the respondents), which is not surprising because that tool is becoming more popular and proves to be effective in the Bulgarian research environment. Unfortunately, most of the survey participants (75%) think that there are no favourable conditions in Bulgaria for transferring academic knowledge to industry and for practical application of the tools mentioned above for the successful achievement of industry-academia partnerships. The negative view on that partnership is also evident in the subsequent responses. Asked to share a specific example of their practice where industry members are actively involved in research projects, only 19% of the respondents point out the National Science Fund as an institution working to improve the academia-industry collaboration. Enhancement of research infrastructure, Doctoral fellowships between research organization and SMEs, and Grant schemes within the NSF are pointed out as good practices towards establishment of industry-academia partnership. About three thirds of the respondents (74%) did not provide an answer to that question which can be interpreted as a difficulty for giving examples of good practice under national funding instruments at all. According to the survey results, the scientific areas that are mostly supported by the business sector are Engineering Sciences (44%), Mathematics and Informatics (26%), and Economy and Business (20%). The group of respondents thinking that no scientific field is supported by the business sector is also quite large (12%).

The survey reveals that industry is also not prepared to enhance the collaboration with academic institutions or to foster mobility of personnel between both sectors. Half of the respondents (50%) did not reply to the question related to sharing a concrete example of good practice for career development of researchers in the industry, more than third (36%) think that "The industry in Bulgaria doesn't really care about science", and 25% announce that "There are no good practices in Bulgaria at all". One of the most important conditions for successful implementation of inter-sectoral mobility is good management and transfer of knowledge and intellectual property. The Bulgarian Academy of Sciences is the institution pointed out to be the best in coping with this role, stated by 21% of the survey participants in one of the open questions. However, 92% of the respondents have not answered the question, which could be due to low activity and lack of information about this issue, or could be related to the above mentioned difficulty to provide examples of good practice.

The government is expected to play an important role for encouraging the inter-sectoral mobility of researchers providing financial and other stimuli, and setting the general scene. However, its role in Bulgaria is not positively assessed by most of the respondents, both for stimulating a dialogue and collaboration among all stakeholders, as well as the development of diversified research career

(Figure 3). The evaluation by the respondents of various aspects influencing the development of strong relations between government, academia and industry, reveals that there is a lack of trust in the governmental policy and funding framework for implementation of the ERA in the country, as well as not enough incentives are in place for attracting private investments in research (Fig. 3).

Figure 3 Government-Academia-Industry Relations

About two thirds of the respondents (60%) expect industry to be directly involved in the development of technology and innovation, and not to rely on support from the state. The other third (32%) prefer the business organizations to contribute indirectly (in relationship with the government: through the creation of lobbies, sponsorship, scholarships, etc.).

Another important focus of the survey is the availability of programs and practices for encouraging and supporting the academia-industry collaboration. The most important instruments that are implemented in Bulgarian organizations are creating academic centres (30%), encouraging students to apply for funding for various programs related to innovation and new technologies (30%), national projects for training of additional skills (communication skills, awareness on IPR, research management, etc.) (23%). Creating student companies is still not so popular instrument in Bulgaria (4%).

Figure 4 National Innovation Policy

The final group of questions is directed at the National Innovation Policy (Fig. 4). They reveal that most of the respondents (66-74%) do not believe that the national innovation policy sets clearly thematic priorities in accordance with the national demand. Besides, the most important innovation fields/technologies are identified according to the scientific areas in which the domestic science must

be developed. The respondents are also not confident of the availability of a clear framework for the policy implementation (74%). For the majority of them, the innovation implementation plan is not launched in practice using specific actions (66%), and the implementation process is not well coordinated among all relevant actors (74%). About two thirds of the respondents (64%) do not agree that plenty of training and education programs are available and help improving the knowledge on innovation. Almost the same percentage (70%) stresses that the quality of the available education and training is not high enough.

3. Conclusions

The enhancement of industry-academia cooperation in terms of research training, career development and knowledge, skills and services sharing, taking into account the protection of intellectual property rights, have to be further promoted, encouraged and also understand especially on national level. Of course the politicians have the major burden to integrated specific measures within the National Development Plans and National Strategic Reference Frameworks in correspondence with the Operational Programmes of the Structural Funds. But university and industry partners have to invest efforts as well especially towards involvement of young people, modernization of educational agendas, cultural and ethical adaptation of new global trends, etc.

The statistics and sociology analyses show that the year 2010 was one of the most difficult for the national industry in Europe and particularly SMEs. This reflected also on the RTD funding and policies, decreasing the level of financial support. Therefore, there is a clear need of boosting investments in innovations in such periods of economic fall-down and promoting under the European Economy Recovery Plan “the need to direct action to “smart” investment” and especially further research development at the manufacturing and business sectors.

Relative Efficiency of Higher Education in Slovenia and Croatia: Inter-country Non-Parametric Approach

Aleksander Aristovnik¹, Alka Obadić²

¹Faculty of Administration, University of Ljubljana, Slovenia, aleksander.aristovnik@fu.uni-lj.si

²Faculty of Economics & Business, University of Zagreb, Croatia, aobadic@fzg.hr

The article measures the relative efficiency of government spending on higher education in selected CEE (with special focus on Croatia and Slovenia) in comparison to selected OECD countries. The article applies a non-parametric approach, i.e. data envelopment analysis (DEA), to assess the relative technical efficiency of higher education across selected countries. When estimating the efficiency frontier we focus on measures of quantities outputs/outcomes. The results show that the relatively high public expenditure per student in Croatia should have resulted in a better performance regarding the outputs/outcomes, i.e. a higher rate of higher education school enrolment, a greater rate of labor force with a higher education and a lower rate of the unemployed who have tertiary education. On the other hand, regardless of the input-output/outcome mix, the higher education system in Slovenia is shown to have a much higher level of efficiency compared to both Croatia and many other comparable CEE and OECD countries.

Keywords

Higher education, funding, efficiency, DEA, Croatia, Slovenia, EU, OECD

1. Introduction

Education influences economic growth; Denison (1985) estimates that typically a quarter of the growth of output per person arises from increases in educational attainment. Higher education plays vital role in driving economic growth and social cohesion. Greater investment in universities increases the quality and quantity of highly educated graduates. The commonly held perception of universities as merely institutions of higher learning is gradually giving way to the view that universities are important engines of economic growth and development. Universities not only generate new knowledge through primary research, they also provide technical support and specialised expertise and facilities for on-going firm-based research and development (R&D) activities (Farrell et al., 2006, p. 8). Academic research and development is now seen as one of the key drivers of economic growth. Countries that have academic institutions performing large amounts of R&D are more able to attract and grow technology oriented companies.

The HE sector, however, has characteristics which make it difficult to measure efficiency: it is non-profit making; there is an absence of output and input prices; and HEIs produce multiple outputs from multiple inputs (Johnes, 2006, p. 273). This article tries to assess the relative efficiency of government spending on higher education in selected CEE and OECD countries, with special focus on Croatia and Slovenia. In this respect, the efficiency of higher education systems is computed using the non-parametric approach of data envelopment analysis (DEA) to capture the different dimensions of those systems and to measure their relative efficiency. The performance of higher education is measured by how well it transforms inputs into outputs. This is the first time DEA estimations have been used to measure the performance of HE systems in these two countries on the macroeconomic level by using a wide range of inputs and outputs/outcomes.

The article is divided into four main parts. After introductory part, first part analysis higher education systems, their expenditures and outcomes in selected CEE and OECD countries. The second part explicate methodology of data envelopment analysis for measuring higher education achievements.

Research results of efficiency effects of higher education attainment in selected countries are presented in the third part of the research. Conclusions regarding the efficiency of the Croatian and Slovenian higher education in comparison to CEE and OECD countries are drawn in final section.

2. Descriptive Analysis

Croatian GDP per capita has been relatively low compared to Slovenian or other European countries. One of the many explanations of this difference could be the effectiveness and efficiency of the country's education system. From this perspective, universities generate spill-over effects from their academic research and teaching, thereby stimulating economic growth (Audretsch and Lehmann and Warning, 2003). Indeed, the close nexus between the university system and economic growth has seen significant attention being paid to the efficiency and quality of Croatian universities. The majority of Croatian and Slovenian universities are government-owned and largely funded by the Ministry of Education and Science[1]. Universities are autonomous bodies established by legislation allowing considerable freedom in their activities. The next section describes the Croatian and Slovenian tertiary systems in more detail.

2.1 The Higher Education Systems of Croatia and Slovenia and Its Expenditure

Higher education (HE) institutions in Croatia encompass universities, polytechnics and schools of professional higher education. Universities may include faculties and academies of arts as legal entities, and may establish a number of other constituent units (departments, institutes etc.). In contrast, polytechnics and professional higher education schools may not establish other HE institutions (MoSES, 2007, p. 33). There are seven public universities and two private universities and 16 private two-, three- or four-year colleges, polytechnics, or academic programs. The central government funds public higher education, although management is fully decentralized to the level of individual institutions (WB, 2008a, pp. 107-109). On the other hand, the higher education system in Slovenia is currently based on four universities with 49 faculties, three art academies or professional colleges, and 30 individual higher education institutions generally established as private institutions. The funds for financing academic activity are allocated from the national budget as aggregate funds for a university or an independent higher education institution (integral financing) and take into consideration the field of study and the numbers of enrolled students and graduates from regular first- or second-degree studies (MHEST, 2010a).

The major inputs for education and higher education in EU and OECD countries come from public expenditures. Public expenditures for higher education in Croatia are less than those in the EU-27, selected CEE countries, OECD countries and Slovenia, which are nearly the same. Private spending on education in Croatia accounts for around 0.75% of GDP compared with ratios of around 0.4% in the EU-15 and EU-25. Despite the relatively high private spending on education there are very few private schools, although there is a growing number of private pre-school providers. School enrolment at the higher education level in Croatia is almost half that seen in Slovenia, but relatively close to the selected CEE average. Although the completion rates are low, in 2008 the number of higher education graduates in Croatia was higher than in Slovenia (see Table 1). While the number of graduates is rising, there is still a mismatch between skills demanded by the market and the skills produced by the education system (World Bank, 2008a, p. 104).

Overall public expenditure on education as a share of GDP in both countries is comparable with the EU average. Slovenian government expenditure on higher education has shown a positive trend in recent years, with nominal expenditures tending to increase faster than the inflation rate. The total amount of government expenditure rose by 5.9% in 2005 and 7.2% in 2006, while the amount of funds for educational purposes went up by 6.4% and 8.4%, respectively, in the same years (Tajnikar and Debevec, 2008, p. 290). By contrast, expenditure at the higher education level in Croatia is far behind that in the selected CEE and OECD countries. The Croatian higher education system currently has too little by way of assured financial funds compared to European standards. The amount of outlays on tertiary education as a percentage of GDP in 2007 was 0.81%, namely, much lower than the EU average (1.3%).

Table 1 Higher Education Indicators – Expenditure, Output and Outcomes in Croatia, Slovenia, CEE and OECD in 2007

	Total Public spending on education (% of GDP)	Public Expenditure on Higher Education (% of GDP)	School Enrolment Tertiary (% gross)	Graduates of Tertiary Education (25 to 29)	Population with tertiary education (ISCED 5-6) aged 25-39
Croatia	4.1	0.8	44.1	20.7	18.2
Slovenia	5.2	1.0	88.0	20.1	21.0
EU-27	5.0	1.1	67.0	38.2	23.2*
OECD average	5.2	1.0	72.0	38.0	26.1*
Selected CEE average**	5.1	1.1***	51.1	43.3***	24.5

Note: * Figure for 1999-2007 average. ** Selected CEE countries - Czech Republic, Bulgaria, Estonia, Hungary, Latvia, Lithuania, Poland, Slovakia.

*** Selected CEE countries – Czech Republic, Estonia, Hungary, Poland, Slovakia.

Sources: Eurostat (2010b); OECD (2009a), OECD (2010), UNESCO (2010); World Bank (2010).

The main characteristics of Croatian education financing are: chronic under-funding, a lack of equity and transparency in budgetary allocation, an unbalanced structure of the education budget in terms of categories of expenditure and source of funds, and a lack of synergy (legislative, professional and institutional) for system change. The 4.1% of GDP share of total education expenditure in 2007 is well below the European average (5.0%), and the current level of funding is insufficient to support the reform process. Physical conditions vary widely from institution to institution, but facilities are often inadequate (OECD, 2001).

Conversely, the main objective of financing higher education institutions in Slovenia is to implement the goals of the national higher education program, along with respecting these institutions' autonomy in terms of the independent formulation of their institutional strategy and how they define the ways to achieve the set goals. The mechanisms of financing using public funds should enable higher education institutions to independently adopt decisions on expenditure and sustainable asset management. An important mechanism for ensuring the financial autonomy of higher education institutions is the integral (lump sum) financing of their academic activity. In the future, an internationally comparable share of GDP will have to be appropriated for the higher education and scientific and research activity of higher education institutions in Slovenia, meaning that the total funds allocated to higher education activity will have to rise (MHEST, 2010b). In this context, at least 1.3% of GDP from the budget and 0.3% of GDP from other sources is planned to be provided for higher education in Slovenia by 2015, and a total of 2.5% of GDP by 2020, of which 2.0% of GDP would come from the budget. At the same time, a new system of financing higher education would be introduced, consisting of a basic and a development pillar as of 2011.

2.2. Outcomes of higher education system

The basic assumption is that higher education systems are multi-product organizations which "produce" at least two different outputs – research and teaching – using multiple inputs. Generally accepted outputs of the higher education production process are the number of graduates of tertiary teaching as a proxy for teaching and the number of publications as a proxy for research (Warning, 2004, p. 396). Number of higher education graduates by universities and single higher education institutions by ISCED 5 and 6 levels in some selected EU countries, Croatia and Slovenia is visible in Table 1. In last ten years there was a significant increase in the number of enrolled and graduates students in Croatia compared to Slovenia, as also the number of student programmes. In Croatia, almost three-quarters of young people who successfully complete secondary school enter tertiary education. These changes correlate to the enlargement and re-organization of HE institutions, primarily establishment of polytechnics and schools of professional higher education (MoSES, 2007, p. 72). In such way, gross enrolment rates for tertiary level has been improving steadily over the past few years in Croatia, but they are still significantly lagging behind the Slovenian's. Gross enrolment at the tertiary level stood at 47.01 in 2007 compared to 85.47% in Slovenia.

Regarding outcomes in tertiary education, for example, although gross enrolment was about 46 percent in 2006 compared to around 53 percent in the EU-10 (Jafarov and Gunnarsson, 2008, p. 11),

the proportion of graduates in Croatia is not high enough. Further, only one-third of students at the tertiary level reportedly complete their programs, with an average completion rate of 6.7 years for four-year programs (World Bank, 2008b). Non-completion rates in tertiary education were also very high, with the Ministry estimating that only one-third of all those enrolled were completing their courses of study. The serious internal inefficiencies at the tertiary level do not seem to have diminished in recent years (World Bank, 2008a, p. 114). The number of graduates in TE over the last 10 years has been rising constantly. A vast majority of students has finished their undergraduate programs (on average 92.3%), whereas 7.7% of students finished postgraduate studies (5.3% a Master of Science degree and 2.4% a doctoral degree). The average share of graduates in the natural sciences was only 4% and has been falling constantly since 1997 (from 4.9% to 2.9% in 2003) (MoSES, 2007, p. 73). A similar situation can be found in Slovenia where the majority of graduates come from the social sciences, business sciences and law, accounting for nearly one-half of graduates at the tertiary education level; as many as 70% of them were women. The smallest number of graduates was recorded in the fields of science, mathematics and computer science as well as agriculture and veterinary medicine – just 1,255 (slightly less than 7% of all) graduates. An observation over time of the trend in graduate numbers at the tertiary education level in Slovenia reveals that this number oscillated around 6,000 in the 1980s and at the start of the 1990s, and then started soaring after 1994. Twelve years ago it exceeded the 10,000 limit. By 2009 the number of all graduates had doubled compared to 1996 and even tripled compared to the period before 1990 (SORS, 2010).

3. Methodology

This research measures the relative (technical) efficiency of higher education in Croatia and Slovenia, as well as in comparison with other selected CEE and OECD countries. Yet the characteristics of the higher education sector make it difficult to measure efficiency: it does not make a profit; there is an absence of output and input prices; and higher education institutions (HEIs) produce multiple outputs from multiple inputs (Johnes, 2006, p. 273). Therefore, a performance evaluation of higher education is based on multiple inputs and outputs and thus regressions based on only one output are unsuitable. To be precise, a non-parametric frontier analysis, namely data envelopment analysis (DEA), is the most recent methodology that is commonly used to examine the problems of measuring the performance of HE institutions (Athanasopoulos and Shale, p. 1997). Therefore, this research uses data envelopment analysis as a methodological tool.

DEA is a non-statistical and non-parametric approach which makes no assumptions regarding the distribution of inefficiencies or the functional form of the production function (although it does impose some technical restrictions such as monotonicity and convexity). Instead, it uses the input and output data themselves to compute, employing linear programming methods, the production possibility frontier. The efficiency[2] of each unit is measured as the ratio of weighted output to weighted input, where the weights used are not assigned *a priori* but are calculated by the technique itself so as to reflect the unit at its most efficient *relative to* all others in the dataset. In a multi-output, multi-input production context, DEA provides estimates of the distance function which is a generalization of the single output production function (Johnes, 2006, p. 274).

In the first step, the frontier is drawn up by the efficient units. In the second step, hypothetical units are generated on the frontier to serve as reference units for inefficient higher education systems. These reference units are constructed as linear combinations of the most efficient units on the frontier. All inefficient units are enveloped by the frontier. On the basis of the empirical production function, in terms of best practice, DEA reveals those HE systems that are on the efficient frontier. It indicates the level of inefficiency of each system compared to the efficient systems[3].

The DEA method is essentially a linear program which can be expressed as follows:

$$\max h_k = \frac{\sum_{r=1}^s u_{rk} Y_{rk}}{\sum_{i=1}^m v_{ik} X_{ik}} \quad (1)$$

subject to

$$\frac{\sum_{r=1}^s u_{rk} Y_{rj}}{\sum_{i=1}^m v_{ik} X_{ij}} < 1; j = 1, \dots, n. \quad \text{All } u_{rk} > 0, \quad v_{ik} > 0 \quad (2)$$

where Y is a vector of outputs; X a vector of inputs; i inputs (m inputs); r outputs (s outputs); n is the number of decision-making units (DMUs), or the unit of observation in a DEA study.

The data set in this research includes input data, i.e. expenditure per student, tertiary (% of GDP per capita) and output/outcome data, i.e. school enrolment, tertiary (% gross), labor force with a tertiary education (% of total) and the unemployed with a tertiary education (% of total unemployment) in thirty-seven countries are included in the analysis (selected CEE, and OECD countries). In order to assess different inputs and outputs/outcome relative to technical efficiency, two models have been tested. Model 1 is based on expenditure per student, tertiary (% of GDP per capita, 1999-2007 averages) (as input) and school enrolment, tertiary (% gross), labor force with a tertiary education (% of total, 1999-2007 averages) and the unemployed with a tertiary education (% of total unemployment, 1999-2007 averages) (as output/outcome). Relative efficiency scores for Model 2 are based on expenditure per student, tertiary (% of GDP per capita, 1999-2007 averages) (as input) and school enrolment, tertiary (% gross) and labor force with a tertiary education (% of total, 1999-2007 averages) (as output/outcome). The program used for calculating the technical efficiencies is the *DEA Frontier* software. The data are provided by Eurostat, the IMF, the OECD, UNESCO, and the World Bank's World Development Indicators database.

2. Research Results

When looking at the results[4], by using Model 1 and applying the DEA efficiency frontier technique within a selected group of CEE/OECD countries to measure efficiency of higher education, Canada, Czech Republic, Finland, the Republic of Korea, Latvia, Lithuania, Poland, Russia, Slovakia and even Slovenia are seen as efficient. Here, the average expenditure per student, tertiary (% of GDP per capita) in the 1999-2007 period measures the input and as the output/outcome we use school enrolment, tertiary (% gross), labor force with a tertiary education (% of total, 1999-2007 averages) and the unemployed with a tertiary education (% of total unemployment, 1999-2007 averages). One can see that some countries come very close to the frontier (e.g. Hungary and Romania), while the other countries are further away and therefore less efficient (e.g. Cyprus and France) (see Table 2).

Table 2 The Relative Efficiency of selected CEE and OECD Countries in Tertiary Education – Model 1 (Distribution by quartiles of the ranking of efficiency scores)

<i>I. quartile</i>	<i>II. quartile</i>	<i>III. quartile</i>	<i>IV. quartile</i>
Canada	Italy	Norway	Cyprus
Czech R.	Ireland	<i>Croatia</i>	Mexico

<i>Slovenia</i>			Belgium
United States			

Sources: World Bank, 2010; UNESCO, 2010; Eurostat, 2010a; OECD, 2010; own calculations

The results of the DEA analysis (Model 1) also suggest a relatively high level of inefficiency in higher education in Croatia and, correspondingly, significant room to rationalize public spending without sacrificing, while also potentially improving, higher education outputs and outcomes (see Table 2). Indeed, Croatia is ranked in the third quartile and in terms of the efficiency scores for public spending, Croatia ranks in the 69th percentile among the 37 countries. With respect to individual output/outcome indicators, Croatia's ranking is in the last quartile for higher education school enrolment, the third quartile for labor force with a tertiary education and the second quartile for the unemployed with a tertiary education. In order to become an efficient country, Croatia should significantly reduce its average expenditures on higher education per student by around 10 percentage points (to around 29% of GDP per capita), to bring it near to the OECD average level.

Further empirical analysis, now focusing on Model 2, suggests even worse relative efficiency results for Croatia. When using only two outputs/outcomes, Croatia's ranking is only 32 (out of 37). Similar to the results for Model 1, in order to become efficient Croatia should cut its average expenditures on

higher education per student by 6.3 percentage points. In terms of the efficiency scores, the efficiency benchmark is represented by Canada, Finland, the Republic of Korea and the USA. In contrast, some CEE countries lag well behind (e.g. Slovakia, Romania and the Czech Republic), especially due to relatively poor output/outcome results (relatively low school enrolment and labor force with a tertiary education). Slovenia is ranked in 13th position and would improve its efficiency score by significantly expanding its labor force with a tertiary education (by around 8.5 percentage points) (see Table 3). According to our descriptive and empirical analysis, it is obvious that the higher education systems in Croatia and Slovenia suffer from relatively high technical inefficiencies (in particular in Croatia). To improve each system's efficiency, performance-based funding models for higher education should be developed and further emphasis should be placed on quality assurance in higher education and the integration of the facilities. Moreover, curricula in universities should also be reformed to better reflect the needs of the economy, whereas dialogue and cooperation between the private sector and universities should be greatly increased. Indeed, trade unions and employers should be actively involved in education reform. That is especially important in the area of vocational higher education programmes in order to reduce labour market mismatches. Improvement of the education system should be a top priority of tripartite dialogue.

Table 3 The Relative Efficiency of selected CEE and OECD Countries in Tertiary Education (Model 1 and Model 2)

<i>Country</i>	<i>Model 1</i>		<i>Model 2</i>	
	<i>Output-Oriented VRS Efficiency</i>	<i>Rank</i>	<i>Output-Oriented VRS Efficiency</i>	<i>Rank</i>

4. Conclusions

Expenditures on higher education systems made an important role in improving economic growth and development. At the same time, they signify an important tax burden on taxpayers. The efficiency with which inputs produce the desired outputs is thus an important public policy issue. In this research, an attempt was made to measure the relative efficiency of higher education across selected OECD and CEE countries, in particular in Croatia and Slovenia, using data envelopment analysis (DEA) in a VRS framework. The research results suggest the significant inefficiency of higher education spending in Croatia and therefore the considerable potential to reduce government expenditure and/or to increase the higher education output/outcome. Conversely, regardless of the input-output/outcome mix, the higher education system in Slovenia is shown to have a much higher level of efficiency compared to Croatia as well as many other comparable CEE and selected OECD countries. The results also

indicate that some developed nations (e.g. Korea, the USA and Finland) can serve as benchmarks for their efficient use of higher education resources.

References

- 1 Observing the higher education institutions as a whole, the ratio of public funds used exceeds 70%, in extreme cases – mainly in Scandinavia – it can reach even 97-98%. It is fair to ask why the state finances universities and colleges to such a high extent, that is, why the state should have a role in higher education (Tóth, 2008, p. 79).
- 2 Efficiency is defined as the relationship between inputs and outputs (outcomes), wherein monetary inputs are considered. Inputs (educational expenditure, students etc.) are “transformed” into outputs/outcomes (number of graduates, their knowledge etc.) through the “production” (pedagogic) process (Bevc and Uršič, 2008, p. 234).
- 3 Modified according to Warning (2004, p. 396).
- 4 All of the results relate to DEA with an output orientation, allowing for variable returns to scale (VRS). An output orientation focuses on the amount by which output quantities can be proportionally increased without changing the input quantities used. Using an input orientation approach leads to similar efficiency results as those presented in the text.

Is it necessary to outsource innovation? Creation and innovation face obstruction.

Sorin Mircea Axinte¹, Ileana Cernica²

¹Scientific and Technologic Park for Micro and Nanotechnologies MINATECH.RO, Romania

²National Institute for Research and Development in Micro technologies IMT- Romania, Bucharest

Financial restraints, the lack of talent, knowledge and professionalism, combined with serious time shortage, are all well-known obstructions that innovation has to face on daily basis. Though all related to a conventional way of thinking, they can still provide us guidance when it comes to prioritizing solutions.

The obstructions we speak of are : limited budget/resources for investing in innovation, the incoherent innovation strategy and the huge time and resource consumption for securing information, as well as the fact that information security never lines up to business targets.

The internal structure of every individual or group of people has its own laws of evolution. It is how this world has been created. The important thing is that, as we reach personal or/and collective maturity, we instantly grow aware of some natural laws, which automatically apply, whether we like it or not, whether we know about them or not.

According to one of those laws, everything evolves and suffers constant changes. Therefore, each entity goes through an infinite number of innovations, regarding all its aspects.

When life bombs us with obstacles, it also comes up with solutions. Due to those obstacles, we can grow up, under constant development, sharing new experiences, living under a new banner, the banner of innovation, which allows us to become whatever we would like to be.

Prioritizing things is highly connected to the very essence of life. It's not a question of choosing between "good" and "bad", but between "good" and "better".

Time, resilience to chance, low budgets and resources, the fear for failure and lack of stimulation, inaction, management culture, leadership, lack of communication, the feeling that nobody is listening to us, reluctance towards risk, too much ego when discussing ideas, refusing to approach active thinkers, economy stagnation, the legal context, fear of rejection, valid models of thinking, career consequences, lethargy, lack of ideas, lack of strategic thought, personal interest, organization structures etc, those are all solid obstacles in the mighty path of innovation. But, can they also become reasons of outsourcing innovation?

Keywords

Barriers of Innovation, outsource innovation

1 Introduction

The OECD's *Oslo Manual* defines innovation as: "The implementation of a new or significantly improved [to the user] product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations". This definition captures both the meaning of innovation as a *process* (implementation) and as a new *artifact or practice* (product, process, method, etc.). A rather more elaborate definition comes from The Oxford

Handbook of Innovation (2004) where Fagerberg notes that: “An important distinction is normally made between invention and innovation. Invention is the first occurrence of an idea for a new product or process, while innovation is the first attempt to carry it out into practice. Sometimes, invention and innovation are closely linked, to the extent that it is hard to distinguish one from another... In many cases, however, there is a considerable time lag between the two.... Such lags reflect the different requirements for working out ideas and implementing them. While inventions may be carried out anywhere, for example in universities, innovations occur mostly in firms, though they may also occur in other types of organizations, such as public hospitals. To be able to turn an invention into an innovation, a firm normally needs to combine several different types of knowledge, capabilities, skills, knowledge, skills and facilities, market knowledge, a well functioning distribution system, sufficient financial resources, and so on....”

Definitions of innovation often stress “the *successful* exploitation of new ideas” – this particular formulation is from the UK’s DBERR (formerly DTI), but echoes the emphasis on success often found in the management literature. But note that “success” is ambiguous – a technical success may be a commercial disaster!

These definitions, and the wider discussions they are set in, indicate that there are different types of innovation and innovation process, varying for instance in terms of:

- types of idea and underpinning knowledge (e.g. technological ideas are emphasized to the exclusion of cultural or organizational ones),
- ways of generating ideas (e.g. research and development is not prioritized as compared to innovations developed in practice or on the job),
- forms of success (e.g. economic return or social benefit and/or acclaim).
- levels of novelty, since some “new ideas” are groundbreaking while others are minor changes in established ways of doing things – there is a classic distinction between incremental and radical innovation that reflects this, and many related concepts have been introduced such as “revolutionary innovations”, “architectural innovations” “configuration innovations”. In innovation is new to the firm, the industry, or the world.

Four main classes of innovation that are discussed in the current literature are now used in the Community Innovation Survey:

- **product innovation** (usually technological), where innovation involves the development of equipment, components, software (or novel assemblages of these);
- **process innovation**, involving new systems or routines of production, again with an emphasis on the tools and equipment and software used in the processes;
- **organizational innovation**, involving where innovation relates to changing management practices or workflow structures;
- **marketing innovation**, involving new ways of relating to customers and potential customers (including new ways of promoting products) - this is closely related to the idea of **delivery innovations**, targeted at transforming the ways in which products or services reach their consumers.

Additionally, there are many types of **Innovation Process** (this is not the same as “process innovation”!) Much discussion centers on Research and Development (R&D) as the way in which innovations are generated. In practice, however, innovations often come from work on the shop floor or front-office, and R&D departments are, anyway, rare outside of high-tech manufacturing (and a few high-tech services) companies. Often, major innovations are organized through project development teams. In some firms and sectors the main influences on innovation are the introduction of new machinery and software from suppliers of such tools; in some, professional associations and industry associations provide an important source of knowledge; in some the clients are a major stimulus for innovative ideas; and so on.

Finally, we should note that the innovation process is itself something that changes over time, from the first development of an idea (invention), through its development into a new product or process, the roll-out of the idea in the innovating organization, and then the diffusion and implementation of this by further users (diffusion); at any of these stages further new ideas may be introduced, the design of the innovation may be adapted in the light of feedback as to user requirements or technical problems, and so on. Two important ideas are the “product life cycle” and the “industry life cycle”. Each refers to a stylized path of development. In the **product life cycle** the picture refers to the development of an innovation from being expensive and hard to use, to being cheap and available for low-skill users (and often mass markets). The focus of innovative effort evolves from one on getting the product to work and to be well-adapted to users, to one of mass-producing it easily and cheaply.

The **industry life cycle** points to the parallel phenomenon, where firms rise and decline and production may be moved from highly knowledge intensive locations to ones characterized by cheap and less skilled labor.

These “life cycles” are useful frameworks for thinking labor product and industrial change, but there are many cases where the patterns describe above are not followed with any precision.

2. Open innovation and barriers in innovation

Research on innovations and barriers to innovation has for a long time been concentrated on trying to find those mechanisms that would help in designing innovation-supporting policies at European, national and company level. Often these studies have, however, been looking at only one of the levels at a time, which has led to oversimplifications and misleading policy implications.

The innovation process is seen as a cycle involving trial and error, where problems at some stages of development lead to a need to re-evaluate earlier stages in the innovation process. The barriers to innovation are not, however, the same for each firm; barriers may be expected to differ, for example, according to the size of the firm, the line of industry, and the degree of innovativeness of the firm.

Business cannot avoid the influence of the recent change in the operating environment: competition has become intensified, knowledge diffusion is becoming increasingly broad and fast, amounts of R&D investments growth rapidly and at the same time the life-cycles of products and technologies are shortening. In order to optimize product development and fit it into shortened time frames, the firms need to be able to utilize multiple knowledge sources, and apply new approaches to management of intangible assets. (Miller and Langdon, 1999)

The concept of open innovation suggests, among other things, that firms can enhance their innovative performance by acquiring knowledge from external sources, as well as benefit financially by using external paths to market for internally generated technologies that do not fit the current business model (Chesbrough, 2003; Gassmann and Enkel, 2004). An open innovation model also emphasizes that innovations emerge increasingly as a result of inter organizational cooperation, which means that the concept is relevant not only at a company level, but also at the regional and country levels. When examining implementation of open innovation in a regional context, however, it is important to notice that economic systems and institutions in different regions and countries differ in their support for open innovation practices (Nelson 1993). For example, the strength of IPR protection varies between countries, which may significantly affect firms’ desire to buy, sell or collaboratively create new knowledge. Moreover, countries differ in various structural and cultural issues that may affect firms’ willingness to use open innovation practices. It is therefore of great interest to identify which factors have the most significant effect on knowledge flows between organizations within a given region or country.

Hence, we view the barriers and motivators to adoption of open innovation practices from three different levels of analysis: (1) internal factors of the firm, such as e.g. R&D intensity and availability of surplus technologies; (2) innovation system level as for instance influence of innovation policies and public funding on firm’s involvement into open innovation processes and (3) cultural level, i.e. certain features of national and organizational culture creating an attitude towards the use of open innovation practices within the company.

3. Theoretical Background on Open Innovation

The notion of “open innovation” was first proposed by Chesbrough (2003 a, b) and has quickly gained the interest of both researchers and practitioners. The model stands for the way of innovation management when company provide internally generated knowledge for the market and external knowledge to flow in for maximizing the benefit of the company. It is also described as “both a set of practices for profiting from innovation and a cognitive model for creating, interpreting and researching those practices” (West et al, 2006, p. 286).

Open innovation can be described in terms of combination of two differently directed processes: inbound and outbound. Inbound process stands for in-sourcing external knowledge through licensing in, spinning in, acquisition (in order to get valuable technology, personnel etc.) and collaboration alongside value chain. The latter can be illustrated at the example of Procter & Gamble, who cooperate with customers, suppliers, competitors and other institutions to pursue ideas, which can be utilized in the process of new product development (Huston and Sakkab, 2006). Outbound process

stands for external utilization of internal knowledge. The 'surplus' of research, not fitting to current business model, used to sit on the shelf within close innovation model (Chesbrough, 2003).

This means that the company had to fiercely protect this surplus by intellectual property rights in order not to lose it (as even the employees of the company could utilize the surplus for establishing own business with venture money).

Open innovation approach states that the surplus can be used for realizing some potential value through selling it away to the other company, which could utilize it better within its resource base and business model.

As described by Chesbrough (2003a,b) the opportunities for sourcing the external knowledge have increased significantly and the outside-in process, or more specifically knowledge acquisition has been widely studied in the academia (Granstrand et al. 1992; Kurokawa 1997; Veuglers and Cassiman 1999), as well as practiced by the business (e.g. Procter & Gamble's Connect and Develop case (see Chesbrough et al. 2006)). While the acquisition of external technologies is nowadays commonplace, the exploitation of technologies and intellectual property (IP) outside the company (outbound open innovation as defined by Chesbrough (2003) and Gassmann and Enkel (2004)) is still observed infrequently (Athreye and Cantwell 2007; Mendi 2007).

According to open innovation model, innovations emerge increasingly as a result of inter organizational cooperation; hence, the environment of this cooperation attracts attention to the national and regional systems of innovation. The national system of innovation (NSI) refers to a framework that aims to explain the differences in innovation performance of nations through differences in their institutional support for such innovation (Lundvall, 1992; Nelson, 1993). The NSI framework stresses the idea that the flow of knowledge (and technologies) between individuals and organizational actors is key to the innovative process. While there are numerous factors that affect these knowledge flows, among the most important is the existence of various "institutions". These include, for instance, a nation's intellectual property (IP) policy, which by determining the formal approach of innovations (through patenting and other laws) has a significant effect on the development and diffusion of knowledge. The set of institutions also provides the framework within which innovation policies (concerning, e.g., public funding of research and development) are formed and implemented (Metcalfe, 1995).

While formal institutions to a considerable degree shape the external relationships among key actors (firms, universities, public research institutes, etc.) in the NSI, there are also structural factors that affect the flows of knowledge between firms. In particular, the industry/market structure affects, and is dependent upon, firms' rent appropriation strategies (e.g., the use of patents and technology licensing; Arora, 1997) and therefore also the knowledge flows between them. Indeed, diverse industries may represent distinct "systems" of innovation even within a nation (Nelson and Rosenberg, 1993). In the cross-country comparisons of NSIs, it is therefore important to take industry specific factors into account as well.

One of the key determinants of Open Innovation practices is the investments made by companies in research and development (R&D) activities, as well as the environmental conditions that foster the development of capabilities and on a regional and national level (Porter and Stern, 2001).

On one hand, firms need to invest into R&D for development of new products and offering them to market faster than competitors. Additionally, creating knowledge assets by intensive R&D often results in surplus technologies available for sale to gain additional profit to reinvest in R&D which in its turn bring to producing new portion of surplus technologies. Active R&D activities of the company would also foster the development of high absorptive capacity (Cohen and Levinthal 1990) and hence the ability of firm to in source the external knowledge would be higher. On the other hand, intensive R&D, as it used to be in the closed innovation model, would supply companies with a lot of product ideas and new technologies, and the need for acquiring the external knowledge would decrease. For two of very first cases of open innovation – IBM and P&G studied by Chesbrough (2003) the adoption of open innovation practices came as a consequence of layoffs in R&D departments and the need to find new sources of product ideas and technologies.

Hence, the intensive R&D investments may create a barrier to company openness:

3.1 Firms with high level of R&D intensity are less eager to embrace inbound open innovation.

3.2 Firms with high level of R&D intensity tend to produce more surplus technologies

Companies that operate in open innovation environment do not have to rely only on internal funding for R&D, and since firms do exist in regional systems the open innovation benefits are best achieved in regional clusters.

This fact was explained yet by economists (Romer 1987; Krugman 1991) pointing out the benefits of geographical proximity and regional concentration of network partners due to reduced production and transport costs and lower costs of accessing information locally. Hence, the role of regional systems for fostering innovation activation and open innovation interactions of the firms is increasingly high, especially for small and middle-sized companies.

The regional innovation system is enabled by knowledge exchanges among different actors of regional network, including governmental institutions. The nature of such knowledge exchange is in large scale defined by national policies enabling the creation and incorporation of innovation within a national economy. The studies on national innovation systems (NIS) focus on the role of nation-state in supporting the innovation activities of local enterprises and to large extent on the government sponsored research. Such state-financed research creates benefits for both the direct recipient and related firms through the spillover effects (Nelson 1993; Bresnahan and Malerba 1999). Additionally, researchers have examined the additional effects of public funding (Buisseret et al.)

1995; Davenport et al., 1998) meaning that public funding motivates company to invest more of its own fund into R&D (since the prerequisite to obtaining the public finance is a certain amount of own capital input to the project). As we have already claimed the increase in amount of R&D funding has a positive effect on the amount of surplus technologies produced by the company. Hence:

3.3 Public funding increases R&D output and amount of surplus technologies

However, alongside with public finding certain restrictions come in act. The national policies on innovation differ from country to country, however the general feature of every additional funding is the concern of who owns the result. A general intellectual property rights (IPR) system and particularly strong, established rules for the protection of intellectual property are referred as appropriate regime in Teece's, 1986. While a reasonable assumption is that under a weak appropriate regime firms are encouraged to protect their innovations, and are thus less inclined to share their internally generated knowledge with others, even the strong appropriate regime cannot endure the ownership of the technology made with the public finance.

The national policies on innovation are the ones regulating the matters of ownership of research results (Braczyk et al., 1998); however, if the ownership of direct research results can be insured by strong appropriate regimes, the ownership of research surplus which emerged from publicly funded research is still undefined issue for most innovation policies. This leads to the contradictory to 2a assumption that:

3.4 Firms are less inclined to sell intellectual property and technologies that result from publicly funded research projects

Another barrier arising from IPR area relates to the costs of IP protection and the procedure of claiming intellectual property. Strong IPR protection encourages disclosure and promotes efficient trade on markets for technology (Chesbrough et al. 2006). Weak appropriateness implies widespread existence of knowledge externalities (Malerba and Orsenigo 1993). Consequently, within weak appropriate regime, each individual firm will have less incentive to conduct in-house R&D; hence the amount of research surplus would decrease as well. Weak IPR protection in the end may lead to the overall rate of private sector R&D decreasing below the levels needed to sustain long-term private returns from innovation, and may therefore necessitate public support for in-house R&D.

Hence, avoiding the above mentioned externalities through strong protection of formal IP is supposed to increase the willingness of companies to develop own in house technologies.

A tight IP regime does mean that it is easier for firms to acquire technologies in the marketplace; and similarly easier to sell or license own technology. IP creates a platform for "co -modification" and transfer of technology (Graham and Mowery 2004) and hence for collaboration within open innovation

model. Hence, the involvement of companies into open innovation may depend on the strength of IPR protection and associated with it costs and formal arrangement:

3.5 The greater the complexity and cost of IPR protection, the less likely firms will engage in open innovation.

The third level of analysis of barriers to open innovation deals with national and organizational cultures. Some researchers (e.g. Takada and Jain, 1991; Straub, 1994; Dwyer et al, 2005) suggest culture has an influence on the diffusion of innovations. The five dimension index scores of culture offered by Hofstede (1991, 2001) explains behavior of individuals and organizations by their cultural peculiarities, measured through collectivism versus individualism, level of power distance, uncertainty avoidance, masculinity or femininity and long- or short term orientation.

3.6 The high cultural long-term orientation other firms causes strong Not Sold Here syndrome and decreases the tendency to utilize outbound open innovation.

This paradigm may be a step in innovation outsourcing. Now that innovative companies are open to product and technologies transfer, the phrase „Not Sold Here” has been replaced with „Open for Collaboration”, this way unlocking the path towards externalizing innovation.

3. Conclusions

1. Our research indicates that economic systems and institutions (in particular the protection of IPRs) may have large effects on the behavior of firms with respect to their engagement in open innovation practices. On the other hand, since our results also suggest that the importance of appropriate regime may differ in the buy and sell sides of knowledge, the effects of property rights protection and its relationship to other structural issues ought to be more fully explored in future research. IPR protection can promote innovation and economic development, through attracting FDI and strengthening incentives to innovate by domestic firms. The coherence between IPR and other policies and among the various entities involved in development and implementation of IPR policies is important.
2. The companies that do not belong to the manufacturing sector seem to be more likely to engage in both inbound and outbound open innovation. Moreover, while a firm's size does not seem to influence its utilization of external technologies, the smaller companies are more likely to have surplus technologies and/or develop technologies for other organizations. This finding is quite consistent with the assumption that small firms rarely possess all the needed complementary assets to commercialize an innovation and therefore must license or sell their technologies to larger companies.
3. The changing of organizational culture, globalization and open innovation are factors which determine the crossing of innovation barriers, through externalization.

The importance of mobility for innovation

Vesna Babaja¹, Neven Duić²

¹Agency for Mobility and EU Programmes, Zagreb, Croatia, vesna.babaja@mobilnost.hr

²Faculty of Mechanical Engineering and Naval Architecture, University of Zagreb, Croatia, neven.duic@fsb.hr

From the beginning of the 21st century the European Union (EU) has been investing efforts into the development of its research and innovation systems, faced with statistics which have brought into question its place on the global market next to competitors from the United States of America and the Far East. In early 2000 the EU started creating the European Research Area, ERA, and has subsequently issued a number of documents and measures in order to advance and improve it. The main purpose of the European Research Area is to create a transnational research community, which would allow for free movement across states as well as knowledge sharing and knowledge transfer. The expected outcome is that this unity in research, along with the transfer of knowledge and technology, will be the impetus needed for the advancement of the innovation system. Today ERA encompasses all EU Member States, as well as the countries associated with the Seventh Framework Programme (FP7) – 39 countries in total, and is still developing. This paper examines the creation and development of the ERA on the basis of communications issued by the bodies of the EU, and the effect this initiative has had on researchers' mobility and innovation.

Keywords

European policies on researchers' mobility and innovation

1. Introduction

At the turn of the century the European Commission was concerned about the competitiveness of the European Union (EU). The statistics showed that the research sector, while active, was not developing at the same rate as it did in the Far East and the United States of America (USA), nor was the research sector translating its scientific advances into innovative products as well as its competitors. The situation, identified as the so-called "European paradox" in 1995 [1], became a discussion issue in the last decade of the 20th century. The "European paradox" refers to the perceived inferiority of EU in terms of transforming the results of technological research and skills into innovations and competitive advantages. In particular, the following facts were cause for concern [2]:

- The average investment in research in Member States at the end of the 20th century amounted to 1.8% of the European GDP (with significant variations among the states), while in the USA it was at 2.8% and in Japan 2.9%. Moreover, this discrepancy was increasing throughout the 1990s.
- According to employment records, in the EU 2.5 of 1,000 employed persons were researchers, whereas in the USA this proportion was 6.7‰ and in Japan it was 6‰.
- During the 1990s the trade balance in technology products in the EU showed a deficit of €20 billion.
- There were twice as many postgraduate European students in the USA than postgraduate American students in the EU, and 50% of the Europeans who did their PhD degree in the USA remained there for a long time, often forever.

In spite of all this, the EU was producing a third of the world's knowledge in science. The desire to keep and support the potential of European science, as well as to once again create a better public

image of science, gave the impetus for creating the European Research Area, with a unified labour market, open also to third-country nationals.

2. Creating the European Research Area

The creation of the European Research Area, ERA, was introduced by the European Commission with the document *Towards a European Research Area* [2] in January 2000. This remains the most important document on this topic. The EU accepted the initiative at the Lisbon conference in March of the same year.

According to the definition to be found in the above mentioned document, the European Research Area should encompass:

- Networking of existing centres of excellence in Europe and creation of virtual centres using new interactive communication tools.
- A common approach to the needs and financing possibilities of large research institutions in Europe.
- A more consistent application of national and European research activities and closer relations between scientific and technological cooperation organisations in Europe.
- A better application of tools and means for encouraging investment into research and innovation.
- More abundant and more mobile human resources.
- Greater European unity in research, based on best practices of knowledge transfer on regional and local levels.
- Integration of scientific communities, industries and researchers of western and eastern Europe.
- Making Europe attractive to researchers from the rest of the world.
- Promoting a shared vision of the ethical issues of science and technology.

In October 2000 the European Commission issued the communication *Making a reality of the European Research Area: Guidelines for EU research activities (2002-2006)* [3], which announced measures to be suggested for each of the fields listed above, and brings guidelines for the changes in research-based Framework programmes, in order to provide a better support for the development of the ERA. Once again an accent was placed on interregional and international cooperation, not only within the ERA, but also beyond, intending to use the dynamic and potential of individual countries and regions by interlocking their possibilities and activities related to research, innovation and technology transfer. Innovation and research capabilities on all levels, with special emphasis on small and medium enterprises, were to be enticed by “collective research”, researchers' networking and mobility, a better exchange of ideas and knowledge.

On this basis the European Commission published a communication in June 2001 named *A Mobility Strategy for the European Research Area* [4]. The Strategy's aim is the creation of an environment conducive to mobility within the ERA, in order to develop, attract and retain appropriate human resources in research and promote innovation. An emphasis was placed on intersectoral and interregional mobility. The document also addresses the possibility of access of researchers from candidate countries and third countries.

The Strategy sets researchers' mobility as a priority, not as an end goal but as a means to optimize research efforts and innovative development. It invokes the communication *Innovation in a knowledge-driven economy* [5], where EU Member States are encouraged to use concrete measures to entice researchers' mobility in order to intensify collaboration between the various actors: research centres, universities, groups of enterprises and individual companies.

3. Reinforcing the European Research Area

In December 2001 the Council of the European Union brought the *Council Resolution concerning the reinforcement of the mobility strategy within the European Research Area (ERA)* [6] which established the creation of an internet portal and the network of mobility centres. Furthermore, the Resolution accentuates the need for the EU candidate countries to be involved in the implementation of the Strategy with a coordinated approach.

In March 2002 at the meeting in Barcelona, the Council of the European Union reached among others the conclusion that the investment into research, development and innovation should by 2010 reach approximately the amount of 3% GDP. Based on this conclusion in September 2002 the European Commission published the document *More Research for Europe – Towards 3% of GDP* [7]. Since the

Council held that two thirds of those investments should come from the private sector, the document "More Research for Europe" [7] cites the development and improvement of framework conditions as a first step. Aiming to make the research sector more attractive to investment, the document states that the development of highly qualified human resources in adequate numbers is a prerequisite for the fulfilment of the plan. It lists the following targets:

- Encouraging more women to enter science & technology careers.
- Encouraging further the development and visibility of poles and networks of excellence for higher education and the research & development sector, competitive with non-European alternatives.
- Encouraging the development and visibility of careers in science & technology in Europe, both in enterprises and in the public sector, by paying greater attention to financial conditions, career paths for young scientists, research equipment and availability of funds for research.
- Facilitating life-long learning, transfer of knowledge and career development through the mobility of researchers within Europe as well as the entry of third country researchers, primarily by removing national obstacles and providing adequate information and assistance at all levels.

Other fields where improvements were suggested include: linking entrepreneurship with research and development, measures to support spin-offs, creating a public research database with improved industry links, adjusting and using the system of intellectual property rights, creating a competitive environment and supportive competition rules, as well as improving financial tools.

Based on the "More Research for Europe" [7] document, in June 2003 the European Commission published *Investing in research: an action plan for Europe* [8], which defined specific actions for reaching the 3%-goal. Since the primary objective was to increase investments from the private sector, the action plan proposed measures to create a dynamic and active research area, attractive to investors and distinguished by excellent researchers, while not bound by restrictive national legislation.

Moreover, counting on the fact that increased investment would lead to new jobs in research, it was considered that by 2010, to reach the 3%-goal, 700,000 additional researchers would be necessary. This gave another dimension to the increase of Europe's attractiveness for educating, inviting and keeping researchers. The action plan cites existing activities, such as implementing the "Mobility strategy for the European Research Area" [4], especially the creation of informational tools and harmonization of social security systems. New proposed actions for the development of human resources encompass:

- Facilitating the opening of national systems for the recruitment, evaluation and further career development of researchers at European and international levels, including the need for a specific regulatory framework.
- Examining the case for further European or concerted measures to substantially enhance the conditions for researchers in the EU, in the framework of the open process of co-ordination.
- Adopting and implementing the foreseen proposals for an action plan and a directive on the conditions of entry and stay of third-country nationals for the purpose of research in the EU.

The next step of the European Commission came in July 2003 with the document *Researchers in the ERA: One profession, multiple careers* [9]. This communication addressed to the Council of the European Union and the European Parliament examines various elements pertaining to researchers' careers on the European level: role and format of research education, differences in recruitment methods, contractual and financial dimensions as well as evaluation mechanisms and career advancement perspectives. This communication revealed structural weaknesses as well as marked differences concerning each of these elements, according to the sectors in which researchers operate or the geographical, legal, administrative and cultural environments in which they work. Furthermore, the communication proposed the launch of specific actions on a voluntary basis aimed at providing a better overall coordination of efforts in favour of the recognition of the researcher's profession, as well as to establish a real European labour market based on the potential capacities of all actors, independently of their geographical location, the sector they are working in or their gender.

With the communication "Researchers in the ERA: One profession, multiple careers" [9], the European Commission commits itself to:

- continue implementing the "Mobility Strategy for the European Research Area" [4];
- create a "European charter for researchers" and a "Code of conduct for the recruitment of researchers";
- develop means to enable income comparisons within the research community, including social security and taxation, among countries, disciplines, sectors and between male and female researchers.

The Commission also suggested several actions to Member States and other stakeholders, among others to set up - in close co-operation with the Researcher's Mobility Portal and the European network of mobility centres - specific researchers' guidance centres at local, regional and national level in all European countries in order to advise on new opportunities for multiple careers in research & development and on the necessary requirements to engage in them.

4. Opening the European Research Area

Keeping in mind the increase of the number of researchers needed to accomplish the Barcelona objectives, and taking into account the fact that the European Community's Sixth Framework Programmes was already opened to researchers from outside the European Union in 2002, in October 2005 the Council of the European Union issued the *Directive 2005/71/EC on a specific procedure for admitting third-country nationals for the purpose of scientific research* [10]. This directive facilitates the regulation of stay for third-country nationals, who come to a Member State for the purpose of scientific research for a period longer than 3 months. It encourages the development of a system based on hosting agreements and the abolishment of work permits for researchers.

In March 2005 the European Commission adopted the *European Charter for Researchers* [11] and the *Code of Conduct for the Recruitment of Researchers* [12], and issued the recommendation for their use [13]. The principles of these two documents aim to enforce equal rights and obligations of researchers, as well as research and funding organisations, regardless of their location in Europe. The Charter [11] defines roles and responsibilities of researchers, organisations where they work and research funders, in order to ensure successful creation, transfer, sharing and dissemination of knowledge. The Code for recruitment [12] aims to improve the quality and transparency of the employment process for researchers, as well as their career advancement.

However, since by 2005 the investments into science and innovation, despite the plans based on the Barcelona objectives to which many EU Member States committed themselves, had not risen as was expected, had actually stagnated, in October 2005 the European Commission published a new action plan: *More research and innovation – Investing for Growth and Employment: A Common Approach* [14]. It once again emphasized the need for the creation of an open and competitive European labour market for researchers, in order to share competencies, knowledge and skill on a transnational level. This action plan lists 19 measures aiming to once again stimulate the investment into science and innovation, divided into four categories:

- Adjust all policies at Member State and EU level to support research and innovation wherever possible.
- Use EU funds and instruments to support research and innovation.
- Improve research and innovation conditions in the business sector.
- Encourage national initiatives and policies through international cooperation.

As one of the results of the ensuing discussion, in May 2008 a new document was published: *Better careers and more mobility: a European Partnership for Researchers* [15]. The "European Partnership for Researchers", EPR, represented a revised strategy for the improvement of researchers' mobility. Namely, despite accomplished results, the objectives set at the Lisbon conference in 2000 were slow to be reached. Not only was the growth of the number of researchers only marginal, even the renewal of existing personnel came into question. Therefore the European Commission suggested setting up partnerships with EU Member States, to devote themselves commonly to achieving significant progress in four key areas:

- systematically open recruitment;
- meeting the social security and supplementary pensions needs of mobile researchers;
- providing attractive employment and working conditions; and
- enhancing the training, skills and experience of European researchers.

For each of these key areas several priority actions were listed, to be fulfilled by the end of 2010. The Member States were moreover expected to adopt a national action plan by 2009, which would identify specific targets and actions to fulfil the objectives of the Partnership. The adoption of EPR by the Council of the European Union was followed by the re-launch of the Human Resources and Mobility Steering Group (SGHRM), composed of representatives from 39 countries (27 Member States and 12 Associated Countries), with the European Commission acting as its 40th member, and with a mandate adapted to conduct this partnership in a flexible manner [16].

5. Europe 2020: Development for the Future

The 2009 Report on the Implementation of the European Partnership for Researchers (EPR) by Member States and Countries Associated to FP7 [16] shows that the SGHRM held five meetings during that year and revealed that National Action Plans were nationally approved and submitted to the SGHRM by 8 countries. A mapping exercise was conducted to determine the national focus areas with regards to the 4 EPR priority areas and showed, among other, that 13 countries were implementing measures to contribute to the objective “ensuring better links between academia and industry”. In these countries the promotion of intersectoral mobility and the increased participation of private sector in research feature in governmental programmes, Research and Development and Innovation Strategies, and other policy documents. Furthermore, during 2009 four working groups were established, including a working group for “Training, Skills and Industry/Academia Relationship”. However, while progress was achieved in improving researchers’ training and skills, the 2009 report states that the aspect of industry/academia relationship needed to be addressed further in 2010.

In the meantime, the impact of the global economic crisis was affecting the research sector, although it diverged across the world regions: while unemployment and public deficits increased more sharply in the USA than in the EU, the crisis has aggravated the labour productivity gap between the EU and the USA [17]. Comparisons based on data from 2008 showed that the EU was still lagging behind the USA and Japan, with a statistically significant innovation gap [18]. Faced with the effects of the global economic crisis, the EU created a new collective strategy to alleviate those effects and create a smart, sustainable and inclusive economy. The *Europe 2020 Strategy* [19], adopted by the Council of the European Union in June 2010, puts forward three priorities:

- Smart growth: developing an economy based on knowledge and innovation.
- Sustainable growth: promoting a more resource efficient, greener and more competitive economy.
- Inclusive growth: fostering a high-employment economy delivering social and territorial cohesion.

One of the headline targets proposed by the European Commission was once again that 3% of the EU’s GDP should be invested in R&D – according to Eurostat in 2009 the expenditure on R&D was at 2.1% GDP across 27 Member States [20]. At the same time, new estimates suggested that achieving the 3% objective by 2020 could create 3.7 million jobs and increase annual GDP by close to €800 billion by 2025 [21].

In order to initiate progress on the headline targets, the European Commission put forward seven flagship initiatives. Among the first to be launched was the *Innovation Union* [18], to improve framework conditions and access to finance for research and innovation so as to ensure that innovative ideas can be turned into products and services that create growth and jobs. Concretely, the “Innovation Union” [18] proposed 10 actions needed to achieve the targets of “Europe 2020” [19], among them are the following:

- The EU and Member States need to continue to invest in education, R&D, innovation and ICT.
- Researchers and innovators must be able to work and cooperate across the EU as easily as within national borders. The ERA must be completed within four years.
- Cooperation between the worlds of science and the world of business must be enhanced, obstacles removed and incentives put in place.
- Remaining barriers for entrepreneurs to bring “ideas to the market” must be removed.
- European R&D programmes need to be open to international partners, while ensuring comparable conditions abroad.

The “Innovation Union” [18] commitments aim to make innovation Europe’s overarching policy objective and cover a wide range of areas and stakeholders. The commitments include:

- The Commission will support business-academia collaborations through the creation of “Knowledge Alliances” between education and business to develop new curricula addressing innovation skills gaps.
- In 2012, the Commission will propose a European Research Area framework and supporting measures to remove obstacles to mobility and cross-border cooperation.
- The Commission will design future EU research and innovation programmes to focus on Europe 2020 objectives and particularly the Innovation Union, while ensuring simple access and stronger involvement of Small and Medium Sized Enterprises (SMEs).
- By 2014, on the basis of Commission proposals, the EU should put in place financial instruments to attract a major increase in private finance.
- The Commission will facilitate effective collaborative research and knowledge transfer within the research Framework Programmes and beyond. By the end of 2011, working closely with Member

States and stakeholders, it will make proposals to develop a European knowledge market for patents and licensing.

Member States were invited to carry out self assessments and identify key challenges and critical reforms as part of their National Reform Programmes.

With the "Europe 2020" [19] strategy, the EU also launched a new ex-ante policy coordination, which started with the first *Annual Growth Survey: advancing the EU's comprehensive response to the crisis* [17]. Namely, in this new policy coordination cycle, each year the Commission will present, in the Annual Growth Survey, its assessment of the main economic challenges facing the EU and recommend priority action to address them, whereupon the Spring European Council will give guidance and the Member States will accordingly prepare their National Reform Programmes, to be submitted by mid-April. This first Annual Growth Survey includes the first progress report on "Europe 2020" [22] and examines the draft National Reform Programmes of Member States. The compilation of all provisional national targets indicated an aggregated level of 2.7 or 2.8% of GDP to be invested into research and development, which is below the expected target of 3% GDP, but which represents a significant effort, particularly in the current budgetary context. The report recommends the removal of obstacles to the growth of innovative companies, including by improving framework conditions and access to finance.

The progress report concluded that the reforms needed to address imbalances and re-start growth were insufficiently defined on national levels. However, it maintains that it is above all important to generate momentum and to give priority to growth enhancing measures within the flagship initiatives. The first National Reform Programmes will be adopted in July 2011.

The role of portfolio foreign investments in the development of emerging capital markets

Because of the information real time transmission, grace to the tight connections between different financial centers, the financial globalization made possible the rapid transfer of financial instruments price volatility, through the contagion effect of markets. Starting from the premise of portfolio diversification and from the need to identify new sources of income, the portfolio investors are going to take advantage of the favorable economic conjuncture and the investment decision on new markets is going to be taken into account only if the expected profitability of the invested capitals (adjusted at a higher level of risk) is superior to the one obtained on mature markets. In this context, due to the specific characteristics of emerging markets (small number of issuers, reduced market capitalization), these markets are more sensitive to the volatility of foreign capital flows. This can create an unstable investment environment, due to the interference between different factors that have an impact upon the risks and return of a portfolio (volatility of stock prices, liquidity of the international capital market, investment cycles, asymmetrical information in the local and international environment and not in the least, portfolio investor's strategies and behavior). The present study analyzes the impact of portfolio foreign investments upon the emerging capital markets. In the analyzed period of time, there can be identified a connection between the foreign investments and the emerging capital markets dynamics and we would say that the „disturbing” effects are of a bigger amplitude in the case of sudden reductions of the volume of portfolio foreign investments in comparison with the effects generated by sudden increases in the volume of portfolio foreign investments.

Keywords

Emerging capital markets, portfolio foreign investments, risk, volatility

1. Introduction

Emerging capital markets have increasingly come to the attention of investors, both those interested in developing some direct foreign investments, but particularly of those aiming at portfolio investments. Thus, starting from the assumption of diversifying the portfolio and identifying new sources of income, portfolio investors will exploit the favorable economic conjuncture and the investment decision is taken only if the expected profitability for invested capital, adjusted to a higher risk degree, is greater than that obtained on mature markets.

Foreign portfolio investment may influence capital market development, both positively, by capital inflows, as well as negatively, by shifting cash into other markets or towards other financial instruments. Due to specific characteristics (small number of issuers, small capitalization), emerging markets are more sensitive to the volatility of foreign capital flows.

According to Bakaert and Harney [1], foreign portfolio investment may lead to structural and functional changes of the capital market: (1) foreign portfolio investment exits, besides the disruptions they create on the financial system by reducing the market liquidity, lead also to negative variations of the assets' price on the market, (2) foreign portfolio investment entries determine an increase of the

securities' price fluctuations in most emerging markets that have received significant flows of foreign investment.

However, we cannot say that the volatility of emerging markets is entirely due to foreign investors' participation. The withdrawal of foreign capital generates a change in the attitude of resident investors who become aware of the changes in market trends and, as a consequence of herd behavior, they perform significant capital withdrawals. On emerging markets, as a result of the manifestation of some financial crisis foreign portfolio investment exits sent shock waves to other international capital markets [3].

The volatility of capital flows implies „a high frequency of flows' reversibility or high variability of the volume of capital inflows" [6], because capital flows are particularly sensitive to changes in domestic and international investment environment. The volatility of capital flows can create an unstable investment environment, because of the interference of various factors that may influence the risks and returns of a portfolio, such as: the volatility of exchange rates, the liquidity of international capital market, investment cycles, the "contagion" effect of capital markets, asymmetric information propagated into the domestic and international environment and, not least, the strategies and behavior of portfolio investors.

In Romania, the liberalization of financial flows associated with the capital account resulted in an increase of the capital market's sensitivity degree to factors from the international environment. In this context, the investors' decisions were increasingly based on the evolutions of the international financial markets.

In the present paper we try to analyze the impact of portfolio foreign investments on the emerging capital markets.

2. The experience of the emerging markets in attracting portfolio foreign investments, in times of crises

In recent years, economic activity has been characterized by a dramatic increase in the international dimensions of business operations.

But, the recent global financing crisis had a pronounced impact on net capital flows to developing countries. Net inflows fell to \$780 billion, reversing an upward trend that began in 2003 and peaked at \$1,222 billion in 2007 (table 1). Private flows (debt and equity) declined by almost 40 percent, driven by the sharp fall in the flow of short-term debt, portfolio equity, and bonds. Both short term debt and portfolio equity flows turned negative, recording outflows of \$12.7 billion and \$57.1 billion respectively. Bond flows remained positive, but the inflow in 2008 was 80 percent below the level of the prior year.

The geography of the international capital market of the recent years, and the factors that lead to this geography, demonstrate that the portfolio investments tend to concentrate on the emerging markets that offer the best conditions. Emerging market economies in Europe and Central Asia and South Asia combined accounted for 55 percent of the overall decline in capital flows to developing countries in 2008, while the net inflow of capital to these two regions fell to \$313 billion and \$63 billion, respectively. Reduced short term debt flows accounted for a major share of the decline in East Asia and Pacific, Middle East and North Africa, and Europe and Central Asia. In Sub-Saharan Africa two-thirds of the decline was in portfolio equity, with the rest in bond financing.

Table 2 Net Capital Inflows to Developing Regions, 2005–08

	(\$ billions)			
	2005	2006	2007	2008
Net private and official inflows, <i>by region</i> :	500	659	1,222	781

Portfolio equity inflows turned sharply negative in 2008 as investors retreated from stock holdings in emerging markets: an outflow of \$57 billion was recorded compared to a net inflow of \$135 billion in 2007. But the impact was limited to a small number of countries: typically ten countries account for over 90 percent of all portfolio equity flows to developing countries (table 3).

Table 3 Net Inflow of Portfolio Equity Flows— Top Ten Recipients

	(\$ billions)

Source: IMF.

The problem that the international investor faces is related to the potential of generating the expected profit out of the international diversification in times of crises that the emerging and developed capital markets have. The way financial crises developed in the last three decades suggest that the promised profits for international diversification tend to significantly decrease during crises (as a paradox, this is the moment when the investor needs them most), especially due to the evolution of correlations between international markets.

3. The impact of the financial crises and the portfolio foreign investments on an emerging capital market. The case of Romania

Evolutions on international financial markets and the dynamics of domestic macroeconomic equilibriums/disequilibrium have led to a reassessment of the risks that have influenced the capital market in Romania.

The growth of risk aversion on international markets and limited liquidity on financial markets have influenced the behavior of non-resident and local investors and determined the contraction in nominal terms of the amounts placed by investors on capital market, but also the contraction of the share which foreign investors had on the market.

Table 4 The evolution of investors in the Bucharest Stock Exchange

The investors' structure		Purchases % of total	Sales % of total
2005	Aggregate Accounts	-	-
	Residents	72,03	78,02
	Non-residents	27,97	21,98
2006	Aggregate Accounts	-	-
	Residents	69,83	75,9
	Non-residents	30,17	24,1
2007	Aggregate Accounts	-	-
	Residents	59,9	65,3
	Non-residents	40,1	34,67
2008	Aggregate Accounts	1,48	2
	Residents	69,85	67,2
	Non-residents	28,67	30,81
2009	Aggregate Accounts	1,68	2,48
	Residents	75,12	78,02
	Non-residents	23,2	19,5

Source: CNVM Annual Report, 2009

In this context, we can say that the Romanian capital market is facing a new long-term trend, a maturation trend. This trend is subject to a multitude of factors that may influence the market dynamics, factors related both to domestic and international developments.

This paper will try to quantify and analyze the relation that exists between BET stock index (the reference index of the capital market, which is a price index shared with free float capitalization of the 10 most liquid companies listed on the regulated market of Bucharest Stock Exchange), purchases and sales of financial instruments of non-resident investors, the source of statistical data being represented by the Bucharest Stock Exchange. The study covers the period from January 2005 - December 2009, monthly series.

The analysis aims at determining the correlation coefficient (Pearson's correlation) between monthly returns of BET stock index and the share of purchases and, respectively, of sales made by non-resident investors in the total of transactions from the regulated market.

Pearson's correlation reflects the degree of linear relationship between two variables. It ranges from +1 to -1. A correlation of +1 means that there is a perfect positive linear relationship between variables. A correlation of -1 means that there is a perfect negative linear relationship between variables.

In the most recent developments that have occurred on the Romanian capital market there were two important moments: mid-2007, when on the mature markets have felt the first effects of the financial crisis, and the year 2008, when the financial turbulences have caused a dramatic reversal of BET's trend and when there have been recorded negative performances on the Bucharest Stock Exchange.

Thus, to refine the analysis, we will determine the correlation coefficients both for 2005-2009 and for the two sub-periods 2005-2007 and 2008-2009 also considered important (see Table 2).

Table 5 Correlation coefficients. BET index – the transactions of non-resident investors within Bucharest Stock Exchange

Period	Correlation coefficient BET index – purchases non-residents	Correlation coefficient BET index–sales non-residents
2005-2009	0.1333	-0.4017
2005-2007	0.2928	-0.2764
2008-2009	-0.1016	-0.5499

Source: Data processed by the authors based on information provided by BSE, www.bvb.ro

Analyzing the data obtained, we can see a low and direct correlation of 0.2928 between the BET index and the stocks purchases of non-resident investors only for 2005-2007. In this context we can say that the investment strategy of non-residents is aimed at achieving a higher return than that obtained on mature markets in risk conditions considered acceptable by them. We can also notice the contribution of foreign investments in maintaining the upward trend of BET, as the index records better performance in the months when the weight of non-resident investors' purchases in total of purchases of listed stocks was high (see Fig. 1).

Figure 1 The dynamics of BET and of purchases made by non-residents investors

Source: Data processed by the authors based on information provided by BSE, www.bvb.ro

Regarding the correlation between monthly returns of BET index and the weight of monthly sales of non-resident investors in total sales within the Bucharest Stock Exchange we can see that in the months when non-residents' sales are higher, the performances of BET index are weaker (see Fig. 2).

Figure 2 The dynamics of BET and of sales made by non-residents investors

Source: Data processed by the authors based on information provided by BSE, www.bvb.ro

The correlation coefficient between BET index and the sales of non-residents is negative, the connection being strong and reverse, especially for the period 2008 – 2009 when it reaches the value of -0.5499 (statistically significant value), which confirms the increase of risk aversion of foreign investors and the of change investment strategy by reducing the share hold by stocks listed on emerging markets in the global portfolio structure.

4. Conclusions

The portfolio foreign investments have often set the trend of the evolutions registered on the emerging capital markets (both positive and negative evolutions), by changing the direction of liquidity towards other markets or financial instruments. Because of the small dimensions in terms of number of issuers, capitalization, daily volume of transactions, we could say that emerging capital markets are much more sensitive to these movements of the foreign capital.

For example, on the Romanian capital market, the amplitude of “disturbing” effects recorded by BET index under the impact of sales made by non-resident investors is greater than that generated by the volume of foreign portfolio investment inflows.

This can be explained by the attitude of non-resident portfolio investors, but also resident investors towards the secondary capital market. The interest shown by investors towards financial instruments traded on the BSE obviously influences the dynamics of the latter. Therefore, the determinants of the investment alternatives can be also considered influence factors of the capital market development.

Developing Internationalization Competence for consultants and managers of micro, small and medium enterprises

Rupert Beinhauer¹, Rene Wenzel²; Adrian Kachelmaier³,

¹²³FH JOANNEUM, Graz, Austria

A very important component of the European economy and its strength are exports – EU internal as well as EU external trade - (DG Economic and Financial Affairs “Economic forecast autumn 2009”, Brussels, autumn 2009). Furthermore SMEs form the backbone of the economy in every European country. But Europe is still facing a problem: some countries lag behind in their internationalization endeavours and are participating significantly less in exports than other countries; this problem has even increased due to the financial crisis.

In scope of a project series a growing number of institutions started to work on the task of developing a curriculum which is intended to be used to train internal and external experts and consultants for internationalisation of micro, small and medium Enterprises. Final aims of this set of projects is to install a certified curriculum for internationalisation consulting, which can be offered by partner institutions all over Europe (and beyond) and to install a Europe-wide network of institutions participating in the further development of the curriculum.

The current research focuses on how to best relate the issues connected to internationalisation of micro, small and medium companies to training programme tailored specifically for this target group. A qualitative survey helped to build a basic understanding of potential problems and challenges SME's face while attempting to internationalize. This analysis includes details of their structure, their relation to consulting companies and how they cope with the challenges of internationalisation. 336 Companies in Austria, Finland, Slovenia, Spain and Turkey participated.

The developed curriculum intends to transfer most recent knowledge from prior projects and research into practice by means of state of the art teaching methodology and improve pertinent skills aiding the target audiences to better tackle the challenge of going international or consulting in such endeavours.

The paper at hand will present the results of the Europe-wide survey and demonstrate how these results were integrated into the development process of the curriculum.

Keywords

Curriculum Development, Education, Entrepreneurship, Internationalisation, SMEs

1. Introduction

The European Lisbon strategy aimed at developing the whole of Europe as the strongest knowledge based economy in the world by 2010. At the forefront of this ambitious aim, which influenced all activities on the European level, lifelong learning and – in terms of economic development – vocational training became a crucial issue. Therefore the participation rate in education has been set as one major Lisbon progress indicator (LIS-F22). Furthermore, participants at a two-day agreed that governments should play a more active role in helping companies to try to expand abroad and provide training in key areas. Increasingly, companies are seeing participation in international markets as critical to their survival, job creation and growth. (OECD, 2006). In 2008 the European Commission started an initiative called "Agenda for new skills and jobs", two of the major aims of this initiative are "Bridging the gap between the world of education, training and work" and "Better matching skills and

jobs" (European Commission, 2011) which aims to support educational institutions by providing a framework for educational institutions of how to set up trainings and relate them to actual jobs. In their expert group report for 2010 the European Commission experts' state that "These challenges, and opportunities, come at a time of serious fiscal restraint facing most, if not all, Member States as well as the EU itself. This requires explicit and sensible choices about priorities for public funding of education and training. We must strongly encourage individuals and employers to invest more heavily in their skills development, not only to secure the best 'value for money' but to reap the benefits of people's potential." (European Union, 2010)

A very important component of the European economy and its strength are exports – EU internal as well as EU external trade. "...in recent years, other factors have become increasingly important in the face of the structural changes engendered by globalisation. These relate to export specialisation, which includes the range and the quality of the products a country exports, and the particular markets it exports to. In this regard, it is important that our countries take advantage of their high technological advancement and well-educated labour forces, to produce higher quality and more sophisticated goods and to redirect their exports towards strongly growing markets." (European Central Bank, 2009) Furthermore SMEs form the backbone of the economy in every European country. "What usually gets lost is that more than 99% of all European businesses are, in fact, SMEs (see definition of SMEs). They provide two out of three of the private sector jobs and contribute to more than half of the total value-added created by businesses in the EU. Moreover, SMEs are the true back-bone of the European economy, being primarily responsible for wealth and economic growth, next to their key role in innovation and R&D". (European Commission, 2011) But Europe is still facing a problem: some countries lag behind in their internationalization endeavours and are participating significantly less in exports than other countries, this problem has even increased due to the financial crisis.

To sum up: It seems to be highly necessary to develop a methodology which allows for the development of a curriculum for internationalisation, especially for small and medium enterprises, which provides the competences which are actually needed by internal and external internationalisation consultants and managers. The INCO project series, which was started by FH JOANNEUM in 2004, has been tackling the issue ever since. One of the follow up projects - INCO2 - has been set up by "bit management" in Austria. "In the short term the results of the project should increase the know-how of consultants to further upgrade their own skills and abilities and the competencies of their clients (SMEs) for their internationalization activities. In the long run the project will add value to the whole European economy, with increasing the competitiveness of enterprises, communities and regions. " (bit management, 2011) Another project dealing with this issue – INCONEXT, a transfer of the INCO-curriculum to Lithuania – has started in 2010.

2. The survey

2.1 How was it done?

With the help of a survey, the INCO2 consortium did take a closer look on SME's in order to get a better understanding of potential participants in the INCO2 courses. Aim was to analyse their structure, their relation to consulting companies and how they cope with the challenges of internationalisation. 336 Companies in Austria, Finland, Slovenia, Spain and Turkey participated. The Inco2 survey was done with the help of the platform Survey monkey in 5 national languages (German, Finnish, Slovene, Spanish and Turkish) an additional version was available in English. Two methods of data gathering were used. On one hand we invited participants to enter their data in survey monkey directly; on the other hand we provided a pen and paper version, which was later on entered in the database by project team members.

2.2 How international and how experience were the SMEs?

Over all participating countries, the results were that 37,8% of all companies were active in the domestic market only, whilst 62,2% were already active in at least one foreign market. Yet a closer look on the different country results showed a significantly different picture. In Finland the focus of participating companies was mainly in the domestic market (75%) most of them (47%) being active in the region only, in comparison most companies in Austria (77%) are internationally active.

As a result of these numbers we expected definite differences in the level of pre-experiences between the participating countries but also between participants in a course. Investments for internalisation

are vastly different in the participating countries responses; we conclude that also the willingness to invest time and resources in the process would be different. So it would be essential to provide different levels of training in providing core material but also additional material which allowed to deepen knowledge for advanced participants. Also it was clear that experienced trainers needed to be involved and briefed accordingly.

Also as a trend in all participating countries, the amount of money invested in internalisation activities is increasing from year to year. This of course underlines the increasing importance of courses like INCO2. Only 12% of the participating companies stated that they are active since less than 2 years pointing at the fact that start-ups should not be the main target group for the trainings and participants looking for knowledge concerning the start-up of a new business would be needed to be pointed elsewhere..

2.3 Where do the managers get their information from when internationalising?

The following were the answer alternatives offered, they are sorted by frequency:

Table 1 Information sources

	Frequency	Average Grade
Research by employees / Internet	118	2,0
Networks / Industrial associations	110	2,1
Public institutions (eg. Chamber of commerce)	102	2,4
Intuition	101	2,4
Consulting companies	82	2,7
Other (specify)	14	2,1

Two things seem to be obvious: consulting companies are the least often chosen source, and they receive the worst grades of all available alternatives (including intuition). Obviously companies prefer internal knowledge and / or support which is free of charge over consulting services. Even if companies pick consulting services, they are less often content with these services than with other alternatives. Looking at these answers it was clear that providing information concerning public support and funding, tailored for each country was a necessary part of training.

2.4. Consulting services – a necessary evil?

Nearly exactly half (50,5%) of the companies stated that they did, at least once buy consulting services, while the other half (49,5%) did not. Mostly the respondents who did use consulting services were content with the results, even though a sizeable amount of answers shows that not everything worked out fine all the time. 26% of companies claim (agree or partially agree) that “consultants sold solutions that did not lead to the desired outcome” and / or that the “analysis of the consultants were incorrect”. Sometimes (29% agree or partially agree) good outcomes could not be implemented because of internal resistance.

We also asked which of the following reasons were the most relevant for engaging an external consulting company. The following alternatives were available, they have been ordered according to the number of “I strongly agree” (the most positive possible) answers as it is highly probable that only strong agreement leads to actually employing a consultant:

1. Lack of internal knowledge (109)
2. To verify management’s belief, recommendations or decisions (86)
3. To deal with a capacity problem (76)
4. Consulting for set up of a business / sales office in an other country (74)

5. To overcome an emergency situation (68)
6. To provide an objective analysis of a problem or opportunity (66)
7. To gain Governmental funding (45)
8. To deal with a sensitive issue (35)
9. To provide the most cost efficient solution (27)

The by far most often picked answer “lack of internal knowledge” showed us clearly that INCO2 should not only target consultants but should also offer the training to internal company experts to allow for acquiring the knowledge themselves, which is, as many SMEs are very reluctant to pay for consultancy, very important. As a bit more than a quarter of the companies who answered the questionnaire (27,2%) used consulting services for internationalizing. The market for internationalization consulting could be considered to be sizeable.

Obviously companies use consulting services rather haltingly, about 45% of companies prefer to not use any consultancy at all, while most others (another 35%) will use consulting sporadically with a maximum of 15 man-days per year paid for. Knowing this for INCO2 the market for teaching these skills to internal consultants might even be bigger than for external consultants. The main surprise in our numbers is, that currently even more companies are looking for consultancy concerning funding opportunities than in the classic consulting fields of Law and Taxation. This of course underlines, how important a module for funding would be. Another interesting result is that 42% of all companies are willing to pay more than 5000€ for internationalisation consulting.

2.5. And what would they like to learn?

We asked which of the following skills were the most relevant for employees concerned with internationalisation. The following alternatives were available, they have been ordered according to the number of “I strongly agree answers”

1. Language Skills (162)
2. Market access and market knowledge (121)
3. Presentation skills in an international environment (119)
4. Knowledge of different market entry skills (115)
5. International project management skills (103)
6. International negotiations (93)
7. Knowledge of funding opportunities (83)
8. Knowledge of contract law for international companies (71)
9. Inter cultural management (71)
10. Knowledge of logistics for international companies (54)
11. Knowledge of individual characteristics of SMEs (53)
12. Financing and accounting for international companies (51)

Also we checked for how good the actual skills of employees are rated by the respondents (ordered according to average grade):

1. Language Skills (1,9)
2. Presentation skills in an international environment (2,0)
3. International negotiations (2,1)
4. Market access and market knowledge (2,2)
5. Knowledge of different market entry skills (2,3)
6. International project management skills (2,3)
7. Inter cultural management (2,3)
8. Knowledge of individual characteristics of SMEs (2,4)
9. Knowledge of logistics for international companies (2,5)
10. Financing and accounting for international companies (2,6)
11. Knowledge of contract law for international companies (2,8)

Asides from language, presentation and negotiation skills, which are not prime focus of the INCO 2 course (but which was - as a result of the survey included as a side topic), international market entry, international project management and knowledge of funding opportunities are, together with a core internationalisation course covering the most important topics. All in all the skills of the employees are rated good to average, with the weakest spots in logistics, financing and law. The results of these

questions were influencing the number of training hours assigned to specific topics. The more important the topic was and the weaker the actual skills of the employees were rated, the more time was assigned to the courses.

2.6. And how could such a training look like?

We asked the survey participants to which extent they agree to the following key statements concerning internationalisation:

Table 2 Agreements to key statements concerning internationalisation

Even as there seems to be a general tendency to agree to all of the statements above, there is definite difference in the level of agreement. The statements “Modern technologies ease our international business activities”, “Our management plays a crucial role concerning the success / failure of our expansion into international business” and “International business activities are the key for our success in today’s economy.” have the highest level of acceptance.

Agreement to “Modern technologies ease our international business activities” shows clearly that modern technologies like a learning platform can and should be used. Agreement to “Our management plays a crucial role concerning the success / failure of our expansion into international business” shows that the target group for INCO 2 should definitely include and perhaps mainly aim at the management level of companies. The agreement to “International business activities are the key for our success in today’s economy” shows that companies consider the topic of internalisation of extreme importance. As a conclusion introducing a comprehensive and successful course for Internationalisation consulting can be successfully sold in the price segment between 5000 to 10000 EUR, but most probably not above.

3. Conclusions

Many universities in Europe already link the competences they teach in their full studies with employer needs and base them on a competence based teaching approach. This process can be, depending on

the size of the target group, the topic and the institution involved, very time consuming and involves elaborate tools like employer and alumni questionnaires, competence catalogues, competence matrices and even e-solutions. However VET offers are often lacking behind in this regard, as they often use evaluation and market research tools that are not so sophisticated and that do not show exploitable results.

Because of budget and time issues it is often not possible to do fully the same for smaller lifelong learning courses. The INCO-project series show that valuable results can be gathered with usage of limited resources. The application of the questionnaire in preparation of a course for Internationalisation consulting shows, that much can be won with little effort. Comparing the curricula of INCO and INCO2 a significant evolution of the later is obvious. A mayor part of the adaptations is based on the results of the survey. Now the INCO2 trainings differ from the predecessor project not only in duration but also in the composition of the courses.

Note that the side project IC&IC changed the target group from small companies to medium-sized companies resulting from analyses of a similar survey. INCONEXT which has started in November 2010 is now in the process of surveying the environmental conditions for Lithuanian SMEs. The project team is curious about the results of the survey and is ready to adapt the curriculum to the needs of Lithuanian companies.

Entrepreneurial process in small and medium – sized organic agricultural holdings in Serbia

Nemanja Berber¹, Vesna Kočić Vugdelija², Jovana Đuričić³

¹Higher School of Professional Business Studies, Novi Sad, Republic of Serbia, berber_nemanja@yahoo.com

²Higher School of Professional Business Studies, Novi Sad, Republic of Serbia, vesna.kocic-vugdelija@teachers.org

³ Higher School of Professional Business Studies, Novi Sad, Republic of Serbia, djuricicj@yahoo.com

Agriculture production has been recognized as the strategic chance for development and successful factor for economic integration of Serbia into European Union. Special section of the agricultural production is organic agricultural production. In the last few years this type of production has been popularized as from the organic producers so as from the state of Serbia. In this area, as in other parts of Serbian economy, entrepreneurship gets more and more important role because entrepreneurial process can be useful in developing and improving small and medium agricultural holdings in way of production, productivity and efficiency. This paper have presented main parts of entrepreneurial process on small and medium agricultural holdings in Serbia, including possible investment calculation in organic production with risk perception, so as the stimulus that have been brought by the state. All three parts of the paper present unique entrepreneurial process created for enhancing market possibilities of organic producers.

Keywords

Organic agricultural production, entrepreneurial process, efficiency, risk, subsidies

1. Introduction

In all industries, the advantage of small and medium – sized enterprises is that they can easily adapt to a market where they operate. Contrary to a widespread opinion that the theory of management is adapted only to large companies, the need for continuous planning and management in small and medium enterprises, because of the above facts, is even more important. In this paper, emphasis is placed on the organization of small and medium – sized farms that are starting with organic vegetable production in greenhouses. In this type of production, especially in the first few years, the range of possibilities is wide, and every decision entails a long – term consequences.

The specificity of the production in greenhouses is reflected in the fact that, unlike the crop production (which occurs in natural climatic conditions) this production takes place indoors, year round. Of great importance is that through the production, market is supplied with specific products during the autumn – winter, i.e. time when natural and climatic conditions do not allow the production in the open. Constructed area under greenhouses in Serbia cannot meet market needs for products in the off – season such as tomato, peppers, cucumbers, etc. and consumers are directed to the imported vegetables.

Serbia has extremely high potential for organic production. The development of organic agriculture could affect the quality of life in local communities and the state as a whole. Long – term, organic farming would help in reducing the gap between rich and poor regions and achieving stability in production. Also, through education and informing of producers and consumers it can be built awareness of the need of consuming organic food in function of health improvement. The necessity of

this research appeared because of the lack of information in management of small and medium households, which make the largest number of agricultural organizations in Serbia. Because of that, and many other facts such as economic result (profitability), social responsibility and environmental preservation, number of organic producers is increasing each year. This can be confirmed by table 1 which shows number of organic producers in region of Balkan and East Europe in the last five years.

Table 1 The organic producers in the region from 2005 until 2009

Year	2009	2008	2007	2006	2005
Country	Producers	Producers	Producers	Producers	Producers
Albania	50	50	100	100	93
Bosnia and Herzegovina	331	304	304	329	26
Bulgaria	254	254	240	218	111
Croatia	817	632	483	368	269
Hungary	1.617	1.614	1.389	1.553	1.553
Macedonia FYR	99	99	127	101	21
Montenegro	29	25	13	15	-
Romania	3.078	2.775	2.238	3.033	2.920
Serbia	2.969	224	-	35	-
Slovenia	2.096	2.067	2.000	1.953	1.718

Source: <http://www.organic-world.net/statistics-europe-production.html> (date of access 31/01/2011)

According to table 1 in almost every country in the region Balkan and near Serbia number of organic producers increased in the last five years. Main increase in 2009 was in Serbia, from 224 to 2.696 producers, Croatia from 632 to 817 and Romania from 2.775 to 3.078. A positive trend of growth in number of producers had Bulgaria, Croatia, Montenegro, Romania, Serbia and Slovenia. In those countries number of organic producers was increasing each year taken into analysis.

The aim of this research is synthesizing all aspects of management and investment opportunities to make appropriate entrepreneurial approach to holdings engaged in organic production of different types of vegetables. Besides that, it is also considered a legal frame work for organic production in Serbia, possibilities and restrictions that are brought by the state.

2. Methodology and data for the research

For research purposes, it has been used methodology of analysis of literature and statistical data in the field of management, agribusiness and organic production, which was completed by a series of interviews with the producers. It has been interviewed six farmers involved in organic production in the Republic of Serbia.

In order to gather the necessary information, we used the technique of direct interviews. In this type of testing, the instrument is prepared as a list of research problems and questions tailored specifically to an individual. Questions are asked in a particular order, and the interview is not a rigid plan, but it serves as a reminder of topics that must be processed. The advantage of partially structured interview is that it allows the possibility of checking some information with others from the same source and makes their comparison [1].

3. Results of the research

3.1 Entrepreneurial process in small and medium – sized organic agricultural holdings in Serbia

Management capabilities in organic production today are as important as technical capacity. This production requires even additional management skills if we have in mind the complexity of the type of production [2]. Besides the above, managers in Serbia do not have enough business experience in

market conditions, and they need help in the knowledge, skills and standards of organic production. One form of assistance is the dissemination of managerial knowledge through consulting [3].

3.1.1 Management of production

Management of the production process is essential for rational logistic action and economic efficiency of reproduction cycle. In agriculture, this segment refers to the planning of work, of labour, of sowing, harvesting, etc. For decision makers in small households the most important are the following plans:

- Plan of the required amounts of vegetables for each period,
- Planting plans with precisely specified dates for each type,
- Plan of the area that is required for normal growth of vegetables,
- Plan of rotation crops,
- Plan of planting crops according to the seedbeds.

3.1.2 Management of finances

Financial management includes planning of investment and current spending, bill paying, book keeping, paying employees, payment of taxes and the like. What is missing in Serbia is, eventually, free training in the field of book keeping for owners of small and medium – sized households, especially because of the complexity of the fiscal system in this field. However, interviewed producers of organic vegetables pointed out the site of Agricultural extension services of Serbia [4], where are found a lot of literature on this subject, and the list of advisors by specialty and regions. For small and medium producers of organic products, the most important is to seamlessly do book keeping that the inspectors require, such as:

- Plan of property,
- Extract from the register of holdings,
- Bills of purchase of seeds and other products and the like.

Decision – makers on households need to learn basic book keeping, to synchronously keep accounts, and to use Excel programme (or other, similar program for calculating and recording).

3.1.3 Human resources management

Possibilities for human resource management in agriculture are numerous. The method of management depends on the owner's management skills. Important is the fact that the wage workers usually use only the kinetic energy and not a creative one, which is used for finding better solutions and practices in business [5]. Therefore, in addition to hiring seasonal workers, there is a need to take into account the human capital that will sustain the entrepreneurial spirit of household.

Human resources in agricultural production can be divided into the following categories:

- *Family members*: the benefits of working with family members are knowledge of the workers who usually work without formal charges and who are dedicated.
- *Local labour force*: the population in rural areas is in most cases the main source of seasonal labour. The benefits of employing them are the proximity and the possibility of finding "trusted" people. The disadvantages are the motivation, education, and their unwillingness to work intensively.
- *Foreign labour force*: in Serbia mostly come from Romania and Bulgaria. The advantage of opting for this work force is an extremely efficient and willing to work more hours, and the disadvantages are the necessity of providing shelter, food and language barriers.
- *Interns and students*: all agricultural educational institution (whether school or university) has in its program a mandatory practice. The advantage of the decision for this work force is in low cost (sometimes even unpaid work). The disadvantages are reflected in the fact that this category of labour generally is available only for part of the season, and at least in August and September, when there is the most intensive work.
- *Woofers* [6]: mainly young people, who travel around the world and work on the farms of countries that are members of the organization WWOOF (World Wide Opportunities on Organic Farms or Willing Workers on Organic Farms), or which are not members, but have "hosts" who care about

their stay at a particular farm. In Serbia there is only one household which is registered as the host for woofers. The advantages of hiring woofers are free labour force in exchange for food and accommodation. They are motivated professionals who have rich experience, so thanks to the most professional of them business can be even improved. The disadvantage is the uncertainty. When they arrive, the moment of departure is unknown. Their working hours are usually shorter than the traditional seasonal work, and there are language barriers.

3.1.4 Management of the process of organic certification

One of the important factors in organic production is the work on the certification process. Final consequence is that without this certificate the price of products will never be justified in the eyes of consumers. This process is logical sequence of events as a result of production plan, management of the household and financial resources. The manufacturer shall maintain records on the use of plots of land intended for organic farming in the prescribed form. These records contain information on the order of applied operations, fertilizer, processing, protection, and irrigation, and all other operations applied before and after harvesting.

All depends on which regulations producers are applying. For example, if an organic product should be disbursed to the Swiss market, then it should be applied to BioSuisse standard [7], which is very rigorous. In this case, there should be no conventional nursery on the estate, i.e. it must all be organic. Then, at harvest it must be used gloves that do not contain latex, and they are supplied exclusively in Switzerland. Also, 7% of the area should remain undeveloped (as an ecological zone). Inspection by EU standards it is much simpler, but the major predispositions are good management skills. Average cost of inspection for certification per hectare is about 300 Euros, and that depends on the inspection agency. It is necessary to bear in mind that the yield in the first year of the certification process does not mark as organic. The so-called conversion takes 3 years.

To established organic production in Serbia, it is necessary to provide spatial isolation of parcels and farms of the possible sources of pollution and shall prescribe the quality of irrigation water and air. Engaging plot of land in organic agriculture can start immediately if the land has not been used in the last two or three years (for perennial plants) or processed without the use of synthetic – chemical means for fertilization [8]. If the plot was used with the funds of synthetic chemical origin, it can be switched to organic agriculture at the end of the transitional period (conversion) – two or three years for growing crops without using synthetic – chemical means. All authority over the certification of organic production has the Ministry of Agriculture, Forestry and Water Management of Republic of Serbia and in 2010 mandate to carry out certification of organic production received eight certification organizations. Based on the report of authorized certification organization, Ministry of Agriculture since 2008 is making the unique records of organic producers (certified and those during the conversion).

3.1.5 Risk management

Agricultural production is subject to many uncertainties. Any farm production decision plan is typically associated with multiple potential outcomes with different probabilities. Weather, market developments and other events cannot be controlled by the farmer but have a direct incidence on the returns from farming. In this context, the farmer has to manage risk in farming as part of the general management of the farming business. Hazards and unforeseen events occur in all economic and business activities and are not specific to agriculture [9].

We will show how options influence decisions and reduce eventual risks that farmers could face on the market. To illustrate, we will say that on October 1, 2008, Serbian organic wheat farmers could have sold their 2009 crop for 320€/t by selling a July 2009 futures contract on the Procurement agency in Serbia.

If wheat price at harvest in July is 300€/t, farmer buys a futures contract for 300€/t for a net gain of 20€/t on the futures market, and then sells wheat for 300€/t in the cash market. His net position is $300\text{€} + 20\text{€} = 320\text{€/t}$. If wheat price at harvest is 340€/t, farmer buys a futures contract at 340€/t for a net loss of 40€/t on the futures market, and then sells wheat for 340€/t in the cash market. His net position is now $340\text{€} - 20\text{€} = 320\text{€/t}$. Furthermore, on October 1, 2009, Serbian organic wheat farmers could have bought an option that gave them the right to sell a July futures contract for 320€/t. If wheat price at harvest is 300€/t, they will exercise the option. More precisely, they will sell a futures at 320€/t, buy one at 300€/t, for a gain of 20€/t. On the other hand, if wheat price at harvest is 340€/t, they do not have to exercise this option.

Even if farmers do not want to trade with futures or with a government, they have some other possibilities to succeed. To moderate some risks, they can do a diversification of the production, or they could make forward contracts with processors. To conclude, there are a lot of options that can reduce the downside risk without giving up the upside potential [10].

3.2 The start – up of entrepreneurial process

Management development in SMEs, unlike large companies, has its specificities. In the first phase of work and business of small companies attention is mostly focused on the product and its placement [11]. This is precisely the period in which the most important are knowledge and skills of producer, because he is the holder of managerial functions.

Reorientation on the organic type of production requires new investments in machinery and means of production. In the growth phase there is a limitation of the resources, and the question of fixed assets is very significant in developing new ways of doing business. In this paper it has been analyzed household that for the first time is performing the process of organic production.

3.2.1 Investment calculation for organic production in the greenhouse

With proper organization and management of the estate, by hands it can be produced up to 3.000 vegetable seedlings (Interviewed producers gave an example of tomato production). Each part of plan, from labour to yield, must be ensured so that the process of production will be effective. Producers, who have been interviewed for this article, and who do not use or use poor machinery, said that, if hand work is intense (From April to August even 50 hours a week), it can also generate a higher yield per hectare than the mechanized work. However, they stressed out that in this case it is necessary to keep the farm level in small businesses and to provide additional resources during the winter.

Organic farming is a production method that requires a big commitment, and thus performance. As the managerial capacity is developing trough experience, in the initial phase of low mechanized organic farming, it should not be produced more than 2.000 seedlings. Overview of the necessary investment for organic production around 2.000 vegetable seedlings is located in Table 2 (The estate and field were not calculated).

Table 2 Material and investment for starting phase of production of 2.000 vegetable seedlings

Infrastructure	Costs €
Greenhouse of 0,3ha	2.000 (average cost)
System for heating greenhouse	1.000
Refrigerator	2.000
Extension for the preparation of seedlings	depends on the existing infrastructure
The main irrigation system	500
Tools and equipment	
Cultivator	2.000
Knapsack sprayers	50
Rakes, shovels, spades and wheelbarrows	70
Black foil	100
Crates, weighing	100
Trailer	200
Total costs	8'020

Note: Costs are approximate for 2010 and they are variable in case of different suppliers

As the certification of organic production takes about 3 years, a medium – term planning is minimal challenge for decision makers. Table 3 presents the medium – term plan of investment on holdings in order to increase production at 15.000 plants.

Table 3 Medium – term plan for production of 15.000 plants

Infrastructure	Costs u €					
	2010	2011	2012	2013	2014	2015
Land	Bought in 2010					
Facilities	Bought in 2010					
Barn (76x22)	Bought in 2010					
Storage			1'000			
Refrigerator				2'000		
Greenhouse		2'000				
Certification			300	300	300	300
Workshop						3'000
Mechanization						
Tractor (30ks)		12'000				
Cultivator		2'000				
Equipment						
Tool for gardening		70		50		
Main system for irrigation		500				
System "drop by drop"			700			500
Other equipment			300			
Van for delivery			3'500		5'000	
Investments per year		16'570	5'800	2'350	5'300	3'800

Such investment plan must be accompanied by an adequate investment program i.e. business plan which is serving as a proof that investments are carefully planned and have operational and financial sense.

3.3 The role of the State in entrepreneurial process

Serbia has enacted a new Law on Organic Production (in May 2010), trying to follow the changes that have occurred in the legislation of the European Union [12]. It has been active from 1st January 2011. Article 4 of the Law speaks about promoting of development and promotion of organic production resources which will be provided from the budget of the Republic of Serbia, grants and other sources. Ministry of Agriculture, Forestry and Water Management, as a ministry of the Republic of Serbia for these questions has provided terms and manners of distribution and the use of these incentive funds in 2010 by the Regulation on the use of incentive funds to support the development of organic production for 2010 [13].

In Serbia's budget for 2010 it was envisaged to subsidize agriculture with nearly 183 million Euros (If you look back years later data indicate that part of the budget allocated to agriculture increased gradually. In 2000 this sector has got 95 million Euros. In 2005 the amount that was allocated to agriculture was 230 million Euros. However, the economic crisis affected the agriculture and the extraction decreased to the less than 200 million Euros). From this amount only 97.000 Euros has been allocated to subsidize producers of organic products, which represents approximately 0.05% of total funds allocated to subsidize agriculture. Incentives for the support of the development of organic production in 2010 was for the intended crop, vegetable, fruit and wine growing organic production which may be conducted in open and closed areas (greenhouses). The support through subsidies was provided by the same regulation and for organic live stock production. The right to use subsidies had individuals as holders of domestic commercial farms, then enterprises and cooperatives if they meet the requirements prescribed by regulation. Exercising the rights to subsidies was not only for the owners of land that is used for organic production, but also the tenants of the land, engaged in organic production. Namely, it was subsidized hectare area in which has been performed the organic production. For crop production per hectare the state approved 243 Euros, for vegetable production 340 Euros per hectare and for fruit and wine production 437 Euros per hectare. The right for encouragement from the Republic of Serbia had producers of organic products that have entered into agreements with certifying organizations authorized by Ministry of Agriculture.

The ultimate goal in the development of organic farming, which is represented in the National Plan for the development of organic production in Serbia, is that the total area under temporary organic production, whether it is a certified or a production during the period of conversion, should reach a volume of 50.000ha in 2014. In order to realize these objectives, it is necessary to take the action plan

in 12 steps, and one of them is to subsidize producers of organic products [14]. So far the part of the budget for financing organic production was low, and the aid was allocated only in the form of direct assistance. There are proposals to provide indirect assistance to organic producers, for example to reduce the rate of VAT in turnover of organic products, but such measures are still only an option. Financial support for organic production has started for the first time in 2005/2006, when the volume of subsidies for organic production was 19.000 Euros. In 2010 subsidies were granted to 82 applicants, and the amount was increased to 97.000 Euros. In addition to this sum the Ministry of Agriculture, Forestry and Water Management together with the Ministry of Economy and Regional Development also subsidizes 50% of the certification costs of organic production. At the beginning of 2011 the plans for the financing of organic production are much more ambitious. The Ministry is planning funds for subsidies for organic production in 2011 two times higher than funds set in 2010 [15]. Even there are no new adopted by laws on the manner of financing agricultural production in 2011, in Serbian budget for 2011 there is planned 12 million Euros more for subsidize agriculture, and perhaps that is signalling that the Ministry will fulfil the promises.

4. Conclusion

Development of organic agricultural production implies many efforts that come from areas of finances, human resources, risk management, law, etc. In this area, as in other parts of Serbian economy, entrepreneurship gets more and more important role because entrepreneurial process can be useful in developing and improving small and medium agricultural holdings in way of production, productivity and efficiency. This paper have presented main parts of entrepreneurial process on small and medium agricultural holdings in Serbia, including possible investment calculation in organic production with risk perception, so as the stimulus that have been brought by the state. All three parts of the paper present unique entrepreneurial process created for enhancing market possibilities of organic producers.

Using methodology of literature analysis and interviews authors were enabled to analyse main parts of entrepreneurial process in organic agricultural production in greenhouses. This process included the analysis of:

- Production management in organic agriculture, with elements of planning,
- Financial management – the accounting and book keeping, with possible investment calculation for new greenhouse,
- Human resource management, where authors made an analysis for possible and needed working force on households,
- Certification management as an important and unavoidable step in organic production,
- Risk management where authors gave optional decisions for possible reduce of eventual risks that farmers could face on the market,
- Involvement of the state in promoting the organic agriculture, where it can be seen a regulatory framework and budget for development of this type of production. The state is trying to stimulate farmers to re – orient on the organic production method, but in the opinion of the surveyed farmers incentives that the state pays are not enough.

At the end of the analysis, authors made a conclusion that organic production in Serbia is still a risky and costly investment. There are many interested producers and enough natural resources for this kind of production, but for entrepreneurial process it is important to include and manage all the elements presented in the paper.

Cost Management and Implementation of ABC Method in Business of Enterprises

Dragana Bešlić¹, Ivana Bešlić²

¹*Higher School of Professional Business Studies Novi Sad, Serbia, draiva@neobee.net*

²*Higher School of Professional Business Studies Novi Sad, Serbia, draiva@neobee.net*

Contemporary organizations operate in conditions of rapid technological development, globalization, implementation of new technologies and fierce fighting in a highly competitive market. Changed business conditions in the form of integration and globalization of markets and increased uncertainty call into question traditional approaches and techniques of business management. To successfully operated under the new conditions, the enterprises put in first plan meeting of needs consumers which demand ever higher quality, functionality and product design with high reliability and quick delivery if this is possible with the lowest price. Such demands of modern customers, the enterprise primarily be answered achievement and maintenance of the lower operating costs relative to competitors, thereby contributing to achieving, maintaining and improving market position. All this requires finding new approaches, instruments and methods of cost management that can respond to changed business conditions.

This paper discusses the ABC method that transforms the way in which enterprise manage costs. Model of cost management based on activities (Activity Based Costing – ABC) involves the deployment costs by activities. ABC method it can be applied in all types of production.

The purpose of this paper is to inform the management of small and medium enterprises (SMEs) about benefits of introducing modern systems calculation costs, especially the ABC method in their business. Application of the ABC model gives more accurate data on product costs compared to conventional accounting system. ABC method is not only precise method for calculating costs, but also it is a very useful guide to improve enterprise performance. The system of activity based costing should to identify activities and to analyze the profitability of products, customers and markets.

Keywords

(ABC method, business of enterprise, cost management, cost)

1. Introduction

Business processes are not possible without the expenditure of resources and costs. Costs represent value expressed in consumptions of labor, materials, fixed and current assets and others of services for achieving certain effects (products, goods or services). Costs are spread through the entire business and is particularly is important know them manage.

Expanding the activities of the enterprises and complex, toward increasing and changing demands of consumers, from product research, its design, to post-sales services, as well as the increasing importance of not only individual but also the overhead costs (particularly management and sales) and the complexity of their full and proper allocation per the places of origin and the holders, imposed the necessity of innovation approach to cost management in order to achieve cost of competitiveness. The subject of this paper is the ABC method wich represent a modern tool for managing complex business operations through a detailed analysis and assessment activities. The main goals of this

paper are: 1. emphasize on the need for cost management per individual of activity or part of the business processes in enterprises, 2. to present basic characteristics of a cost management model based on the activities, 3. on the hypothetical example of business one enterprises illustrate implementation of activity based costing in the allocation of indirect costs to products and 4. familiarize businesses with the benefits of the introduction ABC method in calculation cost.

The paper highlights on the importance of cost management per particular activity or part of the business processes in enterprises, and analyzes the characteristics model cost of management based activities. Then, in the paper is on the hypothetical example of business one enterprise whose the production – sales range make the produces A and B explained in more detail activity-based costing in allocate indirect costs to products. Also, the paper are presents the advantages and disadvantages of ABC method. At the end paper followed the conclusions and a list of references.

Importance of Cost Management In Business Practice

The goal of cost management is achieve the greatest possible long-term benefit from of realized cost or achieve certain management goal with as the lower costs, without long-term negative effects on business results and on competitive position enterprises. Successful cost management in enterprises is carried out using different models of cost management [1]:

- Model of traditional management production costs (TPC),
- Model of cost management based on processes (PBC),
- Model of cost management based on activities (ABC),
- Model of cost management based on the integration approach process/activities (PBC/TNT),
- Model of management target cost (TC),
- Budgeting based on activities (ABB),
- Model balance of achievement (BSC),
- Model of cost management based on continuous process improvement (CC),
- Analysis value (VE),
- Model of management cost of quality (QCM), and other managerial concepts as determinants of influence on the development of information system model for business process management, or overall system management of enterprises. ABC model is now very popular in the area of cost management.

2.1 Model of Cost Management Based on Activities

The model of cost management based on activities is developed since 1984. years, and the large the development a experiences early nineties years [2]. This method follows the trend in costs for each activity or part of the business process. Model of cost management based on activities is formed based on a methodology that measures the cost and performance activities, resources and cost objects, where are the resources involved the activities, while the activities involved to cost objects based on the scope of use. This model take account of the causal link between cost indicators and activities. In within the application of model of cost management based on activities developed are and special terminology in which the terms have the following meaning:

- Resource is the economic element wich is used for the realization of performance activities (eg, wages and material resources are used in the implementation of performance activities). Resources are factors of production wich used to perform activities;
- Activities are a set of tasks or actions that are aimed at creating added value, and they include a set of jobs of similar nature wich are related to the making of products or providing socially useful of services. Activities convert resources - material, labor and technology in the outputs - products and services. The choice of activities depends on the organizational structure, size, services, technical equipment, etc.. When choosing activities often starts from the functions of the company, as possible activities can be listed : research and development, product design, manufacturing and assembly, packaging, delivery, marketing, quality management, etc.;
- Cost objects may be a product, product groups, customer groups, market territories, market segments and the like;
- Cost indicator is the factor that causes changes in the costs of certain activities;

- The system of costs based on activities is system that maintains and processes financial and operating data on resources enterprises, activities, cost objects and measures performance of activities;
- Management based on activities is a discipline focused on management activities as a source improvement of values obtained from the customer and the profit achieved made by insurance those value.

Model of cost management based on activities involves process-oriented organization with developed, documented and implemented business processes. It give answer on the question: "Why are appear the costs?".

2.2 Modern System of Calculation and Allocation General of Production Costs on Carriers of the Costs - ABC System

The calculation of the costs includes collection of information on the costs and their connection with carry of the costs. The carry of the costs (cost object) can be any item or activity that require cost calculation: any product or service wich provides any enterprise can be the carry of the costs. The calculation of the costs can be useful managers for [3]:

- Planning – in predicting future commercial transactions, it is necessary to have some idea of how much are product and service cost, to be are a future outflow of resources could reliably estimated;
- Assessment of alternatives and making of decisions – if is the cost of units less than its price, the product need produce;
- Monitoring results – in order to effectively monitor outcomes, need are information on how much are the expected and actual costs of products or services.

The difference between traditional systems of costing and activity based costing, or ABC system is that traditional system of calculating the costs, allocate the costs to organizational units or points cost, while ABC system allocate the costs to activities. The system of activity based costing should to identify activities wich create loss and that analyze the profitability of products, customers and markets. In ABC system there is a problem of allocation of indirect costs and so based on that applied are two phases costing [4]:

- in the first phase are all indirect costs allocated per activities;
- in the second phase are the costs to activities allocated per products.

Implementation of activity based costing in the allocation of indirect costs on products is illustrated on the hypothetical example of business one enterprises whose the production – sales range make the produces A and B.

Example: Based on data on the number of activities carried out per product and the cost of activities, execute the calculation of the cost for each product. The enterprise can produce two products: A and B. Direct costs making of the products illustrates the following table:

Table 1 Direct costs making of the products.

Products	Production volume (Q)	Costs of materials	Costs of labor
A	8,000	2,500,000.00	1,300,000.00
B	10,000	3,500,000.00	2,600,000.00
Total	18,000	6,000,000.00	3,900,000.00

Indirect costs making of the products are:

- Costs of production resources 3,800,000.00 are refer to the activity of machining of materials 90% and the activity of the preparation machine 10%;
- Costs of service resources 1,400,000.00 of these 800,000.00 relating to stored materials, and the rest of 600,000.00 comprising the staff expenses which are allocate to activities based on the number of persons working on these activities (on procurement (purchase) of the materials 15 persons, on receipt of the materials 10 persons and on control of the material 5 persons).

PHASE I – The amount of indirect costs per activities

Allocation of the cost of production resources illustrates the following table:

Table 2 Allocation of the cost of production resources.

Total	3,800,000.00
Machining of the materials (hours) 90%	3,420,000.00
Preparation of the machines 10%	380,000.00

Auxiliary operations:

$$100\%:3,800,000.00=90\%:x, \quad x=3,420,000.00; \quad 100\%:3,800,000.00=10\%:x, \quad x=380,000.00.$$

Allocation of the cost of production resources illustrates the following table:

Table 3 Allocation of the cost of production resources.

Total	1,400,000.00
Procurement of the materials (purchase)	300,000.00
Receipt of the materials (report of the admission)	200,000.00
Control of the materials (report of the control)	100,000.00
Storage of the materials (types of the materials)	800,000.00

Auxiliary operations:

$$15/30*600,000.00=300,000.00; \quad 10/30*600,000.00=200,000.00; \quad 5/30*600,000.00=100,000.00.$$

ABC system involves identifying the main activities and their causes. Financial Director carefully analyze main activities for operations of the enterprises and establishes six basic activities that take place: machining of the materials, preparation of the machines, procurement of the materials, receipt of the materials, control of the materials and storage of the materials.

The costs in certain activities and the number of activities or causes of the spending in certain activities illustrates the following table:

Table 4 The costs in certain activities and the number of activities or causes of the spending in certain activities.

Activities	Number of activities	Cost per activities	Costs per unit of activity
1.	2.	3.	4. (3:2)
1. Machining of the materials (hours)	4,000	3,420,000.00	855.00
2. Preparation of the machines	100	380,000.00	3,800.00
3. Procurement of the materials (purchase)	5,000	300,000.00	60.00
4. Receipt of the materials (report of the admission)	2,500	200,000.00	80.00
5. Control of the materials (report of the control)	2,500	100,000.00	40.00
6. Storage of the materials (types of the materials)	80,000	800,000.00	10.00

PHASE II – Allocation of indirect costs per products A and B

Transfer cost of activity per products (in RSD) illustrates the following table:

Table 5 Transfer cost of activity per products (in RSD).

Activities	Number of activities per products		Costs per unit of activity	Costs of activity per products	
	A	B		A	B
1.	2.	3.	4.	5. (2x4)	6. (3x4)
1. Machining of the materials	1,000	3,000	855.00	855,000.00	2,565,000.00
2. Preparation of the machines	90	10	3,800.00	342,000.00	38,000.00
3. Procurement of the materials	4,000	1,000	60.00	240,000.00	60,000.00
4. Receipt of the materials	2,000	500	80.00	160,000.00	40,000.00
5. Control of the materials	2,000	500	40.00	80,000.00	20,000.00
6. Storage of the materials	70,000	10,000	10.00	700,000.00	100,000.00
Total costs	-	-	-	2,377,000.00	2,823,000.00

The calculation of cost price by applying of the calculation per activities illustrates the following table:

Table 6 The calculation cost price by applying of the calculation per activities.

Elements	A	B	Total
1.	2.	3.	4.
1. Costs materials	2,500,000.00	3,500,000.00	6,000,000.00
2. Costs labor	1,300,000.00	2,600,000.00	3,900,000.00
3. Direct costs	3,800,000.00	6,100,000.00	9,900,000.00
4. Costs of activity	2,377,000.00	2,823,000.00	5,200,000.00
5. Total (3+4)	6,177,000.00	8,923,000.00	15,100,000.00
6. Production volume (Q)	8,000	10,000	18,000
7. Direct costs per products (3:6)	475.00	610.00	1,085.00
8. Costs of activity per products (4:6)	297.125	282.30	-
9. Total (7+8)	772.125	892.30	-

The basis of allocation of overhead costs to products according to traditional calculation costs is usually volume production. According to this method of cost accounting, general costs per unit of products would be:

$$Tiq = \frac{\sum Ti}{\sum Q} = 5,200,000.00 / 18,000 = 288.89 \text{ RSD,}$$

Ti – indirect or general costs,

Tiq – indirect costs per unit products.

Comparative review of cost price by traditional calculation costs and calculation per activity illustrates the following table:

Table 7 Comparative review of cost price by traditional calculation costs and calculation per activity.

Elements	Products	
	A	B
I. Traditional calculation		
1. Direct costs	475.00	610.00
2. General costs	288.89	288.89
3. Cost price (1+2)	763.89	898.89
II. Calculation per activity		
4. Direct costs	475.00	610.00
5. Cost per activity	297.125	282.3
6. Cost price (4+5)	772.125	892.3
7. Difference cost price (6-3)	8.235	-6.59

In our example, product B according to the traditional method costs more than the product A. When applying the ABC method, the positions are reversed. Activity-based costing provides more accurate cost price, because the allocation of overhead costs per the products takes into account the activities that causes every product or series.

Employees in enterprises may be wary toward implementing ABC systems if they are worried that will the new approaches of the calculation of the costs lead to change priorities of enterprises. Employees are may be afraid of layoffs or changes their working life. If managers of a higher level of force impose the changes that are necessary in order to introduce the ABC system, they risk to are employees alienate, and the resistance of employee may lead to more or less deliberate of attempt to sabotage the new system. Evidence show that it is adopted by a minority of large enterprises that operate in production environments, in service industries and public sectors.

3. Advantages and Disadvantages of ABC Method

Modern method of allocating manufacturing overhead costs to products – ABC method has a higher degree of objectivity in the allocation of overhead costs of production compared to traditional methods [5]. Since the modern manufacturing sectors in developed countries, predominantly capital-intensive, due to the high degree of automation, the use of traditional methods in these circumstances can not provide objective and reliable information on the assessment of profitability of individual products, because in the structure of production modern automated manufacturing sectors a dominant share make up indirect costs of production. Objective and reliable assessment of product profitability can be achieved using modern ABC method that is primarily directs on the allocation of production general costs to products based on factors of spending identified through the participation identified activities in the manufacture of a certain product. However, activities are numerous and consideration of all the activities makes the calculation of costly and vague, which is one of the main criticism of ABC method. The advantages of ABC method are [6]:

- Allows for better control and planning activities,
- Allows to compare the activities per the departments,
- Allows for better operation and wiser making of decisions by managers because he may the better can looks at the relation of cause (activities) and consequences (costs),
- Enabling better cost reduction as the main focus for cost management is on core activities rather than on the products. Good conduct of activities leading to lower costs and to greater competitiveness of products on the market,
- Allows you to obtain more accurate insight into the costs and helps control costs, pointing to multiple causes for emergence costs, etc..

The disadvantages of ABC method are:

- Complex to understand and implement, because must be aggregated and processed large amounts of information,
- Expensive is for implement and to maintain. The costs may include the purchase or development of software, consulting payments, restructuring and the cost layoffs of labor.

4. Conclusions

Quality cost management is features of the successful enterprises and managers. The costs are in the domain of internal sphere of business enterprises and their reduction, with other conditions unchanged, are a sure way to improve results of business. Profits are realized only if is the income from sale products larger from the value of production factors that had to be spent in producing these products. Hence the importance of cost management in business practice is not necessary especially emphasize.

Activity-based costing, or ABC system gives management insight into the structure of costs in manufacturing and selling various products or services. On based the calculated cost of the product or service manager may decide to reduce or increase the price of the product or service. After making decisions about product price the manager can make decisions about the product or service mix, or may make a decision on which products or services need put the emphasis, to increase or to decrease the production of a product and to determine the amount of certain products wich will to be placed on the market.

ABC method can provide enterprises the better answers the following questions: 1 Which the products or services need to put in our product line? 2. How much are cost their production? 3. How are they profitable? 4. Which the cost of products already exist on the workshop ? 5. Where can to reduced the costs? 6. Which to clients should aspire? 7. Where to invest resources in order to maximize value for shareholder? 8. What is our performance in compared to our competitors? 9. How can we improve our performance in order to achieve competitive advantage?.

Adoption of the ABC method in practice is often controversial and met with resistance by employees. Despite disadvantages, the ABC method continues to attract much interest in practice because of better quality informations that provides to the enterprises.

STRATEGY AND METHODS OF FORMING THE PRICE TO SMALL AND MEDIUM ENTERPRISES IN THE FUNCTION OF RESULTS

Ivana Bešlić¹, Dragana Bešlić²

¹*Higher School of Professional Business Studies Novi Sad, Srbija, draiva@neobee.net*

²*Higher School of Professional Business Studies Novi Sad, Srbija, draiva@neobee.net*

In poorer countries, prices are for customers the primary determinant of product selection. Therefore, such countries including and Serbia, should have a market that is characterized a variety of pricing strategies of enterprises and continuous improvement of sales and the subject of this paper is aimed in this direction. The key factors of price policy are: 1 costs. 2. demand, 3 competition on the supply side, 4 economic policy and other governmental actions.

The purpose of this paper is to present the essence of the pricing strategies of small and medium enterprises (SMEs) in Serbia which should be use in order to achieve competitive advantage in the areas of quality, price, terms and special of services. Good success in business is provided if are constantly and timely determined the costs, in order to adequately taken measures aimed in the direction their reducing and bringing into compliance with the sales prices.

At the time of the consumer economy goes the principle: Price - Cost = Profit. In this case the price is known, determined by the market and does not respect enormously high production costs, some manufacturers. This orientation in production to market requires of manufacturers to focus on reducing all costs to achieve the greatest possible profit. Be pleased customer, is key to managing costs.

Effectively designing and implementing of strategies prices requires knowledge of consumer psychology. Small and medium enterprises (SMEs) need to develop and nurture direct relationship with customers and partners, which will result in creating value for clients for which the enterprises exists and of which gets revenue. To permanently survive enterprises in the market should be realize short-term goal (profitability) and long-term goal (customer loyalty), integrated effort, knowledge and experience professional team from marketing, accounting and finance.

Keywords

(costs, price, profit, SMEs, strategies)

1. Introduction

Small and medium enterprises in Serbia should take adequate pricing policy which is a function of maximizing business results. The main problem of price policy is reduced to finding those prices for products and services enterprise that will, in conjunction with volume of the production and sales, with an assortment and costs provide the most favorable result for the planning period. Manage modern enterprise is a complex process. Management of the enterprises should choose the most favorable strategic direction of the enterprise, i.e. Strategy that will create a sustainable competitive advantage of enterprise in the market and its superior performance. For these reasons, the subject of this paper is devoted that.

Proceeding from the purpose of paper ie. of the displaying the essence of pricing strategies which enterprises in Serbia should be used in order to achieve competitive advantage in the areas of quality, price, terms and special services, goals of the paper are: 1. emphasize the role of costs and their

calculation in terms of price policy, 2. explain price formation based on demand and competition, 3. underscore the importance of the target pricing and calculating based of the target cost and 4. present the different strategies adaptation of prices.

The paper briefly is presented the method of price formation based on cost, demand and competition. Also, are exposed the specifics of target pricing and the calculation based of target costs. The paper are presented strategies adaptation of price. At the end paper followed the conclusions and a list of references.

2. Price Formation Based on Costs

Management accounting must has a key role in deciding on prices, particularly when is the price based on costs. Pricing methods are based on accounting information, especially on information of the costs and outputs. The key goals of calculation of the cost are: 1. providing data for formation of the prices, 2. providing data for making the decision, 3. providing data for planning and control.

Costs of production and sales in most cases are the main factors in price formation of the products. However, many enterprises in Serbia make a mistake, because with every change in costs, they work audits of existing prices, which have caused declining of same enterprises. Cost-oriented methods take into account the costs of the product and ignore supply and demand of the products on the market, ignore the competition, and they assume that there is a market demand for the product regardless on its price. Good success in business will be provide with continuously monitoring of the costs and formatting of cost price, in order to adequately taken measures aimed at reducing and bringing them into compliance with the sales prices.

Some enterprises may decide that the goods or services sale for less than the cost of their production. This strategy if they are often applied would cause rapid deterioration of the enterprise. However, this strategy makes sense when [1]:

- there is a large amount of goods that has a short shelf life,
- when the goods or services are treated as a "product-bait", ie. product or service that is used to attract the attention of the buyer on a range of products or on a particular supplier.

The classical method calculations of costs are:

- system of calculation based on actual costs,
- system of calculation based on standard costs,
- system of calculation based on variable costs (direct costing).

Modern conditions of business have caused the inadequacy of applying traditional calculation of costs, because in modern enterprise direct costs of labor are continuously decrease in total costs. Modern systems the calculation of the cost are:

- activity-based costing,
- super-variable costing,
- deferred charges,
- costing operations.

When enterprises can not influence the level of prices, the business success can be increased by reducing costs. Therefore, costs are a significant factor in shaping of the price. On the basis of calculation and knowledge of cost price of products enterprises can develop different business strategies to improve their business results.

3. Price Formation Based on Demand and Competition

According to the economic model of formation prices, demand and supply are basic factors the prices. Before deciding on prices, the enterprise needs to collect information on demand for its products. In a market economy, low demand is a limiting factor for increasing the price of the product. Also, the lack supply of a product results in the higher prices. For example: the price of strawberries in Serbia in the summer months, (when the strawberries are grown in Serbia and they are available in large quantities) tends to be lower than in the winter months, when the offer is lower, because strawberries are available only through imports.

Demand-oriented approach, looks at consumer tastes and preferences. There are the following pricing strategies [2]:

- Sliding prices – starting with a relatively high price, when meet the needs of the market which it is ready to pay, then are reduced level of the price to a lower level of customers;
- Breakdown rates – new low cost products to help you quickly won a broader market;
- Prestigious prices – prices that represent a measure of quality or prestige of the product;
Line rates – use companies that sell not one, but the product line (eg, pants) and for a particular line have a specific price;
- Equally odd prices – e.g. 199.90 RSD instead of 200.00 RSD, this creates a picture in customers head that will pay slightly more than 100.00 RSD, therefore not less than 200.00 RSD;
- Formed back prices – the starting point is the price that the buyer is actually willing to pay and go to backwards, subtracting the margin in the chain of sales;
- Common (packed) prices – the prices of two or more products that are sold under one price package.

The competition is a framework from which prices should not deviate significantly. The competitive approach is an approach that emphasizes what on the market the competition works. Here we highlight:

- Normal price – used for products where the competitive factors dictate the price;
- Higher, the same or lower market price – for some products is difficult to determine market price, so choose one of these three strategies;
- Cost to repair the reputation – to be draw attention to vendors are made promotional cuts of the price.

According to the Law on prices the Government of the Republic of Serbia in terms of free education price, measures of economic policy provide stability of market and prices, and prevent distortion of competition [3]. This law regulates the manner and conditions of education cost of products and services, monitoring movements of prices, activities of state bodies in the exercise of macroeconomic policies on price and other issues of importance for the field price. Price in terms of the law is a monetary value per unit of product or service that has been formed in accordance with market conditions and in accordance with special regulations. The enterprise can not be under the same conditions and at different prices to sell the same type of product or provide the same type of service, unless a special regulation provides otherwise.

4. Target Formation of Price and Calculation Based on Target Costing

Target price is the price of a product which is customer is willing to pay. It is determined by a review of the market (price survey of related products, preferences of consumer and of relative levels of elasticity price), and not based on costs. So, do not determine the cost level of prices, but selling price is determined by market - determined allowable costs. In this method of cost starting point are always the possibility and the requirements of customers. The process of establishing the target cost, the new products have their origin in long-term profit and sales plans, which are defined in the enterprise for a period of five years [4].

Selling price of products or services is determined by demand, competition, supply and economic policy of the state. Therefore, the sale price determined by the market, not cost the enterprise. By research and market analysis are obtain informations about the price that customers (buyers) are willing to pay for quality products they expect. The target selling price is usually a combination of equivalent sales price of existing products and incremental costs, due to the enhanced functionality of the new model [5]. Many Japanese companies use an incremental approach in pricing formation new products, which include compliance with current prices and the value that customers assign any additional product features. Incremental increase in price must be viewed in terms of competitive bids. Target profit margin of products is determined based on previous experience with similar models of products, the company's expectations regarding future profits and assess the competitive power supply.

Subtracting from the target price desired profit margin leads to the amount of target costs or of maximum amount expenses that the enterprise can have in producing a product or service (Target

selling price (selling price per unit of product X target volume of production) - Target profit = Target costs). If it appears that the sum is too low to cover all related costs, the enterprise needs to reduce those costs, so you can achieve the target price. This can include:

- introduction of the program for general reduction of costs,
- investment to would be provided additional production efficiency,
- compromises in the quality of raw materials,
- planning of additional volume production to thereby reducing the costs per unit products (for example, discounts for buying large quantities).

Because of planning measures for reduce costs need is compare the actual cost and market-determined allowable costs. The difference between current (actual) costs and of market-determined allowable costs is subject to reduction. The aim is to predict the final cost which is moving within the range of the target cost. If this is not possible need is stop the product development process, because it will not be able to be sell at target price and enterprises will not make target profit.

The essence of the concept of cost management is that the selling price (cost + profit) is viewed as a constant, as immutable, which is determined by market factors. It is the industrial way of thinking which was developed in Japan, the only cost reduction can provide a profit. Because the proceeds of the sale price given the market, does not mistakes in product design, and it aims to achieve lower purchase prices, but not at the expense of suppliers, but are trying reducing price of components of the products by the continuous improvement of internal processes, with constant maintaining the functionality and performance of products (use and implementation of TQM, JIT and introducing of flexible manufacturing systems). Calculation of target costing - TC is used in [6]:

- developing and improving products,
- planning products and services,
- planning the profit and the involvement of employees in profit,
- improving products by reducing costs.

As part of the calculation of target costs is value engineering, which is based on the detection of alternative design solutions that will increase the value of the product in the eyes of the customer, while keeping their costs at the target level. Process of functional analysis, which is an integral part of value engineering, aims to define a set of functions that will allow the creation of the required characteristics of the product and satisfaction of customers requirements (the value of individual functionality of the product = functionality/cost). The following hypothetical example illustrates the calculation of market - determined allowable direct costs.

For example: The enterprise "X" makes room furniture which consisting of four components. Market research showed that customers rated furniture based on four characteristics:

- comfort 50%,
- nice design 25%,
- low maintenance 15%,
- security 10%.

The customers are willing to the furniture that meets their requirements salary: 50,000.00 RSD with VAT and net 41,000.00 RSD. The enterprise expects profit of 8,000.00 RSD per furniture. The direct costs of the furniture are:

A1 - sponge	17,000.00 RSD,
A2 - pillows	5,000.00 RSD,
A3 - upholstery	15,000.00 RSD,
<u>A4 - wheels</u>	<u>1,000.00 RSD.</u>
	38,000.00 RSD.

The overall costs per unit are 2,000.00 RSD.

Table 1 Market-potential costs per product (in RSD).

ELEMENTS	AMOUNT
1. market price (net)	41,000.00
2. expected (desired) profit	8,000.00
3. market - determined allowable costs	33,000.00
4. overhead costs	2,000.00
5. market - determined allowable direct costs	31,000.00
6. direct costs	38,000.00
7. difference of costs (5-6)	7,000.00

Table 2 Importance of individual components of the product.

Essential characteristics of the product	Rating of the characteristics per components of the product				Requests of the customers (%)	Weighted importance of characteristics of the product			
	A1	A2	A3	A4		A1	A2	A3	A4
1	2	3	4	5	6	7 (2x6)	8 (3x6)	9 (4x6)	10 (5X6)
comfort	60	20	15	5	50	0.3	0.1	0.075	0.025
nice design	30	30	20	20	25	0.075	0.075	0.05	0.05
low maintenance	30	15	40	15	15	0.045	0.0225	0.06	0.0225
security	20	25	25	30	10	0.02	0.025	0.025	0.03
TOTAL:					100	0.44	0.2225	0.21	0.1275

Table 2 was formed on the basis of an assessment team of the enterprise and customers' demands. The rating of the team in terms of influence of each component of the product on the properties of products and the rating of the customers gives weighted importance of each component that is used to determine of target costs per components.

Table 3 Targeting costs per components (in RSD).

Components of the product	Direct costs of the production	Participation of components certain based on properties	Target cost of making components	Reduction of direct costs of the production
1	2	3	4 (3)	5 (4-2)
A1	17,000.00	31,000.00 X 0.44	13,640.00	- 3,360.00
A2	5,000.00	31,000.00 X 0.2225	6,897.50	1,897.50
A3	15,000.00	31,000.00 X 0.21	6,510.00	- 8,490.00
A4	1,000.00	31,000.00 X 0.1275	3,952.50	2,952.50
TOTAL:	38,000.00	31,000.00 X 1.00	31,000.00	- 7,000.00

The strategy of confrontation is a response to all competition that was created not only intense pressure to reduce product costs in all phases of its value chain, but also to increase the quality, functionality, products etc. [7]. Thus, a key role in formulating the strategy of confrontation enterprises has three strategic components and features of the product [8]: 1. Price/cost, 2. Quality and 3. Functionality. The strategy of individual product marks the customers who are willing to accept a product on price, quality, and functionality. The essence of the confrontation strategy rests on the ability of enterprises to develop one of the three characteristics of the product.

The competitive positioning of the enterprise through cost leadership or differentiation is aided by the inclusion of cost calculation in the process of designing a strategy of individual products. By selection of appropriate strategies to individual products are tend accomplish the goals that will enable to the enterprise meet market requirements and the achievement of expected profits.

Practice has shown that for successful competitive bidding is no longer enough to have low costs, but it is necessary to find ways for continually improving the quality and functionality of products. Competitive advantage in the industry and achieving above-average earnings is achieved by the successful combination of generic strategies of low cost and by strategy of the differentiation [9].

The strategy of low-cost requires the lowering of prices relative to competitors. The difference in sale price, with growth in sales volume, resulting in above-average profits. The strategy of the differentiation requires that the enterprise produces unique high-quality products that exceed identity of the brand, and have higher prices. Using strategies of the differentiation the enterprise can achieve above average profits through higher sales prices that include the costs of achieving quality at which are the products differ from other products.

5. Strategies Adaptation of Prices

To set up and implement good price strategy should be more knowledge, research, and power and energy expert team in marketing, accounting and finance. It is a key lever in determining whether an enterprise will to develop or not. Enterprises can apply different strategies adaptation of the price [10]:

1. Geographical price,
2. Discounts and benefits,
3. Promotional price and
4. Differentiation of the price.

When the enterprise applies geographical formation of the price, it needs to decide how to charge for their products to different customers from different locations or from different countries. Many enterprises will granted discounts and bonuses if the payment is done immediately, if there is a big quantity or off-season shopping. The enterprise will grant discounts on the sale price to reward loyal (profitable) customers and to ensure an early payment for goods or services which are sold on credit. Facilitation as well as discounts are the benefits that to give the customer to perform specific activity. Some techniques of promotional prices that are functional to stimulate sales are:

- Pricing to attract customers – supermarkets and department stores often reduce the prices of well known brands in order to stimulate more traffic and additional sales. The leader of the price is aware reduced of price of the product that is well known to customers;
- Pricing for special occasions – for example, sale of school supplies before the start of school year;
- Cash rebates – car manufacturers and consumer goods often offer cash rebates to encourage the purchase of their products in a given period;
- Crediting with low interest – to attract customers, carmakers offer interest-free loans;
- Longer terms of payment – sellers, especially banks and mortgage enterprise involved in selling a car, extend loans for long periods and thus reduce the monthly payments;

There are several ways of forming discriminatory prices:

- Customer as a base – not all customers the same treatment;
- Product as a base – selling the products at much higher prices than the cost of production;
- Place as a base – different prices for customers who are located in different geographical locations;
- Time as the base – when it comes to seasonal products, or before expiration date.

Thanks to studies which are related to consumer behavior, management of the enterprise is able to analyze how formation prices affect on consumers' willingness to buy, or on the satisfaction which it derived by the purchase. With good horizontal and vertical segmentation of customers, the placement of the benefits of the product, and a good analysis of the first available alternatives, it is possible with high confidence to set the right price of the product and based on that allow maximization of the profit and allow further development and growth of enterprises.

6. Conclusions

In the transition period, when begins establishment all more small and medium enterprises, the problem of selecting the optimal strategy in function achievements more adequate competitive position in the market, gains in importance. Strategic decisions – how to determine prices will be reflected in the success of the enterprise and its performance. The enterprises should be oriented towards holistic marketing, i.e. integration of research value, creation of the value and delivery of bonds, with the aim of building long-term, mutually satisfactory relationship between the key stakeholders. Properly set price policy and price strategy allows the enterprise to: 1. reflect the value which is offered to customers compared to competitors, 2. consider what the market actually paid, 3. reaches a certain level of revenue and market share, 4. maximize the profits.

Knowledge of costs is necessary for profitability, but it should not be a decisive factor that will influence on price setting and pricing strategies which specific enterprise adopted for their business. In contemporary conditions, efficient formation of the price should be mainly based on the value for the customer, not based on the cost or on the competition. The method formation of the price by goals means that the enterprise identify marketing goals and establish the price of products to meet the needs of the target market.

The enterprises generally do not determine a single price, but the fact the structural price that reflects: variations in geographical demand and costs, requirements of market segments, the time of purchase, etc.. On available to them is a few strategies of adaptation of the prices: 1. geographical price, 2. discounts and benefits, 3. promotional prices and 4. discrimination of the prices. The efficiency of sales staff and the entire marketing of the team, is reflected in the sales volume of each market segment as well as in relevant business results and profit of the enterprises.

How candidates for employment prepare themselves for the job interview

Analysis of the process of preparation of candidate for the job interview in Macedonian companies

*Ranko Bezar*¹

¹*Faculty of Mechanical Engineering, Ss. Cyril and Methodius University, Skopje, Macedonia, ranko_bezar@yahoo.com*

Management of human resources is a strategic and coherent approach to managing the most important factor in the organization – the people, those who individually and collectively contribute to achieving organizational goals. Human resources management covers the recruitment, selection, training, developing, rewarding, compensating, and motivating the workforce, and must reflect clearly the organization's strategy regarding people, profit, and overall effectiveness. One of the main aim of human resource management is to ensure and obtain at minimum cost the number and the quality of the employees required to satisfy the human resource needs of the organization, which is accomplished through selection and interviews of candidates for employment. Historically, the interview is one of the most commonly used and most liked selection tool [17]. According to [18] job interview right after the candidate application is commonly used way to evaluate applicants. According to the analysis of [22] in the business organizations, the decision on employment usually is made based on job interviews.

The presented survey will be concerning the preparation for interviews of candidates for employment in Macedonian companies, the level of formal training that candidates attend to prepare for interview, as well as the conduct of interviews analyzed in terms of candidates, and impact of innovation in the area of HR.

Keywords

Human resources management, job interview, structured interviews, skills, training,

1. Introduction

Interviews are usually used as one of the tools and methods of selection / recruitment that help making organizational decisions. Because they are flexible, interviews can be used for accomplishing several goals, such as selection of candidates for employment, introduction, and rejection of unsuitable candidates and so on. Increasing the structure of the interview can help managers in achieving their goals or employment selection by minimizing the external influences on the interviewer's and candidate's decisions. By structuring the interviews a standardization of procedures is introduced and minimized certain differences in objective appraisal of candidates for employment. Well-structuring of the interviews, that balance the need for standardization with the need for discretion of the interviewer and the applicant, can ensure that, both organizations and applicants, have pulled out the maximum of the process.

2. Theoretical perspectives

Structuring an interview results in outcomes or scores that are indicative of how the candidate will actually perform on the job [10] [16]. In addition, structured interviews tend to result in very low adverse impact [19]. In particular, there are minor differences in interview results than in the use of many other selection methods [23] [24].

The disadvantages of structured interviews is that they are sometimes less popular with candidates [26]. This might be because structured interviews limit free-flowing conversation and with it the possibility for candidates to steer the interview in a particular direction. Interviewers can reduce candidates' negative reactions about structured interview explaining and expressing support for the method. Moreover, structured questions do not preclude establishing rapport with candidates and expressing friendship, which also are important for the success of the interview.

Two types of highly structured interviews have become increasingly popular as ways of eliciting examples of behavior related to a job or job competency [25] [27] [28].

These interviews differ based on the type of questions asked: Situational interview questions ask an applicant to describe what he or she would do in a hypothetical situation. For example, "Imagine you were in a situation where your team was under significant time pressure to complete a project. How would you handle that situation?", or Tell us about a suggestion you will made to improve the way job processes/operations worked. What will be the result? to see the potential of the candidate regarding innovation. Behavior-based interview questions ask applicants what they did in a specific situation. For example, "Think of a situation where you had to lead a team in a company, or when you implement some innovation in your organization. Describe the situation, your actions, and the results of your actions." Much debate has ensued regarding the merits of these two approaches. Research results have been mixed, with both types shown to be related to later job performance. Some researchers indicate that situational interview questions are more appropriate for a broader audience because they do not require that individuals have extensive work experience [28]. Other research, however, tested this assumption and found this not to be the case. Instead, these researchers argued that the nature of behavior-based questions allows for applicants to apply all types of life experiences to the questions [29]. For example, the behavior-based question example that asked about leading a team could be answered by describing a work team, a sports team, or a school group. Research also suggests that individuals explaining past behavior are able to give considerably more information and detail, helping to provide the interviewer with additional insight. Some researchers have argued that situational interviews are less able than behavior-based interviews to address complex and high-level jobs. Situational questions must accurately represent potential situations that job applicants might face. The higher one is in an organization, or the more complex the job, the more difficult it is to develop situational questions that fully encompass all parts of that job. This means that while the interviewer may be able to differentiate between those applicants who might be poor performers and those who would be good performers; it will be significantly more difficult for the interviewer to differentiate between those who will be good and those who will be great. Behavior-based interview questions, on the other hand, allow applicants to choose their own examples, elaborate on what might be very complex considerations and actions, and then explain in detail the different ways their actions lead to results [25]. Behavior based interview questions assess typical performance—what happens day to day— and show an applicant's motivation to carry out the behaviors he or she thinks appropriate. Situational questions assess maximal performance, or what an applicant would do or consider the best option; they do not measure motivation to apply those skills or whether they are likely to actually perform the behaviors [30].

3. The methodology

The methodology in this study will be based on exact numerical, theoretical and experimental approaches. Using comparative analysis of the results will be given appropriate conclusions for guiding the selection process and the manner of conducting interviews for positions in Macedonian companies.

4. Findings

The survey used a questionnaire with 12 questions of which 2 are open questions. The questionnaire was designed to explore important elements in the process of preparing the applicants for employment. The research involved 124 participants, of which 90 participants were taken as relevant to the survey, which according to key criteria had at least one interview during one year. The participants in the survey, from the aspect of gender, were 63% women and 37% men, and their age breakdown is presented in Graph 1

Figure 1 Demographic information

According to the educational structure, 14% had high school, 61% university degree, and 24% with postgraduate studies.

According to the number of interviews that have attended over the past years, participants in the survey stated that, most of them (64%) applied in the past year in 5 organizations, in 5 to 10 organizations applied 12% of respondents, 10-15 organizations 9% and over 15 organizations, 14% of respondents. (See Graph 2)

Figure 2 Q: Past year I've applied in... organizations

The survey results are statistically elaborated, and in this article will be commented and analyzed several issues that are most important for the analysis of the process of candidate's preparation for employment.

Asked, whether they have had any formal training to prepare for job interview, 91% of respondents said that they did not have attended, and only 9% expressed that they had some formal training.

This may be one of the key data that informs about the degree of preparation of the candidates for employment in Macedonian companies, i.e. that formal knowledge and skills for appropriate performance of a job interview are not available to the applicants for employment. Generally, the applicants for employment are preparing based on personal perception and their own personal experience of the performance in the interview. On the question "Am I preparing myself before going on an interview?" Participants in the survey respondents as shown Graph 3

Figure 3 Q: Am I preparing before going on interview

In the research, 68% of the participants stated that they are always preparing, 19% sometimes, rarely 11% and never 2%, which confirms the relatively high commitment to preparation for performance at interview.

To analyze the method of preparation of the candidates and what they consider as most important in the process, the following question is constructed, and participants expressed themselves as shown in Graph 4.

Figure 4 Q: When I'm, going on an interview I'm preparing for

Most parts of these 44% are preparing data for the company, 35% are preparing for possible questions and 18% of the participants are interested in getting information through their familiar, some of them are asking already employed whether they are satisfied with the company and 6% are rarely preparing.

This analysis leads to the conclusion that most of the candidates are preparing information regarding the organization they are applying to, and less on possible questions and how to respond to them, although it is expected the opposite.

The reason for this method of preparation may lie in the conclusions the way that employers organize and run the interview, i.e. that in the interviews dominated questions refer to the company/ organization or its products and services and less questions which are related to the job, the necessary competencies of the candidates, and the candidates behaviour corresponding to the position.

The second possible reason is that candidates have no formal training how effectively to prepare for interviews and adequate direction they should be focused i.e. on which types of questions they should give an appropriate response.

According to [1] there are 3 basic questions that need to be answered at this stage for the selection interviews for employment:

What are the criteria to be used in selecting candidates - they can be classified as essential or desirable and will refer to the experience, qualifications, competencies and skills as set out in the person specification.

What more do I need to find out during the interview, to ensure that the candidate meets the essential selective criteria?

What other information should be obtained during the interview to ensure the interviewer have an accurate picture of how well the candidate meets the criteria?

The problem with interviews is that they are often inadequate as predictors of performance of the candidates, and during the interview, the interviewer may not cover the basic points unless it is not carefully planned. This is not just a result of many interviewers using inadequate interviewing techniques (such as: they talk rather than listen), but it is often a result of inadequate analysis of the competencies required and as a result, examiners do not know what information need to obtain from the candidates as a basis for structuring the interview.

There are several methods of conducting an interview. Worst is the case when the interview is completely unstructured, which includes random questions that are not based on any understanding of what they are looking for. At best they are clearly structured and related to a thorough analysis of role requirements in terms of skills and competencies.

The content of the interviews may be different. Different interviewers ask different questions, focus on different areas of knowledge and experience of the candidates and trying to evaluate different characteristics. According to [37] as a measure for the structure, the interview should be consistent, based on facts and used by everyone as common metrics for description of the degree of an interview structure.

A meta analysis of interviews showed that unstructured interviews place the emphasis on the candidate's background, his personality, physical characteristics and general mental abilities, while structured interviews the context of the questions for all applicants refer to the mental skills, knowledge related to the job, practical social skills and the degree of integration of the candidates in the organization [25].

In the survey it is also important to note that the question "When I'm going to an interview I'm usually preparing for", 11% of respondents said that they talk to their relatives working in the company they are applying, about their satisfaction with the company, i.e. Are the companies that publish vacancies attractive for them as candidates for employment?

This is another confirmation of previously made similar studies, that during the interviews despite asking questions to assess candidates, interviewers should pay attention on how they represent the company and is the company interesting and attractive to the applicants.

Just as managers are interested in applicants that fit their organizations, applicants generally seek organizations that provide a good fit with their interests and needs [36]. Applicants generally are interested in many of the same criteria: the type of job, location, salary level, training opportunities. However, the type of information they want and how these criteria will affect their decision process are the same for all candidates. Accordingly, interviewers can structure interviews to help applicants make good decisions by taking in consideration the important factors that influence their decision making and the context in which those decisions would be made. This form of interview structure has several benefits. First, rather than providing a standard "speech" about their organizations' positive attributes, interviewers can offer realistic information tailored to applicants' interests. This practice can help the organizations gain an advantage in attracting the interest of the applicants since other firms do not provide such individual approaches.

Interesting data were obtained from the analysis of the types of questions that candidates are using to prepare themselves for the interview. Most of them, 25% indicated that they generally prepare questions based on the position they are applying, 13% questions related to their weaknesses, and only 11% are preparing situational questions and 11% are preparing past behavior based questions. The percentage basically should be higher, considering the fact that the Situational questions and questions related to past behaviors are an integral part of a structured interview. The structure of an interview is an important means to enhance joint decision-making for the candidate and for the interviewer. In 1980, psychologists [14], [20], [11], [12], suggested that the interview could be improved by providing structure, particularly focusing on questions that will highlight the ability of interviewers to make good decisions in different situations. Industrial psychologist [21], suggests another strategy for structured interviews. It is better questions to be focused on past behavior of the candidates rather than on future hypothetical situations, i.e. Situation questions. A review of research in this part of the interviews shows that the biggest problem with a typical interview is a lack of consistency and structure. Regarding this issue there are some suggestions of certain authors suggesting strategies for structuring the interview, thereby indicating that interviewers should have a standard set of questions, to develop a system for scoring the responses of candidates, as well as using more interviews. All these methods help to improve the usefulness and objectivity of the employment interviews.

What is the reason for the low percentage of preparation of these 2 types of questions? Whether is the lack of orientation of the candidates and the low level of formal training or because of poor conducting of the interview by the employers i.e. of not practicing this kind of questions during the employment interviews? This certainly gives new opportunities for new researches in the area of the process of making interviews in the Macedonian companies.

In order to examine the need for formal training about the performance of candidates for employment, in the inquiry is set the question: "If in the formal education (high school or university) in the terms of subject matter is included a training course for presentation for interview, I think it will increase the willingness of the graduates to be more successful in the job search ..results are presented in Graph 5

Figure 5 Q: If in the formal education (high school or university) in the terms of subject matter is included a training course for presentation for interview, I think it will increase the willingness of the graduates to be more successful in the job search

On this question, 52% of respondent expressed that they absolutely agree, and 39% that agree within the formal education to be included training in skills for performance at the employment interview. The total amount of 91% confirmed the desire to upgrade these skills for better performance at the interview, which will naturally lead to their better self-presentation and leaving a better impression on job interview. A similar study conducted by [2] with laboratory study, based on candidates for employment, found that use of self-promotion (compared to other-focused) tactics was related to higher ratings, more job offers, and fewer rejections.

5. Conclusions and discussions

According to the obtained findings from this research about the level of preparation and how to prepare candidates for employment in Macedonian companies, we can conclude that there is a low level of formal training on interview skills of candidates for employment, i.e. only 9% expressed that have attended a formal training of this kind, on the other hand there is a high level that express the desire and need of the candidates for this type of training, i.e. 91% support this view. This opens the possibility of giving a recommendation to higher educational institutions for introduction into the curriculum appropriate chapters which will give adequate knowledge and skills to prospective graduates on how to prepare and be successful in the job search process, through self presentation and appearance at job interviews.

6. Guide for future analysis

According to the results of the research and consideration for the relatively low level of preparation of candidates for employment on Situational questions and questions related to previous behavior, opens up new possibilities for future research in this area, the level of application of structured interviews to Macedonian companies, and the degree of formal training of those who run these job interview. Research in this area confirms that for increased validity of job interviews, one of the criteria is a formal training for proper conducting an interview. Training is probably the most common way to improve interviews [35]. Untrained interviewers are significantly coarser in their assessments, rather than trained in the evaluation of candidates [33]. Thus, training can help in the reliability of the interviewers' judgment and the consistency in different contexts. Researchers have indicated that formal interviewer training enables interviewers to evaluate candidates more effectively (e.g., [31] [32]) and to develop the recruiting function of the interview [34]. Training is an important element of structure in that it increases the likelihood of using other elements of interview structure.

On the other hand the results of these surveys will be used also for providing appropriate recommendations for improving the process of recruitment and selection in Macedonian companies. Practical research in this direction as well as their analysis will show how and to what extent in the Macedonian companies are applied the tools for conducting the interviews and what type of interviews prefer the managers, whether and to what extent are using auxiliary instruments, psychological tests and other information for additional analysis of the candidates, whether managers are formally trained for conducting the interviews. Managers, human resource administrators, employment counsellors and others should strive for continuous improvement in the entire recruitment process, with particular attention to the interview. Continuous improvement will help to insure proper selection decisions in the Macedonian companies. This effort should help decrease turnover rates, increase productivity, improve employee morale, lower grievances and other employee complaints and in general lead to a more stable organization.

According to the survey conducted in 2010 for Macedonia [38], the key recommendations are considered in relation to the recognized weaknesses of the Macedonian companies. One of the recommendations is "inspiring life long learning in the companies", so the training in human resources in the companies for development of skills for conducting job interviews, will contribute to choosing the right candidate or the position, through implementing innovations in segment of HR in order to improve the competitiveness, development and the profitability of the Macedonian companies.

In this paper, the authors analyse the necessity of applying the contemporary concept of entrepreneurship in the Serbian market, with a special emphasis on the role of young people and the possibilities of engaging them in entrepreneurial activities. According to the experience of developed countries, the young people who first start their own business represent an important category for developing an entrepreneurship climate on the national economy level. Serbia still does not have a favourable enough ambiances in which young people can be inspired to start up their own business. As a possible solution emerges the encouragement and education of the young to start and run their own business. Encouraging entrepreneurial behaviour among the young is especially important in countries in transition, which are facing transitory recession.

Keywords

Competitiveness, Entrepreneurship, Knowledge, SMEs, Young entrepreneurs.

1. Introduction

The changes in modern business caused by global economic crisis have influenced companies to change their business philosophy. In other words, companies are forced to accept the model of entrepreneurial behaviour that implies more initiative in the field of innovations and flexibility. Ever-increasing number of companies, different in size, financial capacity and ownership, apply the bases of entrepreneurial behaviour. According to experiences of developed countries the young who start business for the first time represent a significant category for developing entrepreneurial climate on national economy level. Young entrepreneurs in European Union have significant incitements through supporting programs that influence the building of their self-confidence at starting their own business.

2. New models of entrepreneurship development

Entrepreneurship represents continual creative process whose basic objective is implementing innovations in organizations in the function of successful business performance and solving the problems of customers and the society. Successful business in the 21st century will depend on company's relations towards increasing the need for knowledge and implementation of the newest technological achievements in management as well as its capacity to transfer information towards the target groups of customers in the fastest, most understandable and efficient way.

Modern organization must base its business on entrepreneurship concept of behaviour that incites strategic approach grounded on accepting differences, creativity, innovations and responsibility of every individual in the organization. The stress is, here, put on innovations because of the fact that our society is based on knowledge. Companies must apply entrepreneurship concept consciously and organizationally and they should behave „entrepreneurship“ as well as apply innovations constantly. In order to achieve these objectives companies must create an appropriate organizational structure that

allows their employees to behave in entrepreneurial way. Moreover, companies must establish such systems of relations that will enable focusing on such a behaviour.

Entrepreneurial behaviour in modern organization is not related to individuals and their abilities and experience but is mostly based on team work. Therefore, it is developed a model of corporative entrepreneurship that incites team work whose members are motivated to work on achieving success and accepting differences. Big companies should incite entrepreneurship in order to overcome the problems they face while they learn how to work with partners and allies. Big companies make a unit in their organizational structure which behaves completely differently from the rest of the company.

Drucker thinks that every big company should be able to do three important things simultaneously – to improve, to expand, to innovate. He emphasizes that he still doesn't know such a company but that there are numerous companies which are working on that. [1, p. 82].

Majority of economically developed countries are characteristic for the following principles according to which the labour market functions, especially considering the young and their employment :

- unemployment of the young is greater than unemployment of adults and the rates are, at least, doubled;
- increasing the extent of formal education of the young is becoming more significant and this trend will be continued;
- young people are scared of getting married because of the problems related to social security, so they decide to get married later;
- participation of women in employment is becoming more and more significant;
- labour market programs for the young generally have a small rate of return [2, p. 1].

State administrations of developed countries are trying to find out new solutions for employment of the young and the stress is on creating entrepreneurial abilities of young people. Self-employment represents an option for individuals to define their own model of business and development. Governments of developed countries consider self-employment a measure that enables solution of the problems of poverty and employment of the young , so it helps in small business development. Confirmation of this activity is usually based on a great number of potential benefits, among which the following are outstanding:

- entrepreneurship promotes innovations and creation of new work places,
- entrepreneurship and their own business start-up have a direct influence on employment increase on the grounds of creating new work places at present or in near future,
- new small enterprises increase the extent of competitiveness on the level of national economy which makes benefits to customers,
- young entrepreneurs can respond to market requirements flexibly, especially from the standpoint of applying new technologies and following market trends,
- larger extent of self-employment of the young causes self- confidence improvement, as well as social welfare. [2, p. 5].

3. Conditions for incitement of entrepreneurship in Republic of Serbia

Completion of transitional process, in other words, the change in economical society structure – privatization, market economy, liberalization of economic relations with foreign countries, etc., represent a basic precondition of successful international economic flows. Transitional process should enable economic entities from transitional countries for independent market performance, sound competition and making business on international market. Strengthening the private sector and its future development are of essential importance for successful transformation of the economy from planning towards the market one. Development of SMEs sector is significant for privatization because it enables accelerating privatization – SME represents autochthonous private sector and makes possible development of domestic private capital [3].

Development of SME sector is one of essential priorities of domestic economy. Serbian Government has adopted Development Strategy of Competitiveness and Innovations of SMEs for 2008-2013. This strategy should contribute to further strengthening and efficient use of developing potentials of SME sector which will make benefits to economic growth of Republic of Serbia. Such direction should contribute to increasing competitiveness and export, further strengthening the innovation capacities of companies, dynamic employment growth and more equal regional development.

In Republic of Serbia, SMEs participate in the total number of enterprises with 99.8%, with 65.5% in employment, with 67.6% in turnover, and with about 36% in GNP. In the total export SMEs participate

with 50.2%, in import with 64% and with 51.2% in investments in non-financial sector. Micro enterprises are dominating in SMEs sector with participation of 95.6% in the total number and nearly 50% of all employed work in this sector [4, p. 5].

According to the last year's data, in Republic of Serbia, about 40,000 small entrepreneurs closed their business – 3,455 economic societies and 34,909 entrepreneurs' shops. The reasons for such a decline entrepreneurs see in numerous state loads, slow collection of receivables, lack of favourable loans and high interest rates. According to National Agency for Regional Development, the main problem for entrepreneurs represents lack of available monetary resources and then administrative barriers. It often happens in practice that domestic entrepreneurs have liquidity problems so they are not able to collect debts, but the state forces them to pay their receivables in preconceived terms. These problems cause their indebtedness towards banks which later leads to their bankruptcy.

A great problem for Republic of Serbia represents the number of closed medium-size companies as well as those in bankruptcy. The most worrying fact is the loss of work places – when only one medium-size company is closed about 50 to 250 people lose their jobs and new openings are rare.

The owners of SMEs were polled by National Agency for Regional Development and they cited, as a priority problem, the lack of financial means and then administrative barriers, insufficient number of qualified workers, disharmony in standards, lack of market information, little information on technology. Serbian Government is trying to solve all those problems that interfere with basic pillars of development policy of SMEs. One of priority tasks is the so called guillotine of regulations, which means that by simplifying procedures as well as eliminating unnecessary ones it is possible to save about 120 million euros per year. In other words, according to some estimations, our economy loses at least 180 million euros per year because of complicated and unnecessary procedures. However, there has been a delay in realization of this program (only 10 out of 250 proposed regulations have been solved completely or partially) because of unreadiness of state administration to approach this problem in serious and reasonable way. What is new in this field is that companies have been obliged to submit final accounts only at one place since 2010.

Ministry for Economy and Regional Development in cooperation with Serbia Investment and Export Promotion Agency (SIEPA) has taken part for years as a major partner in the Project Support to Enterprise Competitiveness and Export Promotion (SECEP). This project is financed by EU as a part of technical support to Serbia. A consisting part of the program is Development of local suppliers chain which enables domestic small and medium companies to become parts of multinational companies. One of the main barriers is lack of required quality standards which SMEs do not possess. It often happens in practice that suppliers are not able to fulfil severe criteria which multinationals propose. Ministry for Economy and Regional Development via National Agency for Regional Development offers entrepreneurs a wide range of support, both financial and non-financial, trade fair promotions and supporting entrepreneurial projects. Moreover, on the site of this Agency there is an entrepreneurial portal which gives a lot of information to present and future entrepreneurs. The newest project of Ministry for Economy and Regional Development is a cooperation protocol within the project „Establishing partnership for life-long training of entrepreneurs in Serbia“ started by European Training Fund (ETF). Protocol parties are 11 institutions (project partners) whose aim is a common work on creating Strategy and plan of activities for life-long training of entrepreneurs and taking care about measures that every organization should carry out in order to implement the strategy successfully. Institutions included in this project are: Ministry for Economy and Regional Development, Ministry of Education, Ministry of Youth and Sports, Institute for Improvement of Education, National Employment Office, National Agency for Regional Development, Conference of Serbian Universities, Serbian Employers Union, Belgrade Open School, Civil Initiatives and Serbian Chamber of Commerce.

Serbian Government adopted a Program for lending favourable start-up loans, within the support, to those who want to start-up their own business. The planned amount for start-up loans is 2.2 billion RSD. During the period 2007 to 2009 through the contest organized by Ministry for Economy and Regional Development, National Employment Office and Development Fund 6,625 new enterprises were established and 21,121 workers employed which justified financing this program. In addition, through Development Fund, entrepreneurs could apply for start-up loans in amounts from 500 thousand to 1.3 million RSD with interest rate of 2.5% per year and repayment from 3 to 5 years with grace period of one year.

However, according to data provided by National Employment Office, in December 2010, 729,520 unemployed people were registered, which represents a decline of 852 people in comparison to December 2009.

Majority of registered unemployed people are at the age from 25 to 29 years (13.29%), then those from 30 to 34 years (12.46%), from 35 to 39 years (12.03%), from 45 to 49 (11.85%), from 50 to 54 (11.79%) and those from 40 to 44 years old (11.63%) [5]. These data show that financial means

offered by Serbian Government are not sufficient to include all those who need them. This is especially important to young people who represent the most significant resource of the society. In order to incite employment of the young Italian Government donated 1.2 million euros to support solving this problem. Fund for open society as a part of NGO sector provided 570,000 dollars to help a group of 400 young people between 15 and 29 years of age from Bor, Raska, Branicevski and North Banat Districts.

Unfortunately, the young do not have enough business experience so domestic companies are not ready to employ them because they would need a lot of time for their practical professional training. For all these reasons Serbian Government decided to give financial grant to those companies which would employ a certain number of unemployed young people within the employment program „The first chance 2010“. Namely, this program is aimed to provide conditions to young, unemployed people to do three months voluntary practice in companies and afterwards to offer them a possibility to work 12 months as trainees. In order to incite professional training of the young, Serbian Government organized a contest for the program „The first chance 2010“.

Moreover, it should be emphasized that the state has been financially supporting the establishment of clusters and development of innovations in domestic economy for years and by doing this it contributes to improving competitiveness.

According to „Post-crisis model of economic growth and development of Serbia from 2011 to 2020“, one of direct measures of support represent loans; these loans are planned to be given to beginners from all sectors, as well as to beginners in targeted sectors (sectors of medium and high technological fields in industrial production). Unfortunately, these loans are not related to young entrepreneurs because the term „beginner“ is not age limited which increases the number of interested in these loans. However, this kind of support may be significant for young entrepreneurs only if the extent of realization is high.

4. The opinions of young people about start-up business

The research related to „The analysis of the youth's attitudes and opinions concerning start-up of their own business and applying social responsibility“ was carried out from November till December 2010 and it included 580 students oriented towards management. The research results point at the fact that the majority of students - 80.62% want to start their own business. On the other hand, most of them (29.43% i 20.38%) say that the main reasons why they still haven't started it are insufficient financial means, insecure political and economic situation in the country, which all implies that the state incitement measures are not sufficient to young people who would like to start-up their business. What is really worrying is the percentage of the young who still do not see Serbian market politically and economically secure.

The polled students are mostly (68.57%) oriented towards their own means in order to start-up their own business. The reason for such attitude is students' insufficient confidence in banks and other financial institutions which offer financial means for start-up business. However, it is interesting that the students (13.47%) stated associated funds as the second represented answer, which speaks about their developed consciousness and awareness of the importance of associating financial means. In this way, it is possible to make a considerable starting capital that will enable better perspective for young entrepreneurs. In addition, the polled students (54.17%) think that start up loans offered by commercial banks are not favorable. Namely, according to their opinion, start-up loans of commercial banks are overloaded by high interest rates (48.07%) and by a long process needed for obtaining the means (18.53%). The results collected in the research carried out in 2008 and 2009 showed that the students (53.74% and 54.03%) were not satisfied by conditions of start-up loans and they thought that the reasons were high interest rates (80.38% and 33.79%). The 2010 research showed that more than a half of the polled students (51.03%) were not informed about the existence of stimulating means for start-up business. However, even 53.98% of the polled students were interested in becoming the users of these means. Hence, the imperative seems to be permanent informing of young people via media, public presentations at faculties and colleges. In this way the young will be informed about the conditions for getting the loans. It is necessary to involve the following institutions in promoting activities: Serbian Chamber of Commerce, Belgrade Chamber of Commerce, National Bank, Association of Serbian Banks, National Agency for Regional Development, Ministry for Sports and Youth and similar whose aim is supporting youth's employment and their training for starting their own business.

The polled students said that they missed the following knowledge: the elements of entrepreneurship and small business (23.11%), foreign languages (21.60%) and the elements of finance and accounting

(21.45%). The first two categories are expected but it is positive that the students understand that foreign languages are also important for managing a company. In other words, the art of internal and external communication is of crucial importance for successful businessmen.

According to students' opinion (80.00%) there isn't any appropriate ambience for stimulating the young to start-up their business in Serbia. The students suggest the following barriers that are binding them: lack of financial means (32.26%), unstable political and economic situation (29.75%) and too high taxes (20.30%). In the research from 2009 and 2008 the students were not satisfied with (88.08% and 78.70%) the ambience for inciting the young for business start-up. The limiting factors are, in fact, the same as in the research from 2009 and 2008, only the order is different: unstable political and economic situation (29.92% and 36.54%), long and complicated registration procedure (21.62% and 13.75%), as well as too high taxes (35.52% and 10.02%). On the grounds of all collected results from these three researches it is obvious that the important precondition for improving SME sector is creating the right ambience that will stimulate making new and development of the present SMEs. However, three elements are necessary for creating an appropriate ambience: laws/regulations, institutions and associations of entrepreneurs. Therefore, consensus between the state and its institutions and associations is highly significant for creating such an ambience.

The majority of the polled, even 90.33% considers that the state should have the key role in stimulating the young for business start-up. They emphasize the following: favourable loans (28.70%), education (19.33%), laws/regulations related to young entrepreneurs (15.65%), promotion of the youth concept as entrepreneurs (13.22%), market regulation (12.22%) and development of new business centers and incubators (10.46%). The same opinions shared the polled students from the researches carried out in 2009 and 2008 (88.08% and 90.78%) which implies that the state has to be the driving force of entrepreneurship in Serbia. Supporting measures are the same, only priorities are different: promotion of the youth concept as entrepreneurs (25.38% and 26.86%), education (10.38% and 15.10%), market regulation (16.15% and 14.71%), favourable loans (23.08% and 13.14%), laws/regulations related to the young as entrepreneurs (14.42% and 11.76%). Serbian Government has adopted several strategies for development of SMEs and entrepreneurship and activity plans since 2000 but, unfortunately, it hasn't adopted any strategy for inciting young entrepreneurs. It would be hard to say that there is an appropriate ambience for inciting the young as entrepreneurs without such a document. In addition, there isn't any sector which deals with problems of young entrepreneurs within institutions whose activities are related to SMEs and entrepreneurship. In the economic study "Postcrisis model of economic growth and development of Serbia from 2011-2020" in the part which deals with employment estimation and labour market trends there isn't any estimation concerning employment of the young for the period from 2010 to 2020. This is certainly not a good message to potential young entrepreneurs.

Developed countries and EU as well, have special programs for stimulating the youth concept as entrepreneurs. The program assumes cooperation of several institutions and the result is practical competence of the young for managing companies. Our young people do not have such experience and efforts should be taken in improving this unfavourable situation.

5. Suggestions for inciting entrepreneurship of young people on the market of Republic of Serbia

Global economy should enable the regions to bring the wealth from the rest of the world in the future. In order to do this the regions have to be equipped with high educated and disciplined people led by visionary leader able to communicate with the rest of the world [6, p. 256]. Some of these regions are the island Hainan (South China, Province Guandong), Vancouver and British Columbia (Canada), Estonia, Ho Chi Minh City (Vietnam), Coastal and the Island Sakhalin (Russia), Sao Paulo (Brazil), Kjusiu (Japan).

American professor of Marketing of Indian origin, Mahajan, the author of the world bestseller „Solution for 86%“ says: “The state doesn't make business opportunities. Entrepreneurs are those who make them. Whatever the state does it must stimulate entrepreneurship. On this extremely competitive market it is important who has better idea, who knows how to realize it better. Entrepreneurship is not the monopoly of the French, Germans, Americans, Chinese or Indians. The region of the West Balkans is full of entrepreneurs. The problem is in the fact that West Balkan countries are small. They are faced with the challenge of the further growth. But, for the further growth they must have a global vision, they have to turn around and search their chances on the global level” [7].

Serbia has all preconditions to become one of similar regions in the near future if its businessmen change their business philosophy as soon as possible. Capital owners and executives should

establish new elements of competitiveness in domestic companies. It is necessary to overcome old-fashioned policy and techniques of management and to accept modern ones, as well as to learn from the experiences of global leaders and the companies from newly industrialized countries which are exceptionally successful on the global market.

According to some opinions [8], competitiveness, in long terms, cannot be increased by subventions to industry, favourable exchange rate, positive trade balance or low inflation rate. Competitiveness can be improved by increasing productivity. The role of the state is to make equal conditions for all competitors, to protect ideas, innovations, property, to help if it is in the interest of the whole group and not in the interest of any company, and to avoid determining the winners or losers in advance. The issues related to increasing productivity of domestic companies and making equal conditions for all are essential and long-term indicators for overcoming the crisis, especially transitional crisis.

Within the development process of entrepreneurial behaviour in Republic of Serbia it is necessary to improve the business ambience in several ways in order to make the job of the present and future entrepreneurs easier. The process includes the following elements:

- creating regulation framework for faster and easier process of work especially for young entrepreneurs,
- building strategy for development of entrepreneurial concept of the young,
- supporting loans for business start-up to young people,
- stimulating measures for implementation of QMS (individually and in groups), Integrated Management Systems whose aim is development of competitiveness of domestic SMEs,
- more active role of universities in helping entrepreneurs,
- start-up of business incubators and business centres,
- greater engagement of entrepreneur associations in promoting entrepreneurial concept of the young
- promoting entrepreneurial concept as a way for overcoming transitional problems during recession.

It is important to emphasize that the problems related to development of entrepreneurial behaviour should be treated by several interest groups, such as: the state and its institutions and ministries, universities, entrepreneurs associations, media who can give a positive contribution to creating an appropriate ambience for small business start-up.

As we have mentioned before, Serbian Government began improving the business ambience by accelerating slow procedures for registration of companies, giving more favourable start-up loans, professional training of unemployed, etc. What is crucial on the state level is making a strategy for development of entrepreneurial concept for young people that will include several parts: training, knowledge application in practice, institutions for young people and similar.

Training is especially important and a particular attention should be paid to it in primary and in secondary schools and later at universities and colleges. There are certain programs which are being applied in secondary schools but they are not followed sufficiently by appropriate measures of the state, economy and professional associations.

Practical application of the acquired knowledge from the field of entrepreneurship represents a separate segment of the training process and, here, the following institutions have the key role : Serbian Chamber of Commerce, Employers' Union, National Agency for Regional Development, universities, Ministry for the Youth and Sports, Ministry for Economy and Regional Development In this way young people are getting necessary experience which can be later applied in real life, in their own or in other companies.

Promotion of entrepreneurial concept for young people is a special issue which should involve numerous segments within a society such as: media, associations of entrepreneurs, ministries, universities, students' associations. In this way, young people should be given information about entrepreneurial concept, the importance of innovations for entrepreneurs, using certain tools for development and application of business ideas. EU programs may serve as good examples because they approach these problems with special attention.

Moreover, successful domestic entrepreneurs should give speeches at universities and colleges, sharing their experiences, talking about their beginnings, reasons for start-ups and the difficulties they had. In this way, they can incite young people to start their own business and uncover prejudices and stereotypes.

6. Conclusion

Interests for business start-ups are rising everywhere in the world. However, involving young people in entrepreneurial activities requires certain activities of the state and its institutions. The results of this research point at the fact that the state must have the key role in this field on domestic market through issuing certain documents whose aim is promotion of entrepreneurial concept of the young. The projects should involve universities, Serbian Chamber of Commerce and its regional chambers, National Agency for Regional Development, relevant Ministries, and associations of entrepreneurs in order to help those who are planning to start their own business.

Young people consider that the biggest problem in business start-up represents lack of financial resources. Financial support to domestic economy is insufficient and this is especially discouraging for those young people who want to start their own business. The state is trying to change this situation but commercial banks are still in favour of other ways of lending money under much better conditions. Institutions are necessary for creating successful ambience for inciting young people to start-up their business. However, the problem is when their activities are not synchronized and according to The World Economic Forum Serbian institutions are not efficient enough. Institutional cooperation is very important because, only in this way, it is possible to support young people to start their business completely.

However, the imperative in developing entrepreneurship of the young in Republic of Serbia must be creating secure political and economic situation. It represents a precondition and without it there is no normal entrepreneurship development in Republic of Serbia.

Copreneurship as Work-Life Balance Facilitator

Tina Bratkovič¹, Aniko Noemi Turí²

In the recent years the economic crisis hitting all the developed countries resulted in major changes in the economic structure and also resulted in major changes for the companies and private life, having an important input to state economy. Of course this could not avoid women's status at the labour system of the companies and the change of the relation with their private life. In this turbulent time copreneurship as the sharing of the ownership and management of a business between spouses might be seen as a facilitator of work-life balance. The main focus of this study is on the impacts of the European Union (EU) regulation on the work-life balance with a special emphasis on copreneurship as the work-life balance facilitator. Through a thorough analysis we disclose whether copreneurship has any encouraging influence on work-life balance with special regard to women's status at their companies or at economic performance in the EU. The principal goals of the study are to identify copreneurship and work-life balance and examine the correlation between these two concepts. The research results show how EU labour/gender regulation affects women and copreneurs status, level and quality of employment and private life at job contraction practice at the companies. On the basis of the research findings, we might be able to give advice that the growth of supporting regulations are increasing pressure on national and EU level policy decision makers. The study provides significant contributions to gender apportionment at the labour market and to employment effects of parenthood on men and women.

Keywords

Copreneurship, Work-life balance, Employment impact, Gender distribution

1. Introduction

In the last decades the number of working women has significantly increased. Merely the fact that recent years' economic crisis is hitting all the developed countries resulted in major changes to the economic structure, companies and private life. Families in which both partners work full-time are facing new challenges as well. This primary alteration could not avoid women's status at the labour system of the companies and the change of the relation with their private life. By the consequences of the employment uncertainty, or short, unpaid maternity leaves, a vast number of women dare to step into private businesses alone or with their spouses. The main question that arises is how to achieve the balance between work and family responsibilities in this hard economic period and recession at the labour market. Besides working long hours, women also have to engage in domestic work and child care. Women have therefore to cope with multiple responsibilities both at work and at home at the same time.

As a challenging goal to achieve, work-life balance became a much discussed concept not only on the individual level and organizational level but also on EU level. Although many organizations have already been adopting policies that facilitate the balancing of work and private life, the area still needs to be improved and enriched with additional schemes and programs helpful for the process.

Copreneurship defined as couples sharing the ownership, management and responsibility for a business creates conditions in which women and copreneurs as a whole can balance their work with personal life in an easier way. By establishing a family firm it is possible to combine and merge work

and personal life. Therefore, copreneurship can be seen as a facilitator in the process of achieving work-life balance.

There are numerous bright and dark sides of entrepreneurial couples however in most cases the common decision of co-working is based on the family. Reasons can differ or even correspond why women decide by copreneurship. The fundamental argument is the flexibility that a mother desires to be able to take care of family or personal matters while she feels secured that her partner is looking after the business [1]. Other significant factors are that women in copreneurship have chance to live and work according to their values. Couples can frame their own mission and vision that might be left as a legacy for their children [1]. Through a thorough analysis we disclose whether copreneurship has any encouraging influence on work-life balance with special regard to women's status at their companies or at economic performance in the EU. The principal goals of the study are to identify copreneurship and work-life balance and examine the correlation between these two concepts. Through international legal acts the research results show how EU labour/gender regulation affects women and copreneurs status, level and quality of employment and private life at job contraction practice at the companies.

In the next sections the legal background of work-life balance is presented, the role of copreneurship in work-life balance is discussed and the conclusions are drawn.

2. Legal Background of Work-Life Balance

All the same, both on the international and national level there are many fundamental legal backgrounds that are providing women's rights to foster work-life balance. The major point of work-life balance either for women or men is to diminish the gender gap with special regard to unequal treatment, payment between them. With less workplace conflict the motivation and effectiveness is growing that is ensuring the future success. Success at work can positively influence women where they can gain power to fulfil their private life duties.

Universal Declaration of Human Rights (1948), the United Nations Convention on the Elimination of All Forms of Discrimination Against Women (1979), the United Nations Convention on the Rights of the Child (1989), the Beijing Declaration and Platform for Action (1995), the International Labour Organization's Declaration on Equality of Opportunity and Treatment for Women Workers (1975), the International Labour Organization's Declaration on Fundamental Principles and Rights at Work and its Follow-up (1998), as well as the international labour Conventions and Recommendations aimed at ensuring equality of opportunity and treatment for men and women workers, in particular the Convention concerning Workers with Family Responsibilities (1981) [2]. All of the above mentioned declarations, conventions, regulations are serving the same purpose to create an effective equal and well balanced (work) environment for men and women with family responsibilities.

2.1 International Perspective

In 2009 the International Labour Organisation's (ILO) annual report, the Global Employment Trends for Women (GET) 1/ (2009) already informed that the global job crisis is just deepening in consequence of the recession unfortunately with 22 million expected unemployed women. Next to this increasing unemployed numbers, the economic crisis caused many other difficulties to maintain a socially more sustainable work environment for women [3]. Due to this hurdles there is less option to be addressed the gender gap, hence this situation is again more disadvantageous for women then for men.

According to ILO vision on gender equality, there are four Conventions that are promoting opportunities for women. These are the ILO Convention No. 111, of the Discrimination -Employment and Occupation- (1985), Convention No. 100 of the Equal Remuneration Convention, (1951), Convention No. 156 of the Workers with Family Responsibilities Convention, (1981) and the Convention No. 183 about the Maternity Protection (2000), moreover the Part VIII of the Human Resources Development Recommendation (1975) [4].

Convention No. 156 of the Workers with Family Responsibilities Convention already in 1981 illuminates the need to change and emphasises the Convention No. 111 of the Discrimination »does not expressly cover distinctions made on the basis of family responsibilities, and considering that supplementary standards are necessary in this respect« [2].

Additionally this Convention has also stressed that in the fourteenth paragraph of the Preamble of the United Nations Convention on the Elimination of All Forms of Discrimination against Women (1979), to the effect that States Parties are » aware that a change in the traditional role of men as well as the role of women in society and in the family is needed to achieve full equality between men and

women«. [2] Next to this the Convention on the Elimination of All Forms of Discrimination against Women warns to recognise that the problem of workers with family responsibilities are appearances of more open issues regarding the family and society which should be taken into account in national policies [2]. That is why there is an emerge need to create efficient equality between men and women with family responsibilities.

Considering the latest recession and consequently the labour crisis, many of the problems facing all workers are exacerbated in the especially those, who have family responsibilities. Accordingly need rise to improve the conditions of workers in general, and for women workers with family responsibilities.

2.2 European View Point

Further, the paper seeks for the European Union's legislation regarding to the women's status at the labour system. In 23-24 March 2000 the Lisbon European Council emphasised the importance of equality and the facilitation of balance work and family life [5]. Through the Reconciliation of professional, work and family life, there are several regulations that maintain women's situation at workplace. Concerning pregnant women, Directive 92/85/EEC considers pregnant and breast feeding women as a risky group that needs health and safety protection [6]. This Directive also covers maternity leave and discrimination in the workplace. Discrimination at work referring to pregnancy is also covered by the legislation on equal treatment in employment and occupation [7].

Directive 2010/18/EU [8] about minimum requirements on parental leave and time off from work is revising the previous Directive 96/34/EC of parental leave [6]. The directive aims to reconcile work and family life and to promote equal opportunities for men and women in the labour market. These new rules must be applied by all the EU Member States by March 2012 at the latest [6]. The European Commission highlighted a project, named as Strategy 2010-2015, to foster equality between men and women. It is emphasized that inequality between genders does violate Human Rights and can cause economic damages [5].

Hence by developing the equality between men and women, economic and business benefits can be gained. The principle of equality between men and women makes it possible to obliterate those predetermined social standards that women's responsibility is only to take care about the family [5]. Due to this principle old fashioned paradigms will never disadvantage women to step in to the labour market and will not retract men to take an active part in parenthood. It is essential for the future society that both men and women find a balance and take active part in the labour market and in the family life. The above mention principles, rights, maternity, paternity and the rights of children are essential values that need to be safeguarded by us, by the society, the Member States and the European Community.

Concerning the copreneurship, European Commission's projects on balanced participation of women and men in family and working life develop strategies that take account on encourage businesses, in particular small and medium-sized enterprises, to introduce and develop management practices that take account of their workers' family life [5].

In the Commission's "reconciliation package" [5] there is another legislation as well, namely the Directive 86/613/EEC [9] that refers to the equal treatment of self-employed workers and their assisting spouses. Article 2 of Directive 86/613/EEC expresses that the directive covers: »(a) self-employed workers, i.e. all persons pursuing a gainful activity for their own account, under the conditions laid down by national law, including farmers and members of the liberal professions; (b) their spouses, not being employees or partners, where they habitually, under the conditions laid down by national law, participate in the activities of the self-employed worker and perform the same tasks or ancillary tasks. » [9] Next to this, in article 5 it is stressed how important it is to ensure the same conditions without special restrictions in a copreneurship together within a company with unmarried person [9]. In copreneurship, spouses have to respect and follow the universal and European regulations referring to minimum requirements on parental leave for male and female workers, and related employment protection. It is more possible in a copreneurship that spouses pay more attention to gender questions and do not practice discrimination in any way. Concerning the workplace flexibility, spouses can easier agree about changes to their working hours, or return to the same job after maternity or paternity leave. Working together with a spouse might cause certain difficulties such as lack of good communication, professional competition. All these problems can disappear when the spouses turn their focus to common purposes regarding their children's future and balance in work and family life.

3. The role of Copreneurship in Work-Life Balance

Work-life balance is referred to as the successful merger of work and personal life, and it requires the ability to balance the work responsibilities and commitments with responsibilities related to personal life. People who experience work life balance achieve a sense of well-being and feel they have control over their lives [10]. Contrary, people who lack work-life balance, experience work to family conflict. The latter is the result of the interference between work and family domains and if not appropriately managed it can lead into dissatisfaction with the job and family. Work to family conflict has significantly increased among the working population in the last few decades, therefore the interweaving of work and family roles recently attracted the interest of many researches and scholars [10]. Nowadays the majority of people are faced with the problem of balancing their family responsibilities with responsibilities that arise from their employment. When it comes to couples where both partners work, women on average still have more responsibilities for home and family than their male spouses [11], therefore the balance between work and life is especially important for working women. Although the number of organizations providing family-friendly environment is somehow increasing, the support of the male spouse still remains a significant factor in achieving work-life balance. Especially in younger families the role of male spouses has changed. Men have to undertake an active role in sharing home and family responsibilities and supporting the career of their wives [11].

The extensive research on family business showed that women who engage in home-based business ownership, experience less work to family conflict [12]. Furthermore women working in family firms enjoy increased status, job security and flexibility, which makes it easier for them to combine career roles and child care [13]. Within family business which represents an important form of work organization [14] there is a very important field that is attracting the interest of many scholars. It is called copreneurship and it is referred to the involvement of both husband and wife in entrepreneurship. Copreneurship itself is not new. It has been intensively developing in the last few decades as a segment in the family business [for example 15-17]. Copreneurship can be defined as the sharing of the ownership, management and responsibility for a business. Copreneurs try to manage both a business relationship and a personal relationship, therefore home and work domains are integrated into a dynamic system [15, 17-21]. The current research body shows that familial entrepreneurship is under-researched [21]. In particular, there is a lack of empirical research on copreneurship, hence there is the need for future research [22].

Since the 1990s, the number of copreneurs has been growing [23, 18]. Beside the higher involvement of women in business, also downsizing, "glass ceiling" and redundancy are contributing to the increased number of copreneurial teams [18]. Additionally, the shift from corporate values to entrepreneurial values, the increased popularity of home-based businesses and a new concern for family values also led to the growth of copreneurial couples [24]. Extended working hours and frequent business trips are very common in the corporate world. Therefore, autonomy in terms of flexible working hours can be seen as significant advantage of copreneurship [18].

Copreneurs are couples that share a personal and work relationship and often see business as a way of life rather than a way of earning income [22]. Beside trust, commitment and loyalty, work-life balance is also recognized as one of the main benefits of copreneurship [25]. By establishing a copreneurial firm and consequently sharing the management and ownership of the firm allows spouses to balance work responsibilities and personal duties more effectively and flexibly [18]. Flexible work arrangements and shared roles in accommodating the home and family needs were identified as major benefits resulting from copreneurship [17]. Further, women as working spouses in family firms can achieve a greater control over their lives [18]. Very often female spouses join the business after it is successful enough to assure a safe future [26]. In achieving work-life balance the spousal support was found to be a very significant source of support [11]. A successful copreneurship is recognized by trust, reciprocal respect, confidence and affection [27]. Past research show that females in copreneurship have equal needs for achievement than their spouses, have great self confidence, take the strategic role in firm development and manage both life at home and life at work [17]. Although it seems like copreneurs undertake equal roles in home and work domains, the sharing of tasks and responsibilities between spouses in copreneurial firms is not necessary equal [16, 18]. Some research show that often in copreneurship the partners adopt more traditional sex roles than couples that do not share the business activity. Couples with two different career paths often share the responsibilities on the basis of their preferences or abilities. On the contrary, in copreneurship men tend to focus on tasks related to the business domain and work longer hours, while women tend to spend more time for household duties and childcare [16, 17, 21]. The latter is necessary for the success of the firm and the functioning of the family. The needs of the firm as well as family needs may change during the lifetime, therefore the roles of both copreneurs may alternate or be switched.

For example, once the children are grown up, both spouses can devote more time to the business. Past research show that undertaking traditional gender roles in copreneurship avoids the work to family conflict and contributes to a more harmonious marital [18]. In addition, it was found that female copreneurs see themselves firstly as wives and mothers and secondly as business owners and managers [16], hence copreneurship enables women to assume working responsibilities and at the same time to undertake the traditional role of the household manager [17]. The latter contributes to the work-life balance and consequently improves the relationship between the spouses.

In comparison with couples working in a corporate sector, partners who are involved in a common business activity better understand the family's needs, and consequently contribute to a smoother integration of all the activities related to family responsibility into the working day. If necessary, children can be also brought to work which allows the copreneurs to spend more time with them [18]. The family-friendly copreneurial environment often brings benefits also to women that are employed in the family firm in terms of greater consideration of individual family needs. In general, copreneurship promotes a family-friendly work environment for its employees [18]. It was also found that the copreneurs' relationship at work can be motivating and stimulation for the subordinates. However, in order to prevent the misunderstandings and the possible confusion of the employees, it is important to clearly distinguish the roles of the spouses at work [25].

Being copreneurs allows both partners to more effectively and flexibly manage work and home responsibilities in accordance with the abilities and preferences of both spouses. In order to maintain both a healthy relationship and a successful business, the relationship between the spouses has to be based on reciprocal trust and commitment. Living and working together requires from both spouses a lot of compromises. Although the involvement of both spouses in the firm may sometimes result in diverse tensions between family members, it can be still seen as a viable solution for achieving work-life balance [18].

4. Conclusions

The legal background of work-life balance with a special emphasis on copreneurship as a work-life balance facilitator was examined in this paper. Based on the literature review, we argue that copreneurship enable working women to more effectively combine work and home responsibilities, and therefore it has a beneficial influence on work-life balance. Working with their spouses allows women to excel in their careers and at the same time to maintain a work-life balance [25]. The research findings are relevant to students, researchers and EU level policy decision makers.

All the Universal and European regulations, and through the transmission the Member States legislations are corresponding with each other. EU legislation and amendments are followed by Commission's, Council's or Parliament's recommendations where EU Member States' agreements are indispensable for any kind of change. EU has a strong policy for developing work-life balance and to diminish the gender gap inequality. Numerous regulations are ensuring women's rights at the workplace that are safeguarding for example their work returning from maternity or paternity leave, or paying attention at the equal remuneration.

Although from many ways women's status at the workplace is strictly regulated and saved, unfortunately in the practice there are darker than bright sides of this phenomenon. In economically less developed countries, where the recession is still taking its »victims« on the labour market, people, and in our case women are rather focusing only on keeping their job in any circumstances than fighting for their already existing rights. In post socialist countries that are today EU Member States, young generations grapple just to be able to keep themselves where the question is not how to find balance between work and family life, because they do not even have chance to plan a family as a consequence of the today's economic situation. Copreneurship is one of the options how couples could keep together for a common target and how they can respect the opportunity that they can combine professional and private life in an easier way. EU and its Member States should provide labour market and labour policy where people could find adequate and equally paid work, where the conditions are really family friendly and not only in the regulations. This process needs decades but at least it has started and this is already a positive development for our future.

Future research should be directed toward empirical research on copreneurship to examine the work-life balance on real case studies of copreneurs. A longitudinal research would take into consideration different stages in the firm's life cycle as well as the changing family needs, therefore it could provide additional insight in the relationship between copreneurship and work-life balance. Further, a cross-cultural research on copreneurship and its role in achieving work-life balance could provide interesting findings by comparing findings cross-nationally. We can see that work-life balance is a crucial factor

for the socially and economically developed Europe, no matter of recession or labour crises. Our society is based on families and children for who we have to ensure a well balanced environment for a healthy and safe life. Managers, employers and employees, all of us are responsible to promote principles of respect and equality because without these values we cannot set an example to our children and cannot take part in building a better world.

Universities or Higher Education Institutions (HEI) can play a pivotal role in economic regional enhancement as they can act as an intermediary between business, government and research, thus contributing to valuable knowledge creation, knowledge transfer and knowledge implementation. Entrepreneurs face many barriers to growth such as the knowhow, experience and resources to develop and it can be a considerable expense for an individual business or entrepreneur to access certain desired knowledge. Within regions local entrepreneurs hold large deposits of tacit knowledge which is a valuable resource that can lack physical accessibility. The objective of the SLNIW [33] project is to create greater regional accessibility to this valuable knowledge resource and facilitate the transfer of tacit knowledge for local entrepreneurs. Increasing the accessibility to tacit knowledge can help entrepreneurs to develop and grow their business and thus deliver lasting economic benefits to the region’s economy. This paper addresses the value of the role of Waterford Institute of Technology (WIT) and Aberystwyth University (AU) as intermediaries in the economic enhancement of their respective regions through the Sustainable Learning Networks in Ireland and Wales (SLNIW) project. The discussion highlights that the fiscal impact of research and education intermediaries is regionally undervalued and goes beyond the number of spin off and patents produced by such institutions. The SLNIW project is an ongoing longitudinal study in which six self learning networks have been established (three located in Wales and three located Ireland) to increase entrepreneurial self learning. The current paper draws on aspects of preliminary data collected over a 6 month period which indicates that over the course of 6 months communication outside of network meetings increased and ranged from 69% to 81%, of which 49% of that communication was for business issues and 29% for knowledge sharing. Over the initial 6 month period the perception of network members that self learning networks can help reduce barriers to business increased from 59% to 70%. Furthermore, data shows that there has also been an increase in the networks members who actively helped with other network participant’s businesses which increase from 35% to 45% over 6 months. The data collected over the 6 month period shows increased accessibility to local entrepreneurial tacit knowledge and discusses the change in perception of the benefits and value of networking by the network participants over a period of 6 months. The paper argues for greater quantification of the indirect fiscal benefits education and research intermediaries can have on their local economies as displayed via the SLNIW project.

Entrepreneurial Learning, Higher Education, Intermediaries, Regional Enhancement

1. Introduction

Universities and Higher Education Institutions (the two terms will be used intermittently) can have a significant impact on their local economies [1] [2] [3] and the role of the Higher Education Institution in the regional economy has evolved from the pure production of educated individuals to an institution embedded in the growth, development and sustainability of regional and local economies. There is a pre-conceived notion that Higher Education Institutions solely provide economic value by producing spin offs with the result of one piece of research and one patent delivering a viable startup company that will contribute to the development of the local economy [4]. However the impact of Higher Education Institutions on their local economy reaches beyond the direct benefits associated with licensing and contract research [5] as indirect linkages with local businesses can help and support the development of the local business community and economy [6]. Universities are increasingly considered as actors in the economy and play a considerable role in developing, promoting and transferring knowledge exchange and innovation [7]. Bramwell (2008) discussed that Higher Education Institutions and Universities are embedded in regions that facilitate the transfer of technological innovation and knowledge while building and sustaining local networks and flows of knowledge within the global market place. Thus the location of a university can be a significant asset to the development of the local economy [8]. The value of University based intermediaries is supported by Saxenian (1994) [9] in that regional intermediaries aid in the transfer of knowledge within a region and can positively influence the region providing significant positive effects for SMEs [10]. Universities or Higher Education Institutions that behave as local intermediaries generally function within co-proximity of the users and producers of regional knowledge [11] centered between the government and the private sector [12]. As individual organizations, firms and people can act either deliberately or intentionally as an intermediary there is a level of confusion in terms of the range of government, nonprofit and profit making organizations that engage in work that enables the sharing of knowledge, creation of new technologies, business practices, allocation of research partners and the solving of business problems in cohesion to develop regionally and nationally the business environment. Dalziel (2010)[13] argued that there needs to be greater clarification of intermediaries as a separate single class of organization which could also provide a higher recognition of intermediary organizations in strategies for regional, national and business sector development. Furthermore, the full fiscal impact of Higher Education Institutions acting as intermediaries within the local economies is not fully quantified. The following discussion will address in more detail what an intermediary is and what influence an intermediary organization can have on its regional economy.

1. What is an Intermediary?

The term intermediary can be complicated to define due the variations of the form and role an intermediary can take. The purpose of the intermediary is to connect organizations to one another in bilateral or multilateral relationships[14] and its form is often referred to as a bridging organization[15], or a broker [16]. Many of the loosely described definitions of an intermediary infer a relationship between two or more parties however, Howells (2006)[17] discussed that intermediaries are increasingly involved in more complex relationships incorporating vertical and horizontal collaborations. Regionally embedded intermediaries usually take the form of economic development agencies, chamber of commerce, industry and trade associations, technology and business parks, research institutes, networks and business incubators. While an intermediary can be an organization Smedlund (2006) [18] argued that an intermediary can also be a role or mission statement of an organization and many intermediaries function as an intermediary without the explicit mandate to and intermediaries can be further categorized into national, regional and local level actors. Dalziel [19] (2010) discussed that unions and professional societies are not typically classed as an intermediary as their mandate is the development of their own individuals. While the University or research institute technology transfer office can be an amalgamation of both concepts as the transfer office facilitates research and developing intellectual property for the greater good of the local economy and it also generates revenues for its own benefit[20].

1.1 What an Intermediary can do

Intermediaries can perform their role in two key ways; either directly by working with one or more firms to develop innovation and products or indirectly by developing the economic environment and capacity

of regions and nations. Within a specific region or sectoral sphere intermediaries act as intermediary by their ability to connect networks of business, government and University by influencing the flow of resources or the perspectives in which individuals make judgments or decisions in the absence of data or information [21]. Vonortas (2002) [22] discussed that the positive externality effect of intermediaries is not solely technology innovations but more general business functions such as developing business relationships, networking, developing trust, finance, effective management and the training of employees. Literature has emphasised the importance of the function of a local intermediary to cater for the establishment of contacts for local firms, arranging and sustaining networks and increasing the entrepreneurial attractiveness of a region to secure leader firms [23] [24]. Firms can rely on intermediaries to support and facilitate inter-organisational networking activities due to the commitment of intermediaries such as Higher Educational Institutions to establish a starting level of trust for participants. A national intermediary can change law, a regional intermediary can build on basic infrastructure and a local intermediary can improve trust and business relationships within a region [25]. Intermediaries also play a functional part in the reduction of costs in establishing and facilitating relationships for co-operation within projects and alliances[26]. For developing countries the role of the intermediary is critical to the development of the economy via entrepreneurship and knowledge transfer and technological catch up [27]. For the developed or knowledge based economy the intermediary facilitates inter-organisational collaboration of firms, governments and Universities to address long term, social and economic problems.

Technological knowledge transfer from Universities to regional firms underpins the definition of an intermediary in that the role caters for the knowledge transfer from knowledge creator to knowledge user and thus improves the knowledge and competitiveness of a region. In consideration of the University and Higher Education Institution as a regional intermediary its effect and positive economic influence is far greater than the number of spin offs or patents produced. Thus the positive regional effect of the University or Higher Education Institution on its locality can be far greater than first perceived. The current paper discusses the wider impact and value such intermediary institutions can have on their regional economies as displayed in the example of the Sustainable Learning Networks in Ireland and Wales project which aims to enhance regional economies by increasing the ability of local entrepreneurs to self learn and to increase accessibility to entrepreneurial tacit knowledge.

2. The Sustainable Learning Networks in Ireland and Wales Project (SLNIW)

The SLNIW project aims to create and develop business learning networks in West Wales and South East Ireland. In total six networks have been established, three in Ireland and three in West Wales each region consisting of male, female and mixed gender network. The establishment of networks creates a platform or knowledge sharing space in which entrepreneurial orientated SME owners can come together and self learn. The project also aims to deliver sustainable self learning networks and sustainability of the networks infers that post intermediary involvement each network will still be meeting on a regular basis. The SLNIW objective of sustainability in the self learning networks is to provide lasting benefits to both the network participants and their respective regional economies via access to the problem solving skills of the other members of the network and their acquired knowledge.

In the course of this longitudinal study the network sessions were divided into facilitated and self-facilitated sessions. The objective of facilitated sessions was to provide the networks with training in preparation for the self-facilitation stage. Facilitated sessions (conducted from March 2010 to July 2010) for the networks incorporated workshops on change management, team building, and conflict management and training skills analysis. It was also important for network members to take the time to understand that the networks were not primarily about selling to network members but about learning from network members. It is also important that each individual network member believes that they have valuable entrepreneurial knowledge and experience which they can contribute to the network. The objective of the self-facilitated stage is that the networks have complete autonomy and govern themselves, set their own agenda and decide what self learning is of value for the network participants and the group.

3.1 Methodology

As discussed the SLNIW project is an ongoing longitudinal study in which 18 network meetings will be conducted over an 18 month period. The method conducted over the course of the project is participant observation which can be defined as the '*process of learning through exposure to or involvement in the routine or activities of participants*[28]. Each monthly network session is observed by two SLNIW researchers who observe the group interactions and the development of the network.

The monthly observations are also supplemented by a monthly questionnaire which each network member fills in after every network meeting and a more detailed progress questionnaire called the 6 monthly questionnaire which is administered every 6 months throughout the course of the longitudinal study. Data collection is also complemented by observation at inter regional and cross border networking events, on site visits to network participants businesses and on completion of the study the network participants will also be subjected to interviews and reflection of the project. This paper draws on preliminary data derived from the monthly evaluations and two of the 6 monthly questionnaires administered in quarter 1 and quarter 3 of 2010. The following discussion will address data collected from the monthly evaluations and the 6 monthly questionnaires.

3.2 Monthly Evaluations

After every network session the network participants are required to fill in a monthly questionnaire. Part of that questionnaire requests information on how many network members have been in contact with each other since the previous network meeting, how many network members were contacted, the purpose of the communication and the manner in which the communication was conducted. The data collected has concentrated on the self facilitated sessions (i.e. Session 6 to Session 11) as this represents the participants and networks operating under their own autonomy.

From the first self facilitated session in August 2010 69% of the network participants had been in contact with other network members since the previous network meeting. Over the course of the following 6 network sessions the highest percentage of contact registered at 81% (i.e. session 8 and session 10). Over the course of the 6 self facilitated sessions many of the network participants contacted more than one network member between the monthly meetings. For example, in session 6 two people contacted 6 network members since the previous network meeting, in session 7 eight contacted three network members since the previous network meeting and in session 8 ten people contacted one person since the previous network meeting. Over the course of the 6 monthly sessions the level of communication has been high and ranged from 69% to 81%. The level of contact between meetings shows that network participants are engaging with each other and communicating and thus displaying the value of networking. Increasing accessibility of individuals and their knowledge is an objective of the SLNIW project and to date the data suggests that the network participants are communicating and working together. This is further supported by evidence indicating the purpose for such communication (i.e. social, knowledge seeking, collaboration, business, information sharing and problem solving). From session 6 to session 11 the highest rated purpose of communication was for business issues ranging from 39% to 56% with an overall average over the 6 sessions of 49%. Then second highest purpose for communication was information sharing averaging at 29% over the six months and social averaging at 28%.

3.3 Six Monthly Questionnaire

During the course of the longitudinal study the network participants are requested to fill in a 6 monthly questionnaire (i.e. every 6 months). The objective of the questionnaire is to gather data on the network participants and to gauge the divergence of opinion throughout the longitudinal study. The following discussion draws on a selection of questions to support the argument of the wider regional impact and value Higher Education Institutes and Universities can have on their regional economies. The first 6 monthly questionnaire is referred to as the baseline questionnaire which was administered in July 2010 and the second 6 monthly questionnaire which is referred to as Interval 1 which was administered in Jan 2011.

One of the key objectives of the SLNIW project is to aid entrepreneurs in their business growth by reducing barriers to development through the self learning network model. The network participants were asked if a self learning network can help reduce barriers (i.e. finance, staff, confidence, lack of work). The baseline result indicated that 59% of the participants agreed that a network can help reduce barriers and this increased to 70% at the Interval 1 questionnaire. In the baseline survey the

networks were in the facilitated stage and the networks were going through a forming process, however by the Interval 1 questionnaire the networks had spent 6 months together and perhaps had begun to see the benefit of the network and how they can learn from each other.

In the baseline questionnaire 31% of participants agreed that networks can help entrepreneurs to become better managers, which increased to 45% at the Interval 1 questionnaire. While 35% agreed in the baseline that other network members helped with individual participant's business problems this increased to 48% in interval 1. There was a strong consensus of agreement of over 95% in both the baseline and Interval 1 questionnaire that networks can help individual participants to develop new skills for business.

3. SLNIW Contribution to Regional Economic Enhancement

Waterford Institute of Technology and Aberystwyth University as research and education intermediaries contribute to their respective local economies in many ways. The SLNIW project provides an example of that contribution; however the project also displays how certain activities of research and education intermediaries are difficult to quantify and accurately measure in terms of positive impacts on the local economy.

WIT and AU as intermediaries had the objective of enhancing the regional economies in which they locate by supporting and researching SME's and local entrepreneurs. WIT and AU as research and education intermediaries identified that the benefit of networking for the entrepreneur is the access to information, opinion and entrepreneurial advice and access to a constant flow of up to date industrial knowledge of a region. This is supported by empirical research which has shown that there is an association between networking and growth [29] [30] [31] and that an entrepreneur's personal networks and external relations are a critical resource[32] in overcoming barriers associated with growth and development. WIT and AU as intermediaries established six self learning networks to increase accessibility to local tacit knowledge which it is considered a valuable local resource which originates from people, experiences, and places and can require extensive trust and repeated personal contact to be created. In addressing the question if accessibility to tacit knowledge has actually being increased the monthly evaluations at 6 months into the network sessions display that network members are communicating outside of the prescribed meeting hours and that the objective of the majority of the communication is to discuss a business related matter. At the current stage of the project evidence from the monthly evaluations show that network members are communicating primarily for the purpose of business issues and that networks members are often communicating with one or more network members on a regular basis. Therefore the intermediaries have increased accessibility to local tacit knowledge through the establishment and facilitation of the SLNIW project.

The self learning network as an alternative approach to entrepreneurial networking allows for repeated face to face communication through regular monthly meetings and the time taken for network participants to develop trust. Trust is a key issue for the success of the networks. A reflection[33] from a network participant on the difference between the SLNIW networks and subsequent approaches to entrepreneurial networking stated that she was comfortable with divulging information and discussing business problems with the group as the network was confidential. She trusted the confidentiality of the network. The willingness of a network participant to engage and to benefit from the network came from the trust built within the group, their autonomy over their learning, the support they provided for each other and the confidence an individual participant derived from being able to help others. WIT and AU's approach to regional enhancement was to create a alternative networking environment for regional entrepreneurs that allows for the development of trust which in turn affords network participants the confidence to engage without fear of loss of confidently.

The objective of the 6 monthly questionnaires is to gather data on the network participants and to gage any divergence in opinion and perception of the networks from individual network participants. This is important as the self learning network is a different approach to networking and most entrepreneurs would not be familiar with the concept. The entrepreneurs would require time to build trust, to understand that the network is not about selling to each other but about learning from each other. It was also important for the individual participant to realise that they do have valuable knowledge and experiences to contribute to the network. Therefore the network participant requires time to see and apply the value of the network and thus the 6 monthly questionnaire aims to gather this divergence of opinion over the course of the study. The following statements track that divergence of opinion and begin to indicate the change in opinion of the network participants from the start of the study and after 6 months of engaging with the self learning network.

Self Learning Networks can help to reduce barrier to business development

1st 6 Monthly = 59% → Interval 1 =70%

Self Learning Networks can help entrepreneurs become better managers

1st 6 Monthly = 31% → Interval 1 = 45%

Other network members have helped me with individual business problems

1st 6 Monthly = 31% → Interval 1 = 45%

From the 6 monthly questionnaires network participants consider that barriers to business development for entrepreneurs can be reduced by sharing knowledge and networking through a self learning network approach. At the baseline and at Interval 1 of the 6 monthly questionnaires the network participants agreed that self learning can help overcome barriers to development. To date network members are helping each other with their business problems and that the self learning network as a model for business networking can support participants in becoming more proficient managers and to aid in the development of business skills. A reflection from an employee of a network member discussed that he felt the network has had an impact on how the business operates. The employee said he can see a change; the network participant is engaging in a stronger role as owner and managing director and that there is a greater willingness to embrace new ideas and a new way of thinking [33] for business development.

A core objective of the project is to provide lasting benefits and post intermediary involvement with the networks the desired objective is that the networks keep functioning and thus provide a lasting impact to their respective regions. The desired sustainability is that the networks continue to meet on a regular basis; however sustainability could also infer a level of familiarity with local entrepreneurs that allows an individual to feel comfortable to communicate with peers sporadically when the need arises. Sustainable Learning Networks in Ireland and Wales is an ongoing project and the benefits discussed are an indication of the potential impact it will have on the regional economy. To date the SLNIW project has achieved and impacted the local economies of South East Ireland and West Wales by the establishment of the self learning networks. This has increased accessibility to local entrepreneurial tacit knowledge which is a valuable regional resource. Network participant reflections of the value and impact of the networks is supported by the change in perception of the entrepreneurs displayed in the 6 monthly questionnaires. Any improvements in an individual entrepreneur's business will have knock on effects for the regional economy. To conclude this all supports the long term objective of the intermediaries to provide lasting benefits by delivering sustainability of the self learning networks to the regions.

4. Conclusion

As discussed the role and form in which an intermediary can take is varied but ultimately the intermediary is a type of organisation that acts as a bridge or broker between two or more parties. Furthermore the added value of the intermediary role that organisations or institutions can play is overlooked and undervalued. The contribution of Higher Education Institutions and Universities to their regional economies is often cited as the production of an educated workforce and the number of spin offs or patents produced. However, the role of research and education based intermediaries is far more embedded and of greater fiscal value to regional economies than may first appear. The activities and impact of such intermediaries on their regional locality can go far beyond the direct benefits associated with contact research and the commercialisation of knowledge. The SLNIW programme undertaken by WIT and AU as intermediaries displays the potential deeper impact such intermediaries can have on the development and enhancement of regional economies. The SLNIW project which is currently ongoing will contribute to research and understandings on how self learning networks work and why they can fail, while also providing lasting regional benefits by the establishment of the 6 self learning networks in order to understand what makes networks work. Preliminary data from the project indicates that the SLNIW project is having a positive impact on the individual network participants which will provide a knock on effect for the regional economy. In terms of quantification it is possible to determine the value of research and education based intermediaries' contribution to their regional

economics, however not all aspects of the Higher Education Institution regional effects can be so easily measured. Therefore the criteria in which the impact of Higher Education Institutions as regional intermediaries is quantified requires adjustment to take into consideration activities such as the SLNIW project and the benefits it will deliver to its perspective regions during and after the completion of the project

Significant Elements of Management Style in Serbian Industrial Enterprises

Vesna Spasojević Brkić¹, Nikola Dondur¹, Milivoj Klarin², Dragan Čočkalović²

¹ Faculty of Mechanical Engineering, Kraljice Marije 16, Belgrade, Serbia,
vspasojevic@mas.bg.ac.rs

² Technical Faculty 'Mihajlo Pupin', Zrenjanin, Serbia

The subject here is the statistical evaluation of significant dimensions of management style in Serbian industrial enterprises, conducted on a sample of 111 enterprises. Based on prior recommendations of relevant literature, the paper examines critical dimensions of the management style concept using reliability and factor analyses. Reliability was estimated by calculating the Cronbach's alpha coefficient. Exploratory factor analysis was carried out by applying principal component analysis. The obtained recommendations for significant dimensions of management style indicate that its prominent elements are management proactivity, long-term planning and managerial staff motivation. Other dimensions (extent of delegating a task, level of detail and risk taking tendency) are not of equal significance compared to the elements given above. The proposal for further research is the analysis of how some of the significant elements of management style influence other contingency factors.

Keywords

management style, dimensions, reliability, factor analysis.

1. Introduction

The significance of management style as a contingency factor was first stressed by Child in 1972. Mitzenberg supported this view in 1980 indicating that there are three types of leaders' roles, while Lewin and Stephens [1], in 1994, argued that management style is associated with organizational structure. Miller and Droge [1], in 1986, pointed out that there is a link between the size of enterprise and management style. A prominent contribution to the development of contingency theory of the organization was given by Khandwalla [2] who developed the model of organizational functioning, in 1972, where a significant role is played by management style and philosophy as impact factors in the design of organization. In 1996 Burton and Obel [1,2] employed contingency theory postulates to create the expert system Organizational Consultant with a help of the sample of 232 small and medium enterprises encompassing over a million combinations of contingency factors to diagnose the condition of enterprises' organizational structure. Management style is also a significant variable of this expert system.

Top management is carrying out the defined strategy of the enterprise and also defines the enterprise organizational structure, therefore, not unexpectedly, Burton and Obel [3] point at the link between management style, strategy and manner of organizational design. Management style is a manner in which the enterprise management processes information, makes decisions and coordinates the work of employees [3]. There are different typologies of management style, however, we will focus here on its dimensions only, because they are necessary for further analysis. Tab. 1 shows the characteristics of key information-processing dimensions and decision-making dimensions in management style, according to known typologies.

	THEORY X (MC GREGOR 1969)	THEORY Y (MC GREGOR 1969)	MANAGER (ZALESIK 1977, KOTTER 1990)	LEADER (ZALESIK 1977, KOTTER 1990)	AUTOCRATIC (LIKERT 1967)	DEMOCRATIC (LIKERT 1967)	HIGH NEED FOR REALIZATION (MILLER 1982, 1986)	INTERNAL LOCUS OF CONTROL (MILLER 1982, 1986)	FLEXIBLE PERSONALITY (MILLER 1982, 1986)
Tendency to delegate tasks	low	high	low	high	low	high	low	certain	high
Level of detail in decision-making	formally detailed	basic guidelines	very detailed	low level	high	low	analytic and high level	high orientation to tasks	relatively low
Reactivity or proactivity in decision-making			reactivity	proactivity			proactivity	proactivity	reactivity
Time horizon of decision-making			short-term, according to plans	visions of the future	most commonly short	most commonly long	long-term planning	long-term	short-term planning
risk taking tendency	no risk taking	high	no risk taking but with planning	risk taking in accordance with vision of the future	no risk taking	high	no risk taking	neutral	high
Motivation and control of employees	low motivation, a lot of control	motivation with little control	monitoring of details	high motivation and inspiration	control	motivation	strong control	combination of motivation and control	little control

Table 1 Characteristics of key management style dimensions according to known typologies [3]

Actually, the management style dimensions describe the tendency of enterprise management to micromanagement, so a manager with a low-level tendency to micromanagement at lower hierarchical levels has the following characteristics:

- likes to delegate,
- gives general instructions for decision-making,
- is proactive,
- focuses on long-term goals and “looks ahead”,
- takes a risk if necessary, and
- motivates employees more often than he uses punishment.

2. The sample of Serbian industrial enterprises

In Serbia 25,011 industrial enterprises are doing business. Of this number, 1.8% accounts for big enterprises, 4.6% for medium and 93.5% for small. However, production is the predominant activity only in 5% of small and medium industrial enterprises, whereas a larger number of enterprises (71%) are engaged in retail, marketing, consulting etc. in the area of business operations of a certain industry group [4]. Industrial enterprises refer here to the enterprises mainly engaged in industrial production [9]. The number of such Serbian small and medium enterprises totals 1228 only (according to [7]). In 2004 the number of big industrial enterprises was 471 (according to [7]). Due to that, it can be concluded that the population of Serbian industrial enterprises whose predominant activity is production totals 1699 enterprises.

The response in such a type of research ranges from 20% to maximally 60%, according to [5]. If the response from 20 – 30% is assumed, the number from 100 – 150 industrial enterprises can be finally expected in the sample, totaling 5 – 9% of the population of Serbian industrial enterprises, whose predominant activity is production, warehousing, maintenance and the like. The initial sample size is 500 industrial enterprises engaged in production, maintenance, warehousing and the like, which

accounts for approx. 30% of the population. The response to the delivery of 500 questionnaires was received by 112 enterprises, one questionnaire being rejected due to missing of a larger number of data and error in a control question, therefore the response equals 22.22%. Domestic industrial enterprises are doing business within the following four groups: processing industry, traffic, warehousing and communications, production and distribution of electricity, gas and water, and construction industry. Fig. 1 shows the percent of mentioned four groups of industrial enterprises in Serbian industry.

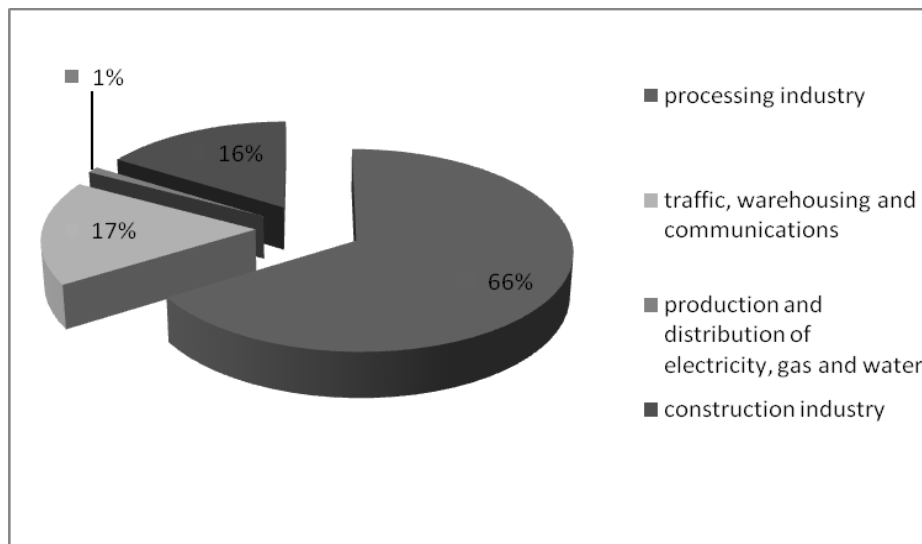

Figure 1 Percent of the groups of industrial enterprises in Serbian industry

When distributing the questionnaires, care was taken of the percent of individual groups in both the population and the sample, which is noticeable from Fig. 2. The response to the delivered questionnaires was not identical in all industry groups. It was slightly higher in enterprises engaged in production and distribution of electricity, gas and water. One questionnaire from the group of personal delivery was rejected due to the discrepancy of a control question (112 responses were received). It is considered that a given sample size of 111 enterprises is sufficient to describe the population adequately, so that conclusions can be generalized to Serbian industrial enterprises.

Figure 2 Percent of the groups of industrial enterprises in the sample

3. Research of significant management style dimensions in Serbian industrial enterprises by factor and reliability analyses

Significant management style dimensions in Serbian industrial enterprises will be determined by applying factor analysis (principle component analysis) and reliability analysis.

In researches there often occur multidimensional phenomena, concepts or states, whose description requires a larger number, most commonly measurable (evident) variables [6]. It is quite natural to tend to analyzing all interdependent variables together (as an entity as a whole) and simultaneously, but not taking one by one out of the context. One of the most commonly used multivariate data analysis techniques is factor analysis, because it allows for simultaneous analysis of several variables to describe the same phenomenon.

Reliability is a degree to which the dimensions take part in describing the concept [6]. The scale reliability for mutually beneficial relations with suppliers will be estimated by calculating the Cronbach's alpha coefficient. This coefficient is an indicator of the extent of random error present in the scale applied to weigh the quantity. The higher the error percent, the higher the risk of drawing wrong conclusions.

Cronbach's alpha is calculated using the formula [6]:

$$\alpha = \left(\frac{k}{k-1} \right) \cdot \left[1 - \sum \frac{s_i^2}{s_{sum}^2} \right], \text{ where } s_i^2 \text{ is a variance for } k \text{ individual measurements, and } s_{sum}^2 \text{ is a}$$

sum of all measurements.

MANAGEMENT STYLE VARIABLES	Mean value after elimination	Variance after elimination	Stand. dev. after elimination	α after elimination	\bar{x} =18.55 SD=3.57 Cronbach α =0.391 Stand. α =0.388
EXT. OF DELEG	15.42202	10.73933	3.277092	.472789	After elimination of SDELEG, NDETALJ i SKL_RIZ Cronbach α =0.789 Stand. α =0.784
DETAIL LEV.	16.10092	12.16413	3.487711	.507380	
MAN. PROAC.	14.96330	7.72342	2.779105	.135595	
L-T_PLAN	15.03670	7.68673	2.772495	.101860	
RISK TAK_TEN.	16.04587	10.70432	3.271745	.397710	
MOTIVATION	15.22936	10.02996	3.167012	.320834	

Table 2 Reliability analysis for management style variables [7]

The main objective of factor analysis is to reduce the information contained in the original variables to a smaller set of new composite dimensions or factors with minimal loss of information. The sample size required for analysis is at least 50 and preferably 100 or more units of observation [5, 8], which is ensured in our sample.

Exploratory factor analysis allows for identification of what objectively exists in data about the model, while factor loading is a correlation between the construct and the factor describing it. The loading level of the factor considered to be important depends on the sample size and the number of analyzed factors. Larger sample size and higher number of factors require lower loading level of the factor. So, for the sample size (111) in this research and the number of factors analyzed, the 0.40 level can be considered significant for the test power of 0.80 and significance level of 0.05, assuming that errors presuppose a double value of a conventional correlation coefficient, even though not infrequent are researches that take 0.30 for the minimal loading level [5, 6, 8, 9]. Principal component analysis, applied here, is used to reduce the dimensionality of constructs, so that only dimensions, i.e. factors providing enough information about the construct remain. This method was developed back in 1933 by Hotelling [5, 6, 9]. There are a series of criteria for determining the number of factors carrying enough information – principal components. However, the most widely used criterion is the Kaiser criterion [5,

In this paper we are examining the Living Lab (LL) concept. Under an Open Innovation environment, we combine the LL and the Mass Customization strategies, so as to achieve customer's satisfaction for a product.

In previous surveys researchers found that consumers are willing to pay more for a personalized product, in order to cover their needs better. Besides there are plenty of companies, more or less known, that have already adopted the LL idea. Namely, they give to their clients the opportunity to shape a product or a service in their own environment. In this way they do not conduct surveys such as market research, but they carefully absorb and consider the information, which stems from the everyday life and the interaction of clients with their product and services.

Furthermore, the validity and the viability of the proposed method was investigated through the production of a product from a well-known Greek furniture industry. During the period of economic recession we ventured to apply the LL strategy while coming into touch with this company and observing the way they currently act. The aftermath of this process is a new leaner procedure that is adopted during the design and production frameworks of a product.

The aim of this research is to overcome industries' idleness and to spotlight customer's capabilities in communicating their desires.

Keywords

Living Labs, furniture industry, Open Innovation, customized products.

1. Introduction

During the last few years a concern regarding the new form of innovation known as Open Innovation is discerned. This new direction enables production procedures, to take a more anthropocentric shape. Many researchers consider that new strategies as Mass Customization and Living Labs (LL) derive from the openness of innovation.

According to the work presented in [1], nowadays, the user-citizen-consumer is becoming as much producer as consumer. Thus, he exhibits into the system of innovation where a great mass of ideas and knowledge are accumulated into a "pool". As argued by Von Hippel and Thomke in [2], the users are more often the source of innovations rather the manufacturers of technology. According to them, users-customers are provided tools so as to design the product that best fits their needs. The basic problem is to overcome design and production limitations and integrate them to user's requirements. By and large, a user can express himself through Mass Customized products and others developed in a LL environment.

Referring to the first strategy, Mass Customization's point of view addresses the need of applying new technologies, aiming at introducing the user into the innovation process. On the other hand, LL represent a user-centric research methodology for sensing, prototyping, validating and refining complex solutions in multiple and evolving real life contexts. The LL approach strives to break the trial and error process of product development [1]. In other words, the goal is to eliminate the precarity while presenting a new product to the market. For instance, LL involves the consumer into the development process, ensuring highly reliable evaluation, resulting in a significant reduction of technology and business risks.

Apart from all these, the combination of Mass Customization and LL has its extensions to Lean Manufacturing. Namely, production line becomes leaner while work is divided into clusters and products are banded together according to group technology principles.

The remainder of the paper is structured as follows: In Section 2, we briefly discuss what LL represent, with a view to the reader's introduction to the field of innovation theory. Furthermore, previous work on LL and open environments is presented. In section 3, we attempt to approximate the notion of a LL by presenting a real life problem. When all is said and done, in the last section we recapitulate the facts and we gravitate to the contribution they have in new life circumstances.

2. The Living Lab Concept

LL are Open Innovation environments where real life conditions do exist. User driven innovation is totally adapted to co-creation processes and Open Innovation Functional Region consists of SMEs Collaborative Networks and Virtual Professional Communities in a Public, Private, Partnership.

In addition, LL have been defined as experimentation environments where technology is given shape in real life contexts and in which (end) users are considered co-producers [3]. This definition differs slightly from the previous, but mainly emphasizes in experimentation as a part of research methodology, i.e. implement the proper level of technological artefacts to experience live scenarios with a large number of users while collecting data which will be analysed in their context during the evaluation activity.

It is indisputable that a LL is a flexible method for developing a new product or a service. In the following table, we try to present some of the most typical and known LL cases, to better understand its breadth of application.

Table 1 Basic Living Lab Applications

Name	Type	Purpose	Source
Galileo Project	Location-based services	Culture, tourism, health, work	http://www.gsa.europa.eu
Visible Living Lab	Enterprise layout	Better exploitation of space	http://www.johnsoncontrols.com
The Place Lab	Department equipped with technologies	Monitor human-technology interaction	http://architecture.mit.edu/house_n/placelab.html

After an exhaustive scrutiny of the LL concept, we have reached to the conclusion that there is a great need of improvement in this filed of research. In the following section we examine a process about developing a product under a LL concept.

The following figure illustrates an outstanding LL advantage, which corresponds to the incubation time of a product. The first step of the latter involves the Research and Technological Development (RTD) processes followed by the implementation of the infrastructure, whilst training and education procedures occur at the end of the pipeline. According to Fig.1 [4] the product is more acceptable from the real market, in case the users develop it. Also, case studies about customized products [5] show that customers are willing to spend more money for new customized products, so as to better cover their needs.

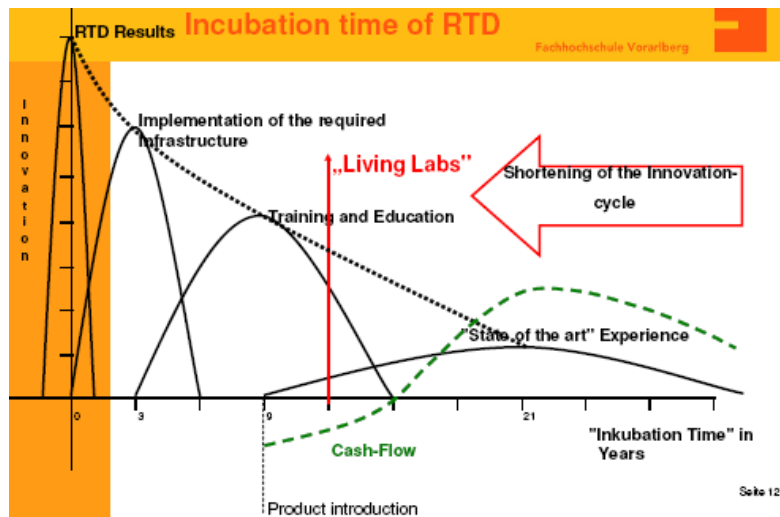

Figure 1 Incubation time of a product [5]

2.1 Success Factors for Living Labs

A LL objective is to enable sustainable, collaborative, multi-disciplinary and user relevant innovation. Hence, it can be assumed that the success of the LL can be measured broadly in terms of the following four basic elements (CoreLabs) [6]:

- Innovation: LL aspire to stimulate creativity and innovation; thus, its main success will be measured against quantifiable, accepted, and sustainable innovations. In the LL context, the three "Ps" exist:
 - Number of peer-reviewed *Publications*
 - Number of legally held *Patents*
 - Number of *Products* that reach the market.
- Collaboration: It has become obvious, since cooperation is one important facilitator for innovation, that collaboration among as many participating stakeholders as possible, and also with different combinations of stakeholders represents an important measure of success of LL. Here, it is important to look at the maturity of the collaboration to stimulate positive outcome of the collaboration.
- Multi – Contextuality: Another success factor is the context. By introducing an environment of multiple and diverse dimensions, users can contribute, evaluate and be evaluated in real life situations. This perspective takes user participation to a new level of multiple and merging contexts.
- Sustainability: To determine long-term success, sustainability becomes a valuable indicator. In the LL context sustainability can be measured in terms of:
 - Durable employment* creation: build on tight binds between employees and employers.
 - Inclusion and equality* issues: include users-customers that have same characteristics to the LL processes.
 - Competitiveness*: a competitive environment motivates industries to commune with innovation.

It is important to note here the significant relevance the LL must offer to its location, intended audience, and stakeholders.

2.2 Combining Living Labs with Mass Customization

As the standard of living has increased in the last 50 years, individualization has received increased focus. At the same time there has been a massive development of technologies [7]. In this environment, customers have the power to demand individually tailored (e.g. Hackett, Massimo Dutti) products that are specifically designed and manufactured to suit their needs [8]. Due to this revolution, companies have discovered the new frontier in business competition: Mass Customization [9]. We firmly believe that this Marketing strategy can coexist with the LL concept.

The creation of a product, or even a service, through a LL practice and a Mass Customization process, can be considered as a round procedure and not as a separate methodology of

customization. Namely, in a LL, a number of developers identify the attributes and functions of a product or a service. In a following step, the product goes across the production line and takes, from a wider amount of end-users, a Mass Customized form. As a result, the enterprise takes into account the feedback provided by the end-users, so as to produce an “ultimate” product with a mass production viewpoint. For a product to reach this point, this means that it has acquired its complete form that contains its purpose or goal of existence. This is what Aristotle called “entelechia” [10].

The following figure (Fig. 2) [11] portrays the whole procedure of developing a product. It simulates a theoretical approach, of how the two strategies could consist a conjoint set. This picture was designed to represent the flow of information inside and outside the enterprise. The vital issue is that in traditional enterprises, information about a product derives from the internal environment (e.g. Marketing Department). The challenge of the presented work is to exploit, as much as possible, the information feedback that many companies receive from their customers. Under these circumstances, we propose LL not as a “panacea”, but as a different and more “open” mentality that companies could adopt, to be more agile and meet customers’ needs better. Thus, to our minds, LL are considered to be an attitude more than a production method.

As far as it is shown in the picture, on the right half there is the LL process, where the product is produced from scratch, according to customers’ instructions. Afterwards, information enters the enterprise and on the left half the Mass Customization process occurs. Obviously, the process takes the shape of a French “8”, which can last forever, if the product doesn’t meet users’ needs.

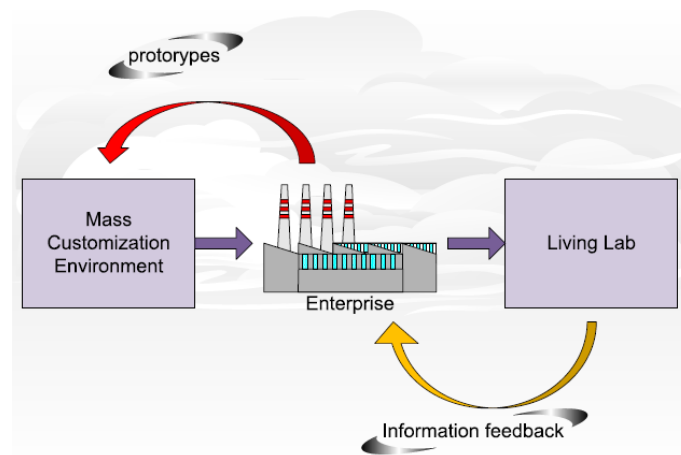

Figure 2 The circular route in a product development process

The aim of this figure is to illustrate the inextricable bind between Mass Customization and LL. Customer becomes the producer of his own product and with his original ideas he also contributes to a “pool of ideas”.

3. An Extension of Living Labs in Real-life Conditions

The starting point was the need of a LL application, so as to validate and prove its viability. Due to financial crisis, industries in Greece gathered that they needed to enhance their Customer Relation Management, aiming to capture customers’ interest more and amplify their relation. For that purpose, under the European umbrella (European Network of Living Labs, ENoLL) and the innovative strategies that foreign companies applied, we detected one useful tool: Living Labs.

A large Greek furniture industry aided our research with its data. Particularly, the Production and the R&D department were those two who provided us with information. The reason why we chose a furniture industry is the fact that our house is the place we live in and more and more people seem to be concerned about shaping their space, as they like. They prefer their furniture not to be of Mass Production.

The challenge was to apply this concept keeping in mind the LL principles and industry’s restrictions. After many months of research and information analysis we concluded that the LL process for furniture should have the following shape.

Figure 3 Row of information, value and work

Analytically, the steps are:

- Customer division: This first step is to create a group of users-customers that have the same characteristics and objectives.
- Customers' participation: Customers are the cores of the whole process, since their desires and needs are indispensable to assign the final product.
- Collect Information: Ways of collecting information should be considered, e.g. interviews, questionnaires, personal informal communication. Companies also receive e-mails and phone calls, in which customers make their comments and remarks about the products or services. This is also an important unexploited source of information.
- Information short-out: After collecting the information, a short-out is needed. By this we mean that the company should fulfil the desires that most people have. Namely, the alternatives should be modularized in a way that they satisfy the majority of users.

Some companies noted that, they are not ready to produce fully customized products due to the complexity of their production lines. Their products seem to be sophisticated and they also need to be synchronized with their suppliers. So, it doesn't depend on the internal shift of a company, but on stakeholders' lack of adaptation. Moreover, the main reason constitutes the fact that customization is not cost effective and companies should find out a way to deal with this.

Enterprises could take a leaf out of the book of ADIDAS that manufactures shoes, t-shirts and jackets that are fully customized using configurators. Furthermore, it should be noted that the company seems to balance the cost effectively. Although there are different challenges for different kinds of product, the main idea of customized products is common.

- Information grouping: It bears resemblance to the previous step, but it is totally different since it represents the procedure that contains the creation of alternative choices available to the customers usually given by configurations.
- After this, the alternatives are ready to be presented to the customers and at the same time, industry should create the G-code needed for the Woodworking Machines.
- Mass production: Afterwards, products are produced in a mass production scale, since mass customization is the mass production of customized products.
- Distribution: The final step, before a possible reiteration of the procedure.

The significant point on the previous graph is the information feedback. This means that, if customers are not satisfied about the product, the procedure is repeated and new characteristics or even products are added to the production line design.

3.1 How to Re-form the Developing Process of a Closet

We have co-operated for six months with a well-known Greek furniture-industry called NEOSET. NEOSET S.A. was established around 80s in Athens and aims to offer qualitative products in low prices. Its innovation was "Furniture-synthesis". For this purpose, consultants and decorators worked together, to generate sets of furniture that could create friendly and agronomical homes. Company's motto is the "Live your House". There are also 100 franchising stores all over Greece and 30 stores in foreign countries. Its infrastructure counts 65.000 square feet and human resources are 1074 people [12].

After elaborative discussion and consideration, we came up with this statement: Companies do need some ameliorative changes of Customer Relation Management, to suit emerging market needs, such as the personalization of products. By this we mean that present R&D practices hinder the progress of product development and innovation. They seem to be too complicated and rigid, eliminating customer vital interference. Additionally, it is generally accepted that extravagant programming and scheduling block agile strategies.

Hence, the furniture industry had indicated the current row of work and information and asked us to modify it to a more lean and flexible one. The product we examined is the closet, because many customers seem to be unsatisfied with the alternatives given to them. Furthermore according to this industry, the closet is a simple product relatively to other furniture. That is to say, it is less complex to be produced and assembled.

The procedure that follows is very catalytic, since effective communication between different departments of an industry builds on the ground of breakthroughs and innovative thinking. It is crucial to underline that the following procedure is a smooth recommendation to the company. We came up with this, after a series of consecutive meetings and brainstorming with people from R&D and production. We all followed the constraints of the present production line, to an extent that we should keep in mind that due to financial crisis, the company couldn't bear any additional cost. So, we propose a pilot reformation of the existing process, having the agility to be differentiated by NEOSET.

<Stage 1>

Problem/terminus detection

Project time planning

<Stage 2>

Concept presentation to the involved departments (e.g. according to NEOSET: Marketing, R&D, CAD and Production Department)

The Marketing department assigns Design Engineer to price the project. The next step is to be implemented.

<Stage 3>

The department mentioned before takes part in a meeting, so as to define how to introduce the product into the real market.

<Stage 4>

Collect all the information that the company can have access. Particularly, the company approaches customers to detect their inner needs and desires. After this, the company should come into touch with the franchisees i.e. the 100 franchise stores all over Greece. These stakeholders are valuable, due to their experience and the fact that they comprise the recipients of clients' feedback. This is the phase where a LL is taking place – there is a lack of traditional Market Research. That is to say, industry-user contact is immediate and without Marketing agency. Finally, the Marketing and R&D departments in association with Design Engineers do the information short-out and grouping. During the grouping stage the closet starts taking a more personalized and customized shape and essence.

<Stage 5>

Design department creates the patterns, based on customers' and franchisees indulgence.

<Stage 6>

Technical designs are planned by Design Engineers and then they are sent to the suppliers. They note some crucial points, according to technical rules. Then patterns are re-created.

<Stage 7>

Technical designs are also presented to the technicians, because they are those who set furniture (i.e. the closet) and face layout problems. Once again, the patterns are available for re-forming.

<Stage 8>

Some samples, based on technical designs, are manufactured and the departments decide the cost of the product.

<Stage 9>

Samples are presented to CAD and Training departments. The former is in charge of creating designs for a large-scale production, while the latter is responsible for instructing and educating franchisees about how to make the product seductive for the customers.

<Stage 10>

After this, the product is launched to the market.

In the foregoing analysis we should spot some significant points that emphasise Living Labs' existence and role:

- Companies count on customers-users claims mostly.
- There is not any Market Research in a narrow sense. We concluded to this point, since the company informed us that there is a vast amount of information related to the functionality and shape of the products, but the departments couldn't integrate this feedback to the general production process.
- Designs are ready only when customers are generally satisfied. Many people may argue that this procedure causes cost, but the Department of Management and the consultants of the company assured that without taking risks, it is difficult to overcome obstacles and compete with other similar companies.
- Departments are meeting together only when there is a grave reason. Many times departments use to meet aimlessly and that is time-consuming and confusing too. They just need to recapitulate the facts-milestones.

In fact, these are the principles that condition Mass Customization and LL under the umbrella of lean and open procedures. Should this process be applied, different stakeholders have to reconsider their duties and functions.

4. Conclusions

To sum up this brief presentation of a LL methodology, the aim of this paper was to highlight users' significance during research and development processes. Problems do exist and they are mostly related to the fact that customers prefer products that are ideal to them. According to NEOSET, Greek industries need to evaluate and turn to advantage customers' interest, to achieve a sustainable and stable relation with them. It is not that companies are unaware of the diversity of people desires, it is just that they didn't pay much attention to them, because during all these years they were assuming customer needs and neglected possible diachronic changes of user requirements.

The conclusion to be made is not that LL are the unique method to approach customers, but LL could help as to observe customers' deeper acting in their real and daily lives. There will definitely emerge new Marketing methods such as LL, the mission is to outmarch traditional Mass Production mentality and adapt leaner and more open processes to reach customers. The data that NEOSET have, shown that reducing cost is a short-term solution and this does not empower the sustainability of the company-customer relationship.

As far as future work is concerned, research should focus on customer grouping. The previous process should be examined partially because of its complexity and diversity. It is an important process to understand what customers deeply need and divide them into classes, so as to deliberate, in a better way, the image they have in mind, about how the ideal product looks like, to their minds. It is obvious that users from different social, educational and geographical fields have much different priorities and requirements.

Designing a Jaw Crusher using Value Analysis-Part I

Florin Chichernea¹, Alexandru Chichernea²

¹Transilvania University of Brasov, Brasov, Romania, chichernea.f@unitbv.ro

²Transilvania University of Brasov, Brasov, Romania

Implementation of Value Analysis in designing of industrial equipment is a demonstrated need for a long time in highly developed industries. Beneficial results of applying this creative, functional and very practical multidisciplinary approach can see at all the products that surround us in everyday life.

The paper presents a complete study of Value Analysis applied concretely to a selected part of one jaw crusher. The phases and iterative operation of the Value Analysis method are presented. Value Analysis combines both engineering and economics without, however, placing neither engineering nor economics first. They both are similarly important, as can be concluded by the end of this paper.

Keywords

value analysis, optimum variant, jaw crusher

1. Introduction

Value Analysis (VA) is a method that provides an operating technique using a creative and organized approach. It is managed by a group, each of them selected by their expertise in specific subjects and coordinated by a Value Analysis expert.

The Value Analysis group activity is managed in eight stages:

1. selecting research topic,
2. information on the research theme,
3. creativity, search the ideas and the solutions,
4. analysis of the solutions developed,
5. development of the chosen solution,
6. presentation of the solution,
7. implementation of the solution,
8. verification of the technical solution.

An example of Value Analysis is presented, applied to the redesign of a jaw crusher (figure 1 and figure 2) used for primary crushing of a wide variety of materials in the mining, iron and steel and pit and quarry industries.

Figure 1 Jaw crusher: 1 – fixed crushing jaw; 2 – framework; 3 – moveable crushing jaw; 4 – eccentric shaft; 5 – flywheel; 6 – safety lever; 7, 8 – the bar; 9, 10 – adjustable wedge system; 11 – belt drive; 12 – material for crushing.

Figure 2 Jaw crusher.

The paper presents a complete study of Value Analysis applied specifically to one equipment, with one finality: re-design one selected part and establishing the optimum constructive solution from the technical and economic viewpoint for one part participating in one functions with a high cost: the framework participating at the functions: *F5 - supports the assembly, F10 - ensure rapid change defective components, F11 - ensure user safety and F12 - provide user interface.*

2. Establishing the list of technical functions

Table 1 presents the list of functions of the jaw crusher.

Table 1 List of functions

Symbol	Functions	Type of functions	Technical dimension of functions		
			Name	UM	Value
F1	Ensure crushing	FS*	force	daN	1100
F2	Includes components	FS	volume	m ³	0,42
F3	Ensure adjustment	FC**	height	mm	10 – 25
F4	Ensure material supply	FS	flow rate	m ³ /h	0,4 – 4
<i>F5</i>	<i>Supports the assembly</i>	<i>FS</i>	<i>force</i>	<i>daN</i>	<i>11000</i>
F6	Ensure material removal	FS	flow rate	m ³ /h	0,4 – 4
F7	Supplies working energy	FS	torque	daN*m	1000
F8	Transforms electric energy into mechanical work	FS	mechanical work	J	-
F9	Ensure kinematic chain protects	FC	force	daN	1100
<i>F10</i>	<i>Ensure rapid change defective components</i>	<i>FC</i>			
<i>F11</i>	<i>Ensure user safety</i>	<i>FC</i>			
<i>F12</i>	<i>Provide user interface</i>	<i>FE***</i>	-	-	-

*FS – Service function, **FC – Constraint function, ***FE – Estimation function

3. Establishing the levels of importance of the functions

Table 2 presents the value weighting of functions.

Table 2 Value weighting of the functions (* - X coordinate). Step 1

Functions	...	F4	F5	F6	F7	F8	F9	F10	F11	F12	Total
F1		0	0	0	0	0	0	0	0	0	
F2		0	0	0	0	0	0	0	0	0	
F3		0	0	0	0	0	0	0	0	0	
F4		1	0	0	0	0	0	0	0	0	
F5		1	1	0	0	0	0	0	0	0	
F6		1	1	1	0	0	0	0	0	0	
F7		1	1	1	1	0	0	0	0	0	
F8		1	1	1	1	1	0	0	0	0	
F9		1	1	1	1	1	1	0	0	0	
F10		1	1	1	1	1	1	1	0	0	
F11		1	1	1	1	1	1	1	1	0	
F12		1	1	1	1	1	1	1	1	1	
No.of points		9	8	7	6	5	4	3	2	1	78
Ratio		0,11	0,10	0,09	0,07	0,06	0,05	0,03	0,02	0,01	1
*Percentage		11,5	10,3	8,97	7,69	6,41	5,13	3,85	2,56	1,28	100

The percentages of value weighting of functions are presented in the last row of the table 2 and the product value is equal to the sum of the functions levels and is equal to 78.

4. Economic dimensioning of the functions – step 1

The cost of physical components of the jaw crusher is supplied to the function or functions which take part, shown in table 3, the functions – costs matrix.

The costs are approximated in the first step for the constructive variant of figure 1 and photo 1.

Table 3 The functions – costs matrix. (*Y coordinate, ** monetary units). Step 1.

No.	Parts	F u n c t i o n s										Cost part**
		..	F4	F5	F6	F7	F8	F9	F10	F11	F12	
1	Framework			370		60	55	20			5	620
2	Mobile jaw											
3			15			90	28	100	20	12	25	310
...												
...						70	60	10	40		30	490
...	...		720	500	550	220	200	300	250	180	110	5330
Total cost			735	870	550	440	343	430	310	192	170	6750
Ratio			0,19	0,19	0,01	0,05	0,01	0,04	0,06	0,08	0,02	1
Cost of functions			10,9	12,9	8,15	6,51	5,08	6,37	4,59	2,84	2,52	100

The percentages of the cost weighting of functions are presented in the last row of the table 3

5. Diagrams

The percentage values of the value and cost weighting of functions from the last row of tables 2 and 3 are introduced in table 4, where calculations are made using the method of least squares (*MLS).

Table 4 Computational elements for plotting the diagrams. $^{**}S = \Sigma(Y_i - a \cdot X_i)^2$; $^{***}S' = \Sigma(2 \cdot a \cdot (X_i)^2 - 2 \cdot X_i \cdot Y_i)$.

MLS	F u n c t i o n s										Total value
	...	F4	F5	F6	F7	F8	F9	F10	F11	F12	
X_i		11,5	10,3	8,97	7,69	6,41	5,13	3,85	2,56	1,28	100
Y_i		10,9	12,9	8,15	6,52	5,08	6,37	4,59	2,84	2,52	100
$(X_i)^2$		133,1	105,2	80,54	59,17	41,09	26,29	14,79	6,574	1,644	1068
$X_i \cdot Y_i$		125,6	132,2	73,12	50,14	32,57	32,66	17,66	7,293	3,229	1043
$^{**}S$		0,145	8,246	0,381	0,989	1,390	1,854	0,69	0,115	1,604	20,0
$^{***}S'$		8,784	-58,9	11,08	15,3	15,12	-13,9	-6,43	-1,74	-3,24	0

The parameters have the following computed values: $a = 0,98$, $\alpha = 44,3^\circ$, $S = 20,1$ and $S' = 0$.

Based on the values for coordinates x_i and y_i presented in table 4 the diagrams of figures 2, 3 and 4 are drawing. The drawing of the diagrams is done automatically by a computer program.

The diagram of the value weighting of functions (figure 2), showing the ranking of the functions by their value, the diagram of the cost weighting of functions (figure 3), showing the ranking of the functions by their functional cost and the diagram of the value and cost weighting of functions (figure 4), showing the comparison between the percentages of value and cost weighting of functions. This diagram is the most important part, is actually one modelling of the Value Analysis approach applied to optimize the jaw crusher of economically and technically viewpoint.

The diagram of figure 3 reveals a Pareto type distribution, meaning that 20 - 30% of the total number of functions, include 70 - 80% of the total costs of the functions. These functions are F1, F2, F3 and F5.

Figure 2 Diagram of the value weighting of the functions. Step 1.

Figure 3 Diagram of the cost weighting of the functions. Step 1.

The real situation is represented by the shape of the straight line in figure 4, plotted by means of the smallest squares method and showing disproportions in the distribution of costs and in the contribution of the functions to the value of the jaw crusher.

An analysis of the diagram of figure 4 showing that the functions F12, F11, F10, F9, F5 and F2 are located above the regression line, indicating high costs, not justifiable in relation to the value.

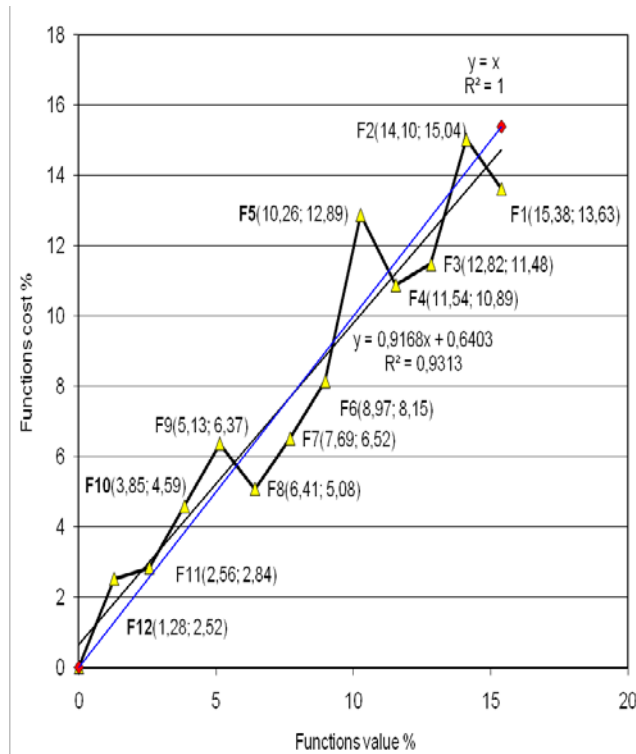

Figure 4 Value and cost weightings of the functions. Step 1.

To reduce the cost of the functions F12, F11, F10, F9, F5 and F2 will be used in phase 3 of the Value Analysis study (phase of creativity, the search the ideas and the solutions) the morphological analysis presented in table 5.

This study will be made only for the four functions:

F5 - supports the assembly, F10 - ensure rapid change defective components, F11 - ensure user safety and F12 - provide user interface.

Table 5 Morphological analysis

Functions	Possible variants
F5 - supports the assembly,	F5 ₁ – welded framework, F5 ₂ – screw assembly framework, F5 ₃ – cast framework, F5 ₄ – combined framework,
F10 - ensure rapid change defective components	F10 ₁ – easily remouvable panels, F10 ₂ – easily remouvable parts, F10 ₃ – compact device, F10 ₄ – simple device,
F11 - ensure user safety	F11 ₁ – protective devices, F11 ₂ – protective screens, F11 ₃ – alarm systems, F11 ₄ – functioning surveillance systems, F11 ₅ – protects mouving parts,
F12 - provide user interface	F12 ₁ – external shape, F12 ₂ – color, F12 ₃ – arrangement in space, F12 ₄ – ergonomics,

The number of variants that can design with the technical solutions of this morphology, for these four functions is $F5_i * F10_i * F11_i * F12_i = 320$.

For these four functions, structural variants are still in large numbers, to find new technical solutions, can use several methods of sorting one new technical variant like: screening matrix, morphological

analysis through sequence, morphological analysis by listing ordered, morphological analysis by sampling, examined criteria, multi-criteria analysis.

An analysis from the technical and economic viewpoint will be carried out in order to select a technically optimum variant for one of the part.

6. Conclusions

In the first part of the Value Analysis study, in the paper entitled "DESIGNING A JAW CRUSHER USING VALUE ANALYSIS, PART I", was determined deficiencies functions of jaw crusher, which are:

F5 - supports the assembly,

F10 - ensure rapid change defective components,

F11 - ensure user safety and

F12 - provide user interface.

By identifying the deficient functions the directions of re-conception of the existing product are determined, with a focus on solutions for the constructive and technological achievement of these functions.

A correctly completed critical evaluation will directly lead to the identification of what can be called the deficient functions of the analyzed product, that is of those functions that include useless costs.

The deficient functions from the economic viewpoint appear as:

- very expensive functions in relation to the others,
- too expensive functions in relation to the existing technical possibilities of achievement.

In the second part of the Value Analysis study, in the paper entitled "RESIGNING AND OPTIMISATION A JAW CRUSHER USING VALUE ANALYSIS, PART II" will determine the optimal variants for one part of jaw crusher, the framework who contribute at the functions: *F5 - supports the assembly, F10 - ensure rapid change defective components, F11 - ensure user safety and F12 - provide user interface.*

value analysis, optimum variant, jaw crusher

1. The Analysis of the Constructive Variants

In this second part of the Value Analysis study, continuation of the first part of paper entitled "DESIGNING A JAW CRUSHER USING VALUE ANALYSIS, PART I" will determine the optimal variants for one part of jaw crusher, the framework who contribute at the functions:

F5 - supports the assembly,

F10 - ensure rapid change defective components,

F11 - ensure user safety and

F12 - provide user interface.

The analysis of the constructive variants for the parts is presented on.

Table 6 presents the denoting by 10 assessment criteria of the analyzed constructive variants of the parts.

Table 6 Synthetic table with the analyzed constructive variants.

No.	Analysis criteria	Type of mechanism		
		welded	screw assembly	cast
1	Functional characteristics	3	3	3
2	Semi-product	1	2	3
3	Mechanical machining	1	2	3
4	Mounting	1	1	3
5	Repair	2	2	2
6	Rigidity	2	1	3
7	Ergonomics	3	3	3
8	Aesthetics	3	3	3
9	Degree of protection	2	1	3
10	Cost	1	2	3
	TOTAL	19	20	29

2. Economic Dimensioning of the Functions – Step 2

The score obtained by the cast variant is less than the welded and screw assembly variants and choose the cast variant.

The cost of physical components of the jaw crusher is supplied to the function or functions which take part, shown in table 7, the functions – costs matrix for step 2.

Table 7 The functions – costs matrix. (*Y coordinate, ** monetary units). Step 2.

Ratio			0,11	0,11	0,08	0,06	0,05	0,06	0,04	0,02	0,02	1
Cost of functions			11,3	11,4	8,44	6,75	5,26	6,6	4,06	2,64	2	100

By introducing the new data into table 8 the diagrams of figures 5 and 6 are plotted.

These diagrams will be compared to those of figures 3 and 4.

Table 8 Computational elements for plotting the diagrams. Step 2.

No.	MLS	F u n c t i o n s										Total value
		...	F4	F5	F6	F7	F8	F9	F10	F11	F12	
1	X_i		11,5	10,3	8,97	7,69	6,41	5,13	3,85	2,56	1,28	100
2	Y_i		11,3	11,4	8,44	6,75	5,26	6,6	4,07	2,64	2	100
3	$(X_i)^2$		133,1	105,2	80,54	59,172	41,09	26,29	14,79	6,574	1,64	1068
4	X_i*Y_i		130,2	116,5	75,76	51,951	33,74	33,84	15,64	6,7694	2,55	1056
5	S		0,016	1,481	0,186	0,7269	1,152	2,338	0,069	0,011	0,53	10,9
6	S'		2,946	-24,9	7,751	13,116	13,76	-15,68	-2,034	-0,536	-1,86	0

$$S = \sum(Y_i - a*X_i)^2; S' = \sum(2*a*(X_i)^2 - 2*X_i*Y_i).$$

The parameters have the following computed values: $a = 0,99$, $\alpha = 44,7^\circ$, $S = 11$, $S' = 0$.

It can be noticed that S have smaller value than in the initial variant.

Table 8 provides the necessary values for plotting the following types of diagrams:

- the diagram of the value weighting of the functions is identical with figure 2; this diagram has not changes, as the value of the system and of the functions has remained the same,
- the diagram of the cost weighting of the functions (figure 5); the diagram of figure 5 presents the functions cost weighting,
- the diagram of the value and cost weightings of the functions (figure 6); figure 6 presents the value and cost weightings of the functions in step 2.

In this diagram is observed the developments of the cost of functions in step 2 of Value Analysis study:

1. F5 from 12,9 %, in first step of Value Analysis study (figure 3-part I) decreases to 11,3 % in second step of Value Analysis study (figure 5),
2. F10 from 4,59 %, in first step of Value Analysis study (figure 3-part I) decreases to 4,06 % in second step of Value Analysis study (figure 5).
3. F11 from 2,84 %, in first step of Value Analysis study (figure 3-part I) decreases to 2,64 % in second step of Value Analysis study (figure 5).
4. F12 from 2,52 %, in first step of Value Analysis study (figure 3-part I) decreases to 2 % in second step of Value Analysis study (figure 5).

Figure 5 Diagram of the cost weighting of the functions. Step 2.

Figure 6 Value and cost weightings of the functions. Step 2.

At the moment, in the second step the calculation shall be made as follows:

- others functions can be situated above the regression straight line,
- these are analyzed and their costs reduced, then the regression line is re-plotted and the functions relocated above it are noted; these functions too are analyzed in view of reducing their costs, followed by the re-plotting of the regression line, ..., etc., etc.

Hence the constructive solution is improved from one iteration to the other.

3. Conclusions

In two steps of Value Analysis study one part of jaw crusher, the framework who contribute at the functions: *F5 - supports the assembly, F10 - ensure rapid change defective components, F11 - ensure user safety and F12 - provide user interface* was redesign and optimized:

- from engineering viewpoint: from welded variant, to the screw assembly variant and finally to the cast variant.
- from the economic viewpoint (figure 7):
 - a. the cost of function F5 decrease from 12,9 %, in the first step of Value Analysis study to 11,36 % in the second step of Value Analysis study (decrease with 13,5%),
 - b. the cost of function F10 decrease from 4,59 %, in the first step of Value Analysis study to 4,06% in the second step of Value Analysis study (decrease with 12,9 %),
 - c. the cost of function F11 decrease from 2,84 %, in the first step of Value Analysis study to 2,64% in the second step of Value Analysis study (decrease with 7,47 %),
 - d. the cost of function F12 decrease from 2,52 %, in the first step of Value Analysis study to 2% in the second step of Value Analysis study (decrease with 26,2 %),

Figure 7

- in the third step of Value Analysis study are analyzed other functions above the regression straight line (for exemple F2, F9) and their costs reduced, then the regression line is re-plotted and the functions relocated above it are noted; these functions too are analyzed in view of reducing their costs, followed by the re-plotting of the regression line, etc. etc.
- in the third step of Value Analysis study are analyzed other functions above the regression straight line and their costs reduced, then the regression line is re-plotted and the functions relocated above it are noted; these functions too are analyzed in view of reducing their costs, followed by the re-plotting of the regression line, etc. etc.

At the end of the Value Analysis study the points are aligned as perfectly as possible along the straight line $y = a * x$, with a tilt of 45° , this is the optimal situation, the values weighting of functions and the functions cost weighting are equal, the final interest in Value Analysis study.

Trade fairs – a tool for the spread of innovation

Trade shows in Europe have traditionally served as a tool for bringing innovations to market. This is particularly evident in business-to-business relationships. In many European countries trade shows are regarded as the secondary tool - after personal sales - in terms of efficiency and effectiveness in the presentation of new products and for entering new markets. Today the transformations associated with the development of the knowledge-based economy can be seen at trade shows. The primary sales functions of trade shows, which in the late twentieth century gave way to communication and relationships, are currently undergoing another change. All forms of knowledge sharing at trade shows are gaining increasing importance. It is no longer the same presentation of a new product. Knowledge about the possibilities of its application, modern technical knowledge and the ability to solve customers' problems is becoming a major element of trade shows. A manifestation of these changes is the growing interest in conferences and seminars taking place during European trade shows, resulting in the transformation of fairgrounds into conference centres. This trend has a different intensity in European countries, however, it is strong enough to be interesting in the context of the spread of innovation. This paper presents reflections on the nature of innovation and its diffusion, and then analyzes the changes in the function of trade shows and finally suggests a plan of a research.

Keywords

Clustering and networking, knowledge transfer, trade fairs, conferences

1. Introduction

Trade fairs since their inception have been associated with innovation. The first exhibitions aimed exclusively to present the latest solutions and newest trends. In this paper we consider the trade fair in relation to the key elements proposed by Rogers in the study of innovation [1]: the innovation communication channel and entities of the trade fair model taken as a fair system of social innovation. Traditionally trade fairs are perceived as industry meetings concluded with a transaction, whereas trade fairs also have an information-promotional function. The appearance of non-selling aims does not stem from a decrease in the significance of the trade function of trade fairs, but is due to an increase in the significance of promotion in contemporary exchange [2]. The classic form of trade fairs is becoming blurred as a result of functional complementarity of meetings, events, conferences and the exhibition. Through convergence the trade fair is becoming a multifunctional industry event. Particularly noticeable is the trend towards combining trade fairs with conferences. However, in the research and publications on the trade fair industry not enough attention is being paid to this phenomenon. This paper aims to show the specificity of trade fairs and trade fair conferences as a tool for facilitating the sharing of knowledge and the stimulation of innovation and is conceptual in nature. The authors, based on a literature review and the research findings of an exploratory study offer a qualitative approach to studies on the role of the trade fair in the diffusion of innovation.

2. Trade fair development

Trade fairs have a long tradition in Europe. Today trade fairs have become a multifunctional and complex marketing tool that allows for the presentation of the enterprise and its products, and also facilitates contact between customers and contractors. Contemporary industry trade shows constitute at the same time a forum to present new products, services and ideas, to exchange information during meetings, seminars and conferences, and to make contacts and establish cooperation. Participation in trade fairs is treated first of all as a tool for communicating with the world and for building and sustaining contacts with other market players. Thus, trade shows today have three main purposes (applied to both groups of trade fair participants - visitors and exhibitors) [3]:

- to give companies access to information about the technologies,
- to enable producers to be in face-to-face contact with their competitors, clients or suppliers,
- to provide companies with the opportunity to meet existing partners without having to travel to many different locations [4].

In analyzing the results of research conducted by fair trade industrial organizations it should be emphasized that the objective of gaining information and knowledge about new solutions is declared by visitors to a greater extent than by exhibitors [5].

3. Trade fairs as an innovation communication channel

The knowledge-based economy is based on the creation, transfer and practical use of knowledge and information [6]. In the knowledge-based economy, the production of ideas rather than goods is the source of economic growth [7]. Trade fairs are events that contribute to one of the pillars of the knowledge economy as defined by the World Bank - the creation of the conditions for displaying and comparing innovations and for knowledge exchange. In this way, the trade fair organizer provides the institutional conditions for the development of the knowledge-based economy.

The impact on mutual learning and innovation results from interactions between spatial proximity and relational, institutional and social proximity. Torre [4], meanwhile, has shown that innovation does not require constant spatial proximity. However, it is necessary to temporarily support the various phases of the innovation process. From this perspective, trade fairs, as temporary organized forms of spatial proximity, enable companies access to knowledge and opportunities for interaction similar to those provided by permanent spatial proximity. Consequently, trade fairs can be viewed as temporary clusters [9] which gather together in one place actors from different regions, equipped with a diversity of knowledge and competence [10].

An innovation is communicated through certain channels over time among members of a social system [1]. Trade fairs are events during which the spread of abstract ideas and concepts, technical information, and actual industry practices from innovators to adopters take place. During trade fairs interactions and events specifically relevant for the first two stages of the innovation adoption process occur. In the knowledge stage the trade fair participants are exposed to innovations presented by exhibitors. During the persuasion stage the individuals interested these innovations may see the products, collect data, talk to exhibitors and compare their opinions with those of their competitors. The integration of conferences and seminars into trade fairs enables contact with opinion formers and market leaders who are influential in spreading information about an innovation [1].

In the initial period of their development, the success of the trade fair depended on the quality and quantity of its exhibitors. However, the trade fair model has changed - to attract exhibitors now it is necessary to ensure the adequate quantity and quality of the visitors. This has led to a shift in attention from the needs of the exhibitors to the expectations of the visitors.

Trade fairs allow the systematic acquisition of information about competitors, suppliers and customers and their technological and strategic choices. During trade fairs the participants try to get an overview of current technological and other trends. At most international trade shows, firms are said to have access to information about global developments and "buzz" [3]. As a result, trade fair participants can gain wide access to information about what is happening in their industry. This allows them to assess their own performance against that of the industry as a whole and to make decisions about their future strategies and new product development.

With the growing importance of knowledge in the economy, the development of new forms of communication during trade fairs, such as conferences, seminars and workshops, can be observed [11]. Trade fair conferences are designed for the process of knowledge exchange. For this reason trade fair-accompanying congresses and congress-accompanying trade fairs are increasingly

regarded and made use of as an attractive platform for knowledge transfer with an immediate effect. Participation in such types of meeting is a direct result of the objectives associated with the acquisition of knowledge about current news and trends in the market [2]. The factors contributing to this increase in popularity of new forms of trade fair communication also include the infrastructure owned by the trade fair operator, which is required for the staging of professional conferences.

4. Trade fairs as an innovation social system

According to the Rosson and Seringhaus model [13], the trade fair is an event that can be analyzed through the prism of actor interactions, and more generally through the prism of the interaction network of the actors involved both directly and indirectly in trade fairs. The main participants of the exhibition are the representatives of companies in the given industry. The trade fair participants, the organizer and the environment in which the trade fair takes place are all contribute to relationships that exist both before and after the exhibition. This means the phenomena of the trade fair and its conferences may be analyzed in terms of the network approach.

4.1 Trade Fair Participants

Trade fairs play a key marketing role in most industries and many firms allocate a significant portion of their marketing budgets to participation in these events. The exhibitors intensify their social relations with their customers during trade fairs and attempt to attract new customers, to market their products, to display new designs or functionalities and to negotiate potential contracts [14]. The global face-to-face interaction that takes place at international trade fairs in many ways acts as a substitute for the buzz that takes place in a permanent cluster.

Exhibitors maintain the large investments required to bring their innovations, prototypes, and expert personnel to trade shows in order to signal their competencies to current and potential customers [15]. An individual company's approach to the trade fair depends on its market position. If it is stable, its main objective is to meet with its clients and to reach out to new ones. However, start-ups, or those in the early stages of their development aim to get to know the market and to test their ideas about their marketing and selling arrangements. These companies will therefore be interested in more broadly-based fairs that attract regulatory and industry organizations, and incorporate parallel conference or education programs [16]. It seems important for innovating firms to focus on the spatial agglomeration of competitors, suppliers and customers during trade fairs. In the stages of maturity proximity is less important [8].

Trade fairs make many different sector trends visible and act as a test of the market acceptance of new products ready for launch as well as prototypes and design studies. In particular, small and medium-sized companies benefit from trade fairs because their innovations attract more interest in the spotlight of a trade fair than they otherwise would - almost 90% of the exhibitors at German trade fairs want to present innovations [17]. For visitors, access to new solutions and developments is far more important than any buying objectives [8], and the opportunity of seeing innovations is one of the most important factors attracting them to trade fairs. Industrial buyers attend trade shows to learn about new solutions, suppliers, and products [18]. By viewing products and prototypes and interacting with exhibitors and other market players, visitors obtain tacit knowledge about market offerings that would otherwise be difficult to acquire. However, visitor learning is often related to broader issues rather than to purchase [19,10].

4.2 Trade Fair Operators

The trade fair organizer creates an institutional environment which guides and facilitates the actions needed to present innovations and exchange knowledge about them. In realizing this function, the role of the organizers of trade fair events has evolved from that of facilitating the physical space to the broader one of being a catalyst in the encounter of supply and demand. Their focus, which in the past was mainly on the exhibitor, has now become more balanced by the allocation of more of their resources to the acquisition of the sufficient number and quality of visitors [20]. The organizer has to find a suitable model of feedback effects of the trade fair, in which the relevant audience is attracted by the innovations presented by the exhibitors. The more populous and attractive audience that can see the exhibition, the more likely exhibitors are to present their innovations. It is essential to ensure

the participation of the market leaders because they are considered to be the industry's main sources of innovation and the most important information providers on current technologies and market trends. The organization of seminars and conferences can enrich the program, but not decisively affect the perception of the trade fair. However, in launching a new trade fair the conference program can act as a magnet – in this case, innovation won't be presented at the exhibition, but it may be said about them during a conference.

4.3 Influence Market

Concerning the creation of conditions for innovation, industry bodies and the trade press and media are key groups in the influence market domain [21]. These are complementary institutions for the trade fair organizer. They may aim at familiarizing their members and readers with the industry's innovations and also at stimulating it. Industry organisations are often organizers or co-organizers of trade fairs. The industry media is an important partner for the exhibition organizer, and is also an important channel for informing the industry about the innovation occurring at the trade fair.

4.4 Trade Fair Cities

Trade fairs are primarily treated by city authorities as an element which enriches the city's offer and is an instrument of its promotion. Trade fairs and conferences are activities which generate mass travel movements and are a high spending type of business tourism with profound effects on cities [22]. Trade fairs are perceived as attracting free-spending visitors booking downtown hotel rooms, eating at restaurants, and thronging theatres and night spots [23, 24]. From the city's point of view, trade fairs and conferences are mainly perceived as an element of business tourism. In this sense, trade fairs support and are a part of a city's tourist function. When treating trade fairs and conferences as a potential element to give a city a competitive edge, the question arises: to what degree should and may the city authorities influence their development. The question is especially valid with regard to the role of trade fairs located in Europe, since 60% of the 15 million square meters of exhibition space available worldwide is located in Europe [2]. Therefore, European cities attribute great significance to trade fairs in their strategic records. City authorities expect that a dependence of trade fairs on conferences rather than dependence of conferences on trade fairs will become more and more noticeable. Two common trends can be distinguished: the location of trade fairs within city limits and support for the convergence of exhibition and conference functions. Both phenomena may be taken as features that can be common patterns of European trade fair development [2]. Consideration of the impact of trade fairs on cities' innovation is hard to find in the literature. As trade fairs provide a rich arena for the processes of knowledge exchange where small observations or hints may lead participants into new ways of thinking and to change their scope for creating novel and profitable combinations of existing ideas and capabilities [9]. Contact with new solutions and, in particular, international market leaders during trade fairs can be inspiring and can stimulate innovation amongst the inhabitants of the city and local companies. This aspect is not yet understood.

5. Research proposal

Despite the long history of the development of trade fairs and their important place in the economy, their role in the process of innovation diffusion has not been the subject of extensive research. The majority of the studies are "how to" articles or, at best, conceptual works [25]. Trade fairs are mostly approached from the exhibitors' point of view – their targets, decisions and participation evaluation, and, most of all, sales techniques [26]. The important role of trade fairs in the field of business-to-business marketing is stressed concurrently. A less-frequently considered option is the opportunity of using exhibitions for sales purposes as well as communicative ones [27]. Another research domain is drawing attention to visitors' aims and their comparison with those of exhibitors, as well as reflections on the functional role of trade fairs in urban development. Aside from general acknowledgements that such effects exist, there are no reference in the literature to trade fairs through the prism of knowledge sharing and the creation of innovation. The exceptions are a few works where the authors have looked at trade fairs and conventions as "temporary clusters", whereby because of spatial proximity knowledge sharing is easier among trade fair participants [9, 10].

To answer the fundamental questions about the extent to which trade fairs stimulate the processes of knowledge creation and dissemination it worth departing from the internal factors (from the trade fair

organizer's perspective internal factors can be treated exhibitor-visitor relations), and turn to "external" approaches. The network approach to innovation [28] emphasizes the importance of external relationships. The systems of innovation approach [29] places emphasis on the holistic and ubiquitous nature of innovation, and also on the complex web of interactions and on the institutional environment guiding and facilitating the actions and interactions of economic agents too. From an external perspective actors share knowledge through interrelationships and knowledge can be extrapolated only through interactions, which provide the basis for receiving new knowledge [30]. Assuming that during the diffusion of innovation process the trade fair acts as a channel of communication, as well as an element forming part of the social system, we will treat them as a network which is a collection of long-term relationships that occur between two or more entities [28]. It is an analytical approach, which assumes that within the networks continuous interaction, interdependence occur with a lack of clear boundaries and structure. Therefore, it focuses on how the structure and composition of ties affects companies and their relationships rather than how companies affect these bonds.

From a management perspective, an analysis of the interactive business world may be conducted within three dimensions: network pictures held by network actors, outcomes of interactions between actors, and efforts to influence the interactions between them [31]. In studying trade fairs as a channel for the spread of innovation, one must specify: (1) how distinguished actors perceive their position and role in the diffusion of innovation, (2) what kind of innovation outcomes are expected by these actors, (3) what resources are involved and what actions are undertaken by the actors when using trade fairs as a channel for the spread of innovation. The network approach should not lead to the loss of the previously-discussed effects resulting from the proximity of exhibitors and visitors to create temporary clusters. However, it is necessary to define a broader look at this issue, including the perspectives of the trade fair organizer, industry bodies and the cities / regions in which trade fairs are held.

6. Exploratory research

Due to the lack of reference studies our proposal is of a general nature, therefore it was decided to perform exploratory research. The conclusions will be used to construct the final research concept. The exploratory research was conducted in Poland, where trade fairs remain a very important marketing tool, especially in business-to-business relations. According to the data gathered in 2009, twenty companies organized 206 trade fairs and exhibitions, with the participation of 26,519 exhibitors (4,421 from abroad) and 883,330 visitors at exhibition space which amounted to more than 500 thousand square meters [32]. To explore the role of the trade fair and its associated conferences in the diffusion of innovation process a number of in-depth interviews were conducted with trade fair participants (from the construction and the stone industries), representatives of the trade fair organizer, representatives of the city authorities and representatives of industrial magazines.

6.1 Trade Fairs Participants

Interviews with exhibitors and visitors indicated that the role of trade fairs in the diffusion of innovation may depend on factors related to the particular industry. In industries where competition is very strong (as is the case in the construction industry), the trade fair is the right place to present new products and to seek information about innovations. However, if the industry is based on cooperation and good relations (as is the case in the stone industry), knowledge about new products is less significant. Other important factors are the structure of the industry and the role of its opinion leaders – if there are no such actors expectations towards trade fairs in the development of innovation are lower. Visitors to stone industry trade fairs do not perceive either the organizer or the trade press as entities that should stimulate the presentation of innovations at trade fairs. Such expectations were only held with regards to the exhibitors. With the increasing importance of the Internet, visitors have begun to look for possibilities for obtaining non-standardized information from previously inaccessible sources. Trade fairs, besides being a meeting place for sellers and buyers, have become a contact point between policy makers and designers, technologists and those responsible for new solutions. Responding to these demands, exhibitors now try to provide the presence not only of salespeople on the stand, but also of people with technical knowledge. however, they are unable to meet with all of the visitors who expect this. The solution to this problem is in communication based on the one-to-group model. During trade fairs this may take the form characteristic of conferences: from meetings to large conferences, seminars, and in some industries even congresses. Interactions traditionally made at the stand will also be transferred to other locations: dedicated spaces for presentations, as well as conference areas.

6.2 Trade Fair Organizer

The representatives of the trade fair organizer perceived their role quite differently than the other respondents. They drew attention to the significant increase in the number of conferences organized by the exhibitors during the fair. In their opinion there is still not enough interest in these conferences from the visitors. According to one representative of the organizer, the main reason for this lies in the attitude of Polish exhibitors to trade fair conferences. Following a European trend, they have now begun to communicate with visitors through conferences, but they still do not put much emphasis on this, instead focusing on activities related to the stand. The result is that their participation in conferences is well-prepared in terms of organization, but in personal terms and with regard to content visitors expectations remain unfulfilled. However, respondents stressed the dual character of the conferences staged by the exhibition organizer, which may complement the fair (in the situation where the markets are developed and there are active professional organizations) or are a major attraction for visitors who have the opportunity to participate in these conference and also meet exhibitors at the stands (e.g. in the medical and gardening industries). This occurs when new trade fairs are launched and if there are no professional industrial organizations or they do not hold a strong/leading position. The representatives of the organizer claimed their organization to be a major player in the market. In their opinion it is important for exhibitors that the organizer stimulates the sharing of knowledge (by organizing conferences, competitions and demonstrations).

The trade fair organizers seem to be oblivious to the innovative impact of the exhibition on the environment in which it is held. Research conducted by the Polish exhibition industry on its impact on the national economy included the relationships between exhibitions and various elements of the micro- and macro-environment but not on innovativeness [32].

6.3 Influence Market

A direct in-depth interview with a representative of the media industry indicated that an attempt was being made to create a position integrator industry, and also to transfer information about innovations within industry. From this perspective, the trade fair is an event that helps them to develop their image as a promoter of innovation, for example, by organizing conferences and demonstrations. Therefore, the organizer of the trade fair can be a media partner, and also a competitor. The information gathered on the role of industry organizations indicates that their position in many industries in Poland is poor and that trade fair participants, trade fair organizers and the media do not perceive them as pro-innovation forces.

6.4 Trade Fair City

An in-depth interview with representative of the local authorities dealt with two related issues - the impact of trade fairs on the development of the city, and factors related to ownership, since the city of Poznan is the co-owner of the trade fair organizer and its grounds. From the perspective of the city authority representatives trade fairs as a business activity (together with the supporting infrastructure), have a vital importance in the city's socio-economic development. The consequence of this is the fact that trade fairs have an impact on the city's identity, and cities can build their image as trade fair cities and use trade fairs for promoting themselves. The research confirmed that the city authorities perceive trade fairs and conferences mainly through the prism of business tourism. On the other hand, respondents see the role of trade fairs and conferences as a place for knowledge sharing and the diffusion of innovation. This attitude was reflected in a promotional campaign for the city launched last year based on the slogan "Poznań - city of know-how". However, the potential of the trade fair as an event which brings together innovations is not used at all. There are also no efforts aimed at inducing the city's inhabitants, local entrepreneurs, or university staff and students to get to see new innovations during the trade fairs.

7. Conclusions

The results from the previously-discussed preliminary studies show that the network approach can give valuable information on the role of the exhibition space in the spread of innovation and the perceptions of the roles of different actors in this process. Noticeable were the claims by survey respondents of having significant places in the network whilst devaluing the roles of the other entities.

Contrary to the idea of cooperation in business networks, the actors in the network surveyed were convinced that they can conduct their innovation activities independently of others. It is therefore necessary to continue research in this area. The research design should facilitate the identification of the impact of trade fairs on the spread of innovation. This would require the gathering of information at several points in time both before and after the trade fair. In relation to the lack of cooperation between the actors in a network, an element of the study should be to develop a picture of the network. By identifying the links between actors in the spread of innovation as reflected by the respondents and incorporating the element of time it should be possible to better understand the phenomenon of trade fairs and conferences. The main limitation of the studies may be the lack of portability of proven business networking applications to others, as yet unexplored. It appears that the system is dependent on the structure of the industry, the role of the markets in the economy of the country and the relationship between the city and the organizer of the trade fair.

In designing further research, the place of the trade fair organizer in the industry should be taken into consideration. The case of Poznan International Fair, as a state-owned company that is the market leader, is unique. In the times of socialism and the centrally-planned economy exhibitions held in Poznań were treated as a “window on the world” for many industries and Poznan International Fair was seen as the pivotal player. To this day this image may remain in some industries. Meanwhile, the trend, which started in Germany, for creating and organizing trade fairs in the vicinity of industrial clusters can also now be seen in Poland. In this situation, the perception of the position and role in the network of the trade fair organizer can vary significantly.

The research results may be significantly affected by cultural and national contexts, since trade fairs play different roles in different parts of the world. In the USA, the trade fair is mainly a meeting place for buyers and sellers. In Europe, the importance of communication and relationship-building can be observed: in Germany, trade fairs, at which there are at the same time and place a dozen or so specialist shows, play a significant role as a communication tool for companies with the market. In the UK, on the other hand, the importance of trade fairs is rather low, with conferences and marketing events developing dynamically instead [33]. Cultural factors should be taken into consideration in further research. There are several dimensions in which Central and East European Countries trail far behind the other EU countries. In the production sectors, the CEECs have a structure resembling the characteristics of the industrial society, while the EU as a whole is more a prototype of the post-industrial society. The CEECs have a different pattern of research funding, and they are also lagging behind in overall research funding [34]. In these countries, in the days of the centrally-planned economy, trade fairs were an essential tool for gaining foreign contracts. Since the fall of socialism, trade fairs have been used by foreign investors to enter these new markets, and therefore trade fairs should still be considered as an important channel for contact with innovation.

²Faculty of Economic and Business, University in Zagreb, Zagreb, Croatia

Technology is becoming increasingly important element for economic competitiveness. International trade of goods and services is constantly changing as a result of the development of ICT - Information and Communication Technology. By interconnecting information technologies we can increase both amount and value of information available to individuals, firms, markets, and governments, allowing them to make more efficient choices and to achieve better performances. Development of ICT industry represents technical advantage in many sectors, and has uplifting influence on economy and society altogether. Fast flow of information through different platforms, is important for development of new services, and for increase of number of IT firms. Croatian ICT industry lags in strength and outspread when compared with ICT industry of EU members. This paper will present current development of IT industry in NUTS II regions, and of each individual region in Croatian IT industry, paper will also include an insight in trend expected changes in the IT industry.

Keywords

Information and Communication Technology (ICT), IT industry, Croatian economy, NUTSII (Nomenclature of Territorial Units for Statistics), regional competitiveness

1. Introduction

Information and communications technology (ICT) has become a major driver of economic growth. Investment in information and communication technology has enabled new technologies to enter the production process, to expand and renew the capital stock, and to sustain economic growth. Diffusion of the Internet, of mobile telephony and of broadband networks all demonstrate how pervasive this technology has become.

Information society is of great significance for EU governments and their policies. Consequently they are actively working on regulatory framework for infrastructure and services, stimulation of technological research and applications development, raising awareness of the significance of information society, and monitoring indicators which are important for measuring influence of ICT on economy, society and culture. Many EU initiatives and interventions, including the financing of economic development, are a part of ICT and information society development framework.

Information and communications technology includes information and communication equipment, software, support services, information services and communication services. According to European Information Technology Observatory and in cooperation with IDC, the world ICT market in 2007 was worth 2.115 billion € (Europe 33.1%, US 28.4%, Japan 13.7%, others 24.8%) of which telecommunication market was worth about 1.137 billion € (Europe 31.7%, US 20.5%, Japan 13.8%, others 40.0%) and IT market was worth about 987 billion €. Croatian IT market in 2007 was worth about billion dollars.

2. IT industry in Croatia

Croatia is one of the leading countries of Central and Southeast Europe in application of ICT in economy, but it is still behind some more developed EU countries. Existing administrative division of Croatia matches the statistical criteria NUTS I (entire Croatia), NUTS II (North-West Croatia, East

(Pannonia) Croatia and Adriatic Croatia (Table 1.), NUTS III (counties) and LAU 2 (municipalities and cities).

Relevant data, assorted by counties, necessary for measuring regional competitiveness in IT industry, according to NUTS II (Nomenclature of Territorial Units for Statistics), was provided by FINA (financial agency).

Table 1 Regional division of the Croatian NUTS II

	Area (km ²)	Population (number)	Population (%)	GDP per capita PPS 2003 (EU 27 = 100)
Central and East (Panonian) Croatia	23.174	1.351.517	30,46	36
Adriatic Croatia	24.696	1.427.008	32,16	50
North-West Croatia	8.672	1.658.935	37,38	66
CROATIA	56.542	4.437.460	100,00	52

Source: Croatian bureau of statistics[4]

ICTs are highly pervasive technologies and the ICT sector underpins growth in all sectors of the economy. Research shows that service enterprises in the ICT sector are among the three most innovative companies in the entire service sector.[1] Europe has been experiencing an increase in research and development expenditure in the service segment of the ICT sector, especially in the software industry, which has compensated for the decrease in the research and development expenditure in ICT manufacturing.[2] When the Croatian ICT sector is concerned, the service industry outperforms manufacturing. ICT services have been growing faster than the average of the ICT sector, and the lot of employees in the ICT sector belongs to services. In 2008. there are 83,000 active companies in Croatia, including also 2,630 in the field of information technology.

Indicators of IT industry development and its changes in Croatia, from 2002 to 2007 are shown in table 2. All three monitored indicators of development of IT industry in Croatia (Number of IT companies per 1000 inhabitants, Number of employees in the IT industry per 1000 inhabitants, and Average revenue per IT Company (million Kn.)) show a growth rate of 7 – 10% in monitored period of time (2002 - 2007).

Table 2 An indicator of development of Croatian IT industry, 2002-2007.g.

	2002	2003	2004	2005	2006	2007	Growth Rate 2007/02
Number of IT companies (per 1000 inhabitants)	0,39	0,46	0,47	0,49	0,52	0,55	7%
Number of employees in the IT industry (per 1000 inhabitants)	1,52	2,05	2,08	2,18	2,44	2,68	11%
Average revenue per IT Company (million Kn.)	2,95	3,92	3,86	4,25	4,64	4,86	10%

Source: Financial Agency (FINA), author

North-West Croatia with its growth rate of 11% in the monitored period is the greatest contributor to the development of IT industry in Croatia.

2.1 NUTS II Croatian Regions IT industry

All three NUTS II regions have a positive growth rate in the monitored period, as shown in figure 1, (North-West and Adriatic Croatia +7%, Central and East (Panonian) Croatia +6%)

Source: Financial Agency (FINA), author

Figure 1 Number of IT companies of the Croatian NUTS II regions

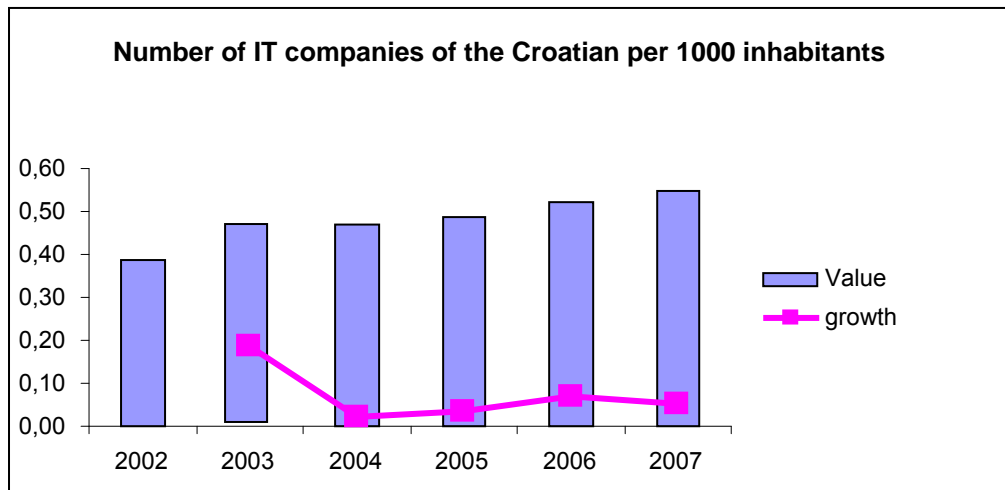

Source: Financial Agency (FINA), author

Figure 2 Graphic indicators of competitiveness of Croatian and its NUTS II region

Average income for IT company from North-West Croatia is 36% higher than Croatian average (figure 2.). Reason for that is found in the fact that Zagreb, capital city, with its high population density, good infrastructure and large number of IT companies is part of North-West region. All other counties in North-West region have much smaller income per IT company than Zagreb county.

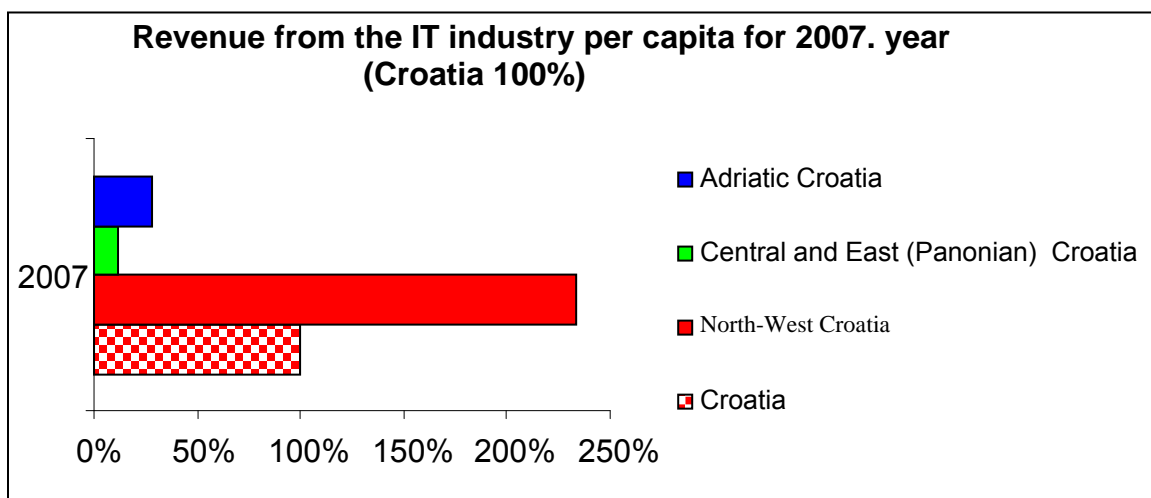

Central and East (Panonian) and Adriatic Croatia are below Croatian average by all competitiveness criteria. Looking at number of IT companies and their growth rate in the monitored period (Figure 3)

we can notice a fall of growth in 2006.- 2007. period. Figure 4 shows comparison between average income of IT industry per capita of all regions and of Croatia whose income is shown as 100%. It is clear that Central and East (Panonian) region has the least share in overall IT industry income. North-West region participates with 67%, Adriatic region with 17%, and Central and East region with 16% of overall income.

Source: Financial Agency (FINA), author

Figure 3 A graphic representations number of IT companies of Croatian

Source: Financial Agency (FINA), author

Figure 4 Revenue per capita of Croatian for 2007. year

3. Trends in IT industry

Hardware (PC, servers, printers, peripheral devices, networking equipment, etc.) holds the largest share of IT market. In the monitored period overall number of IT companies has significantly increased, index change is 42% and growth rate 7%, and employment rate in IT industry shows index change of 77% with change rate of 11%. There is visible increasement of number of employees in IT industry. According to information above we can easily come to conclusion that in market segments of software and services there is room for more intensive development than in hardware segment. Average IT company income in monitored period has index change of 57% with a growth rate of 10%.

Growing number of IT companies and of their employees is recorded in all regions, with North-West region leading in all the monitored segments. Growth rate of IT companies is almost same in all regions, but when it comes to number of new employees and average income North-West region is leading with employees growth rate of 13% and IT company income growth of 11%. Central and Eastern region is the following with the employees growth rate of 9% and IT company income growth of 4%. Adriatic region takes the last place with the employees growth rate of 8% and IT company income growth of 3%. But in 2007 Adriatic region has almost two times more IT companies and employees in IT industry per 1000 inhabitants, and 7% larger income per IT company than Central and East region.

Development of ICT industry represents technical advantage of multiple sectors and has an uplifting influence on economy and society overall. Research and investments in ICT will not bring much use by itself, unless the application of ICT in services and products is developed, and economy is adapted to new business models that ICT enables. Main areas of ICT influence on economy are organization structures, acquisitions and application of new knowledge. Financial crisis has also hit the IT industry which is now after years of growth facing the decline of business activities (figure 5.). In 2009, computer equipment, software and IT services sale, in Croatia, have dropped 17%, and last year (2010.) the fall was reduced to 5%. Although the recovery of croatian market, largest in the region with the share of 41%, is on the horizon prognosis for 2011. predict only further reduction of the fall.

All of the above urges the IT industry to restructure and rethink the ways of doing business but also at the same time opens new business opportunities.

Figure 5 Revenue Croatian economy and IT industry from 1996. to 2009. year

4. IT technology and the Internet

In any industry, Internet performs a number of discrete but interconnected activities that affect the activities, such as operating fabricating, sales or delivering products. Convergence between enterprise intranets and the Internet contributes to development of services such as content distribution and access infrastructures directly offered on the Internet.

Speed of information flow through different platforms is important for; development of new services, increasing the number of IT companies, and increasing the number of employees and income. Availability of broadband internet is one of the basic elements through which the local administration attracts investments, enable distance learning, and enable adequate healthcare.

Table 3. shows number of users of broadband networks and number of internet users in Croatia. There was no data for 2002-2003 period so we monitored only 2004-2007 period. Number of broadband network users has increased in the period from 2003 to 2007 with the growth rate of 94%. In 2007 Croatia has 387.050 users of broadband networks and the number of internet users has increased to 1.984.850, with a growth rate of 12%.

Number of broadband ADSL networks sorted by NUTS II regions is shown in figure 6.

Figure 6. shows number of ADSL accesses for Croatia and its NUTS II regions. Accesses per 100 inhabitants on 3/2008.; North-West region (12,1), Adriatic region (10) and Panonian region (5,3).

Table 3 Review of Croatian telecommunications indicators 2002 -2007

	2002	2003	2004	2005	2006	2007	Index change	Rate change
Broadband access subscribers			23000	116000	251800	387050	16,83	94%
<i>change</i>				404%	117%	54%		
Total number of Internet Users			1375328	1472400	1684600	1984850	1,44	12%
<i>change</i>				7%	14%	18%		

Source: T-Hrvatski Telekom, author

Source: Telekom, author

Figure 6 Croatian ADSL access 3/2008.g per 100 inhabitants

Penetration of personal computers is a standard indicator used to show the basic parameters of information development of a certain country.

Taking in consideration uneven methodology, available data is very heterogeneous. Having that in mind we have taken data from International Telecommunication Union as referent. ITU uses a calculation of number of computers per 100 users as an indicator of penetration of personal computers in certain country.[3]

Figure 7. shows penetration of computers and broadband internet in Croatia for the 2002-2007 period. It is clear that Croatian users score better in internet access than in personal computer penetration.

Source: ITU, author

Figure 7 Penetration of computers and internet in Croatia for the 2002-2007 period.

5. Conclusion

Development of ICT industry has a positive effect on entire economy, with an emphasis on knowledge transfer from ICT to other activities. There are problems concerning analysis of ICT industry in connection with official classification of ICT industry which is based on NACE classification. ICT companies are partly classified within the industry. Croatian companies in non-financial segment with ten or more employees relatively early adopt ICT (over 95% of companies has internet access). On the other hand when looking at effective use of ICT Croatian companies have weaker results than EU 25.

All three NUTS II regions of Croatia show growth trends in IT industry. Central and East region shows the lowest results and North-West region is gone far ahead, with the income of IT companies in 2007, 36% higher than Croatian average. There is a strong interest in all regions for better use and improvement. Croatian IT industry is still falling behind when compared with EU members. Impact of telecommunication technology is still weak on developing markets because the effect on GDP growth starts after a long period of economic adjustment to new technologies and after reaching awareness of the necessity for a total reorganization of business processes according to the availabilities that ICT provides.

Lack of investments in ICT is visible throughout Europe but particularly in Croatia. There are many reasons for it but lack of managerial skills and knowledge and low level of ICT utilization are primary.

The growth in the European ICT services industry largely has been driven by innovation particularly within telecommunications and ICT consultancy, who have exploited new mobile technology and rapidly diminishing processor costs.

Innobarometer Romania 2010

Bogdan Ciocanel¹, Sorin Mircea Axinte², George Bala³

¹*CIT-IRECSON-Bucharest-Romania*

²*Scientific and Technologic Park for Micro and Nanotechnologies MINATECH.RO, Bucharest-Romania,*

³*ANCS-National Authority for Scientific Research-Romania*

The innobarometer analyzes and sets hierarchy of region development capacities, in order to create and maintain innovation at the level of economic operators. Regional innovation scoreboard is compared to Romania's 8 development regions. This is being calculated based on the 64 analysis criteria (indicators), included by the innobarometer : 57 quantity criteria and 7 quality criteria. Data has been extracted from official sources, exhaustive research, statistic inquiries and various polls.

In order to get a more accurate view on regional innovation, we have elaborated an evaluation chart, based on 5 innovation criteria: potential of innovation management, potential of generating knowledge, capacity of innovation and integration in a relation based system, innovation activity performance and intellectual property.

Each factor has been divided into sub factors of characterization, after which a number of 16 sub-factors have been obtained. Each sub-factor received an evaluation indicator (criteria). The regional innovation scoreboard has been obtained by aggregating the 16 sub-factors.

Hierarchy has been set from the most innovative to the least innovative. The relatively large number of criteria used by the innobarometer ensures a clear view on innovation for covered regional economies and serves as back-up, in case of misinterpreting one certain criteria. The impact of a single criterion is limited.

Regional innovation is a field of economic knowledge, which analyzes factors and politics which influence the capacity of a certain region, in order to create and maintain an environment which supports novelty for its enterprises and which grants enhanced prosperity to the local population.

Enterprises are highly dependent on the environment in which they activate. Some regions support innovation more than others do, by creating an environment which facilitates innovation of economic operators and by encouraging long term duration. The innobarometer sets hierarchy and analyzes those regional environments.

Keywords

Innobarometer, Innovation, Potential of innovation management, Region development capacities, Regional innovation

1. Introduction

1.1 What is the innobarometer?

The Innobarometer is a report on innovation at the level of development regions and also an access point towards regional innovation, offering landmarks and targeting tendencies which highlight the regional economy innovations.

The Innobarometer analyses and classifies the capacity of regions to create and maintain an environment that sustains innovation. Innovation at regional level is not restricted to the introduction of

what is new, because access to what is new is favored by political, social and cultural aspects at regional level. Thus, the regions must provide an environment that has the most efficient structure, institutions and policies, which encourage innovation at the level of the economic operators.

The Romanian 2010 Innobarometer covers the 8 development regions.

The evaluation criteria were chosen following a thorough research performed by the Technology Information Center IRECSON (TIC-IRECSON) using the economic literature, international and national sources, appraisals of the business community, of the RDI community, of public local administrations and academics, as well as the results gathered from research and development projects. The criteria will be revised and updated on a regular basis, since there are always new theories, research and data, and the economy evolves. A close collaboration with the innovation and technology transfer entities, members of the ReNITT network (Technology Information Centers, Technology Transfer Centers, Technology and Business Incubators, Science and Technology Parks) also contributes to the existence of relevant data, as much updated as possible, about the innovation and technology transfer activity at regional level. In the innovation and technology transfer field, ReNITT is a unique network at the national level, made up of 55 entities that collaborate in order to promote the technology transfer processes at national and regional levels.

1.2 What does the Innobarometer analyze?

The Innobarometer analyses and ranks the capacity of development regions to create and maintain an environment that supports innovation at the level of economic operators. The regional innovation scoreboard is presented comparatively for the 8 regions. Its calculation is based on 64 criteria (indicators) for analysis, included in the Innobarometer: 57 quantitative criteria and 7 qualitative criteria. The data were gathered from official sources, through exhaustive research, statistical surveys or opinion polls.

In order to gain an overall view of innovation at regional level, a model of appraisal was drawn up. It is based on 5 innovation factors: innovation drivers, knowledge creation, entrepreneurship, applications and intellectual property. Each factor was divided in descriptive sub factors, thus obtaining 16 innovation sub factors, to which appraisal criteria (indicators) were attributed (Innovation, Cooperation and Collaboration, Carrying out new products/services/technologies, market modernized or implemented by new/market modernized technologies, CDT Activities, Consultancy Activities, Promotion Activities, Marketing and Distribution, Technical and Economical Documentation, Invention Patents, Protected Industrial Designs and Models, Others (copyright, trademarks, recipes, geographical indications, vegetal and animal species etc), Formal and Informal Education, Staff involved in research activities, in marketing, promotion, forecasting and supervising the economic environment, Sustaining Innovation in front of public authorities, Public/Private Potential of generating knowledge).

By aggregating results extracted from all 16 sub factors, we have obtained the regional innovation degree. The regions are ranked from the most to the least innovative. The relatively high number of criteria used by the Innobarometer provides a clear image of innovation for the regional economies that were analyzed and serves as a guarantee if a certain criterion is misinterpreted. The impact of a single criterion is limited.

1.2.1 What does this mean exactly?

Innovation at regional level is a sphere of economic knowledge, which analyses the factors and the policies influencing the capacity of a region to create and maintain an environment that supports innovation for its enterprises and ensures a greater prosperity for the population.

This means that the enterprises depend to a large extent on the environment in which they operate. Some regions sustain innovation more than others, providing an environment which facilitates the innovativeness of economic operators and encourages long term durability. The Innobarometer ranks and analyses these regional environments.

1.2.2 Why is the innobarometer unique?

The Innobarometer can be considered the first point of access to innovation at regional level, since it is an annual publication containing benchmarks and objective innovation tendencies. It can also be considered a national benchmark for statistics and poll data that signal innovation at the level of

development regions. It primarily focuses on relevant data and the collaboration with the 55 members of the ReNITT network. It is easy to accomplish the analysis of a region's economic situation or to obtain classifications based on certain economic aspects, but it is very difficult to find comparable data about innovation in the 8 regions. In fact, the Innobarometer is a matrix with more than 60 criteria regarding the 8 regions, which are then introduced in various classifications.

1.3 Who uses the Innobarometer?

The Innobarometer is a dynamic benchmark, which will be permanently updated for the decisional authorities. The business community will use it as an essential instrument in determining the investment plans and the appraisal of locations for accessing what is new. The regional development agencies and public local administrations will discover important indicators, in order to compare their policies with those of other regions and to appraise the innovation performance through the course of time. The academic community will be able to use the data in the Innobarometer in order to better understand and analyze the way in which regions (and not just enterprises) compete on the market.

2. INNOVATION SCOREBOARD AT REGIONAL LEVEL

2.1 Innovation scoreboard of development regions

Place	Development region	Score
1.	Bucharest-Ilfov	72,49
2.	South-East	31,73
3.	North-West	29,56
4.	North-East	29,44
5.	Center	28,90
6.	South	28,04
7.	West	26,05
8.	South-West	21,35

Figure 1 Innovation scoreboard of development regions

Figure 2 Innovation scoreboard by “innovation drivers”(left);
Innovation scoreboard by “knowledge creation”(right)

Figure 3 Innovation scoreboard by “entrepreneurship”(left);
Innovation scoreboard by “applications”(right)

Figure 4 Innovation scoreboard by “intellectual property”

2.2. General comparison and comparison by innovation factors

Regions	General classification	Classification by factors				
		Innovation drivers	Knowledge creation	Entrepreneurship	Applications	Intellectual property
Bucharest - Ilfov	1	1	1	1	1	1
South-East	2	2	8	4	2	4
North-West	3	5	5	2	7	7
North-East	4	4	7	7	3	3
Center	5	6	6	6	6	2
South	6	3	2	3	8	8
West	7	7	4	5	5	6
South-West	8	8	3	8	4	5

2.3. Ranking the regions by innovation subfactors

Regions	Innovation drivers				Knowledge creation		Entrepreneurship	
	Formal and non-formal education	Personnel involved in RTD activities	Personnel involved in promotion, marketing, prognosis and monitoring the business environment	Innovation support at the level of public authorities	Public	Private	Innovation	Cooperation and collaboration
Bucharest-Ilfov	1	1	2	5	1	1	2	1
South-East	5	7	1	4	6	8	3	5
North-West	7	3	5	3	3	6	1	4
North-East	2	6	3	6	2	7	6	5
Center	3	5	4	7	5	5	8	2
South	6	2	6	2	7	2	5	3
West	4	8	8	1	4	4	4	6
South-West	8	4	7	8	8	3	7	6

Regions	Applications				Intellectual property			
	Producing new-to market products/technologies or new/updated services or implementing new/updated technologies	RTD activities	Consultancy activities (services)	Promotion, marketing and distribution activities	Techno-economic documents	Patents	Protected industrial patterns and designs	Others (copyright, trade marks, recipes, geographical indications, vegetation and animal species)
Bucharest-Ilfov	4	1	4	6	1	1	1	1
South-East	1	6	2	2	2	6	4	8
North-West	7	8	7	1	5	4	7	7
North-East	5	5	1	7	7	3	3	3
Center	3	7	5	5	6	2	2	2
South	6	3	6	8	8	7	8	5
West	2	4	8	3	4	5	6	6
South-West	8	2	3	4	3	8	5	4

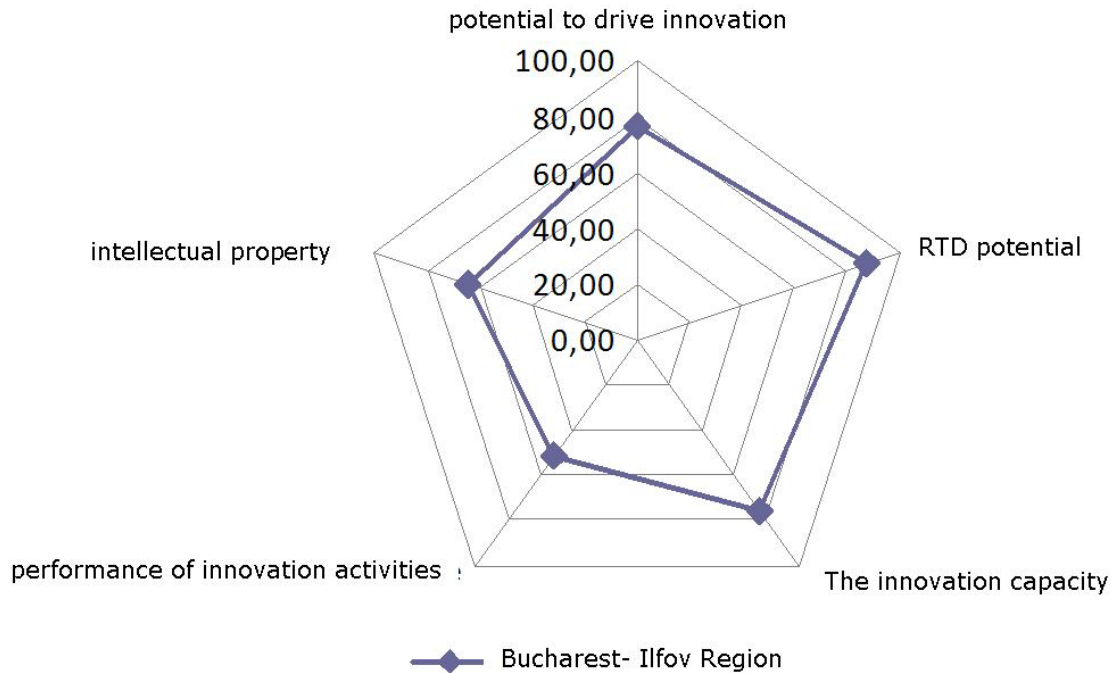

Figure 5 The Bucharest–Ilfov Region-General Chart

3. Conclusions

The Innobarometer actually reflects the innovation degree in Romania.

Regarding this analysis, the Bucharest- Ilfov Region is by far, in top of all innovation.

This phenomenon can be explained through the concentration of a large number of Research and Development National Institutes in this area. Also, here is located one of the greatest technical universities in Romania, “Politehnica Bucuresti”, followed by a large number of small and medium innovative enterprises.

Also in this area of development is mostly done in the country GDP. Based on this datum, each development region, can analyze the facts of the phenomenon and also see all barriers in innovation development regions.

The small and medium enterprises (SMEs) have a critical role in stimulating economic development, especially in less developed countries and therefore there is expressed interest of the government to strengthen this sector. The SMEs are facing many problems in business threatening their survival and development. There are numerous factors from the external environment within the company cannot influence, but must accept their effects and adapt to their business. In transition countries that are not enough economically developed there is a problem of "chain of insolvency", where companies owe each other mutually, credit periods are any longer and the collection is uncertain. In these business conditions SMEs and entrepreneurs tend to realize the main goal and reason of its business, i.e. to be profitable and at the same time liquid and able to pay payables on time. This situation is particularly burdened SMEs and entrepreneurs, who have weaker financial resources. This paper will mainly analyze the economic environment for business of SMEs and entrepreneurs in Serbia, a country which is not fully completed the transition process.

Key words:

Economic environment, liquidity, SME, entrepreneur

1. Introduction

Small and medium enterprises (SMEs) have an important role in the economies of many countries, especially developing. Government of those countries should be focused on the development of the SME sector as leverage in economic growth promotion. Globalisation and day-to-day changes in technologies, availability of information, strong competition on the global level, especially pressure of competitors from Chinese and Indian markets, make the role of SMEs become more important. Importance of SMEs can be observed through the increasing of employment, diversification of economy structure, boosting of innovation, technological progress and benefits for the whole society. Depending on the development and characteristics of the national and local environment within SMEs exist and operate, their nature and forms will differ. SMEs can be classified as micro, small and medium-sized enterprises. All of them need all kinds of support (institutional, financial, political, etc.) in order to survive first start-up years and to develop their business. The aim of this paper is to explore how business environment could help or burden business of SMEs, considering their endeavour to be liquid and solvent. Here will be especially described business environment of Serbia and position of SMEs within.

2. Typical characteristics of SME sector in EU and Serbia

One of the main challenges facing the European Union (EU) Member States is the need to boost entrepreneurship. That is one of the ambitious objectives set by the Lisbon European Council in March 2000, with a view to improving performances in terms of employment, economic reform and social cohesion within the EU. The role of SMEs in the European economy has been studied at the highest political level. In the March 2008 European Council gave important support to an initiative for further strengthening SMEs' sustainable growth and competitiveness, named the "Small Business Act" [1, p.4].

Diversity of SMEs forms and special characteristics of their business requires careful recognition of their needs in order to achieve full potential through different instruments of support. SMEs are particularly sensitive and vulnerable in the first couple years and many of them do not survive. There are 23 millions of SMEs in EU, they represent 99 % of all enterprises in the EU, provide around 90 million jobs, and employ 2/3 of total number of employees in private sector. SMEs are socially and economically important and contribute with 60 % to GDP of EU. Similar situation is in USA and Japan. SMEs sector is the most important instrument for the dynamic development of economy.

Table 1: Criteria for classifying SMEs in EU and Serbia

Enterprises	European Union			Serbia		
	Headcount	Turnover	Balance sheet total	Headcount	Turnover	Balance sheet total
medium-sized	< 250	≤ € 50 million	≤ € 43 million	50-250	€ 2,5 -10 million	€ 1,5 – 5 million
small	< 50	≤ € 10 million	≤ € 10 million	5	≤ € 2,5 million	≤ € 1 million
micro	< 10	≤ € 2 million	≤ € 2 million	< 5	-	-

Source: European Commission http://ec.europa.eu/enterprise/policies/sme/facts-figures-analysis/sme-definition/index_en.htm and Serbian Business Registry Agency

Table shows comparison of criteria for classifying SMEs in EU and in Serbia. An enterprise qualifies as an SME if it meets either the turnover ceiling or the balance sheet ceiling, but not necessarily both [2].

Numerous studies explore key reasons and factors for starting-up own business and decisions on self-employment. According to the European Commission Flash Eurobarometer for year 2007 [1, p.10], Europeans still prefer employee status, while citizens of USA usually opt for self-employed status. The main argument for preferring employee status is the desire for a regular, fixed income (46% of European respondents and 34 % of American respondents) [1, p.12]. Other reasons for preferring employee status are: fixed working hours, benefits of social security, lack of an ideal business opportunity, lack of finances and the lack of skills required for self-employment, administrative difficulties regarding self-employment [1, p.14]. On the other side, according to the research the most important reason that citizens prefer to be self-employed is self-fulfilment due to interest in the job (in EU 66%) and in USA personal independence (45%) [1, p.19].

Researching the main important obstacles for being self-employed are: lack of finances (25 % of EU respondents), lack of skills and lack of a business idea and administrative difficulties [1, p.52]. At the same time the greatest fears and risks of being self-employed are the possibility of going bankrupt or losing their property (51%) by Europeans, while Americans' greatest fear is the uncertainty of a regular income and spending a lot of time and energy on the start-up project [1, p.85]. Common problems, fears and obstacles by Europeans and Americans are lack of finance, complexity of the process, lack of information and risk of failure [1, p.90].

In developed countries categories that prefer being self-employed are men, the youngest citizens, those who are still in education, those who are self-employed, and those whose parents are also self-employed. On the other side women, citizens between 40 and 54 years of age, those who completed their education between the ages of 16 and 20, manual workers and those whose parents were both employees will rather be in status of an employee [1, p. 10].

Table 2: Typical profile of entrepreneur in Serbia

Criterion	Description	%	Description	%
Age of entrepreneur	36-55 years	65 %	under 35 years	16 %
Age of entrepreneur in time of starting business	under 35 years	67%	under 25 years	25 %
On the top of hierarchy	men	80 %	women	20 %
Education	high school	47 %	higher education	44 %

Source: Serbian Employer Union

In Serbia the situation is different. Entrepreneurs are usually citizens that already have some experience in business and that are not young as entrepreneurs in EU or USA. More than a half of them have experience in own business more than 11 years, while SMEs have longer continuity in doing business. Main reasons for self-employment by Serbian entrepreneurs are recognized business chance, personal independence and possibility for business in the same branch within they worked earlier. Some characteristics of entrepreneurs in Serbia are similar with entrepreneurs in EU and USA, as developed regions, but there are still more fears, uncertainty and obstacles for entrepreneurship in Serbia.

Table 3: The level of development of SME sector in Serbia, period 2004-2008.

	Year				
	2004.	2005.	2006.	2007.	2008.
Number of SMEs	285.139	276.695	268.515	296.086	304.017
Number of employees	752.740	810.862	870.979	906.669	940.159
Share of SMEs in the total number of enterprises (in %)	99,7	99,7	99,8	99,8	99,8
Share of SMEs in the total number of employees (in %)	54,7	59,0	63,1	65,5	67,2

Source: Serbian Employer Union

Data in table indicate that number of SMEs and number of employees grew constantly until the 2008, year of starting global financial crisis. Share of SMEs in the total number of enterprises was higher than 99 % in each year. It should be added that micro enterprises participate with 87 % in total number of enterprises and they employ about 15 % of total number employees

Table 4: SME sector in Serbia in year 2009

Share of entrepreneurs in total number of enterprises and entrepreneurs	66 %
Share of employees in SME sector in total number of employees	42 %
Share of SMEs in GDP	33 %
Share of SMEs in total export of Serbia	49 %
Share of SMEs in total import of Serbia	58 %
Change of number of SMEs and entrepreneurs 2009/2008	- 45 %
Productivity index 2009/2008 (Gross Value Added/Number of Employees)	- 4,3 %
Profitability index 2009/2008	- 15,5 %
Average Investment / Enterprise (in EUR)	9.200

Source: Business and Finance Journal, www.bifonline.rs

There are 222.301 entrepreneurs (66%) out of 334.262 enterprises and entrepreneurs in Serbia in year 2009 [3]. SME sector has accepted big number of employees from big companies, which were included in the privatization process. Most of them are directed to micro enterprises, whose number marked growth rate of 32 % It is the first time that number of entrepreneurs who closed their business is bigger than number of start-ups. The number of start-ups is also reduced and for the first time is under 10.000 for the year. It signals unenviable situation in SME sector in Serbia that is affected by

global economic crisis and reflects accumulated problems in real sector of Serbian economy. Productivity index of SMEs marked negative value, as well as profitability index. Due to high production costs SMEs have problems with competitiveness.

3. Characteristics of business environment for SMEs in Serbia

The key problems of Serbian economy are low rate of economic growth, high rate of unemployment and high import dependence, followed by low and insufficient export inflows. The unemployment rate increases continuously and current rate is about 26%, while between 200.000 and 400.000 people (the newest data published by IMF) lost their jobs since the beginning of the global financial crisis and more than 60 % belong to the SME sector. The following rate of poverty is also high and it is estimated to 8,8 % [4]. In the period 2001-2009, GDP grew by the average yearly rate of 4,8 %, but due to the global crisis marked negative growth of 3 % in year 2009. In the third quarter of year 2010 was noted positive growth of GDP, by rate of 1,5 %. Business activity of SMEs in 2009 compared to 2008 decreased for 14,7 %, as well as profitability of entrepreneur sector, that fall down to 40 %.

Administrative procedures in starting-up new business act still burdening and disincentive to many potential entrepreneurs. European Commission make efforts to simplify procedures and reduce cost of starting a business and in year 2010 average time and cost to start-up a private limited company is 7 days and cost is € 399, compared to 8 days and € 417 in 2009 or 12 days and € 485 in 2007 [2]. According to data for Serbia in year 2008 was needed 23 days compared to 18 days in 2006, for procedures of starting business. Modern and responsive public administrations can make a major contribution to the success and growth of SMEs by saving them time and money and hence freeing resources for innovation and job creation. E-government and one-stop shops, in particular, have the potential to help improve service and reduce costs and some institutions in Serbia have implemented e-government in order to reduce costs, simplify procedures and establish easier availability of public services to citizens.

SME sector in Serbia have positive impact on neutralising negative effects of transition, but still is not driver of economic development of Serbia. Problems are insufficient number and weak economic power of medium-sized enterprises, the lack of relationships between SMEs and scientific and research institutions, small possibilities for emerging and competition of domestic SMEs on international market. Some barriers for boosting entrepreneurship and innovations in Serbia are underground economy, tax burdens, unavailability of public procurement, long average collection period, existing of monopolies, complicated and expensive administrative procedures. Represent of SME and entrepreneurs identify some main problems in doing business. They are lack of finances and market information, lack of certain profile of employees, lack of knowledge and experience in implementation of standards, difficult access to new technologies. All of these problems require considerable support and engagement of government institutions in order to overcome problems of SMEs.

Serbian government supports development of SME sector through different funds and programs, especially for start-ups, unemployed, innovators, undeveloped municipalities. Some of programs support clusters and business incubators establishing, as well as internalisation of business. Although, main problems for SMEs and entrepreneurs in Serbia are primarily lack of finances, lack of management and technical skills, difficulties in access to information and technologies, low level of cooperation with big systems and companies, barriers in entering markets of developed countries due to strong international competition. Banking credits are still too expensive und unavailable to the most of the interested SMEs and entrepreneurs and in disproportion to the real capabilities of this sector. Banks have high provisions and transactions costs that are not proportional to the small amounts of micro credits, designed for SMEs and entrepreneurs. Micro credits are at the same time high risk credits and for them are also required reserves in order to keep stability of financial and monetary system. All of these facts make micro credits too expensive, but often the only financial source for entrepreneurs and micro enterprises.

4. Liquidity problem and importance of supportive role of economic environment

In developed countries too is noted that SMEs are facing to higher regulatory and administrative burden in comparison to larger businesses. It has been estimated that where a big company spends one euro per employee because of a regulatory duty, a small business might have to spend on average up to EUR 10 Euros [5]. Worth of public procurement markets are estimated to billions of Euros and it account for 16% of the European Union GDP. However, because of complicated and long procedures, lack of experience and information SMEs, especially young enterprises, are discouraged to participate in the public procurement procedure. Big companies are usually awarded by contracts in public procurements. The same situation is in Serbia, where SMEs cannot overcome administrative and other burdens and have greater participation in public procurements.

Government should reduce complicated and expensive administrative procedures in order to improve economic environment and make better conditions for business of entrepreneurs and SMEs. It will encourage entrepreneurship and innovations and result in great number of start-ups. European Commission defined a set of 10 principles in four essential fields for SMEs in order to promote economic environment in across the EU member states. SMEs should have easier access to the financial resources, especially to micro credits and venture capital. Financial support should help them to pay timely their trade payables and other liabilities and manage liquidity successfully as well as to develop new products and services. EU gives considerable financial support to SMEs and entrepreneurs through different programmes, such as the Competitiveness and Innovation Framework Programme (CIP) that channelled finances via European Investment Bank (EIB). There is also European Agricultural Fund for Rural Development that supports entrepreneurship in rural areas.

Weak and unstable financial position of SMEs is additionally burdened by problems of invoice payment and average collection period. In Europe SMEs usually have to wait between 20 and over 100 days on average to get their invoices paid. One of the four main reasons for insolvency is the problem with the late payment. It results in the loss of 450 000 jobs and of €25 billion every year across the Europe [6].

The term liquidity can be considered as the ability to pay liabilities timely and on the other hand as the speed of turning assets into the cash. Cash is the most liquid assets but holding cash without investing is the least profitable. Having a cash reserves can be particularly useful by purchasing new equipment needed for producing product or services that can improve profitability of enterprises. Between enterprises as lenders and their potential creditors exists information asymmetry and that is one of the reason why enterprises cannot borrow when and in the amount they need (Myers, 1984). Managing enterprise's finances especially working capital includes a permanent trade-off between liquidity and profitability [7]. Being illiquid in the longer period can have dangerous consequences, mainly in the form of bankruptcy or insolvency.

Liquid assets can be converted to cash quickly without having to reduce the asset's price very much [8]. Managing liquidity of SMEs implies question how liquid they should be to ensure timely payment of their liabilities, but at the same time to invest cash budgets profitably. Full liquidity analysis requires the use of cash budgets, but by relating the amount of current assets to current liabilities it can be calculated two commonly used measures of liquidity or liquidity ratios. One of them is *current ratio* calculated by dividing current assets by current liabilities. If enterprise is getting into financial problems, it pays off its liabilities with delay, borrows more from the bank and so on. Current ratio is the most commonly liquidity measure, because it indicates are the liabilities to short-term creditors covered by current assets, that can be quickly converted into the cash [8]. Another liquidity ratio is *quick or acid test* calculated by deducting inventories from current assets and then dividing by current liabilities. Inventories are usually the least liquid position of current assets, they turn slowly into the cash and are exposed to losses in the case of liquidation. Hence, acid test is more rigorous liquidity measure and indicates firm's ability to pay off short-term liabilities without relying on the sale of inventories [8]. Many enterprises compare their liquidity ratios to benchmark or an industry average, and it is useful in managing finances. There is significant relationship between size of an enterprise and its liquidity, i.e. smaller enterprises have lower level of liquidity.

According to theory, current ratio should have value of 2, i.e. current assets amount should be at least twice bigger than current liabilities. Average current ratio in Serbian enterprises in the period 2007-2009 was 1,128 and it amounts only one half of required ratio value. Average acid ratio in Serbia represents 70 % of required value. Serbian Employer Union estimates that average collection period for more than 60% of enterprises is about four months, and one/tenth of receivables has never been

paid. In the conditions of illiquidity chain in Serbian economy, the least chance to survive have actually SMEs and entrepreneurs. Due to effects of global financial crisis and constant liquidity problems, many SMEs that have growth potential, but not enough financial resources to survive long collection period, will become a part of big systems and companies. Additional problem is disproportion between periods of assets mobilisation and time availability of financial resources. In other words, enterprises invest short-term financial resources in fixed assets that also finally results in illiquidity. Due to long average collection period and time disproportion between assets and their sources, enterprises are forced to borrow capital from the bank that has price in the form of interest on capital. Interest rates in Serbia are higher than in EU members or other developed countries, due to higher country risk and fact that banks in Serbia mostly supply capital on international financial market. Serbia has external debt of EUR 23 billion and bank participation in external debt amounts to EUR 4,8 billions, that indicates great dependence of banks in Serbia on international capital. Average weighted interest rate on capital borrowed from Serbian banks (September, 2010) was 12 % and one out of four borrowers. In Serbia should be applied experience of many European countries where are defined measures for reducing average collection period, especially for public sector liabilities. European Parliament and EU Council are aware that due to their weak financial potential, business of SMEs is the most sensitive and exposed to highest risk of insolvency. In „Small Business Act“ there is one directive that defines the longest collection period in relationship to SMEs and it must not be longer than 30 days.

Table 5: Average Collection Period in European countries, 2010.

Country	Germany	France	Spain	Croatia	Greece	Slovenia	Bulgaria	FYR Macedonia	Serbia
ACP* (in days)	18	24	32	34	37	39	44	76	128

*ACP – Average Collection Period for all enterprises, not only SMEs

Source: Eurostat, Centre for European Economic Research, European Investment Bank (EIB)

From the table can be concluded that the most developed countries have the shortest average collection period. Enterprises in South East Europe (SEE), that passed through privatization process have longer average collection period, are faced to liquidity and survival problems and exposed to higher risks, especially SMEs.

Serbian Employer Union conducted research of average collected period by SMEs and entrepreneurs in 2010. It is processed sample of 10636 small, 714 medium enterprises and 7984 entrepreneurs. Results are shown on the next figures.

Figure 1: Average Collection Period for Small Enterprises (SE) in Serbia, 2010.

Research has shown that 791 out of 10636 small enterprises (SE) faced collection period longer the 180 days, 2415 SE waited between 90 and 180 days, while 1356 SE collected receivables up to 90 days and only 436 SE collected receivables in period shorter than 60 days.

Figure 2: Average Collection Period for Medium Enterprises (ME) in Serbia, 2010.

Research has shown that 26 out of 714 medium enterprises (ME) faced collection period longer than 180 days, 157 ME waited between 90 and 180 days, while 101 ME collected receivables up to 90 days and only 32 ME collected receivables in period shorter than 60 days.

Figure 3: Average Collection Period for Entrepreneurs in Serbia, 2010.

Sources for Figures 1,2,3: Serbian Employer Union, calculations by authors

Research has shown that 1207 out of 7984 entrepreneurs faced collection period longer than 180 days, 687 entrepreneurs waited between 90 and 180 days, while 1019 entrepreneurs collected receivables up to 90 days and only 350 entrepreneurs collected receivables in period shorter than 60 days.

5. Conclusions

The development of entrepreneurship has important benefits from the economic and social aspects. Entrepreneurship is on the one side driving force for the jobs creation, competitiveness and growth and on the other side it contributes to personal fulfilment and achievement of social objectives. There are numerous factors important for starting up a company, like having idea or opportunity, financial resources and needed knowledge and skills, existence of unsatisfied market segment or niche, as well as economic environment conditions. Complicated, time- and resource-consuming administrative procedures are great obstacles in encouraging entrepreneurship and innovativeness. In EU and other developed countries there is significant support to SMEs and start-ups, that contributes to economic growth and employment. Due to smaller financial potential SMEs are more exposed to risk that comes from economic environment. One of those risks is unwilling prolongation of collection period, that can turn down liquidity of every enterprise, especially of SMEs. In Serbia as underdeveloped country at the end of transition process, is especially expressed illiquidity problem. Economy is characterised by chain of illiquidity that threatens survival of many enterprises. Government and institutions of Serbia should encourage SMEs through different programmes, make more friendly and supportive economic environment and take efforts to shorten average collection period in the national economy. Regulation

of illiquidity problem on institutional level should results in greater number of start-ups and successful SMEs, higher rate of employment and benefits for economy and society as a whole.

The supportive role of investment funds and insurance companies to entrepreneurship and innovations

Jelena Ćirić¹, Vladimir Njegomir²

¹ Faculty of Technical Sciences, Novi Sad, Serbia, jciric@uns.ac.rs

² Faculty of Law and Business Studies, Novi Sad, Serbia, njega@eunet.rs

Entrepreneurship and innovations are capital intensive activities and they usually cause above average exposures to risks. Financial systems of developed economies facilitate financial savings transfers to most profitable investments, among which special place belongs to entrepreneurship and innovation. Previous experience in Serbia and other countries in the region had demonstrated primarily orientation to foreign financial sources, either through donations, foreign direct investments or foreign banks' loans. However, without mobilisation of domicile financial savings it is impossible to achieve long-term and sustainable ability for realisation of entrepreneurship and innovation ideas and thus economic development. This paper analyses the role of institutional investors, investment funds and insurance companies, as sources of long-term financial resources of entrepreneurship and innovations.

Keywords

entrepreneurship, investment funds, insurance companies

1. Introduction

Institutional investors are financial institutions that institutionally invest collected capital and at the same time join the individual risks of small investors. This helps ensure a better balance between risk and return than is generally available through direct investments of individual investors. Institutional investors have a number of common characteristics, but that does not mean that they are homogeneous. The subject of this paper is the role of institutional investors – insurance companies and investment funds as a financial support to entrepreneurship and companies. The aim of this paper is to explore and point out the role and importance of institutional investors as long-term financial sources on the less developed financial markets of Serbia and other former Yugoslav republics. The expected outcome of this paper is to present and clarify reasons and advantages of including institutional investors in financial supporting on micro level – to the entrepreneurs and companies.

2. The role of insurance companies

2.1 Insurance as a form of risk protection

The key role of insurance in the economy is the protection from risk. Insurance realize this role by the associating risks, i.e. by associating economic subjects exposed to the same type of risk. Compensation and risk joining encourage entrepreneurial activities and increase credit supply given that it enables compensation claims and risk management that otherwise might not be diversified. Especially are considered non-life commercial insurers such as property insurance against fire, flood, and machinery breakdown, various types of liability or downtime. The link between economic activity and insurance has existed since the early days of industrialization. A typical example is the United

Kingdom, a country where the insurance had a very important role in stimulating economic activity, development of innovation and economic development. For example, in the period between the years 1790 and 1862 the rate of industrial growth and rate of growth of demand for providing insurance cover for assets and production capacity were almost equal.

From the perspective of individual entrepreneurs, insurance implies periodic payment of relatively small amounts of insurance premiums in exchange for providing coverage from the uncertain but potentially significant damages that may occur if insured cases are realized. The most important contribution that insurance coverage has for entrepreneurs in the field of risk management, which is a fundamental aspect of all entrepreneurial activity, is enabling entrepreneurs to take greater risk than they would be able without insurance. Entrepreneurs often make the effort, to reduce the risks to a minimum. It could mean giving up lucrative opportunities, or cancel the entrepreneurial and innovative activities. For example, a local manufacturer could give up export-oriented enterprise without the existence of transport insurance, due to concerns that its goods could be completely lost. Empirical studies indicate that insurance has a strategic importance for the companies. For example, Seog [2] considers the case when buying insurance affects the strategic behavior of companies and individuals in product markets. The same author discusses the hypothesis that companies buy insurance coverage in order to improve competitiveness [3]. It is proven that a higher level of commercial insurance makes companies more aggressive. Therefore, insurance as a key form of risk management, affects encouraging entrepreneurial activity.

2.2 Insurance as a financial source for financing entrepreneurship and innovations

From a financial point insurance is a creating of cash reserves in the form of insurance funds. Financial assets accumulated in insurance companies get the characteristics of a specific capital, depending on the type of insurance. On the other hand, life insurance is the most advanced form of savings, it is a long-term savings. Therefore, the insurance industry is an important source of funds for capital investment and accumulation, and thus represent a significant opportunity, particularly in developing countries, for financing real continuity and expansion of social reproduction. Interest of every society is that funds raised in the reserves of insurance companies become larger.

Premiums are collected in advance and reserves that are not required for compensation of current losses and costs can be invested to companies. Insurance companies as institutional investors invest these reserves in government and municipal bonds as well as in corporate stocks and bonds, which supports the construction of shopping centers, hospitals, schools, factories, apartments, and new machinery and equipment. Investments increased stocks of capital goods, and promote economic development, which indirectly contribute to employment. In addition, the total supply of funds available for loans is increasing due to insurance premiums paid in advance, so that the cost of capital in the form of interest rate becomes less for the economy than it would be without insurance industry. Also by mobilization of financial savings insurance and reinsurance companies improve the efficiency of the financial system in three ways [4]: a) help to reduce transaction costs by connecting lenders and borrowers of financial savings, b) create liquidity - the insured have immediate access to financial sources based on compensation and savings and users of insurance funds have possibility to return borrowed funds in the more future periods and c) provide economies of scale in investment because they mobilized huge resources from the accumulation of small amounts of individual insurance premiums, which provides support for large investment projects and promote economic efficiency.

According to European Association of insurance and reinsurance companies total investments of European insurers to the economy in year 2005 amounted to EUR 6371 billion, while investments of the insurance industry in year 2004 were on average 53% of GDP (gross domestic product) of European countries [5]. Total investments of insurers in Europe were reduced from EUR 7,200 billion in year 2007 to EUR 6500 billion in year 2008 due to financial crisis, but in year 2009 they increased by 8% and amounted EUR 6800 billion [6].

2.3 Insurance sector in the former Yugoslav republics

Economic growth together with liberalisation, privatisation, and the increased presence of foreign companies that brought substantial financial strength, new products, and advanced risk and asset liability management practices, have had the strongest impact on the development of regional insurance industries. Although the role of insurance activities is still relatively modest in all countries

of the region with the exception of Slovenia, there is strong growth potential especially for life insurance. In general life insurance is less developed compared to non-life insurance, and accounts for a relatively modest share of the countries' insurance market in terms of gross written premiums.

Table 1 Comparative review of the key indicators of the insurance sector in Serbia, countries of the region and the EU

		Number of insurance companies	Total insurance premium (in 000 EUR)	Life insurance premiums (in % of total premiums)	Insurance density (premium/p.c. in EUR)	Insurance penetration (premium share in GDP)
Serbia	2008	20	588994	12.16%	78.55	1.87%
	Change compared to 2007 (in %)	110.00%	104.22%	114.88%	104.22%	100.00%

Macedonia	2008	12	104565	4.15%	51.70	1.61%
	Change compared to 2007 (in %)	100.00%	104.76%	155.76%	104.76%	93.60%

Source: calculations by the authors, Insurance Supervision Agency, CEA Statistics, Croatian Financial Services Supervisory Agency, National Bank of Serbia, Insurance Agency of Bosnia and Herzegovina, National Bureau for insurance of Macedonia

On the base of these comparative data it is obvious that the insurance market of Serbia is underdeveloped. This is indicated primarily by the fact that the share of life insurance in the total insurance premiums is only 14.88% while the average in the European Union is over 83%. Also, the two most developed markets in the region of former Yugoslavia, measured by the size of insurance premiums, the share of life insurance in the total premium amounted to 31.83% in Slovenia and 26.30% in Croatia. Measured by the size of the total insurance premiums and insurance premiums per capita, the Serbian insurance market is in front of the insurance market in Bosnia and Herzegovina and the insurance market in Macedonia. Therefore, it is evident that there is the lag of the insurance markets in the region in comparison to the insurance market of the European Union. Although Slovenia is the only country from the former Yugoslavia as EU member (since the year 2004), their insurance market also marked results under the average of European Union.

3. The role of investment funds

3.1. Investment funds on the European and world financial market

Investment funds, usually in a form of mutual funds, are financial intermediates that collect the savings of individual investors and raised funds invest on the financial market. According to the Gitman and Joehnk [7] when investors buy shares in a mutual fund, they become part owners of a widely diversified portfolio of securities. Mutual funds are the most appropriate form of capital mobilization. They appeared much later than the banks, but as financial institutions they contribute significantly to the deepening of capital market and its development. Investment funds are also useful in terms of a whole society because they represent an attractive mechanism to attract capital of small individual investors, putting it at the disposal of businesses. Otherwise, individual owners of capital would be rather chose consumption than savings, or would deposit funds in bank accounts, with much lower returns. Investment funds offer a rational way for small investors to involve and increase the rate of savings in a national economy.

Data of the European Funds Assets Management Association – EFAMA [8] for year 2009 show that the European investment funds industry comes to recovery. There has been marked positive growth in net assets value (NAV) and net sales of funds, in accordance with the equity market recovery, recovery of capital markets and restore of investor confidence. Across Europe net assets of investment funds increased by 15.6% and from EUR 6 to 7 billion in year 2009. When we look at investment funds worldwide, at the end of the third quarter of year 2009 has marked an increase in their net assets value for 10% to the amount of US\$ 22.38 trillion, or US\$ 23.0 trillion at year-end 2009 [9].

Table 2 Worldwide mutual funds net assets in EUR billions, June 2010

Region	June 2010 (in bn EUR)
USA (mutual funds)	9.150
Europe (UCITS and non UCITS)	7.492
Asia and Pacific	2.242
America (excl. USA)	1.640
World	20.623

Source: Investment Company Institute www.ici.org

According to the newest published data from June 2010, data on worldwide fund assets in EUR billions can be noted that the sector's investment funds in the European financial market by net assets value of the funds coming close to the U.S. financial markets as the most developed in terms of fund numbers, net asset value, net inflows and others indicators of funds performances. Net assets value of investment funds in the financial markets of USA represents approximately 45%, while assets in European funds (UCITS and non-UCITS) represents about 36% of total worldwide fund's net assets value. Regarding that total net assets value of investment funds represents half of gross domestic product (GDP) of the European Union, it is clear that investment funds have an important role in the European economy and European financial market. Investment companies manage by long-term savings, invest in the European financial market, buy shares and provide short-term financial sources for European companies and employ many workers.

Statistical data collected from 45 countries around the world shows that the total number of investment funds is about 66,000, while approximately 26,000 funds (or 38% of fund net assets) is invested in shares [9]. These data support the fact that it is very important to the company to raise needed capital for finance its business and encourage innovation through issuing securities, especially shares. More than 1/3 of all investment funds in the world invest in shares. Therefore, companies need to attract the attention of potential investors, by issuing shares that will be publicly traded on the stock exchange. Transparent and successful business is the best way to attract capital owners, who are interested to invest in a company, idea or project. By issuing securities and initial public offer (IPO) companies are becoming visible to the capital owners who could financially support

companies' development. It is important to notice that emerging markets experienced significantly larger gains in stock prices than occurred in the United States and other developed countries.

3.2 Investment funds in Serbia and former Yugoslav republics

Investment funds sector is the most developed in Croatia and Slovenia, where funds first appeared 15 years ago, after the realisation of mass voucher privatization process (MVP). In Croatia are dominated money market funds and in Slovenia equity funds that primarily invest in shares of foreign issuers. Investment funds in Montenegro, Macedonia and the Republic of Srpska appeared later and their numbers in the financial market was drastically lower, with the lower transparency and weaker performances. It can be seen in the table below.

Table 3 Investment funds in former Yugoslav Republics

Country	Number of investment funds	Net Assets Value (in €)
Croatia	128 open-end 4 close-end 4 real estate	2 billions
Slovenia	130 open-end	1,98 billions
Montenegro	7 mutual	n.a
Macedonia	9 open-end 13 private	n.a
Serbia	15 open-end 3 private 2 close-end	8,7 millions
Republic of Srpska	3 open-end 14 close-end	67 millions

Source: Securities Commission Republic of Serbia, Securities Commission of FYR of Macedonia, Croatian Financial Services Supervisory Agency, Securities Commission of Republic of Srpska, Securities Market Agency of Slovenia, Securities Commission of Republic of Montenegro n.a – not available

The first investment funds have emerged in Serbia in early 2007 and after the initial successful performances; they were affected drastically by the global financial crisis. The effects of the crisis had extremely negative impact on the shallow and volatile financial markets not only in Serbia, but in all countries of our region. It happened a decline in demand and prices of securities on the stock exchange, which is consequently reflected in the decline in value of investment units of all funds and negative returns over a long period of time. Today is the same situation where the value of investment units is lower than their value at the fund establishment. The total net assets value of the funds in Serbia in February 2011 is RSD 920 million or about EUR 9 million [10].

4. Importance of institutional investors as financial sources on micro level

The need for more intensive presence and successful performances of institutional investors in the Serbian financial market, can be observed in the context of the economic environment and business conditions for enterprises and entrepreneurs. In the last decade after democratic reforms in Serbia, total external debt is constantly growing, and the end of 2010 the amount reached as high as EUR 23.1 billion [11] and has a share in the gross domestic product (GDP) of 77.1%. It is slightly below the high indebtedness according to the standards of International Monetary Fund (IMF) and the country is highly indebted when external debt exceeds 80% of GDP).

Table 4 External debt of Serbia, total and by sectors, in EUR billions, 2006-2010.

Sector	September 2006 (EUR billions)	September 2008 (EUR billions)	September 2010 (EUR billions)
Public sector borrowing	7	6,3	8,3

Sector	September 2006 (EUR billions)	September 2008 (EUR billions)	September 2010 (EUR billions)
Private sector borrowing	7,6	14,2	15,2
		3,5 banks 10,7 enterprises	4,8 banks 10,4 enterprises
Total external debt	14,6	20,5	23,5

Source: National Bank of Serbia <http://www.nbs.rs/export/internet/cirilica/80/index.html>

From the table it can be seen that in all observed years more than half of total external debt is private sector borrowing, particularly medium- and long-term borrowing of enterprises. Often it is the purchase of plant and equipment from foreign producers or sellers financed through the credit lines of foreign banks. Based on the amount of short-term private sector borrowing, it can be concluded that the enterprises usually borrow short-term from domestic banks in order to maintain liquidity. The total amount of loans granted by banks to entrepreneurs is about EUR 1.5 million.

Privatization in Serbia began over a decade, but has not yet been fully completed. The problem becomes more pronounced as the privatization process is nearing completion and inflows are reduced, while simultaneously the level of foreign direct investment per year decline.

Table 5 Foreign Direct Investment (nett) in Serbia, in US\$ millions, 2000 – 2010

2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010
50,0	165,0	475,0	1.365,0	966,0	1.550,0	4.264,0	2.523,2	2.716,9	1.864,8	1364,1

Source: European Bank for Research and Development (EBRD) - *Transition Report*

From the above table can be seen that the level of FDI since the beginning of democratic change in Serbia in year 2001 were continuously increasing until the year 2006 (with the exception of year 2004) but then begins to decline.

After the reform of the banking sector, most banks in Serbia are become members of foreign banking groups, but were established as domestic legal entities and the large financial sources that place to businesses and citizens of Serbia banks supply on the international financial market. It speaks of the great dependence of domestic banks and their placement on international financial sources. Higher country risk in Serbia in comparison to economically developed countries increase interest rates as the price of borrowed capital. One of the reasons for the higher price of borrowed capital is tight monetary policy of central bank that is trying to keep inflation and credit expansion under control, by increasing the effective interest rate, required reserves and other financial instruments. It should also be added a high bank margins that all causes high price of borrowed capital and a great burden for enterprises and entrepreneurs. With the strengthening of competition among banks and the more significant role of institutional investors (investment, pension and insurance funds) on Serbia's financial market can be expected a reduction in price of borrowing. Average weighted interest rate on bank loans (September, 2010) amounted to 12% [11]. The global financial crisis has contributed to increasing the number of problematic loans in the banks' portfolio, which together with the constant depreciation of the domestic currency makes difficult paying out the loans by enterprises and citizens. It forced all market players to take very conservative credit policies, making it difficult for enterprises to access to financial sources needed for financing their business and development.

Global financial market is gradually recovering, but the Serbian financial market is still shallow and underdeveloped, and reflects the problems in the real sector of the economy. Companies in Serbia are hesitant and do not have sufficient information regarding the implementation of the Initial Public Offer – IPO, although this may be the cheapest and very effective method of financing enterprises' development. IPO represents issuing and the first public trade of shares on the primary market. In this way, the company offers its shares to a wide range of potential investors and acquired capital necessary for financing its development. If the Serbian companies more often decided for an IPO, the number of investors would be increased and large institutional investors such as investment funds and insurance companies would be more interested to invest capital to the enterprises whose securities are on the stock exchange. As a consequence of the lack of qualitative securities on the stock exchange and the underdevelopment of financial market in Serbia, there is only one stock exchange - Belgrade Stock Exchange (BSE), which the only five share issuers on the prime market [12] and 3 share issuers on the standard market. Most of the other about 1600 companies are on the unregulated market and its shares are not publicly traded.

We should also bear in mind the fact that savings in foreign currency as deposits in commercial banks in late 2010 amounted to around EUR 7 billion [11] and it is estimated that there is additional EUR 1

billion savings that it is not mobilized by banks or institutional investors. In such circumstances it is very important that mutual funds and insurance companies mobilize small amounts of individual owners' capital and form capital funds that will be invested in stocks and corporate bonds, municipal bonds and other securities of different issuers. This increases the efficiency of using capital as a limited resource and promote its rational allocation in the national economy, but also provides significant financial support at the micro level. Without strengthening the capital market and the greater presence of institutional investors can not be immobilized capital of domestic and foreign owners required for financing the real sector of economy and providing financial support to the development of entrepreneurship and innovations. We should also bear in mind that because of above-mentioned country risk and high dependence of international financial market, there is a high price of capital borrowing capital needed by companies and entrepreneurs for financing business. By including institutional investors as long-term financial sources, it is encouraged development of capital markets and increases the supply of capital, facilitates the access to the capital in the real economy and consequently reduces the price of capital borrowing. It is therefore important that companies through their transparent and successfully business attract institutional investors to invest capital in home issuer's securities.

In the markets of Serbia, Macedonia and Montenegro for several years has operated an investment fund SEAF South Balkan Fund BV Fund [13] , as a part of the global investment company SEAF - Small Enterprise Assistance Fund. This fund invests in companies that have excellent growth and development potential, to them can be added value in different ways and they needed additional capital to achieve faster growth rate. SEAF Fund provides capital and operational support to companies that can not access traditional sources of capital, and operate in markets that are still developing. SEAF provides access to alternative sources of capital, linking the selected companies with reputable strategic partners and investors on a global level, the active management support in improving finance, strategic and operational management. Although by investing in selected companies SEAF becomes co-owner, the advantage for the enterprise is that there is not high borrowing costs (as by the traditional bank loans). Financial resources for financing development of private companies could be in the amount of EUR 300,000 to EUR 2,000,000. SEAF invests primarily in medium-sized private companies, but also Start-up Company if the owner has relevant experience and is willing to share financial risk with SEAF. It is important that private companies are majority owned by domestic owners (min. 51%), that the management team is experienced and has a clear vision of the future development of the company and a strong ambition to achieve rapid growth of the company. Regarding that after several years fund sells its shares in the company and withdraw from the ownership structure, achieving higher rates of return, in accordance with the taken risk, it's needed to exist a clear vision of exiting the investment through the sale of shares in the capital to the existing owner , management, financial or strategically partner, or through IPO. More of these funds on the underdeveloped financial markets could be very useful for many small or newly established enterprises with solid development potential, a unique product or service, and the deficit of capital, management experience and contacts for easier emerging on foreign markets.

5. Conclusions

Investment funds and insurance companies as institutional investors could be an important support to small and medium enterprises (SME) and entrepreneur by participating in long-term financial sources of companies, as the majority or minority owner, for a limited or unlimited period. This would contribute to increasing efficiency of enterprises, strengthening existing market positions and capturing new market segments, improving the quality of products and services and financing new developing ventures. It is important that there is a common interest between management of an enterprise and fund management, which is primarily profit. Additional motivation may be sectoral or regional economic development. The decision on the institutional investors' participation in the capital of SMEs will primarily be made on the base of the financial statements, plans and projections, prospectus, and enterprises should try to attract institutional investors as a quality long-term financial sources through corporate governance, transparent business and continuous improvement of performances. Incentives for institutional investors for investing in the enterprises will also be finishing the privatization process, when ownership structure will be clearly defined and profitable business, business goals and development orientation of the enterprises will be factors which help in making decisions about investing in specific enterprises. All this should be observed in the context of growing total external debt of Serbia, especially private sector borrowing. Due to the more and more difficult

debt servicing from the point of state as well as of a company, alternative sources of capital should be more used instead of traditional banking credits.

The more institutional investors on the domestic financial market and the more accumulated capital will ensure that they in accordance to their investment objectives invest in various sectors, branches, companies that have already proven their business or those are yet to develop. In this way, institutional investors are becoming co-owners of enterprises, but they also allow easier and cheaper access to long-term financial sources which are usually scarce. Because of intensive competition and taking the traditional credit activities from banks, institutional investors contribute to increasing the more quality and fewer prices of financial services and capital.

Comparison of Innovative Two Models for Estimation Production Times and Costs

Predrag Cosic¹, Dragutin Lisjak², Branimir Nadih³

¹Faculty of Mechanical Engineering and Naval Architecture, University of Zagreb, Zagreb, Croatia, predrag.cosic@fsb.hr;

²Faculty of Mechanical Engineering and Naval Architecture, University of Zagreb, Zagreb, Croatia, dragutin.lisjak@fsb.hr;

³Faculty of Mechanical Engineering and Naval Architecture, University of Zagreb, Zagreb, Croatia, branimir.nadiah@fsb.hr;

Robust regression analysis model as a possible approach to time/cost estimation is used for the estimation of requested results based on the previous stochastic results and experiments. The requests for classification consideration of the product shape and process sequencing are important conditions for designing a general model for the estimation of production times. In fact, it means development of a technological knowledge base. As a result of our analysis, we have created eight regression equations with the obtained index of determination, with the most important independent variables different for 2D and 3D model. The observed level of subjectivity, constraints and errors were the reasons to use neural networks as the second approach to estimate production time. According to the presented results, we can conclude that the assumption on the use of a neural network for the production time estimation in relation to a robust regression analysis model is justified. For all experimental models the applied backpropagation neural network gives better values of key performance indexes (R, R², RMSE, NRMSE).

Keywords

Estimation of Production Times, Technological Database, Stepwise Multiple Linear Regression, Neural Network

1. Introduction

An experienced process planner usually makes decisions based on comprehensive data without breaking it down into individual parameters. So, as the *first phase* it was necessary to establish a technological knowledge base, define features of the 2D drawing (independent variables), possible dependent variables, size and criteria for sample homogenization (principles of group technology) for carrying out analysis of variance and regression analysis. The *second phase* in the research was to investigate the possibility for easy automatic, direct finding and applying 3D features of an axial symmetric product to the regression model. The *third phase* in the research was to investigate the possibility for the application of neural networks in production time estimation and to compare the results between the regression models and neural network models. As it can be seen from references there are different approaches for data receiving from AD (STEP) [1], integration of CAPP, CAD/CAM and business activities [2], development of database system of mechanical components [3,4], and integrated product engineering [5] for costs estimation and rapid cost estimation [6], application of neural networks in estimation of production time [7], connection from CAPP, CAD, CAM; DFx to DFA through product development [8] etc. The most important characteristic of our approach presented in this paper is estimation of production times using group technology, regression analysis and neural networks [7], [9, 10, 11].

2. Drawing Features and Technological Database for Production Time Estimation

Very frequently (especially in the case of SMEs) it is necessary to respond quickly to some important requests for offers, generated for individual or batch production

It must be noted that technological knowledge and speed of process planning are often more important than the technological level of equipment, skills and knowledge of people who implement the technology. So, very often in practice we can be faced with the following:

1. A great amount of time spent on planning of the technological process for a product without any specific contract being made concerning the order for manufacturing of the product,
2. Signing of a contract without estimated precise production times/costs necessary for product manufacturing and realization in accordance with contracted production.

Technological processes are basically based upon product drawings with adequately defined dimensions, tolerances (dimensional and geometrical), surface roughness, batch size, shape and kind of material, heat treatment, requested delivery, disposable equipment, tools, etc. The fundamental idea in the approach [10, 11] to production time estimation is investigation of the existence of some kind of relationship between the shape and data from the drawing and the process type, process sequencing, primary process, way of tightening, selection of tools, machine tools, production times, etc. As one of the *first steps in our project research*, we defined possible shapes of raw material and 30 potential basic technological processes.

3. Development of Stepwise Linear Multiple Regressions

As the result of previous research, sample homogenization, classifier selection and stepwise multiple linear regressions, we obtained: 8 regression equations, percentage of explained effects, relative error (7-30%), etc. (Table 1). The lowest relative error 8.01% (Table 2, for grinded discs, AC102 No. 5) and the highest index of determination $r^2 = 0.9851$ for the grinded discs group are the consequence of the simultaneous action of logical operators (round bars, discs and fine machining – i.e. diameter tolerance better than IT7). Thus, with the simultaneous action of several operators, a lower scattering of production time values has been achieved, i.e. better homogeneity of the created group.

The *second phase* in the research was the investigation of the possibility for easy automatic, direct receiving of 3D features of the considered axial symmetric product into the regression model. The defined requirement resulted in the development of the process for the transfer of parameters from 3D models with a low level of subjectivity. It is a very fast and reliable process via CAD report to the regression model [12]. As the possibility to improve our precision for forecasting production times of “new unknown products” in our research we choose, in the next phase of our research, neural network to compare validity two method: linear multiple stepwise regression and neural network model.

Table 1. Explanation of the meaning of used symbols

Symbol	Physical unit	Meaning of the symbol
f_{ea}	-	Features of 3D
K	-	Coefficient of time
K_s	-	All dimension lines
r^2	-	Index of determination
t	(min)	Machining time
x_1	(IT)	Order of tolerance outside diameter
x_2	(mm)	Outside diameter of material
x_4	(mm)	Width of material
x_6	(mm)	Length of material
x_8	Class h	Roughness of open areas
x_9	HRC	Hardness of product
x_{10}	(mm)	Outside diameter of product
x_{11}	(mm)	Inside diameter of product
x_{15}	-	Number of product perspectives
x_{16}	-	Number of descriptions of product
x_{18}	-	Number of location marks (geometry)

Symbol	Physical unit	Meaning of the symbol
X ₁₉	-	Number of dimension line tolerances
X ₂₀	-	Number of special dimension lines
X ₂₁	-	Number of usual dimension lines
X ₂₂	(1/class)	Roughness request Ra
X ₂₃	(1/mm)	Location request (geometry)
X ₂₄	(1/mm)	Dimension request
X ₂₅	(1/IT)	Diameter request
X ₂₆	(mm ²)	Area of sketch
X ₂₉	(N/mm ²)	Ultimate tensile strength of material
X ₃₀	(m ²)	Requested area of sketch
X ₃₁	-	Mass strength of material
X ₃₂	(mm)	Thickness wall of products
X ₃₃	-	Ratio of diameter and length
X ₃₉	-	Number of all dimension lines
X ₄₀	-	Product complexity
X ₄₂	(Class h)	Difference in roughness
X ₄₃	(dm ²)	Difference in superficial areas of material
X ₄₄	(cm ³)	Volume of material
X ₄₅	(kg)	Mass of material
X ₄₆	(mm)	Difference in outside diameters
X ₄₇	(mm)	Difference in outside diameter of products
X ₄₉	(mm)	Difference in thicknesses
X ₅₀	(mm)	Difference in lengths
Y	(min)	Production time

4. Neural Network Model

Artificial neural networks (ANN) are inspired by the biologic neural system and its ability to learn through examples. Instead of following a group of well defined rules specified by the user, neural networks learn through intrinsic rules obtained from presented samples. The most commonly used ANN architecture is the multilayer *backpropagation neural network*. Backpropagation was created by generalizing the *Widrow-Hoff* learning rule to multiple-layer networks and nonlinear differentiable transfer functions [13]. Input vectors and the corresponding target vectors are used to train the network until it can approximate a function, associate input vectors with specific output vectors. Standard backpropagation is a gradient descent algorithm, as is the *Widrow-Hoff* learning rule, in which the network weights are moved along the negative of the gradient of the performance function. The term *backpropagation* refers to the manner in which the gradient is computed for nonlinear multilayer networks. *Backpropagation* neural networks often have one or more hidden layers of sigmoid neurons followed by an output layer of linear neurons. Multiple layers of neurons with nonlinear transfer functions allow the network to learn nonlinear and linear relationships between input and output vectors. There are numerous variations of the basic algorithm that are based on other standard optimization techniques, such as conjugate gradient and Newton methods. The one used in this paper is the *feedforward backpropagation* training algorithm designed to minimize the *mean square error* (MSE) between the actual (estimation) output (a , A) and the desired (target) output (d , T). Figure 1. shows the principle of the *feedforward backpropagation* training algorithm.

Figure 1 Principle of the feedforward backpropagation training algorithm

Where is: V_{ij} - weight between the input layer and the hidden layer, W_{jk} - weight between the hidden layer and the output layer, X_i - input signals (value of chemical composition), i - number of neurons of the input layer, I - number of inputs of neuron j in the hidden layer, Y_j - output of the hidden neurons, j - number of neurons of the hidden layer, J - number of inputs of neuron k in the output layer, Y_k - output signals (mass of eluted ions per gram of samples), k - number of neurons of the output layer. For the estimation of performance of the learning algorithm in solving the specified task, performance index was defined. Performance index enabled comparison of the applied neural network algorithm with other learning algorithms. The most frequent performance index is the normalized root mean square error – $NRMSE$ (1).

$$NRMSE = \frac{\sqrt{\frac{\sum_{n=1}^N (d_n - a_n)^2}{N}}}{\sigma_{d_n}} \quad \sigma_{d_n} = \sqrt{\frac{1}{N} \sum_{n=1}^N (d_n - \bar{d})^2} \quad \bar{d} = \frac{1}{N} \sum_{n=1}^N d_n \quad (1)$$

Where is: N is the total number of patterns, d_n is the desired (target, T) outputs, a_n is the actual (estimation, A) outputs, σ_{d_n} is the standard deviation.

Table 2. Presentation of created regression equations

No	Shape of product representative of product group	Regression equations	Index of determ. r^2	Relative error [%]	Comment on regression equation
1	Whole sample A0000	$t = -11.69 + 16.95x_{45} + 1.22x_{40} + 0.54x_{47} + 127.47x_{22} - 3.24x_{18} + 0.15x_{32} + 0.03x_6$	0.736552	30.74	Model is developed with procedure in advance. Three independent variables are omitted x_8 , x_{19} and x_{33} .
2	Round bars A00B1	$t = 55.47 + 22.43x_{45} + 1.162x_{40} + 0.43x_{11} + 1.61x_{50} - 5.41x_8 - 3.26x_{18} + 1.78x_{42}$	0.74285	30.95	Model is developed with procedure in advance. Two independent variables are omitted x_1 and x_{26} .
3	Shafts AB101	$t = 6.13 + 0.83x_2 + 1.27x_{39} - 3.30x_8 + 5.51x_{46} - 6.86x_{18} + 0.09x_6 + 124.33x_{22}$	0.807626	25.90	Model covers more narrow field of rotational parts. It gives better results than No.2.
4	Discs AB1C1	$t = -5.17 + 0.73x_{47} + 0.93x_{40} + 5.25x_{20} + 0.52x_{24} + 139.11x_{30} + 0.23x_{32} - 0.51x_{33}$	0.809405	24.24	Similar results as in No.3.
5	Discs-with fine machining AC102	$t = -60.78 + 0.59x_{47} + 0.47x_9 + 0.74x_1 + 0.25x_{10} + 0.84x_{39} + 291.07x_{25} + 5.9x_{15}$	0.985057	8.01	Model covers more narrow field of rotational parts. It gives better results than all the previous models.
6	Rotational parts AB103	$t = -37.11 + 0.94x_{40} + 0.03x_{29} + 319.22x_{26} + 0.13x_{23} + 114.67x_{43} - 80.98x_{45} - 0.46x_6$	0.893321	27.06	Model is better than No. 2 as a result of higher degree of homogenization of data. Solution is better with omitted variables x_2 and included variables x_6 , x_{23} , x_{43} and x_{45} .
7	Flat bars A0004	$t = -10.96 + 0.58x_{40} + 34.50x_{45} + 218.42x_{22} - 5.48x_{50} + 185.03x_{26} + 0.39x_9 - 0.50x_{49}$	0.900332	15.92	Constraints are greater for all variables so results are better.
8	Sheet metals A0005	$t = 0.47 + 1.27x_{40} + 137.45x_{45} - 13.23x_{43} - 0.70x_{43} + 0.28x_4 + 0.05x_6 + 3.91x_{16}$	0.900823	24.04	Model is characterized with the presence of complex variables x_{40} , x_{43} , x_{45}

5. Experimental Results

As a better method for solving the problem of production time estimation, we proposed a three-layer backpropagation neural network the simplified structure of which is shown in Figure 2. Presented input parameters (LM, NG, sl, SOK, mM, DUP, lZH) refer to the model A0000. Output parameter (TO) is the estimate of time in minutes. Parameters $n_2=20$ and $n_3=15$ represent the number of neurons in the second and third layer of the network. Between the layers the following transfer functions are applied: *tansig-tansig-purelin*. Data important for neural network training are: Performance goal: 0.0001, Learning rate-0.01, Ratio to increase learning rate-0.5, Maximum performance increase: 1.04, Maximum performance gradient: $1e-10$, Momentum constant: 0.9, Number of layers: 3, Number of neurons: 20-15-1, Transfer functions: *tansig-tansig-purelin*, Number of epoch to train: 15000. For neural network training the available experimental data are divided in three sets: training set (70%), validating set (15%), and testing set (15%). The same model of experimental data division is applied to all models. The following parameters are selected as *key performance indexes* of the neural network model (*NNM*) in relation to the regression model (*RM*): R (correlation coefficient), R^2 (determination coefficient), RMSE (root mean square error) and NRMSE (normalized root mean square error). Below in Figure 3. through Figure 6., for each experimental model the graphical presentation of parameter R values and tabulated values of parameters R, R^2 , RMSE and NRMSE are given.

Figure 2 Simplified model of the used neural network of A0000 model

6. Conclusion

According to the presented results (Figure 3. through Figure 6.), we can conclude that the assumption on the use of a neural network for the production time estimation in relation to a classical robust regression model is justified. For all experimental models (A0000, A00B1, AB1C1, AC102, AB103, A0004, A0005) the applied backpropagation neural network gives better values of key performance indexes (R, R^2 , RMSE, NRMSE). The biggest difference between the key performance indexes for *NNM* and *RM* estimation models is in the case of model A0005 (input set of 35 data), and lowest in the case of model AC102 (input set of 25 data). The next differences in key performance indexes of individual models ranged from the highest to the lowest values are as follows: AB103, A0004, AB1C1, A00B1 and AC102. The lowest difference between the *NNM* and *RM* estimation model in AC102 (finely machined discs) follows from the nature of the model independent variables and their values that are from a relatively narrow range. The reverse is true for the biggest difference in A0005 (sheets), because of the relatively wide range of independent variables. The key performance indexes in *NNM* estimation models are significantly better than those in all proposed *RM* models, especially in the case of A0005. The reason for this is the proper selection of transfer functions (*tansig - tansig - purelin*) within the backpropagation neural network layers which provide approximation of linearities and nonlinearities within independent variables, as opposed to the regression model whose approximation is only linear. It should be also noted that the estimation by the *NNM* model would be even better if the experimental data had not been divided in three sets (training set, validating set, and testing set), and thus the estimation made by *NNM* model is based on 70% of presented data in contrast to the *RM* model where for obtaining of the regression function all experimental data are always presented.

Technology Transfer Through Spin - off Companies - from academic research to commercialization in the Life Science Sectors

Aleksandar Cvetkovski¹

¹*Faculty of Medical Science, University Goce Delcev, Stip, Macedonia,
aleksandar.cvetkovski@ugd.edu.mk*

1. Introduction

Technology Transfer (TT) is a complex process involving the shift of codified knowledge, know-how and management techniques. TT is defined as the transfer of the results of basic and applied research to the design, development, production, and commercialization of new and improved products, services or processes. Knowledge embodied in products is precursor for transfer of technology. The transfer process emphasizes the value and protection of the intellectual product of the researchers.

In knowledge-based industries, the transfer of product and process technology from development to manufacturing might be an overlooked component of the product development effort. Many companies make the mistake of simply tying this transfer to manuals and data rather than actual knowledge. The companies that excel are those that realize that the ability to develop and scale up a robust, cost-effective manufacturing process for each new product is critical to new product commercialization. Companies that have this ability realize many benefits, including reduced time-to-market; optimal product cost at launch, effective manufacturing scale-up, improved product quality, and increased development efficiency [1].

Universities have long been recognized for their excellence in education and research. However, over the last few years they have increasingly been taking on the function of innovation drivers. By translating their intellectual assets into useful products and services, universities can take on a new role as engines of economic growth.

Spin-off Company refer to new established firms as result of cooperation between entrepreneur(s) and existing firm(s) who team up and start new venture together based on group findings.

Spin-off companies confront to idea of entrepreneurs as solitary actors who challenge the existing status quo. Spin-off entrepreneurs build their companies on existing structures and knowledge.

Funding of spin-off companies is based on initiatives for undertaking a risk for venturing and investing by individuals and by compelling incentives of other existing organizations i.e. companies which do start new companies: entry to new markets, employment schemes or rejection of non-profitable divisions [2]. Hence, spin-offs pay a role in creation of industrial clusters and the spatial distribution of knowledge [3].

TT and commercialization of innovations resulting from university research are increasing sources of business development and economic diversification. When a university-developed technology is identified as having commercial application and business potential, it may be transferred via a license of the intellectual asset to an existing company. However, for a variety of reasons, including the lack of a receptor company, the commercialization route may begin with the formation of a new start-up company ("university Spin-off Company") which, via a license agreement or assignment of the technology from the university, becomes the receptor.

2. Organizational structure of spin-offs and how TT does takes place in spin - offs

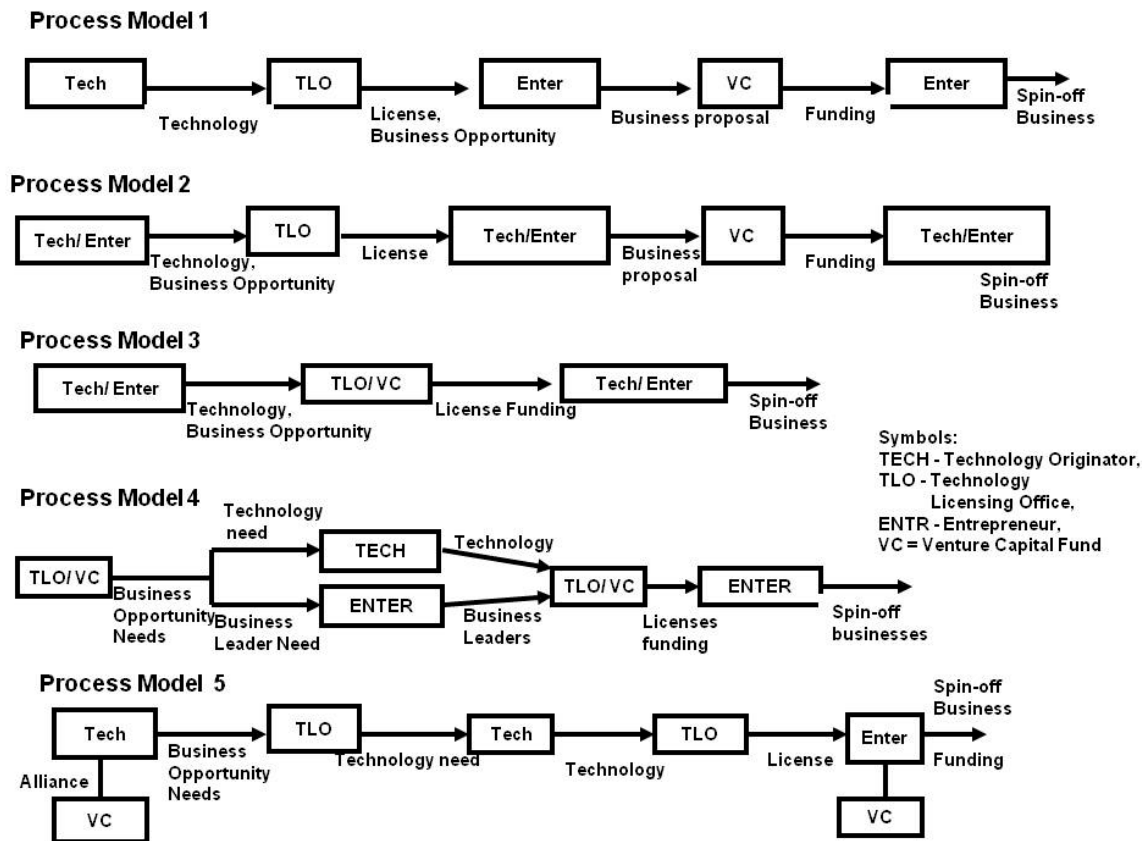

Spin-offs are separate business entities that are founded by using investment funds. The parent organizations usually provide the technological base, supplemented on occasion by some risk capital, in return for equity. Some R&D organizations have their own Venture Capital (VC) whereas others depend on outside sources of VC. In the corporate setting spin-offs appear to be most pursued when the parent organization is not very familiar with either the new technology or the new market. The corporate spin-off seems to provide a good way to establish a new technology or get into a new market and for this reason holds some attraction for R&D-based organizations. The choice to the organization between licensing and spinning off is not always available as different technologies or innovations and different circumstances may favour one method over the other.

Technologies that emanate from university can be transferred toward two modes. The first is direct transfer from university(s) to industry and encompasses consulting services that professors offer to industry, collaborative research, out-licensing of technology and spinning-off new companies. Second, indirect, mode is referred to creation of graduates who bring knowledge, skills, and an entrepreneurial attitude to their latter jobs and their communities. In Study issued by Bank of Boston in 1997 is underlined that from 4000 spin-offs founded by Massachusetts Institute of Technology (MIT) graduates 1 000 are located in Massachusetts. These companies employ 1,1 million people and realize over \$ 232 billion in sale, and share 5% of the employment and 10% of the economic base, as well [4]. Comparing to US (United States), one of the main barrier in Europe to successful entrepreneurship, innovation and product development is the lack of variety in forms of finance along the "Venture Capital chains". According to Peter Schintlmeister from EUROTRANS-BIO Europe currently have over 1,600 biotech companies, which all have the potential to become key drivers of public welfare and economic growth, but which also have high requirements in terms of capital, business environment, people, as well as public and political support. In 2004, under Dutch Presidency the following strategic priorities and argumentations for EU Life Science Sectors have been underlined [5, 6]:

- Sub-optimal and unbalanced funding at different stages in the business life-cycle and exacerbated imbalances by geographical and stock-market fragmentation cause restricted competitiveness of Europe's life science sectors;
- By helping to offset some of the commercial risk involved with incentives and benefits Council/Member States and Commission to examine the creation of a specific status for "young innovative companies", to provide schemes to entrepreneurs, employees, investors and companies across Europe to reward innovation.
- Council and Commission should regularly monitor the evolution of the various sources of capital and their impact on the European biotech industry's global competitiveness.

3. Key Roles in the Spin-Off Process

In spin-off process four principle groups are involved: the technology originator, the entrepreneur, the R&D organization itself, and the Venture Capital (VC) funds i.e. investor. Vibrant interaction are essential among all those participants in process of transfer a technology from R&D organization where it was developed to industry where it will be incorporated into usable products and services. Surveys made at several universities and R&D organizations that have attempted to spin-off new companies indicate five different models of interactions showed in Figure 1 [7].

- Model 1: Technology push with independent principal groups
- Model 2: Technology push/business pull with an entrepreneurial technology originator
- Model 3: Technology push/business pull with an entrepreneurial technology originator and an internal venture capital fund.
- Model 4: Business pull with internal venture capital funds.
- Model 5: Business pull with an entrepreneur/venture capital fund alliance.

Figure 1 Models for formation of spin-offs

Model 1 is the most basic of the five and from this model derives Model 2 and Model 3. The existence of an entrepreneurial technology originator in Model 2 markedly increases the degree of business pull in this model compared with Model 1 [8]. This model applies to about one-third of the MIT spin-offs and most of the Stanford spin-offs. Model 3 is more likely to be successful in the case where a R&D organization is itself inactive so far, as spin-off activity is concerned but the community in which the organization exists is one where spinoffs, entrepreneurs and venture capital funds are common. By using an internal venture funds, organizations spur the spinning-off process on the marketplace. The GE, Kodak and Xerox approaches in their foundations are variants of Model 3, with their own internal financing generally restricted to seed stage and initial product development financing. Model 4 is a more likely outcome than Model 3 when a R&D organization chooses to develop a venture capital fund to increase spin-off activity in an environment that is not rich in venture capital and where spin-offs are uncommon. Harvard Medical School created its Medical Science Partners fund consistent with the Model 4 approach. The alliance perceived in Model 5 is based on the venture fund's belief in the capabilities of the entrepreneur to succeed with a spin-off opportunity that is, at that stage, in turn the entrepreneur trusts that the venture fund will provide the funding if a suitable opportunity is discovered. Generally the technology licensing office of the R&D organization takes an active role in finding suitable technologies to satisfy the entrepreneur's need. The entrepreneur will not have any involvement in the invention process (This model is used at Harvard and MIT).

All those five models outline the basic objectives of the interactions that occur between the parties:

- TT from R&D organization is performed in a controlled manner, usually through licensing agreement. The technology that is provided establishes the initial core competences of the new company;
- Identification of business opportunity and creation of business based upon this opportunity. This makes balance between technology and established the other functions required by business to interact with customers, such as a product and supply chains;
- Providing the management resources for the company that give the direction and control necessary for it to succeed;
- Investing funds in the business that will be urged for additional growth. This growth can potentially meet the demands of the principal parties involved in TT through financial and other less tangible means.

The five process models emphasis the sequences of interactions between the parties and the objectives of these interactions.

The main criteria to determine the commercial potential for TT deal and the questions relating to requirements that have to be met are shown in Table 1.

Table 1 Criteria to determine the commercial potential for TT deals

Benchmark	How to meet specified benchmarks
Strength of the intellectual property	Is the IP right protected? What are the barriers to entry? Is there scientific merit or other validity to the work? How quickly and inexpensively can it be presented as a product that has the right physical and technical specifications, the right price, and achieve the right level of market penetration? <i>For life sciences:</i> strong pre-clinical data, animal studies, ADME and toxicity data are required.
Technology platform	Will the technology spawn more products later, or is it a one-trick pony? What is the value added to the R&D chain? Will other companies be willing to pay for it?
A sense of the regulatory pathway and the cost of going down it	For life sciences, what are the clinical trials going to look like? Has the FDA worked with this type of technology or product before?
An idea of the size and timing of the market	Is this serving an unmet need? Are people actually ready to pay for it? What are the competing products or technologies? What is the reimbursement potential? For medical devices, treatments or vaccines, is it something that will be reimbursed through the current (and future) medical payment system? Does the technology readily lend itself to being produced in quantities that are economically attractive? In other words, are there impediments to using semi-skilled assembly technicians to build the product? Does it require special materials or components that are particularly expensive or have a difficult procedure or are hard to handle?"

There is a general consensus that licensing is most effective if it directly involves the inventor and the inventor's institution. According to Jill Sorensen, director of the Office of Technology Management at the University of Illinois at Chicago, the university sector in US has been highly successful in its technology transfer efforts since it was given the right to own and license university inventions under the Bayh-Dole Act in 1980. Prior to 1980 when university patents were generally owned by the federal government, no more than 10% of those patents were licensed to industry for commercialization. Data for FY98 on university licensing activities show that universities are filing in excess of 4,000 patent applications a year and issuing more than 3,500 licenses or options to license annually. Trend data show a cumulative total of licenses and options issued since 1991 standing at over 20,000 and that the percentage of licensing activity has doubled between 1991 and 1998.

4. Conclusion

Successful spin-offs are not built on one product, but on the ability to use their research and technical advantages in an adaptive manner which keeps them ahead of their competition. When evaluation of technology is undertaken for possible spin-offs formation, following elements must be considered:

- Understanding of the long-term technology commercialization;
- Opportunity (its scalability, manufacturability, applications, and marketability);
- A focus on commercializing the benefits of a technology rather than the technology itself;
- A clear plan of what the next generation product will be, or needs to be, in order to remain competitive.
- Business planning, (clear business plan, sound management, budget forecasting and a financing strategy, and marketing and production plan);
- Recognition of the needs and priorities relative to the commercial plans of the company – and a strategy to keep them clearly delineated;
- Clear lines of reporting and obligation, and an awareness of the risks of conflict of interest and conflict of commitment;
- A well understood development program with recognition of the progression needed from the research focus to the commercialization focus – with an emphasis on the critical nature of the time to market;
- Communication on a regular basis to keep all parties informed;
- Management with proven experience in the particular high technology sector, an experienced board of directors and the ability to access experienced R&D personnel and facilities;
- An understanding of the market opportunity;
- Access to financing at all stages (technology development, seed capital, venture capital, and public markets);
- A solid, well-understood and protected technology.

Therefore, it is necessary to create environment that will spur the process of technology transfer toward the spinning-off of new companies from university and launching them on the marketplace. Also, the pragmatic communication should focused more on the coordinating strategic alignments, target technology essences, and a shared vision to where the technology transfer project will guide both (all) involving partners; more than just routine-typed work communication.

Creativity and innovation are closely related concepts. Creativity is the act of creating new ideas, approaches or actions, while innovation is a process that involves the application of creative ideas in a specific context. But the basis is knowledge (learning or education). This brings us to link education-creativity-invention-innovation.

One of the main forces that direct the new economy is knowledge. Knowledge employees use to make decisions or take actions important for the organization and therefore the people with adequate intellectual capital are strategic resources in modern companies. Modern business is characterized by globalization. It affects the work force in the world in two fold: greater mobility of capital affects the growth or reducing unemployment rates in some countries, and on the other hand, globalization affects the increased mobility of labor. Countries are looking to attract foreign capital, because it provides a further development, while companies are trying to ensure timely development of new skills already employed or they are trying to attract new qualified workers. Considering the decline in birth rate, particularly strong in Europe, it is obvious that in the future will be present the struggle for human resources, especially those educated.

Holders of development are young, competent people. The modern world is developing knowledge-based economy, in which the basis is education. While a growing number of experts said that the Serbian education should be aligned with market demands, it is true that a large percentage of the population has only primary school. The percentage that is set aside in the national budget for education is the lowest in the region, while adult education is almost not subject of thinking. However, through changes in the education system Serbia is trying to fit into the European educational space, create pre-conditions for its own development and development of the region.

Keywords

Creativity and innovation, Education, Work force and intellectual capital, Knowledge-based economy.

1. Introduction

The rapid development of technology, transportation and communication enabled the process of globalization. The main feature of globalization is that national borders are not important in economic terms, because free trade and mobility of labor and other resources led to the destruction of borders and the creation of global markets. In such environment, the fastest and the most adaptable to the changes ones survive [1].

Globalization creates a higher degree of competitiveness between companies. Company must have the right people in the right place. It is necessary to recruit competent and talented people, to be successful. However, this is just the first step that needs to take a successful organization. It first has to attract quality employees, and further to invest in their development and retaining, in order to keep them in the company. Organizations and countries must have educated and competent people in order to adequately respond to the demands imposed by globalization process.

In the era of machine people were not so important, and things were at the center. In the era of information technology, things are secondary, and knowledge is in the center. The company's value comes not from things but from the knowledge, skills, intellectual property, competence, and everything of that are contained in people [2]. But, there is no knowledge without education. So the basis of knowledge-based economy is a formal education and further lifelong education.

However, poor educational structure is what appears as a problem in Serbia and in the environment.

2. The characteristics of the modern business environment

The basic forces that drive the new economy are:

- Knowledge - intellectual capital that is seen as the source of competitive advantage of modern organizations,
- Change - which is becoming a normal phenomenon in the organization, given that organizations must adapt to constant, rapid and complex changes. Those changes reduce the certainty and predictability in organizations,
- Information technology - that allowed the process of globalization,
- Globalization - which affect the flows of capital, change the organizational structure of the company, encourage networking and the creation of various partnerships.

However, if globalization is considered as a basic characteristic of today's business environment, then we can say that it is enabled by information technology (which allows companies to operate in remote locations compared to the parent company), and that it has as a consequence different types of changes that are constant, and that require a higher degree of knowledge of all employees and participants in the global competition. Those changes are necessary in organization, in order to adapt to a new business conditions, take advantage of some chances as well as power and to avoid the threats and weaknesses.

Internet and information technology have changed the nature of the business and competition, because the information can be freely and easily exchanged, there is electronic commerce, it is possible to conduct meetings, although participants of the meeting are not in the same place, companies can be managed without a physical presence of managers, and there is more and more (especially in areas of services) virtual organizations.

Power of buyers has increased. They influence the reduction of prices, demand higher quality or better service and they are turning competitors against each other. Their power is even greater if they are concentrated or buy large quantities of products that are important to the sell of seller. Also, if the products that customers buy are standard and undifferentiated, customers are assured that they can find alternative suppliers and they are turning companies against each other, etc.

Knowledge and continuous learning are critical elements of success today. New economy led by those who effectively manage knowledge - who create, discover and combine the knowledge in order to create new products and services faster than competitors. Because of that companies require special skills of employees. The state borders are not a problem for companies looking for the best employees so here we can talk about the global labor market. All this increases the mobility of employees. Various aspects or segments of the environment that should be analyzed are: demographic, socio-cultural, political-legal, technological and economic segment.

3. Educational and age structure of population in Serbia

Given the global movement of capital and labor, for one country to attract foreign capital, is important educational structure of unemployed in the labor market as well as employees. Highly-educated workforce attracts sophisticated technology, while new investments into the country provide new jobs, higher living standards and thereby keep the existing highly qualified people in a country. All this creates a space for new investments in education.

Total educational structure of population in Serbia is quite unfavorable. According to the latest census from 2002 the 21.9% of the population older than 15 are without completed primary education, 23.9% of the population has completed primary school, 41.4% had secondary education while only 11% of the population has a university and college education. In accordance with this data, it means that nearly 46% of the population have a minimum education.

Table 1 Population aged 15 and over by educational attainment in Serbia, according to the 2002 census [3]

	Number of residents	Participation in the population (15+), %
No school and 1-3 years of primary school	483679	7,7
4-7 grade of primary school	896847	14,2
Primary education	1509462	23,9
Secondary education	2596348	41,1
Higher education	285056	4,5
High Education	411944	6,5
Unknown	137895	2,1

If we look at the structure of the population over 15 years by educational level and age, we can see that the largest percentage of illiterates are in category of the population over 65, but what is worrying is that the large number of illiterate people and those with secondary education are in category of the population between 15 and 24.

Figure 1 Population older than 15 years by educational level and age (share in total population in 2002) [4]

Structure of unemployment is not so good as well, but a large percentage of unemployed in the category of high, higher and secondary education, giving hope to investors that on the labour market is possible to find quality and competent people that could be employed.

UNEMPLOYED ACCORDING TO LEVEL OF PROFESSIONAL EDUCATION
- Annual average, 2009 -

Figure 2 Unemployed persons by level of education, annual average 2009 [5]

Demographic aging is a fundamental and general feature of the Europe population. People in Serbia are between the oldest demographic groups of population in Europe. Among the countries of former Yugoslavia, Serbia has the highest aging index while among the countries of Southeast Europe (Balkans) a higher aging index have only Bulgaria and Greece.

Table 2 The aging index for some countries in the region [4]

Country	Year	Total population	Average age	Share in total population (%)			Ageing index (65+/0-14)
				0-14	15-64	65+	
Serbia	2003	7481245	40,4	15,7	67,5	16,8	1,07
Slovenia	2003	1995033	39,6	15,0	70,2	14,8	0,99
Croatia	2003	4442200	39,8	16,6	67,1	16,3	0,98
Bosnia and Herzegovina	2002	3828397	37,3	18,3	69,5	12,2	0,66
Montenegro	2003	618407	35,7	21,1	67,1	11,8	0,56
Macedonia, FYR	2002	2038651	34,8	21,5	68,0	10,5	0,49
Bulgaria	2003	7845841	40,7	14,6	68,4	17,0	1,17
Greece	2000	10554404	40,3	15,2	67,6	17,3	1,14

4. Perspectives for development of Serbia and the region

Although the situation regarding education of the population in Serbia is not so great, encouraging is that there are positive trends and the desire to improve this situation.

When we compare the situation in 1991 and 2002 it is notably the reduction of Serbian municipalities with high percentage of illiteracy (over 10%). This trend is present today, and probably will continue in future.

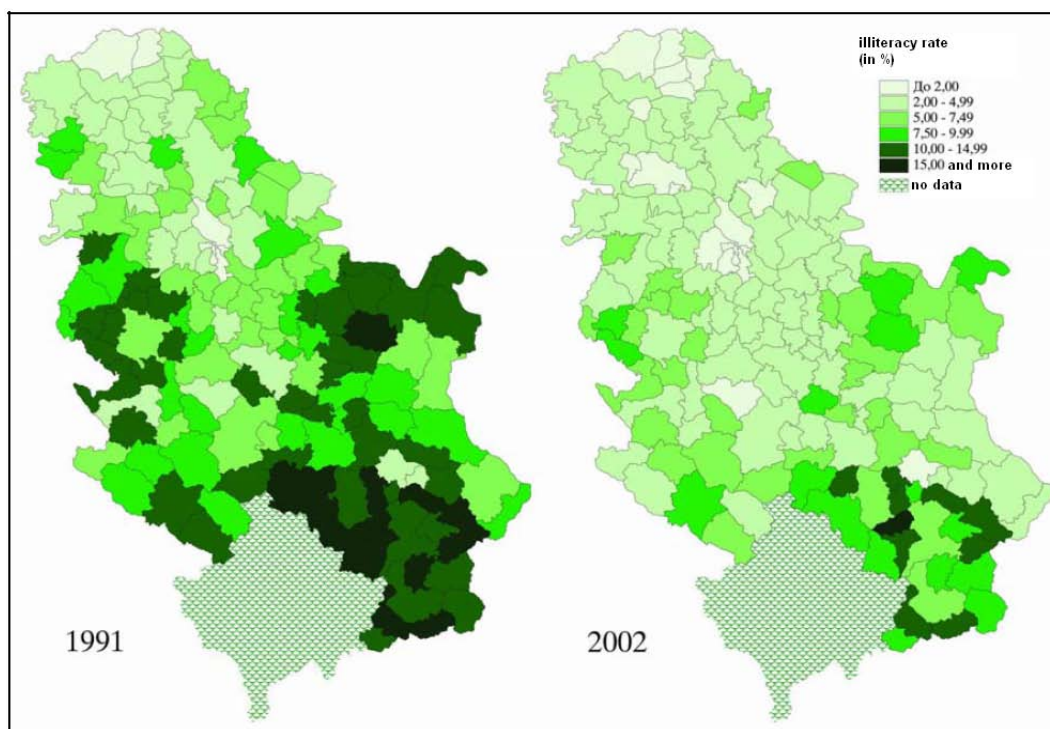

Figure 3 Rates of illiteracy of the population older than 10 years - Serbia in 1991 and 2002 (by municipalities) [3]

According to the UIS (UNESCO Institute of Statistics) the average enrollment rate in Central and Eastern Europe is 50%. In region of Central and Eastern Europe, Baltic countries and Slovenia are the only ones approaching to the average enrollment in North America and Western European countries, which have a rate of 67%. Albania is lagging behind the countries of region, while Croatia and Serbia are typical representatives of the region [6].

Table 3 Gross enrolment ratio for some countries in the region [6]

Country	Gross enrolment ratio (%) for 2002
Albania	15,8
Montenegro	Not available
Croatia	35,8
Slovenia	66,7
Serbia	43,0

source: UIS (UNESCO Institute of Statistics)

These countries must make further efforts to catch Slovenia, Western Europe and North America, although since the early nineties to the school year 2006/2007 the total number of students in these countries has doubled. The upward trend in student enrollment is steady over the past decade but it is necessary to ensure that investment in higher education and student standard are harmonized with the increase in number of students also.

Since 2002 universities in Serbia every year produces increasing number of graduates, masters of Science, PhDs.

Graduates, Masters of Science, and PhDs					
Year	2002	2003	2004	2005	2006
PhDs	303	359	394	468	401

Graduates	12,099	13,224	14,968	19,678	20,872

Source: Statistical Office of the Republic of Serbia

Figure 4 Graduates, masters and PhDs in Serbia [7]

Many believe that education reform is crucial for the modernization of Serbia, and therefore it should be accelerated, because the further development of the education system fastest approach to the European Union. The implementation of accreditation procedures in higher education institutions in Serbia meant the introduction of a range of standards, which higher education institutions had to comply with in order to be accredited. Introduced standards have to ensure quality of education and comparability and evaluation of higher education institutions. What would also be useful to educational institutions is to follow the path of their students, in order to determine how they are successful in employment, notice possible problems and implement some improvements in their curricula.

We can say that from the education can benefit individuals, organizations and the wider community as well. Education brings to individuals better business opportunities, higher income, better quality of life, better social status. If we look at the organizations, educated individuals more easily acquire new knowledge and have less resistance to change, reduce the need for retraining, provide flexibility to the organization more than necessary today and the like. If we look at the wider community, educated people are informed, active, rarely lose their jobs and when this happens these periods are lasting less and they are less reliant on social welfare.

One can no longer learn enough to be a fully functioning member of a society in one's youth. Extended life expectancy coupled with dramatic changes in economic, social and cultural situations mean that both individuals and societies must continue to learn – or be left behind and become marginalised [8]. Lifelong learning aims to increase employment rates and to strengthen the competitiveness of the economy of a country.

The education system in Serbia must comply with the requirements of the labor market. The link between education and the labor market is obvious, given that those who are students today, tomorrow will be those who will be on the labour market and look for a job [9].

The annual review of the most competitive countries of the World Economic Forum (WEF) for 2009-10, covered a 139 economies, including all countries of South East Europe. Some of them improved and some deteriorate its position relative to 2009-10. Serbia has dropped three places, from 93 to 96. In fact, each country is assigned a rank based on a wide range of competitiveness factors, divided into 12 groups. Groups included health and basic education, higher education and training and labor market efficiency, among others. In the report are given also opinions of more than 13,500 business leaders, which opinions are collected through surveys conducted in countries that were surveyed.

From countries in the region Serbia, Greece, Croatia, Romania and Slovenia have the worse rank than in previous (2009-10) year. Montenegro (which joined the group of 50 the most competitive economies in the world), Bulgaria, Macedonia, Albania and Bosnia and Herzegovina occupied a better position in 2010-11 as compared to the previous year, while Turkey is the only country in the region that has retained its position.

Among the most problematic factors for doing business in all countries in the region are inefficient government bureaucracy (the first place in Croatia, Greece, Macedonia and Turkey) and corruption (on the first place in Serbia and Bulgaria), access to finance (on the first place in Albania, Bosnia and Herzegovina, Romania and Slovenia) and inadequate infrastructure (on the first place in Montenegro). Other factors included restrictive labor regulations, policy instability, tax laws and so on. These are also the factors on which these countries must work in order to improve their own competitive position.

Table 4 Global Competitiveness Index (GCI) 2010–2011 and 2009–2010 [10]

Country	GCI 2010–2011 Rank	GCI 2009–2010 Rank
Slovenia	45	37
Montenegro	49	62
Turkey	61	61
Romania	67	64
Bulgaria	71	76
Croatia	77	72
Macedonia, FYR	79	84
Greece	83	71
Albania	88	96
Serbia	96	93
Bosnia and Herzegovina	102	109

(according to: The Global Competitiveness Report 2010-2011, World Economic Forum)

According to assessment of business leaders in the field of education system quality ahead of Serbia are located, in the region, Montenegro, Slovenia, Albania, Macedonia, Romania and Bulgaria. According to the quality of scientific research institutions, Serbia is on the fourth place, behind Slovenia, Montenegro and Croatia, while by the cooperation between industry and universities in research and development, in front of Serbia are only Slovenia and Montenegro.

Table 5 Competitiveness in quality of the educational system, quality of scientific research institutions and university-industry collaboration in R&D, among Balkan countries [10]

Quality of the educational system		Quality of scientific research institutions		University-industry collaboration in R&D	
(1 = not well at all; 7 = very well)					
Country rank	Mark	Country rank	Mark	Country rank	Mark
37 Montenegro	4.4	27 Slovenia	4.7	37 Slovenia	4.2
47 Slovenia	4.2	36 Montenegro	4.4	52 Montenegro	3.8
54 Albania	3.9	51 Croatia	4.0	71 Serbia	3.5

86 Serbia	3.3	83 Romania	3.3	103 Romania	3.1
89 Croatia.	3.3	88 Greece	3.3	110 Bulgaria	3.0
95 Turkey	3.2	89 Turkey	3.3	112 Greece	3.0
102 Bosnia and Herzegovina..	3.1	104 Bosnia and Herzegovina	3.0	117 Bosnia and Herzegovina	3.0
118 Greece	2.9	128 Albania	2.5	138 Albania	2.2

(according to: The Global Competitiveness Report 2010-2011, 2010 World Economic Forum)

All of factors that are listed as bad for the competitiveness of countries in the region should serve as indicators of what needs to be changed. However, competent and educated individuals are that which would be missing in the global economy and on what it will be based. Because of that, all countries should be oriented on improving the situation in the education system and encouraging lifelong learning.

5. Conclusions

Countries that would have trained and equipped staff in global economic conditions will be those who will benefit. However, there is a critical investment in the education system. To be good, education system must be compatible with the chosen development strategy of the country, as well as being able to quickly respond to labor market [9].

Serbia, together with countries in the region must work to raise the educational level of the population. Over time, due to globalization wages will globally equalize, so the competence of employed and unemployed in the labor market, will be the comparative advantage of some countries. These countries will be in a position to attract capital, as well as clean and sophisticated technology.

Despite previous opinion, that Serbia have a cheap labor, the latest researches show that in the environment we have a countries with cheaper workforce, but foreign investors in Serbia attract labor force flexibility, willingness to quickly learn, adaptability to the new business culture, but also motivation and loyalty [11].

Balkan countries should benefit from the reports, as the report of World Economic Forum. This type reports discuss what is poor in these countries and what should be done. What are the indicators of developed countries, those that are among the top 50 economies of the world, can show what should be targets, and benchmarking with the best and analysis of those who were in a similar situation but have advanced, could show what to do.

Polymetallic or complex Cu-Zn-Pb-Ag-Au sulphide concentrates can be treated by bioleaching combined with proper hydrometallurgical processes. Likely, thermophilic bacteria would be used aiming to get efficient copper bioleaching from chalcopyrite. Indirect bioleaching of Zn-Pb-Cu-Ag-Au sulphide concentrates is based on applying ferric leaching of the polymetallic concentrates by means of bio-regenerated ferric sulphate solution.

Indirect bioleaching is a biotechnology that presents important advantages when apply to bioprocessing of zinc and zinc polymetallic concentrates such as high metals recovery, fast kinetic of 4-5 hours to get full metals extraction, sulphur oxidation to elemental sulphur (avoiding sulphuric acid generation, while pyrite mineral remains untouched), and use of conventional reactors (aeration is not required) and normal process equipments.

On the other hand, the development of high-efficiency bioreactors for ferrous iron bio-oxidation based on flooded fixed-bed model has opened the way to succeed in the potential commercial application of this innovative bio-hydrometallurgical technology, being especially attractive to benefit zinc and lead bulk or polymetallic concentrates containing other valuable metals like copper, silver and gold.

In addition, a great variety of concentrates is feasible to be processed, e.g. in the range of 15% to 60% Zn and rest Cu-Pb-Ag-Au metals content, and concentrates in the range of 15% to 25% Cu and rest Zn-Pb-Ag-Au metals content. By biotechnology applied on polymetallic concentrates will be produced electrolytic copper and zinc plates via solvent extraction and electrowinning of bioleach solutions.

Biotechnology, Metal bearing sulfide minerals

1. Introduction

All mineral processing technologies have an effect on the environment. Therefore, the development of innovative, environmentally friendly technologies will be extremely important, and minimising waste generation and using wastes to produce useful by-products maintaining economic viability is a goal for the process, and biotechnology is one of the most promising solutions to deal with those mining problems compared to pyrometallurgical routes [1].

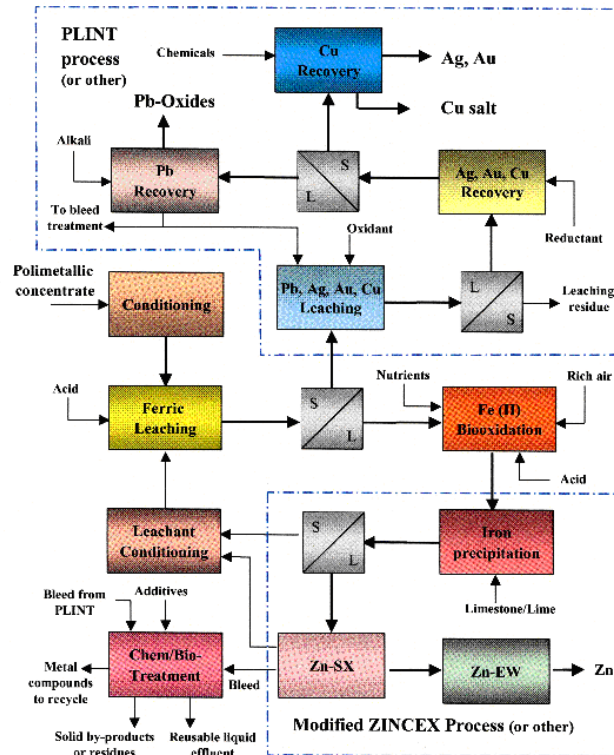

Figure 2 Indirect bioleaching of Zn-Pb-Cu-Ag-Au sulphide concentrates

4. Process Description

A descriptive diagram of the process can be seen in previous Figure 1. The indirect bioleaching processing route for Zn-Pb-Cu-Ag-Au concentrates, starts with a chemical leaching step where the zinc is extracted from the solid to the aqueous phase by means of the chemical oxidation process using ferric sulphate as main reaction. Major areas shown in the diagram are: Ferric leaching, Bio-oxidation, Iron precipitation, Iron redissolution, Solvent extraction and electrowinning (Modified Zincex™ process), PLINT process (lead, silver and gold recovery), Effluent treatment.

The process flowsheet for the indirect bioleaching of Zn/Pb concentrates that contain Cu-Ag-Au is shown in next Figure 3. As a conceptual block diagram it shows the main steps and streams for the zinc and lead recovery [2].

- Ferric Leaching
- Biooxidation and Iron precipitation
- Iron redissolution
- Zinc Solvent Extraction
- Zinc Electrowinning
- Effluent treatment
- Lead and silver recovery

4.1 Ferric Leaching

According to flowsheet for the indirect bioleaching of Zn-Pb-Cu-Ag-Au concentrate presented in Figure 3, the indirect bioleaching processing route for polymetallic bulk concentrates starts with a chemical leaching step.

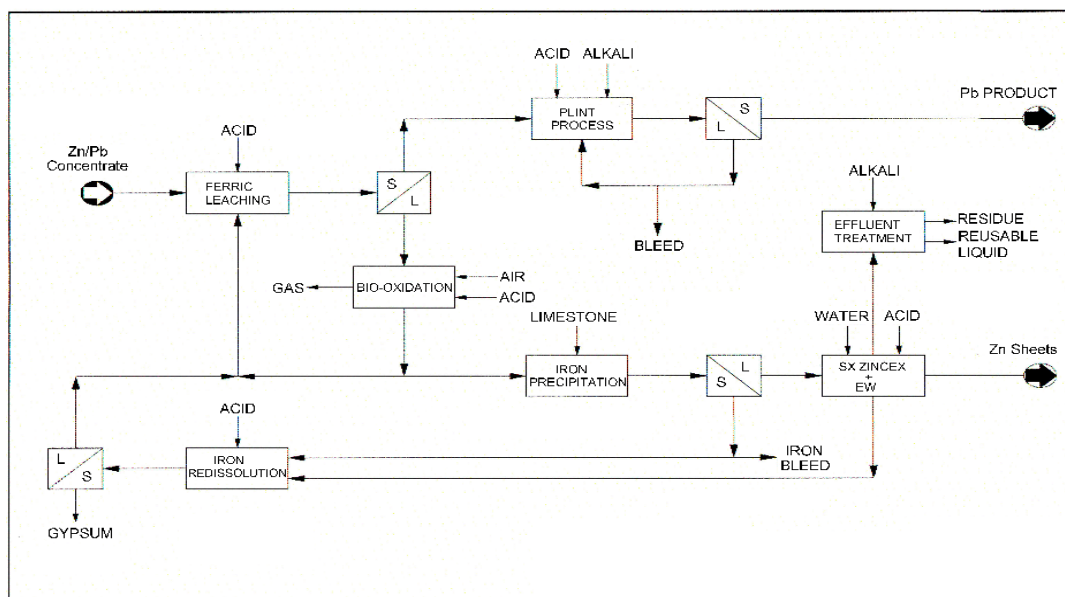

Figure 3 Indirect bioleaching block diagram.

Zinc is extracted from the solid to the aqueous phase by means of the chemical oxidation process using ferric sulphate according to the following main reaction.

Lead sulphide is transformed in lead sulphate remaining in the solid phase due to the low solubility of this compound in sulphate media.

Lead sulphide is transformed to lead sulfide according to chemical reaction:

Silver follows a similar pathway. Under conditions of high temperature, low acidity, and high ferric ion concentration, silver precipitated as insoluble silver jarosite ($\text{AgFe}_3(\text{SO}_4)_2(\text{OH})_6$) [3]:

The ferric leaching step is composed of stirred tank reactors arranged in cascade so that the pulp passes from one tank to the next by overflowing.

The feed is made up of a high density pulp of the Zn-Pb/Cu-Ag-Au concentrate and a part of the leaching residue. The feed flow is mixed at the leaching reactors at a ratio corresponding to 7-8 % solids with ferric solutions coming from the biooxidation and iron redissolution steps. Flow of ferric solution is set so as ratio of ferric ion to zinc and lead in the concentrate is in excess of 25 %.

The temperature is set at 90°C. The pH is regulated at 1.25 by adding H_2SO_4 .

4.2 Biooxidation and iron precipitation

The biooxidation step is composed of one stage in biooxidation pool arranged in parallel. Air is injected through a system of membrane disk diffusers installed in the bottom of the pools.

The clarified ferrous solution from the previous stage enters the bioreactors at a temperature of 30°C. The air flowrate to the bioreactors is $20 \text{ Nm}^3/\text{hm}^2$. Conversion efficiency of ferrous to ferric ion is high, Fe(II) concentration at the outlet is 0.5 g/l.

Biooxidation step is presented as chemical reaction:

The bio-solution which is not recycled back to ferric leaching, is sent to a precipitation step. Iron precipitation step is performed in reactors arranged in cascade.

Iron precipitation step is presented as chemical reaction:

Iron is precipitated by means of limestone addition at pH 4. Addition of a small amount of H_2O_2 is needed to assure all iron is ferric.

4.3 Iron redissolution

The iron precipitation step is composed of reactors arranged in cascade. Iron is redissolved by means of sulphuric acid addition at pH 1. Part of the acid needed comes from the acid aqueous raffinate produced at solvent extraction.

Iron redissolution is presented as chemical reaction:

Rest of acid needed to reach the pH setpoint is supplied as concentrated sulphuric acid.

4.4 Zinc Solvent Extraction

Solvent extraction Unit consists of the following stages:

- Extraction
- Washing
- Stripping
- Depletion
- Bleed neutralization
- Organic regeneration

At solvent extraction, through a series of extraction/stripping stages, a zinc sulphate purified solution is obtained using ZINCEX process technology (TR).

Extraction:

Stripping:

The extraction step is composed of conventional mixer-settlers. The pregnant liquid solution enters this stage with a determined zinc concentration. Then it is contacted with the organic solution (D2EHPA diluted in kerosene) coming from the depletion stage preloaded with zinc. As a result, the zinc is loaded in the organic while the aqueous phase exits as an acid raffinate.

Next, the organic phase enters the washing stage to avoid impurities to enter the next step, the stripping stage, where it is contacted with spent electrolyte from the electrowinning unit producing high quality electrolyte.

Finally the organic raffinate is sent to the depletion stage in order to recover the zinc content in the extraction aqueous raffinate.

4.5 Zinc Electrowinning

This purified Zn loaded solution is sent to the electrowinning step to obtain SHG Zn cathodes.

The zinc deposition on the cathodes is carried out with a current efficiency of 91 %. No significant side reactions (except from hydrogen evolution) are considered since experience shows that SHG zinc is obtained with the MODIFIED ZINCEX™ process.

4.6 Effluent treatment

In order to produce a final effluent free of metals it is necessary to implement a bleed treatment stage. No design parameters and flowsheet is given for this area since it is considered as conventional technology.

4.7 Lead and silver recovery

The leaching residue can be treated by means of different techniques to get efficient extraction of valuable metals, namely precious metals, lead and copper. The PLINT process is very flexible and adaptable to process conditions required by the feed materials. For instance, acidic conditions, oxidant addition, etc., can be used to attack jarosite matrix if convenient.

The process route of lead recovery from the leaching residue follows a first step where it is leached in a hot brine solution and a second one, a precipitation step where lead in solution is recovered in form of carbonate concentrate.

Chemical reactions involved in the leaching process of lead and silver are.

Finally, the silver and gold are recovered from solution using a proper reductant, e.g. lead powder, producing metallic cement that is purified to obtain silver/gold bullion for the market. Lead is precipitated with an alkali to produce pure lead oxides or carbonate concentrate ready to be commercialised and able to be processed at any primary or secondary lead smelter without generating any waste or slag.

5. Conclusions

To date, biohydrometallurgy has been industrially applied to recover copper and gold from ores and concentrates; while copper is recovered through heap bioleaching, gold is extracted using stirred bioreactors. Within *BioMinE* [4] project, an European consortium composed of industries and top experts in biohydrometallurgy have developed an innovative indirect bioleaching application dealing with zinc concentrates and zinc polymetallic concentrates; hopefully, the achieved successful results will open the way for bioprocessing of a wide variety of zinc and lead polymetallic or complex minerals deposits that are abundant and can be found in Europe and worldwide.

This study is supported by the Ministry of Science and technology of the Republic of Serbia (Grant N° TR-034004).

The Role and Importance of Investment Banking in the Financial Industry and Innovation

Ljupco Davcev¹

¹*Faculty of Economics, Goce Delchev University, Stip, Macedonia
ljupco.davcev@ugd.edu.mk*

Investment banking is among the important subjects in the agendas of politicians, financial regulators, manufacturers, local and global market participants and students. Great and enhanced expansion of this sector in terms of size and geographical coverage, undergoing changes, and impact on the structure of the economy and financial system in recent years are topics that are processed constantly. To understand this position in investment banking, you need to develop the main characteristics, basic functions and development of this industry, the factors responsible for the development of investment banking, as well as the relationship between the activity of investment banks and the activities of institutions part of this category of business. Major role in laying the foundations of the investment banking play the evolution of investment banking in major industrial countries, as well as the position and influence of investment banking in the broader context on the development of the financial industry as a whole.

Keywords

financial innovation, transformation, expansion, economic development, bank evolution

1. Introduction

Among the most specialized segments of the finance industry, with the basic function to bring together ultimate savers and saving collection institutions with those who wish to raise additional funds for investments, is the investment banking. Also, this type of banking helps the holders of accumulated wealth to reallocate their assets in accordance to the preferences using the combination of the risk, reward and liquidity attributes of financial assets. Taking in consideration these functions, we can observe the institutions involved in investment banking as financial intermediaries. So, there is a significant distinction between commercial banks and saving institutions that gather and decide themselves on the allocation of savings in comparison to the investment banks. The progression and development of the financial markets is directly connected with the development of the investment banking because the use of financial market is in the basis of the operations made by the institutions acting as investment banks.

Investment banker acts as an intermediary between corporations that need money and those who have assets such as pension funds or investment funds. Of course the investment banker charge fee from the corporation that sells securities, and this fee depend on the size of the offer, the risk of the company and the type of the security.

The role of investment banker is critical for the distribution of securities in developed economies. Investment banker emerges as a signatory or taker of the risk through purchase of the securities from a corporation which sells and their redistribution to the public. He can even continue to maintain market distributed securities long time after their distribution in the public.

As the corporations became bigger and global, they will have a need for bigger investment banks, which will provoke consolidation in the investment banking industry in developed economies. The biggest investment banks which can take the significantly bigger blocks of securities are dominating in the developed financial markets. That is why the development of investment banking is crucial for the development of the financial markets in the developing countries or countries that are on their way to become part of the developed countries. The investment bankers are important advisers of the corporation, advising the companies for strategic mergers and acquisitions, or even going out on the international financial markets.

2. Reasons and causes for the progress of investment banking

The progress of investment banking is in fundamental nature linked to the development of capital and allied financial markets on which its activities are centered. The expansion of capital and allied markets is, in turn, a manifestation of the interaction between underlying economic forces on the one hand, and the regulatory framework on the other. In addition, must be mentioned that the institutional and social factors that relate to the distribution and exercise of property rights in financial assets and the way that these affect the structure and changes in the character of industry. Basic economic forces affect and influence the evolution of investment banking in two ways. First, by increasing real per-capita income and they alter the nature of demand for financial services, causing ultimate savers and financial intermediaries to seek the most attractive mix of financial assets in terms of risk, reward and liquidity attributes in relation to their preferences and constantly changing evaluation of individual financial assets. This factor leads to a rise in demand for investment banking services, compared with services offered by commercial banks' activities. Furthermore, those wishing to obtain additional external funds for investment and/or consumption (deficit units) are able to select more easily the most methods and financial instruments they believe suitable for their needs. Secondly, fundamental economic forces directly and favorably affect investment banking services – all of which use and rely on financial markets (and above all capital markets) – by increasing their appeal. They achieve this by lowering relative costs and enhancing the attraction of investment. Both these influences are propelled by technological advances. Thus, in terms of cost and other attributes, economic forces improve the relative position of the demand for, and the supply of, investment banking services. The regulatory framework (depending on the bias it has) can either accelerate or decelerate this progress by altering the relative position of investment banking services at any particular time vis-à-vis commercial banking services, and by changing the relative attraction of the mix of attributes of financial instruments linked to the operation of capital and allied markets. The regulatory framework affects the development of investment banking through its impact on financial innovation. If it has an anti financial markets prejudice, especially anti capital markets bias, it will delay financial innovations designed to improve the efficiency and effectiveness of markets and investment banking services linked to them. If it has anti commercial bank prejudice, it will speed up and stimulate financial innovation, improving the competitive position of market transactions offered by investment banking, as compared with bilateral transactions between financial intermediaries counterparties. The anti-financial-market bias can assume the form of prohibiting the issue of some securities on capital markets, making them very complex and expensive and in effect raising the relative attraction of bank loans compared with capital market instruments, to providers and users of funds.

Apart from economic factors and the regulatory framework, the development of investment banking is affected by the distribution of property rights and the way that they are exercised. This is part of the issue of corporate governance. The transformation of first stage of capitalism-when owners of assets also manage them and there is no conflict of interest between them to management capitalism-when owners delegate the power to manage and decisions about the distribution of cash flow generated by the assets they control to financial capitalism- when the rights to manage assets and decide on the distribution of cash flow is delegated by owners to saving-collection financial institutions favors investment banking activities over traditional banking. It favors investment banking (and financial and especially capital markets) because the spread in ownership and delegation of the power to manage by owners places increasing importance on the ability to obtain, interpret and act on the basis of comparative information relating to the appeal and the combination of risk, reward and liquidity attributes of individual assets. This is only possible because of the expansion of financial and allied markets, which enables those who have powers delegated to them by owners of assets to initiate corrective action resulting from changes in the perception of the relative attractions of competing assets and opportunities as shown by basic capital markets indicators. Thus the move from direct to indirect ownership, and then the delegation of powers to financial intermediaries, favors a switch to instruments linked to financial markets, which are at the heart of investment banking and its development.

3. Investment banking in major countries

The differences in the present position of investment banking in major (and other) countries can be attributed to the different impact of, and consequently interaction between, economic, regulatory and social factors responsible for the evolution of investment banking and the financial system.

In the United States the development of investment banking has been significantly faster, more pervasive and widespread than in other countries. This has been so because the rise in per-capita income and wealth in the United States has been more rapid, the advance in technology specific to investment banking and finance has been faster and the regulatory framework has always had a marked anti-commercial-bank bias. Also the social and institutional factors have favored and still favor investment banking and capital and other financial markets by supporting and reinforcing the trend toward rising importance of collective savings, with their reliance on financial markets: in other words the spread of institutional (financial) capitalism through the popularity of mutual funds and above all the rapid growth of pension funds. The US regulatory framework has discriminated in favor of investment banking in the background of rising demand for external funds needed for industrialization until World War II (and reflecting the rapid growth first of utilities in the second half of the 19th century, and then of industry and commerce accompanied by a rise in the size of organizations), it constrained bank branching and limited the size of individual bank loans by linking them to bank capital. This increased the demand for external funds in the form of securities issued on capital markets at home and overseas, as well as the demand for investment banking services and the use of capital markets in the financial centers. The demand for investment banking services relating to the restructuring of the US economy in the successive waves of mergers and amalgamation that began in the last two decades of the 19th century has reinforced the momentum behind the growth of investment banking. The US Glass-Steagall Legislation and the Great Depression, while reducing the demand for underwriting, added to the demand for restricting. The post- World War II period was accompanied by the emergence of institutional investment, especially by pension funds, in addition to the continued expansion of underwriting and corporate restructuring. Alongside the capital markets, there emerged a market for corporate control, reinforcing investment banking's extraordinary ability to create new financial instruments- extended recently to those concerned with the pricing and trading of risk (ie, on the derivatives markets), which started gaining momentum from the mid-1970s.

In the United Kingdom the development of banking (as in the United States) has been propelled by a rapid rise in income and wealth, by a neutral regulatory framework and by positive changes in social and institutional factors. The emergence of capital markets in the 18th century and their rapid growth in the 19th century were the foundation for the expansion of investment banking, which until World War I was concerned predominantly with the raising of funds for foreign borrowers (who drew on the rapidly growing level of savings in Britain linked to the growth in income). In the period between the wars, demand for external funds also came from domestic industry and was accompanied by demand for industrial restructuring services. At that time, alongside closed-end investment funds, there emerged open-end investment funds. After World War II, there was increasing demand for underwriting and for industrial restructuring, which grew rapidly as the United Kingdom entered a period of de-industrialization. Accompanying this trend was explosive expansion of public and private pension funds and open-end investment funds.

The regulatory framework in the United Kingdom has been neutral. There are not, nor have there been, any formal or informal constraints on commercial banking activity or on underwriting and other investment banking activities. While after World War II there were some restrictions on commercial banks, these were accompanied by limitations on the use of capital markets. Thus the UK development can be said to reflect the impact of natural forces.

In Germany the main factor affecting the development of investment banking has been the anti-capital-market character of the regulatory framework, the very slow evolution of social and institutional arrangements and, until after World War II, a slower pace of economic growth than in the United States and the United Kingdom. The anti-capital market nature of the regulatory framework assumed the form of prohibiting the issue of certain types of securities and, prior to World War II and until recently, very complex authorization procedures and a heavy securities transfer tax on bonds and equities, as well as other restrictions. Linked to this is the very slow progress as regards the dispersion of wealth. The ownership of wealth is still heavily concentrated in family units, which until now have been unwilling to reduce their holdings and prefer to raise additional funds in the form of loans from banks with which they have worked in the past. Thus banks- although they are and have been universal and free to offer all types of services, including investment banking services – had until recently no incentive to extend their services to underwriting.

The proprietarily capitalism characterizing the German economy was accompanied until recently by pension arrangements that involved the use neither of financial or market intermediaries nor financial (and especially capital) markets, in that funds set aside by companies were used by them for investment. Although the German economy has experienced very rapid economic growth in the last 40 years, and its regulatory framework has been shifting from an anti- capital- market to a neutral stance, its social and institutional pension arrangement lag considerably behind those in the United States and

the United Kingdom. As a result, investment banking in Germany is still in the first (bank - oriented) phase of development and at the beginning of the second (where the open financial market become more important), while the United States and United Kingdom are both in the third, market oriented phase.

In Japan investment banking has specific features linked closely to the system of corporate governance, which is centred on industrial and financial groups. These groups are successors to similar groups that existed prior to World War II and were centered on family units. At the centre of these groups were banks with a controlling stake in other group members. The banks at the centre, together with other financial institutions, provided external funds to the members in the form of bank loans, and to a much smaller extent, loans raised through capital markets. Associated with and supporting this structure of corporate governance was, until recently, an anti- capital- market biased regulatory framework. This imposed demanding conditions on the issue of bonds, domestically and overseas, and also imposed, until recently, wealth taxes on transactions in equities. Until 1987 the issue of commercial paper was also banned. As a result, investment banking in Japan can be said to be in the early stage of development and moving ahead rather slowly.

4. The provision of investment banking services

While the growth in demand for investment banking services is determined by the interaction of economic, regulatory and social factors, the institutional structure of supply depends entirely on the regulatory framework and the capacity and willingness of individual financial units to supply services and products.

Without the legal separation of investment banking – or some or all of its three main components (ie, underwriting, restructuring and management of funds) – from commercial banking and other financial activities (such as life and non-life assurance), this activity tends to be in the hands of commercial banks, which either engage in it directly or set up special subsidiaries or affiliates. Thus in the United States until 1929 over half of underwriting and restructuring activity is estimated to have been in the hands of commercial banks operating through affiliates. It was only after the Glass- Steagall legislation that underwriting became concentrated in the hands of separate investment banks, now, though, it is beginning to drift into the hands of commercial banks. The United Kingdom is the only country where until recently there was a ‘voluntary’ separation between investment banking business and commercial banking, with the important proviso that ‘accepting houses’, which were responsible for the bulk of this business, also engaged in a highly specialized type of commercial banking linked to the acceptance business.

Thus as a broad generalization it can be said that investment banking tends to be offered by universal banks as a service to their clients or by specialized securities firms operating on a global, regional or domestic stage. The question of how best to offer investment banking, traditional banking and insurance services is a very important one, the answer to which is relevant to regulators and members or the industry alike.

5. The influence of investment banking on the financial system

In as much as investment banking enables the financial system to prefer some of its basic functions better and more efficiently, its evolution is one the important factors propelling the development of the financial system as a whole. The fundamental functions that the financial system must perform are: first, to run and manage the payment, clearance and settlement system; secondly, to provide liquidity; third, to transfer savings from surplus units to deficit units and to allocate these according to respective risk, reward and liquidity preferences; fourth, to monitor and discipline units using externally raised funds; and finally, to price, transfer and trade risk.

Investment banking can be said to stimulate the system’s pace of transformation in that it helps to move the system from the blank- oriented phase, where all five functions are performed by commercial banks by way of bilateral agreements, to the market- oriented phase, where markets pay an increasing in the performance of the last three functions, and then to the securitized phase, where markets and investment banking dominate the financial system. This path of progress is economically beneficial as it: reduces the resources employed to perform some of these basic functions; improves quality in that it improves the risk- evaluation, risk- sharing and risk- diversifying functions, substituting joint market judgement based on jointly shared information for bilateral judgment; and finally, by increasing scope, enhances the ability of an economy to carry more risk, to respond more rapidly to

changes and to take remedial action in relation to the performance of units using externally raised funds.

Seen from this perspective, investment banking and its involvement in 'marketisation' are propelling factors in the economic improvement and development of the financial system as a whole. Investment banking is thus one of the crucial elements in the expansion and extension of the division of labour associated with better and more comprehensive financial information collection, processing and communication, which is at the heart of economic progress.

6. Conclusion

Looking ahead, both economic and social and institutional factors are likely to continue extending their influence in favor of expanding investment banking, and changes in the financial system's regulatory framework will inevitably follow. The globalization of the world economy can be expected to lead to a rise in the relative importance in other countries of investment banking, and to the convergence of the financial system and regulatory approaches. The attention paid to, and the need to contain, systemic risk are likely to accelerate this trend, placing financial markets and investment banking even more firmly at the centre of finance and banking.

Most of the research on innovation in organizations has been conducted in Western countries and there is a lack of understanding of the innovative behaviour of firms operating in CEE. Therefore, the research objective of the present study is to examine the impact of entrepreneurs' values on innovative behaviour in a sample of 200 Bulgarian organizations. Our empirical results demonstrate that some work values of entrepreneurs and managers are significantly associated with the innovative behaviour of the organization. Further, the fit between organizational values and work values of employees is related significantly to innovative behaviour. Findings from the present study may benefit owners and managers in Bulgaria and may have practical implications for policy makers, consultants, educational institutions and training providers.

Keywords

Values, Innovative behaviour, Bulgaria

1. Introduction

Innovation in organizations is a contemporary topic, which has attracted increasing research attention due to rapidly changing business environment. Organizations must continuously introduce innovative products and processes in order to gain competitive advantage in the marketplace. It was acknowledged that innovation is context-specific and context-sensitive activity [1]. Transition economies in Central and Eastern Europe (CEE) have been going through profound economic, political, and institutional changes. Private firms have increasing role for innovation, employment, and gross domestic product in this region. Entrepreneurship in transition economies in CEE has attracted significant research attention, but the role of entrepreneurs' values for innovative behaviour is still largely neglected. Most of the research on innovation in organizations has been conducted in Western countries and there is a lack of understanding of the innovative behaviour of firms operating in CEE. It was acknowledged that organizational culture plays important role for innovation management [2]. Organizational culture influences the support and implementation of creative solutions [3]. Empirical studies reveal that values distinguish innovation-supportive culture [2]. Martins and Terblanche (2003)

suggest that shared values and beliefs of the members of organizations affect innovation in the following ways:

- Through the socialization process which allows individuals to learn acceptable behaviours and the forms of activities;
- The values and beliefs are enacted in established forms of activities and behaviours and are reflected in structures, policies, practices, and procedures, which influence directly creativity.

Therefore, the research objective of the present study is to examine the impact of the values of entrepreneurs and managers on innovative behaviour in a sample of 200 Bulgarian firms. Findings from the present study may benefit owners and managers in Bulgaria and may have practical implications for consultants, educational institutions and training providers.

2. Research Methodology

2.1 Sample

This study uses a sample of 200 entrepreneurs and managers responsible for innovation management in Bulgarian companies. The sample was extracted from a database with information about organizational culture in Bulgarian enterprises containing more than 1000 respondents. The information was gathered by the means of a structured questionnaire in 2009. The questionnaire includes questions about the characteristics and elements of organizational culture of the company, characteristics of the respondents, and characteristics of the company. Table 1 presents the characteristics of the sample.

Table 1 Characteristics of the sample.

	Number	%
Respondents' sex		
Male	106	53%
Female	94	47%
Respondents' age		
Less than 30	79	39,9%
Between 30 and 50	102	51%
More than 50	19	9,1%
Respondents' level of education		
University degree	187	93,5%
other	13	6,5%
Respondents' tenure (years)		
Less than 6	140	70%
Between 6 and 10	38	19%
More than 10	22	11%
Company's size		
Less than 101	132	66%
Between 101 and 500	30	15%
More than 500	38	19%
Sector		
Manufacturing	42	21%
Trade	44	22%
Services	114	57%
Location		
Sofia	161	80,5%
Other	39	19,5%

The sample contains roughly equally men and women. 47% of the respondents are women, while men represent 53% of the sample companies. Almost 40% of the respondents are less than 30 years old. More than half of the respondents are between 30 and 50 years old. The great majority of the respondents possess a university degree (93,5%). Most respondents (70%) have spent less than 6 years in the company, while only 11% of the respondents report tenure of more than 10 years. Almost 60% of the sample companies operate predominantly in the service sector, while about 21% of the sample companies are manufacturing businesses. Enterprises (SMEs) with less than 101 employees represent 66% of the sample firms, while enterprises with more than 500 are 19% of the sample. More than 80% of the studied companies are located in Sofia. The great majority of the sample firms (84%) are private enterprises, while the rest of the sample firms are either state-owned enterprises (6,5%) or enterprises with mixed ownership (9,5%). More than 43% of the sample firms have Bulgarian owners, while 34% are foreign ownership. About 22% of the sample companies report having foreign legal entities or individuals among owners.

2.2 Variables

The variable INNOVATIVE_BEHAVIOR describes the innovative behaviour of the sample companies. It is composed by 6 items measured on a 5-point Likert scale. The Cronbach's alpha of the scale is 0.613. In this study we asked respondents to rate the importance of the following 13 work values on a 5-point Likert scale (1- of utmost importance to me; 2 – very important; 3 – of moderate importance; 4 – of little importance; 5 – of very little or no importance): challenging work, desirable place, high earnings, cooperation, training / improving skills, social insurance, appreciation for work, working conditions, independence, security, advancement and promotion, skills / abilities, personal / free time. The empirical indicators for identifying the significance of the work values are the following (these indicators are based on [4]): HOW IMPORTANT IS IT TO YOU [4]:

- Have challenging work to do – work from which you can get a personal sense of accomplishments? (CHALLENGES);
- Live in an area desirable to you and your family? (PLACE);
- Have opportunity for high earnings? (EARNINGS);
- Work with people who cooperate with one other? (COOPERATION);
- Have training opportunities (to improve your skills or to learn new skills)? (TRAINING);
- Have good fringe benefits? (FRINGLE BENEFITS);
- Get the recognition you deserve when you do a good job? (RECOGNITION);
- Have good working conditions (good ventilation and lightening, adequate work space, etc.)? (WORK_CONDITIONS);
- Have considerable freedom to adopt your own approach to the job? (INDEPENDENCE);
- Have the security that you will to work for your company as you wants to? (SECURITY)
- Have an opportunity for advancement to higher level job? (ADVANCEMENT);
- Fully use your skills and abilities on the job? (SKILLS);
- Have a job which leaves you sufficient time for your personal or family life? (FREE TIME).

In order to assess the fit between organizational values and the values of employees (VALUE_FIT) we asked respondents if the organization hires employees whose values coincide with organizational values. The respondents had to give answers on a 5-point Likert scale (1= agree completely, 5= disagree completely). Chi-square test was used to determine whether the work values and the extent of value fit are systematically associated with innovative behaviour.

3. Empirical results

3.1 Description of respondents' values

Table 2 reports the mean of the importance ratings of the studied work values for the sample and the percentage of the respondents, which have rated the respective values of utmost importance. More than half of the respondents have rated the values challenges, earnings, and advancement as extremely important. About 45% of the respondents perceive cooperation, training, skills, and recognition as extremely important. Less than one third of the respondents have stated that fringe benefits, working conditions, independence, security, and free time are of utmost importance for them.

The analysis of the work values of entrepreneurs and managers included in our sample allows establishing a hierarchy of values based on the average values for the whole sample, which comprises 3 distinctive levels of value priorities. The factors of the highest importance are security, fringle benefits and free time (at this level of interpretation they are important for all studied respondents). The second level comprises a group of 6 work values: place, cooperation, recognition, training, independence, and skills. At the lowest level of the value pyramid are the factors advancement, earnings, and challenges. The presented hierarchy of values represents the status of the respondents and can be considered as an indicator of his/her unsatisfied needs (deficits). In one of the main explanation schemes, high levels of significance (of a certain factor of labor situation) can be considered as an indicator of a strong deficit of a certain "good". It was acknowledged that the perceived level of significance depends on the extent of problemising (have / haven't attitude toward...), the evaluation of the real situation with regard to the desired situation, the selected specimens for comparison, the stable and situational aspects of the attitudes toward the evaluated phenomenon, etc.

Table 2 Work values of respondents.

Values	Very important (%)	Average
CHALLENGES	59,5%	1,5
PLACE	40,5%	1,8
EARNINGS	51%	1,5
COOPERATION	44%	1,7
TRAINING	47%	1,7
FRINGLE BENEFITS	26%	2,0
RECOGNITION	45,5%	1,7
WORK_CONDITIONS	26%	2,0
INDEPENDENCE	31%	1,9
SECURITY	27,5%	2,1
ADVANCEMENT	56,5%	1,6
SKILLS	44,5%	1,7
FREE TIME	28%	2,1

2.2 Values and innovative behaviour

Table 3 presents the results of the chi-square analysis of the association between value fit, work values and innovativeness. Two work values (CHALLENGES and FRINGLE BENEFITS) are significantly associated with innovative behaviour. Not surprisingly, entrepreneurs and managers, who value highly work from which they can get a personal sense of accomplishments tend operate more innovative companies ($p < 0.01$). The presence of the work value CHALLENGES among entrepreneurs and/or managers may be related to exerting more effort to solve difficult and challenging problems and tasks and searching for creative solutions and novel approaches. As key decision-makers in the company, they may require similar behaviour from their subordinates. In turn, such behaviour exhibited by entrepreneurs and managers may lead to highly innovative behaviour of the company as a whole.

As was expected, the entrepreneurs and managers, who value highly fringle benefits are more likely to operate highly innovative organizations ($p < 0.05$). The provision of fringle benefits may be a significant stimulus for managers and entrepreneurs to be creative and proactive, to implement novel approaches and practices, to take risks, and to be flexible and adaptive in order to increase company's wealth and to secure fringle benefits for the future periods. Surprisingly, other work values examined in this paper do not have a statistically significant relationship with company's innovative behaviour.

Table 3 Values and innovative behaviour.

Value	Chi-Square Test
CHALLENGES	86,9***
PLACE	59,8
EARNINGS	34,2
COOPERATION	47,2
TRAINING	56,3
FRINGLE BENEFITS	106,8**
RECOGNITION	64,0
WORK_CONDITIONS	55,6
INDEPENDENCE	46,2
SECURITY	50,1
ADVANCEMENT	32,3
SKILLS	38,0
FREE TIME	69,8
VALUE_FIT	130,0***

* p < 0.1 ** p < 0.05 *** p < 0.01

The high degree of fit between work values of employees and organizational values exhibits a strong statistically significant association with company's innovative behaviour ($p < 0.01$). It seems that the high degree of fit between work values of employees and organizational values may be related to exerting more effort to accomplish companies' goals and plans by managers and employees. As values are an important determinant of individual and organizational behaviour, the presence of such fit may lead to a better convergence of the behaviours of employees, groups, and the organization as a whole.

3. Conclusions

The innovative behaviour in organizations operating in transition economies in Central and Eastern Europe has not been given sufficient attention in the literature. This paper attempts to create a better understanding of the role of work values of entrepreneurs and managers for innovative behaviour in a sample of 200 Bulgarian companies. Our empirical results reveal that some work values of entrepreneurs and managers are significantly associated with the innovative behaviour of their companies. These findings reinforce previous empirical findings from Western countries about the role of values for innovation in organizations. Interestingly, the high degree of fit between work values of employees and organizational values exhibits a strong statistically significant association with company's innovative behaviour, which may be due to a better convergence of the behaviours of employees, groups, and the organization as a whole.

Several limitations of our study should be noted. First, our sample is not representative and the findings should be interpreted with caution. Second, data was collected through a self-reported survey and thus may be subject to cognitive biases and errors. Third, a number of other individual, organizational, and environmental factors, which are not included in this study, may be related to innovative behaviour. Forth, our findings may be influenced by specific features of the Bulgarian cultural and institutional environment and therefore may not be applicable to other transition or mature economies. Finally, due to the cross-sectional design of the research we cannot deduce causal relationships.

In order to enhance the understanding of innovative behaviour in companies operating in a transition context, future research needs to examine the following aspects. First, future research should examine other factors posited by theoretical and empirical literature as affecting innovative behaviour, which are not included in this study. Second, the proposed relationships should be verified in a representative sample of Bulgarian enterprises. Third, future research should also examine to what extent the findings of this study can be generalized to other transitional countries. And finally, a longitudinal analysis should complement the findings in this research in order to confirm causal relationships.

Our findings about the role of work values and the fit between work values of employees and organizational values for innovative behaviour have important practical implications for entrepreneurs, managers, policy makers, consultants, recruitment and selection specialists, and training experts.

The Regional GDP Inter-relationships: Macedonian Regions

Branko Dimeski¹

¹ Faculty of Administration and Management Information Systems, St. Kliment Ohridski University, Bitola, Macedonia, branko_dim@yahoo.com

Approaching a higher standard of living and well-being of the regional population in Macedonia is a condition sine qua non for sustainable, equal and polycentric model of regional development.

There is a general agreement, that Macedonian regions are characterized with huge economic, social and cultural disparities. In order to eliminate those disparities, one needs to know what the causes and the relationships of the regional disparities are. Accordingly, the empirical research among the Macedonian regions has to be done in order to determine some possible causes for those disparities in order to eliminate those disparities in the future.

The goal of this paper is to search for some of the possible relationships and causes of the regional development disparities by testing the relationship between regional GDP as an independent variable and the regional entrepreneurship, regional scientific research, regional infrastructure and regional population as dependent variables. An appropriate statistics will be calculated in order to determine the possible relationships between the variables.

For the purpose of testing the relationships, the below theoretical model is constructed. In testing the relationships, will be used the administrative regional databases that are gathered and stored by the State Statistical Office of the Republic of Macedonia. The existence of the purely theoretical model below will be empirically tested in the Macedonian regions.

Keywords

Entrepreneurship, GDP per capita, Infrastructure, Macedonian regions, Research

1. Introduction

Balanced and sustainable economic development in the entire territory of the Republic of Macedonia is the main goal of the policy for the regional development which is characterized with high growth rate

and competitive regions with relatively low disparities among them, with effective utilization of natural, human and energy resources and with economic and social cohesion where the population enjoys good standard of living. Accordingly, the policy of balanced regional development is a very complex and lengthy process due to the fact that is multi-dimensional process with economic, demographic, spatial, cultural, social and many other development aspects. All these aspects require awareness and good understanding of the concept of regional development, very good coordination and full dedication of all the players in order to successfully coordinate the macroeconomic policy with regional and sectoral policies with a primary goal of reducing the disparities among the regions. Macedonia has already started several years ago to work intensively on development and implementation of the policy for the balanced regional development. [1]

The basis characteristics of the 8th regions indicate that they all have relatively equal natural resources potential, equal cultural and historical heritage. However there are still disparities in the level of the economic development among them. According to the decision of the Government of the Republic of Macedonia [2], on the Classification ranking of the planning regions based on their economic development, the most developed region is Skopje region, while the least developed is the North East region. The parameters that are used for this classification are the development index, economic-social index and demographic index. To estimate the socio-economic index the following parameters are used: gross domestic product per capita, budget revenues per capita and the growth of the added value of the non-financial sector. The development index is an average of the socio-economic and demographic index.

As a result, the three indexes are crucial in calculating the overall aggregate regional economic development index of the region. Furthermore, the variables that are involved or are in any relationship with the GDP per capita budget revenues or the growth of the non-financial sector are far more important in calculating the overall regional economic development index.

However, the goal of this paper is not describing and analyzing the regional disparities in the Republic of Macedonia. According the available data, there is no doubt that they exist. Instead, in this paper, will be test the role of regional entrepreneurship, regional population, regional infrastructure and regional research in maintaining sustainable regional development measured and expressed by the regional GDP per capita among the 8th planning regions in the Republic of Macedonia. In examining the possible relationships between the regional GDP (gross domestic product) per capita and regional entrepreneurship, regional population, regional scientific research and regional infrastructure, will be utilized the existing administrative data on regions that is collected, stored and provided by the State Statistical Office of the Republic of Macedonia. According the available data, the appropriate statistical tools and calculations will be applied.

What follows is a theoretical and empirical conceptualization about the five variables that are subject of analysis in this paper. The results and conclusions of the research can serve as a recommendation to all relevant institutions in the country that are dealing with the issue of regional development and for future same or similar research that can be done in the field of regional economic development, entrepreneurship, research and innovation.

2. Theoretical approach: Data and Model

2.1 Regional GDP

The economic development of a region is, as a rule, expressed in terms of its gross domestic product (GDP). This indicator is also frequently used as a basis for comparisons between regions. GDP measures the economic output achieved within national or regional boundaries, regardless of whether this was attributable to resident or non-resident employed persons. Thus the use of GDP per inhabitant is only straightforward if all employed persons involved in generating GDP are also residents of the region in question. Accordingly, the GDP value of the region will be deflated with the number of regional population residents. [3]

Taking all the above in consideration we will use the denar value of regional GDP per capita for the Macedonian regions. The data is provided in below Table 1 by the Macedonian State Statistical Office. [4]

Table 1 Regional GDP per capita (in denars)

Region	Year/Total								
	00	01	02	03	04	05	06	07	08
Vardar	104226	114900	118014	128477	128453	137830	170187	184937	196028
East	89423	80494	83871	87518	92505	100654	115672	134114	173815
SouthW.	93072	86462	93420	82897	90475	93484	106970	115083	150771
SouthE.	99128	95993	100269	109073	115327	132375	141360	162758	168211
Pelagonia	131898	135129	150913	155602	148740	146867	154671	174589	208990
Polog	57701	51563	55029	62851	61616	67796	76968	84913	95277
NorthE.	75580	61948	65105	68765	66679	69789	82837	92566	122014
Skopje	180300	183497	188570	190383	210413	231053	254010	294884	314531

As it can be noticed from the Table 1, does not exist data for 2009 and 2010. That will diminish our research taking into consideration the fact that the State Statistical Office does not yet provide data for some years about the regional entrepreneurship, regional infrastructure, regional population and regional scientific research. In other words, like any other research, we are forced to make analysis and calculations on the available official data that exists at the moment.

2.2 Regional Entrepreneurship

The regional entrepreneurship in the Macedonian regions is best represented by the total number of micro, small and medium-sized enterprises. [5] They represent the entrepreneurial sector of the economy and are best indicator of the entrepreneurial activity in the respected region/s. In testing the relationships, will be used the data that is generated as a total sum of micro, small and medium-size enterprises for each region. The sum of each region will represent the total scope of the entrepreneurial activity for the respected region. The aggregated numerical data will serve as a measurement of the variable named *Regional entrepreneurship*.

As the below Table 2 shows, the data is not provided for 2007 and years before 2007 by the State Statistical Office. [4]

Table 2 Companies according the number of employees

Region	Year					
	2008			2009		
	1-9	10-49	50-249	1-9	10-49	50-249
Vardar	3991	229	89	4695	237	95

2.3 Regional Population

Table 3 below provides data about the regional active population, employment and unemployment rate among the active population. Because the regional GDP represents the regional output of all products and services produced annually by the employed active population, the data of employed active population out of the active population rate will be used as empirical measure of the contribution of the population to the regional economy expressed by the deflated value of GDP considering the active population rate. Accordingly, the population employment rate will be used as an empirical expression of the variable named *Regional population employment*.

As with other data, the data for regional employment rate by the State Statistical Office is available just for 2007 and 2008. [4]

Table 3 Employment, Unemployment and Active population rate

Region	Year					
	2007			2008		
	Active population	Emp	Unemp.	Active population	Emp.	Unemp.
Vardar	54.4	30.5	43.9	57.9	32.7	43.6

Skopje	52.9	34.5	34.7	58.31	33.3	37.3

2.4 Regional Infrastructure

The regional infrastructure is represented by the total length of local and regional roads in the region. Accordingly, the empirical value of the variable named *Regional infrastructure* will be represented by the total length of transport infrastructure in the region.

Table 4 below represents the total length of regional infrastructure in km. [4] The total length of regional infrastructure is the measure of the scope of regional public investments and represents the business attractiveness of the locality present and future investments in the region.

Table 4 Total Length of Regional Infrastructure (in km)

	2006	2007	2008	2009
Vardar	1088	1120	1088	1089
East	1245	1183	1183	1183
SouthW.	1301	1303	1358	1247
SouthE.	902	910	920	919
Pelagonia	1165	1173	1180	1147
Polog	1193	1261	1303	1448
NorthE.	909	900	880	951
Skopje	1192	1305	1328	1274

2.5 Regional Scientific Research

Finally, the research institutes and centres (within universities, non-governmental organizations, or foreign research institutions etc.) are very important factor for regional development. The Table 5 provides the data for the number of researchers on regional level for the 8 regions in Macedonia. [4] The number of researchers will be used as empirical data set for the variable named *Regional scientific research*. As other data, the State Statistical Office only provides data about the number of researchers for 2006 and 2007. Also, it can be noticed that for Vardar, Polog and NorthEast region for 2006 the data is not available. Thus the research will be oriented in analyzing 5 instead of 8 units of analysis for 2006.

Table 5 Total number of employed/enrolled scientists/researchers

Region	Year	
	2006	2007

2.6 Theoretical Modelling: Regional GDP Interrelationships in Macedonian Regions

As a result of the previous analysis, the below Figure 1 is depicting the possible theoretically defined interrelationships between the regional GDP per capita, on one hand, and regional entrepreneurship, regional scientific research, regional population and regional infrastructure on the other hand. In the following section the model will be empirically tested by using the previous described official available data provided by the State Statistical Office of the Republic of Macedonia.

Figure 1 The Regional GDP interrelationships

3. Empirical approach: Testing the Model

In order to test the above theoretically assumed hypothetical relationships, the numerical data series were entered in SPSS (Social Package Statistical Software) for each of the variables. The alternative statistics, such as the Pearson correlation coefficient (r) and statistical significance (α) was calculated for each assumed relationship, considering the limits of the available data. Because of data constraints, the regression analysis can not be calculated at this point because there is no data for all the variables involved at least for the last 10 years. As a result, the research has faced an objective limitation in order to be fully completed with calculating the regression coefficient and R-adjusted. The correlation results are displayed in Table 6 below.

Table 6 Pearson Correlation and Statistical Significance (2-tailed) test

	Regional Population Employment (2008)	Regional Infrastructure (2008)	Regional Entrepreneurship (2008)	Regional Scientific Research (2007)
Regional GDP per capita (2008)	Correlation= .076 Sig.= .859 N= 8	Correlation= .274 Sig.= .512 N= 8	Correlation= .841** Sig.= .009 N= 8	Not available data
Regional GDP per capita (2007)	Correlation= .195 Sig.= .644 N= 8	Correlation= .269 Sig.= .520 N= 8	Not available data	Correlation= .846** Sig.= .008 N= 8
Regional GDP per capita (2006)	Not available data	Correlation= .103 Sig.= .808 N= 8	Not available data	Correlation= .834** Sig.= .010 N= 5

***. Correlation is significant at the 0.01 level (2-tailed).*

As we can see from the Table 6, the regional GDP for 2008 is positively correlated with the regional entrepreneurship ($r = .841$) for 2008 and regional scientific research for 2007 and 2006 ($r = .846$ and $r = .834^{**}$ respectively). The correlation is statistically significant ($\text{Sig.} = .009$) and ($\text{Sig.} = .008$; $\text{Sig.} = .010$) respectively. In other words, $p \leq 0.01$ significance level or $p \leq t\text{-test}$. [6] The Pearson correlation coefficient states that there exists a strong correlation between regional GDP per capita, regional entrepreneurship for 2008 and regional scientific research for 2007 and 2006.

On the other hand, between the regional GDP and the regional infrastructure ($r = .274$; $r = .269$; $r = .103$) and regional population employment ($r = .076$; $r = .195$) respectively, there is no correlation. The correlation is not statistically significant ($\text{Sig.} = .512$; $\text{Sig.} = .520$; $\text{Sig.} = .808$) and ($\text{Sig.} = .859$; $\text{Sig.} = .644$) respectively. In other words, $p \geq 0.01$ significance level or $p \geq t\text{-test}$ of statistical significance of 0.01 which states that there is 1% confidence that or with 99% confidence level can be said that the relationship between the GDP per capita and regional entrepreneurship and regional scientific research is not occurring by incidence.

In other words: *Between the regional GDP per capita, on one hand, and regional entrepreneurship and regional scientific research, on other hand in the Republic of Macedonia there is a positive and strong relationship. That means that the higher the scope of the entrepreneurial activity in the region, the greater the value of regional GDP per capita and vice versa. In addition, the higher the number of researchers in the region, the greater the value of regional GDP per capita and vice versa.*

4. Conclusions

According the available data on regions in the Republic of Macedonia, the empirical research on Macedonian regions revealed that there is no relationship between the regional GDP and regional infrastructure and regional population employment. Without entering in a further discussion about the reasons for non-existing relationships, the results in this paper argue that all relevant institutions in the Republic of Macedonia that are dealing the issue of regional development and regional disparities must consider the role of entrepreneurial activity and research. By stimulating and even financing the entrepreneurial activity and scientific research, the Government of the Republic of Macedonia can successfully cope with the problem of Macedonian regional disparities in those regions that are less developed or are below the national development level. The higher entrepreneurial activity will alleviate the internal and external regional migrations by exploring the local resources and the new business ideas can open the doors for local businesses and new industrial bases. The scientific research is of extreme help for developing a direction in which way the entrepreneurial activities must go. In other words, entrepreneurship and scientific research go together, and can stimulate powerful innovation ideas for regional infrastructure development and regional employment growth. Without

regional research there are no innovation ideas and rich entrepreneurship activities in the region. As a result of the empirical test, the regional GDP interrelationships in the Macedonian regions gave the below empirically proven model that is displayed in Figure 2.

Figure 2 Empirical model of the Regional GDP interrelationships in Macedonian regions

Collaborative production systems design through USIT method

Svetoslav Dimkow¹

¹Technical University of Sofia, Business Faculty, E-mail: sdim@tu-sofia.bg

The Bulgarian industry is strongly focused on the EU markets. One of the most promising directions for development of the Bulgarian industrial enterprises is the development of business partnerships with industrial enterprises from the European Union. Most problematic for the development of such partnerships are the unsuitable characteristics of the production systems in the Bulgarian industrial enterprises. The present work suggests a process for development of the production systems characteristics, based on a Unified Structured Inventive Thinking method (USIT). The main characteristics which should be possessed by the production systems of the contemporary industrial enterprises are described. There is a description of the stages of the suggested process for elaboration of the production systems characteristics.

Keywords

Production systems, small and medium enterprises, Inventive thinking, cellular manufacturing systems

1. Introduction

Manufacturing industries are under the economic pressure to compensate increasing cost and create added value. Under these conditions it is necessary to change the paradigms from former cost orientation to competition, added value and sustainability. Manufacturing is the key area which has the potential for change. But it is not only a question of research and engineering, it is even a question of business systems and activation of the human resources to implement innovation as fast as possible to change the practice from cost and profit optimization to competition, innovation and sustainability.

A revolutionary change from tayloristic to sustainable manufacturing is required to solve the coming problems in the industrial world: sustainability of enterprises and business; sustainable technologies in products and processes; global environmental and social standards of work.

2. Challenges for the Manufacturing Enterprise to Achieve Sustainable Development

Manufacturing enterprises are striving to achieve sustainability through changes in products, processes, and systems. Refocused efforts on the development of sustainable technologies can further aid continuous improvement and stimulate revolutionary advancements industry-wide. Current and future challenges facing the manufacturing industry are addressed in terms of manufacturing enterprise, product life-cycle design, and manufacturing processes and systems.

Small and medium enterprises as subcontractors. Small and medium-sized manufacturing companies (SMME) play a significant role in today's economy [1]. 99 % of the companies are SMMEs [2]. Many SMMEs are subcontractors to larger companies [3] and are therefore highly dependent on them. Historically, a subcontractor works for a limited number of larger customers [4]. Competitive advantages have been low price and whether the subcontractor is located near the customer [4]. This is however changing and more and more SMMEs are aware of this challenge and try to increase their customer base.

The challenges for the SMMEs have increased [4] during the last years. The challenges come from the increasing globalization and the increasing customer demands. The globalization increases the access to new technologies, to new knowledge, and to new markets, but the competition also becomes more severe.

Supporting Function of Lean Production Systems in Small and Medium Enterprises. Small and Medium-sized Enterprises are facing the hard competition of global markets and the more specific and higher requirements of the customers everyday. In order to cope with these challenges many enterprises implement a lean production system. For the implementation of a lean production system a continuous support of a well-structured qualification background is necessary.

Lean production systems do not only help to reduce waste in the production process but also allow the enterprise to focus on customer value [5], [6], [7].

3. Engineering Design Theories of creativity

Theories of engineering creativity draw on theories of creativity in general. However, limiting the focus to engineering domains enabled researchers in engineering creativity to present their theories in less abstract, more concrete terms.

Creative Design as Case Based Reasoning. The process of engineering design draws to a large extent on the retrieval of past designs or design principles which are then adapted to current requirements. Past designs can be stored in two different granularity levels, both of which can potentially give rise to creative designs: pieces of elaborate design solutions at a low granularity level, and first principles at a high granularity level.

Creative Design as Increasing Dimensionality. Cagan and Agogino [8] express a concept of creative design that is similar in view of the creative process in general: "Non-routine Design differ from routine designs in that the latter are derived from a fixed space while the former are characterized by an expanded design space". Based on their definition of non-routine design, Cagan and Agogino suggest a computation mechanism that uses optimization information to make decisions on how to manipulate and expand the design space by introducing new variables, thus increasing its dimensionality.

Creative Design as Overcoming Contradictions. According to Altshuller, a design is creative when it resolves a conflict but not through tradeoff or compromise [9]. Altshuller generalized his theory by observing a large number of engineering inventions and juxtaposing them with ordinary or routine solutions suggested for the same problem.

Creative Design as Function Sharing. Function sharing in mechanical design, according to Ulrich [10], is the simultaneous implementation of several functions in an artifact, by a single structural element. Ulrich states three main reasons for the importance of function sharing in engineering design: first, designs that exhibit function sharing are in most respects better than those that do not (fewer parts, easier assembly, less required maintenance, better performance due to decreased size and weight etc.); second, awareness of the process of function sharing allows the designer to think in a modular, decomposed fashion with the option of subsequently using function sharing to make the design more efficient; third, function sharing is one of the sources of novelty or interest in mechanical design.

4. Methods for Supporting the Creative Process

Four of the most popular, creativity enhancements methods are used currently by corporations. The methods differ in their underlying principles, reflecting the various theoretical approaches for the creative process presented in the former sections.

TRIZ. TRIZ a Russian acronym for Theory of Inventive Problem Solving (or *TIPS* in English) was developed by Altshuller [9] and is continually being developed and modified. TRIZ is composed of a few distinct problem-solving and problem-definition procedures and principles as well as a unifying algorithm called ARIZ.

Brain Storming. Brain Storming [11] is perhaps the most popular and most widely used creativity enhancement method. It is a group method that divides the thinking process into two main phases: idea generation, and idea evaluation. The strict rules of brain storming prohibit any sort of evaluation within the idea generation phase. In this stage, 'crazy' ideas are most welcome; producing as many ideas as possible is encouraged.

Synectics. Synectics means joining together of different and apparently unrelated elements. According to Gordon, who developed Synectics [12], problem-solvers often fail to discover a creative solution because the problem may be either too familiar or strange. Synectics uses analogies and metaphors as a means to turn the familiar into strange and the strange into familiar. Synectics, like Brain Storming, encourages suspension of judgment, and also 'play with apparent irrelevancies' during what is called the *excursion* stage. In the excursion stage, different analogies are used to view the problems from different directions and to direct the thoughts toward a creative solution.

Morphological Analysis. Morphological analysis [13] is used mainly to invent new products rather than solve problems. Using this method, the inventor first constructs a list of the properties of an existing product and the possible set of discrete values the property can assume.

5. Overall structure and overall procedure of unified structured inventive thinking method (USIT)

Basics of Unified Structured Inventive Thinking (USIT). USIT was developed by Ed Sickafus [14] in 1995 and intensively used at Ford Motor Co. At first he adopted Israeli SIT (Systematic Inventive Thinking) [15], which was a much simplified version of TRIZ, and then he introduced a new framework and built USIT. Nakagawa have introduced USIT in Japan since 1999 [16] and have extended it further by reorganizing TRIZ methods of solution generation into the USIT framework [17].

Overview of USIT. The goals and characteristic features of USIT may be summarized as follows[18]:

- USIT is a methodology concentrating in the "Concept Generation Stage", which is at the uppermost in the course of product/technology development.
- USIT intends to be applied to real practical problems for rapidly generating multiple conceptual solutions.
- USIT provides a clearly defined simple procedure for applying the methodology. The procedure is composed of three stages, i.e. Problem Definition, Problem Analysis, and Solution Generation.
- The technological system of the problem is described in clearly-defined terms of Objects, Attributes, and Functions.
- Elements of techniques in USIT are simple and well explained in guidelines. Especially, there are only four techniques used for the solution generation, and they are used in correspondence to the concepts of Objects, Attributes, and Functions.
- No outside knowledge bases and software tools are used in USIT.
- Engineering details, such as specifications, figures, numbers, costs, deadlines, etc., are put aside the consideration during the USIT procedure. This choice aims to make the concept generation as freely and widely as possible.

Overall Procedure in USIT. The Overall Structure of creative problem solving is realized in USIT by the use of Overall Procedure as shown in a Flowchart in Fig. 1.

Problem Definition Stage: The process for converting user's specific problem into Well-defined specific problem. This process is usually carried out through a group discussion in the USIT project team.

Problem Analysis Stage: In order to obtain the understanding of the present and ideal systems in the Well-defined specific problem, the following three analysis methods are carried out in sequence:

- **Function and Attribute Analysis of the Present System:** The present system in the problem is analyzed with the following two methods in sequence: Functional Analysis; Attribute Analysis.
- **Space and Time Characteristics Analysis:** Draw some diagrams for revealing characteristic features of the system/problem with respect to space and to time.
- **Particles Method:** A process for identifying Ideal Solution and imagining desirable actions and desirable properties is carried out in the following sequence: Sketch the present system; Sketch an Ideal System; Imagine an ideal result and draw it, without trying to draw any means to achieve the result; Draw 'Particles' with x marks; Draw x marks at the positions where the sketch of the Ideal System differs from that of the present system; Imagine Desirable Actions and draw them in a hierarchical diagram; Ask the magical Particles to achieve the goal of the ideal solution, and then break down the actions that the Particles are imagined to be doing for us; List up desirable properties

Solution Generation Stage: Process of generating many pieces of new ideas and then building up conceptual solutions for new system(s). Five solution generation methods in the form of USIT Operators are applied repeatedly without any fixed order: Pluralization of Objects; Dimensional Change in Attributes; Distribution of Functions; Combination of Solution Pairs; Generalization of Solutions.

These five USIT Operators are always applicable to the elements of the present and solution systems expressed in terms of Objects-Attributes-Functions, and to the known and newly-generated solutions.

Implementation Stage: Conceptual solutions are to be evaluated, experimented, prototyped, designed, manufactured, installed, tested, etc. so as to make them real into successful specific solutions for users. This stage needs technical and business capabilities and decisions, and hence is out of the range of USIT as a creative problem solving methodology.

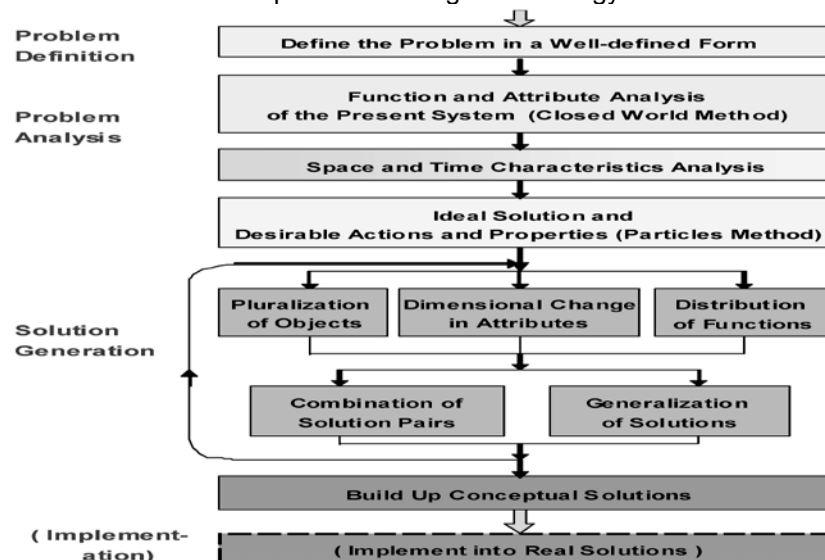

Figure 1 Overall Procedure in USIT

6. Case Study

This is a case study report of solving an everyday problem. Simplified and unified process USIT have been used in this study in a rather informal manner.

The present problem is related to the design of manufacturing system capable of supporting business partnership of SME in furniture industry.

For the solution of the problem, the author has led multiple discussions on the causes of the problem and on possible solution ideas with managers of Bulgarian enterprises from the furniture industry. The results of these discussions are documented in reports which were used as a basis for development of the requirements for the production systems in the furniture enterprises. Afterwards, the author has worked further to build up the conceptual solution. The whole process of analyzing the problem, generating ideas, and constructing a solution was described in the report of a pilot scientific-research project. The present paper is based on this report.

6.1 Setting the problem

Start of the work. A producer of furniture gets an offer for business partnership by a partner in Italy. The Italian partner possesses designer developments of furniture for dining rooms and bed rooms.

The conditions for the business partnership are very favorable but the industrial enterprise in Bulgaria has some doubts that its manufacturing system is not flexible and adaptive enough in order to produce the requested quantity of furniture within the deadlines required by the Italian partner. Concerned is a great variety of products, produced in small quantities of only several items.

Confirming the focus of the problem. The production system of the Bulgarian enterprise is equipped with contemporary computer controlled machines (CNC). These machines create at the Bulgarian market product portfolio similar in complexity and scope to the one in the Italian partner order.

The machine operators and the people responsible for the furniture assembling are qualified enough. However, a shortage of staff could be felt and therefore most of the operators have two or three working places. This is also the reason for the recent delays with clients' orders.

Another serious disadvantage is the relatively high amount of work in progress. The reason is the production organization as well as the bottle neck in the production system planned for the cutting machine.

Due to some organization problems, the rhythm of the production process is not satisfactory and overtime work is needed during the weekends.

This approach to the production organization has two negative consequences: considerable labor costs and unforeseen quality of the manufactured products.

Because of the insufficient skills of the technologist, production organizer and dispatcher the functionality of the production equipment is not fully exploited and the efficiency of some working centers (machines) is inadmissibly low.

Relatively high is the level of technological waste which is mostly due to technological problems.

A number of efforts have been put to elaborate the production system but up to the moment they are futile because of the excessive workload of the staff.

Important problems of the production system are the multiple motions of details and furniture units between the working centers during the manufacturing of the products. The reason is the close fitting area of job shop and the irrational location of the equipment.

Problem definition. USIT (Unified Structured Inventive Thinking) has been used as the main process for problem solving. The discussions at the initial stage may be summarized in the style of Problem Definition in USIT:

- **Unwanted effect.** In case of business partnership with the Italian party there is a risk of delay with the implementation of the orders and unstable quality of the manufactured products.
- **Task/goal.** To reconfigure the existing production system of the enterprise in order to increase its flexibility and consequently, to evade delays of the orders and instability in the products' quality.
- **Sketch of the problem situation.** The problem situation is displayed on fig.2.
- **Plausible root causes.** Inappropriate arrangement of work centers, incomplete and ineffective usage of the equipment, inappropriate system for shop floor control are the main reasons for the insufficient flexibility and adaptability of the production system. This, on its side, generates risk of undue implementation of the orders and unstable quality of the manufactured products. (e)
- **Minimum set of relevant objects.** Product portfolio; structure of business processes; manufacturing system; production planning and control system.

6.2 Analysis of the problem

In the stage of problem analysis, have been used various methods in a flexible way. The analysis processes are described in a logical way as follows:

Space and time characteristics analysis. A furniture manufacturer produces economical living room and bedroom furniture. Products include night tables, dressers, chests, entertainment units, headboards, wardrobes, wall units and a number of other products made of particle board, solid pine or oak. Approximately 112 unique products, considering color and style, are manufactured.

The production system is situated in one working premise on an area of around 630 m² and the system is composed of 14 work centers.

The five main operations for manufacturing the products include cutting, edge banding, drilling, pre-assembly and assembly. Typically, the required components for the parts are processed over two days.

Current methods for product manufacturing. The characteristics of the existing situation include a re-configurable building and a production system with straight line flow and layout designed for high volume production, components produced to intermediate stock, lower product delivery lead time due to an assemble-to-order production technique, doweled products which contribute to lower flow time, and simpler material handling with clearly de-marked work-in-process buffers at each section and at the machines.

Throughput satisfies the functional requirement for orders' deadlines and defines the process capacity of each operational section. The process capability and capacity at each of the five operational sections matches the total required throughput of the system.

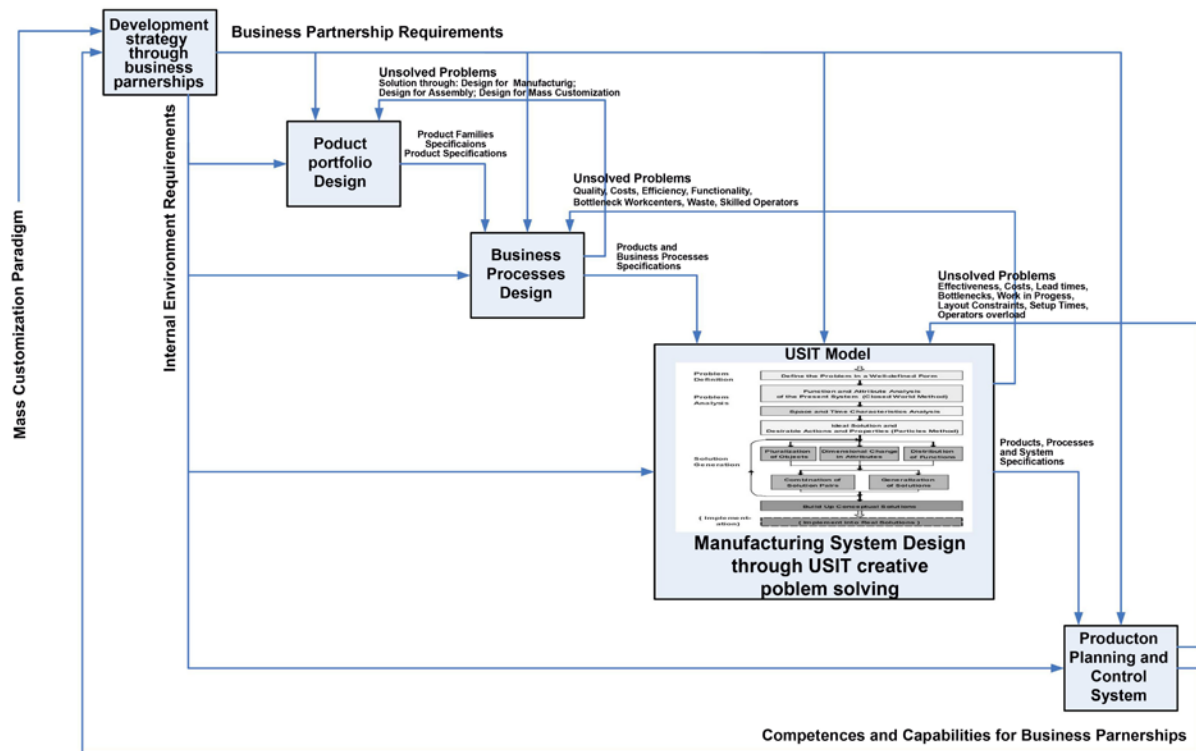

Figure 2 Problem situation

Understanding the overall structure of the problem. Throughout these analyses from multiple points of view, were memorized various facts, observations, views, solution ideas, etc. For the purpose of understanding the overall structure of the problem, first was applied the grouping technique.

On the basis of thorough literature research as well as the personal experience of the author, was reached the conclusion that for the solution of the problem should be created a new production system which corresponds to the requirement of providing customized production.

In order to come up to this requirement, the current production system should be substituted with cellular manufacturing system, possessing complicated structure of requirements. These requirements should be arranged in four main groups.

Understanding the essence of the problem. Summarizing the whole analysis, the essence of the problem can be described as follows: First and foremost, should be defined the functional requirements of the system at the highest level of its hierarchy in the functional domain.

At this stage many functional requirements should be established. Each functional requirement established at this stage should lead to a completely different manufacturing design. Therefore, close attention should be given to all functional requirements before a single functional requirement is adopted at this highest level. In this work the following has been selected as the highest functional requirement - Providing customized production.

The following lower functional requirements set is defined for decomposing the functional requirement of providing customized production, determined above.

- To classify and group products/parts and machines for simple material flow
- To develop resources capability based on product specifications
- To rearrange resources to minimize waste
- To provide production based on customer demand.

Classification and grouping products/parts and machines. This is a very important step for the success of transition from traditional manufacturing to cellular manufacturing.

The first step in this branch is to establish the high volume products through Product-Quantity (Pareto) analysis..

Resources capabilities development. In this stage, activities including waste elimination, for the design of a lean process, rearrangement of resources in agreement with the takt time, fixing training needs and motivation of the workforce are accomplished.

Resource rearrangements. At this stage lean manufacturing principles are the guiding principles of the design step. In this step, the focus is the waste elimination. Therefore, in rearranging the resources waste due to motion, material handling and imbalances between resources is minimized.

Production control. Satisfying customers by right amount and just-in-time production can only be accomplished through pull system. However, just-in-time systems require a steady pull on all products in the family. In order to ensure a steady pull, a leveled/mixed production schedule must be established.

6.3 Generating ideas and constructing solution concepts

As a next step, these ideas were examined more closely the range of solution ideas was expanded. During this stage were made efforts to figure out ideas so as to expand the current state of technology and to think of new approaches in relation to psychology and social behavior.

Design parameters, which satisfy the functional requirements, established in the previous step, were selected on the basis of the author's conclusions reached as a consequence of discussions with managers of furniture enterprises.

In order to make the correct design parameter selection, a design parameter set corresponding to the functional requirements set established before, must be exhaustively generated. The design parameter "Cellular manufacturing system design (CMS)" has been selected to satisfy the main functional requirements provided above – "Provide customized production".

The production system, which can answer customer's needs in an efficient way through elimination of waste, reduction of lead time and improved quality is a CMS designed with lean manufacturing principles in mind.

In satisfying the four functional requirements stemming from the main functional requirements provided above – "Provide customized production", the following design parameters are in response: Development of Procedure for defining product/part families and machine groups; development of Procedure for working out production resources capability; Design of Product oriented layout; Design of Pull production control system.

Solution ideas to the problem of Classification and grouping products or parts and machines.

In this stage, final assignments of parts to cells are realized. Particular attention is given on eliminating of exceptional parts for decreasing inter-cell part movements. Furthermore, due consideration is also given to reassignment of machines to different cells for elimination of inter-cell movements.

Solution ideas to the problem of Resources capabilities development. In this stage, activities including waste elimination, for the design of a lean process, rearrangement of resources in agreement with the takt time, fixing training needs and motivation of the workforce are accomplished.

Solution ideas to the problem of Resource rearrangements. At this stage lean manufacturing principles are the guiding principles of the design step. In this step, the focus is the waste elimination.

Solution ideas to the problem of Production control. Satisfying customers by right amount and just-in-time production can only be accomplished through pull system. However, just-in-time systems require a steady pull on all products in the family. In order to ensure a steady pull, a leveled or mixed production schedule must be established. This leads to developing the appropriate Heijunka schedule and the necessary visual management tools including Kanban system for successful implementation.

6.4 Conceptual solution of a new cellular manufacturing system

On the basis of the ideas generated above, has been built a consistent set of conceptual solutions addressing the present problem. They are presented in details at the report of the pilot project.

7. Conclusion

This paper has applied the USIT methodology to the problem of development of Cellular manufacturing system, which ensures providing customized production in the sphere of furniture manufacturing and allows to the analyzed Bulgarian industrial enterprise to accomplish fruitful business partnership with the Italian contractors.

The analysis of this problem has revealed that a simple technical approach is not suitable at all, but rather complex approaches are necessary and more appropriate. Thus the problem was analyzed from multiple aspects, including product families, business processes, production control etc.

A number of root causes and corresponding contradictions have been revealed and solved one by one to find basic directions for a new solution system.

The process of proceeding to the solution was described. Then, on fragments of such ideas, a consistent conceptual solution was built.

On the basis of this overall view, the new basic choice in the technical aspect is expected to have solved most of the problems.

aldi@fmi.uni-sofia.bg

Development of embedded software systems is an innovative discipline of software engineering. However, creation of truly engineering methods in this field is a challenging task due to some important specific requirements of embedded software systems. Special attention should be turned to improvement of general purpose software engineering methods for development of software systems and adapting them to different domains of embedded systems development. It is generally accepted in embedded systems research community that different domains (spacecraft systems, automotive systems, process control systems, medical equipment systems, etc.) should have specific approach.

The focus of the paper is on development methods based on modular software architecture of the system. This means that one should look at it as a composition of interacting software components and the connections between them should have first class status. The goal of this paper is to analyze and evaluate usage of different architectural styles with respect to how they affect different non-functional requirements of embedded software systems. Styles represents a generalization of the best practices in architectural design of systems in this domain, which include configurations of typical software components and the connectors between them.

Architectural Styles, Embedded software systems, Software architecture

1. Introduction

A rapidly growing area of modern computing systems is formed by the so-called embedded systems. According to IEEE an embedded system is any *computer system that is part of a larger system and performs some of the requirements of that system; for example, a computer system used in an aircraft or rapid transit system*. A popular vision about is that an embedded system is nearly any computing system other than a desktop, laptop, or mainframe computer [4]. Throughout this paper we accept the following definition about embedded system: a mixed hardware/software system dedicated for a specific application and is part of and reactive to a larger, physical system to which it is at least logically connected.

Embedded systems cover a large range of computer systems: from very small computer-based devices to large systems monitoring and controlling complex processes. It is believed that major part of all computing systems today (more than 98%) belongs to the embedded systems domain.

Embedded software systems are possess some particular characteristics that distinguish them from general-purpose systems. Among them are [4, 14]:

- Limited functionality – this means that the system offers a same set of features to the users. Usually no additional programs may be installed to execute together with the initial software on the embedded system. This means that usually embedded systems do not have strict requirements for scalability.

- Tightly constrained – embedded systems have very high restrictions on available CPU performance, memory, power consumption and etc. These determine also high requirement towards software non-functional characteristics.
- Reactive and real-time – many embedded systems are designed to react to changes in system's environment and should produce output following some hard deadlines, i.e. – to work in real-time manner.
- Safety-critical – some embedded systems may be integrated into hardware, responsible for safety critical operations. Such systems have very high requirements for safety, availability, reliability and etc. Additionally in some of these systems the product life cycle is very long – in can stretch to several decades (for spacecraft software).
- Hard-to-change – Embedded software systems are usually tightly connected with the underlying hardware platform and written in low-level programming language, which makes them very difficult to change.
- The development machine architecture is often different from the target machine. The hardware for the target machine is often developed concurrently with the software, and therefore not available until late in the project.

Most of these characteristics fall into the area of non-functional requirements. The distinction between non-functional and functional requirements comes from the vision of functionality and the constraints that restricts execution of this functionality. While functional requirements define what software should do, non-functional requirements define how (in what way, under what boundaries) it should do this. Among the non-functional requirements fall reliability, availability, security, performance, time constraints, scalability, usability, maintainability and so on. Non-functional requirements are sometimes also referred as quality characteristics extra-functional properties or “-ilities”.

Examples of embedded systems that have all of the above-listed characteristics are applications in medical and life-support systems, automotive industry, control of industrial processes, aero and space systems and etc. It can be concluded that many of the most important requirements for embedded systems are related to these extra-functional properties. This also becomes a strong reason for raise in the cost of development and maintenance of such systems.

In this context, there is a strong need for application of software engineering practices to embedded systems. Currently many software engineering methods are successfully applied to different classes of embedded software applications. However, we have identified strong need for additional research on software architecture and for embedded systems [5, 6]. As software architecture is broadly recognized to be a crucial factor in satisfaction of non-functional requirements of software systems it is obvious that research on software architecture specifically oriented towards embedded systems is crucial for success of software development projects in this area. In this paper we analyze and evaluate usage of different architectural patterns, known as styles, in embedded systems.

The rest of the paper is organized as follows: Section 2 briefly describes the notions of software architecture and architectural styles; section 3 represent usage of architectural styles for embedded software systems and finally section 4 concludes the paper.

2. Software Architecture and architectural styles

Software architecture is an emerging software engineering discipline that concerns a high-level, abstract model of the software system. It has been subject of extensive research [8, 9, 11, 13] in recent years, but in terms of embedded systems there is still lack of support in the area. This is mainly due to the fact that software in most embedded systems is designed together with hardware.

As a new notion there is still some misunderstanding in its formal definition. For example, Bass defines architecture [2] as *the structure or structures of the system, which comprise software components, the externally visible properties of those components and the relationships among them*. Structures represent different views of the system like module decomposition, process view, deployment view and etc. Another definition is given by [7], which says that *software architecture is an abstraction of the runtime elements of a software system during some phase of its operation. A system may be composed of many levels of abstraction and many phases of operation, each with its own software architecture*. In our current research we focus on module decomposition view of the system, which encompass the following entities:

- Software components – these entities represent computational aspects of systems, aimed to fulfil the functional requirements towards software. They are usually regarded as black-boxes

that encapsulate certain functionality and may communicate only through their input/output interfaces. Components may represent abstractions either for on-site implementations developed on demand during realization of software project, or COTS (Commercial-off-the Shelf) components [1], purchased by third party in order to minimize the time and cost for implementation of certain functionality.

- Component connectors – aimed to abstract coupling, integration and communication between software components. Connectors should receive first-class status (equal to components) in software architecture in order to alleviate problems with integration of components. Such problems include interface or data mismatch, unsecure interactions, etc. Abstracting interconnections into separate modules also helps to decrease complexity of specification and to increase the level of reusability of connectors themselves.

Main goal of software architecture is to enable understandable and (most importantly) reusable fulfilment of non-functional requirements towards software systems. Software architecture serves many goals and is used in many software development related activities, including [2, 3] assessment and evaluation, configuration management, dynamic software architectures, and code generation.

Software architecture means nothing if it is not documented in uniform and understandable way and in order to achieve maximum benefit from the description of software architecture, it is needed to be able to formalize it. Software architecture should study the system beyond the algorithms and data structures of the computation. Instead it should provide means for reasoning about the software system at four abstract levels [12]:

- Functionality of components and connectors.
- Interfaces, exported by a component to the rest of the system.
- Interconnection and structure of the architectural elements (components and connectors). This interconnection is called architectural configuration.
- Rules for the architectural styles. Architectural styles capture past experiences with architectural design and represent previous attempts for construction of software architecture that have proved to be successful.

The list of currently known architectural styles is far from exhaustive and is an open area for research. In this paper we consider the following architectural styles:

- Layered style
- Pipe and filter
- Blackboard
- Client-server
- Service-oriented architecture
- Message-oriented style

In next section we are going to scrutinize architectural styles with respect to their usage in embedded software systems.

3. Architectural Style for Embedded Software Systems

In this section we consider some of the most popular architectural styles and their application to embedded software systems.

3.1. Layered style

This is the most widespread architectural style. The system built according to that style is divided into layers and each of them provides certain functionality. Only adjacent layers may invoke functionality and communicate with each other. This way it is easy to change something into a given level of the style, while this change affect minimal other parts of the software. Nearly every system implements it, as it represents a suitable abstraction which enables reuse and increase systems' scalability and modifiability. Embedded systems do not make an exception of this rule, as every embedded system has the following basic architecture (Fig. 1).

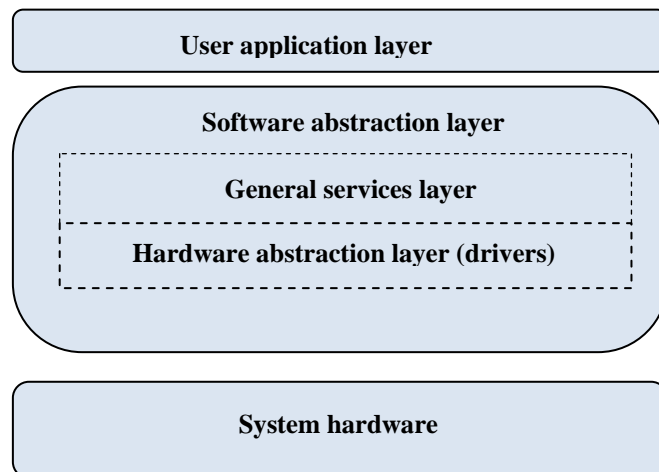

Figure 1 Layered style for architecture of embedded software systems

Architecture shown on fig. 1 may vary, depending on different domain areas of embedded systems. One aspect is that each system should have hardware abstraction layer in order to achieve independence from the underlying hardware platform and increase reusability. Other aspects of the architecture concern for example the automotive domain. There exist hard requirements for real-time execution and the general services layer should be further divided into layers with responsibilities for resource allocation, task scheduling, time management and etc. However such specialization of architectural styles for specific domains is out of the scope of this paper and is a matter of further research.

3.2. Pipe and filter style

This is one of the simplest architectural styles known, it suppose that the system is decomposed into modules, called that subsequently process some data, passed between them by connectors, called pipes (Fig. 2). Each filter just process the input information and then passes it through the pipe to the next filter, which process it in its own turn.

Figure 2 Pipe and filter architectural style

This style is very appropriate to all classes of embedded systems as it offers simple interaction pattern that aids to scalability, predictability and reusability of components.

3.3. Blackboard style

Blackboard style represents a number of components, sharing common information through a connector, called blackboard or repository (fig. 3). When a component wants to send some data to other components into the system, all it has to do is to write it into the repository and this way make it available to others. This style is very appropriate to embedded systems because it save computation resources when components share large amounts of data, or one component produce data more often than other components need it.

Figure 3 Blackboard architectural style

As it is difficult to maintain the format of data when changing or updating components, this style hampers reuse of software components in the embedded system. This style also lowers reliability of systems, because blackboard represents single point of failure. Predictability is also compromised in case of many components with intensive interactions because the blackboard represents a shared critical resource.

3.4. Message-oriented style

This style is also known as implicit invocation, because usually there do not exist typical method calls between components in the system. Instead a certain message is sent and each module that is interested in the event that caused message should take specific actions. Component interfaces here are listeners and the speciality in this style is in the connector, which should be regarded as a message passing framework, which should take responsibility for shipment of the message to each component listener. There exist two possible implementations of this style, the first is with broadcasting connector, which broadcasts the message and each system component decides by itself if it should take any specific actions. The second implementation has more sophisticated connector, which keeps track of possible events, and components associated with each event. Then it sends the message only to those system components that are interested in it.

When applying this style software architects should keep in mind issues about possible delays in message passing and processing. This also become an issue when ensuring reliability as additional processing is added with tracking if the message has been processed. On the other hand, this style favours reuse of the functionality, implemented in the server.

3.5. Client-server style

This is another very popular software architecture style. In this style a number of components serve as clients and issue predefined requests to a server, which in turn returns results depending on the request received. Usually the server does not have any information about its clients, their number or characteristics. Almost every information or enterprise system is based on the concept of client-server interaction. The well known and recently very modern notion of service-oriented computing actually originates from this architectural style. With respect to embedded systems, when applying this style specific non-functional requirements to the server should be taken in mind to achieve reliability and predictability of the overall system. For example, the response time is very important in order to assess the overall performance of the embedded system. For this reason the service-oriented implementation is not suitable for embedded systems, because in its classical implementation, it is not easy to predict the workload of the service and how many clients will make requests to it.

3.6. Discussion

This paper presented 5 architectural styles with respect to the possibilities for their usage in embedded software systems. Of course the way a software system is implemented is far away from just picking up a style and applying it to the architecture. Usually a number of architectural styles is applied together to build the overall system architecture. Actually custom styles are possible to be developed for each system in turn. However the study of each style alone helps in better understanding of the issues that concerns specific types of systems. Table one summarize the applicability with respect to particular requirements of embedded systems ('+' stands for enrichment of the property, '-' for hampering the property and 'o' is neutral).

Table 1 Applicability of architectural styles to embedded systems

	Performance/ real-time execution	Reuse	Reliability	Scalability	Predictability
Layered style	o	+	o	+	o
Pipe and filter	o	+	o	o	+
Blackboard	+	-	-	o	-
Message oriented	-	+	o	o	-
Client-server	o	+	-	o	-

As seen from table 1, every system usually requires a balanced combination of different architectural styles in order to achieve all of its non-functional requirements. Further analysis of the results in the table show that additional research in architectural styles is needed to improve reliability of embedded software systems.

3. Conclusions

Embedded software systems are an area where traditional software engineering methods are difficult to apply due to a number of specific requirements and restrictions that such systems have. Special approach is needed in every area of software engineering and this paper focus reports some initial research in software architectural styles for embedded systems. Five architectural styles are analyzed and evaluated with respect to their applicability to embedded software systems having in mind the specific requirements such systems have. This research will help in definition of architectural styles specifically oriented towards given embedded systems (medical, automotive, process control, etc.) and also will help in definition of different styles particularly oriented towards different non-functional characteristics of embedded systems, including reliability, scalability, real-time execution, etc.

As a matter of further research we will focus on development of architectural styles for automotive embedded systems based on specific requirements for reliability, real-time execution and predictability.

²Belgrade business school – Higher education institution for applied studies, Serbia gotom@neobee.net

³Higher School of professional business studies Novi Sad, Serbia, ninadjurica@yahoo.co.uk

Information gathered through marketing research present a foundation for introducing new products and / or engaging new processes. Innovative activities are a combination of ideas and information that bring about positive changes in company. Satisfying the consumer needs and gaining their loyalty is the main prerequisite in order for a company to introduce innovative activities. Although the innovation process is quite expensive and risky, it is nevertheless a condition without which a company can not secure a long-term sustainable competitive advantage on the market. One of the most important ways in which companies improve and grow is by achieving business success through innovation. In order for innovation to be successful, a company needs to have entrepreneurial spirit and a set of specific skills.

Keywords:

customer, innovation, marketing research, product

1. Introduction

Innovation is every product, service, idea or technological process that is perceived as an new. Innovative activities are vital to maintain competitive advantage. Sometimes even a small innovation can add value and create competitive advantage. Innovation is measured by the company's efforts to find new opportunities and innovative solutions. Innovation should be happening in all segments of the organization, every department - in all aspects of the value chain.

According to the degree of innovation of innovation can be radical and gradual (incremental). Radical innovations cause departure from existing practices. These innovations usually result from technological change. Radical innovation can lead to the creation of products or processes that can be patented, thus giving the company a strong competitive advantage. Incremental innovations reinforce existing practice or lead to minor improvements of products or processes. These innovations increase revenue by creating a new product that is offered to the market and reduce costs by enabling new capabilities which the costs are reduced to a minimum and improves productivity. Some innovations may be extremely radical, while others may be gradual to a lesser extent. Most innovation is between these two extremes.

In order to improve its competitive position through innovation, companies can use the following innovative activities:

1. Encouraging creativity and experimentation. These activities shall be updating and improving products or services or the improvement of procedures performed within the company.
2. Investing in new technology, research and development and continuous improvement. In order for innovation to be successful, the company has to draw benefits from the latest technology. This often requires significant investment.

In this paper we will deal with the development of new products and services as innovative activities of companies. Depending on the degree of innovation for the enterprise and the market, the term "new product" has three basic meanings:

1. Brand new product - a product that is not only a complete novelty for the firm, but also for the market. Of enterprises that develop this type of product are the real innovators.
2. Modified existing products - new products that represent an improved version of existing products. New features of the product can improve the image of the company and products on the existing market. A company can modify existing products in different ways: innovation of existing products, product line extension and so on. A special form of modification is the repositioning of products that allows better positioning of existing products in new market segments.
3. Imitative products - products that are new for a given company, but not unknown product market.

Companies can choose different strategies for product development and services. Leaders have the initiative to develop new products and services. Companies copy successful innovations if they think that the risk of introducing entirely new products is too large. The choice of strategy of development of new products and services depends on the corporate mission and goals, organization size and nature of new products and services.

Depending on the strategies of product development and services, all businesses are classified into proactive and reactive. Proactive companies initiate a major change by creating entirely new products and services. Companies that follow a reactive strategy of developing products and services, launch new products and services that are imitation products and services of competing companies on the market or introduce a modified version of the existing products and services. In this market scenario, the company applies a reactive, but wisher strategy - strategy of "sit and wait". Companies can choose a defensive strategy focused on differentiation of products and services.

Imitators typically invest about 50% -70% less than an innovator. Lower costs and greater prospects for success seem rational enough to prefer to imitate products and services of competitors, but to develop entirely new products and services. However, the danger of imitating leaves little room for differentiation of products and services from the competition, which is considered one of the main reasons why companies recently have difficulty to retain customers.

2. The process of developing products and services

Development of new products and services is a process that involves a series of activities starting from the idea of a new product / service until the launch of the product / service to market. Development of new products and services is the result of an interactive process involving experts from different functional sectors within an enterprise, as well as individuals outside the organization. Development and introduction of new products is very expensive and risky. Depending on the industry, 60% to 90% of new products fail at the outset. Lack of marketing research is leading cause the failure of products. The other most common reasons for failure of the products are technical problems in the design or manufacturing error in the time and harmonized product. Duration of individual phases and the degree of development of products and services caused by many factors such as product features and services, target market, the impact of competition, available resources and so on.

The process of developing new products and services can be broken down in the following eight stages:

1. Generating ideas
2. The selection ideas,
3. Development of the concept of product / service and testing,
4. Development of marketing strategy
5. Business analysis,
6. Product / service development,
7. Market testing,
8. Commercialization / launching new products / services.

2.1. Generating ideas

The process of developing new products and services begin generating ideas. Generating ideas includes all activities of the companies which seek to collect ideas for the development of products and services. Ideas for new products and services may stem from internal sources (official procedures for the development of new products and services sector for marketing and marketing research, consumer complaints and complaints) or sources outside the bank (advertising agencies, marketing research agency, competitors, intermediaries, consulting firms, universities, publications).

Marketing research plays a very significant role in generating ideas for the development of new products and services. About 40% of ideas for new products and services are collected in this way, and about 13.5% of ideas collected from other internal sources [6, pp. 106]. The company uses different marketing research techniques (personal interviews, focus groups, brainstorming and so on) to identify problems and needs.

2.2. Selection of ideas

Collected ideas will be ranked based on certain criteria in order to perform their selection, or to accept good ideas for the development of new products and services and also rejected the bad. The most commonly used criteria for the selection of ideas are:

1. compatibility with the company objectives, such as profit, market share, sales volume, customer loyalty;
2. compatibility with the resources and compliance with capital, production, marketing, and distribution.

When you set the list of uniform criteria, it is necessary to determine their relative importance and then evaluate the idea to each of these criteria. The overall ranking of an idea about a new product / service is obtained as the weighted index as the sum product of the relative importance of each criteria and evaluate ideas according to each criterion, where the rating usually expressed on a scale from 0.0 (lowest score) to 1.0 (best score) [3, pp. 92].

2.3. Concept development and testing

Selected ideas in the previous phase of the development of new products and services are translated into the concepts of product / service for further development and testing. The idea of a new product / service are the kinds of products / services that the company may launch in the market, while the concept of product / service is an elaborate version of the ideas described in a way understandable to consumers. Any ideas about a new product / service can be turned into several concepts of products / services depending on the target consumer.

The concept of product / service testing on a specific group of potential customers to discuss the proposed content of the product / service, which allows the company to further reveal the motives and attitudes of consumers, and to gain insight into how best to position and promote the product or service. After developing the product/service concept, following its testing to see a reaction of potential customers. At this stage of products and services development, the company usually uses exploratory research with focus groups of patients.

2.4. Marketing strategy development

At this stage of product development, the company makes a preliminary strategic plan for the introduction of new products / services to market. A preliminary strategic plan consists of three parts. The first part of the plan describes the size, structure and the target market behaviour, the planned positioning of products / services, sales, market share, and predicted a profit for the first few years. The second part of the plan describes the planned price, distribution strategy and marketing costs in the first year. The third part of the strategic plan describes long-term sales, profits and planned marketing mix over time.

2.5. Business Analysis

Upon identification of appropriate marketing strategies needed to transform an idea into a clear and complete business proposal in which they are listed in detail the advantages and prospects for success as well as for failure. At this stage of product development, the company has to evaluate of costs, sale and profit. Marketing research, together with other components of marketing information system, provides the basic elements for the projection of sales [3, pp. 93]. In addition to the profitability of new products / services, it is necessary to evaluate and its compliance with burial offerings. If a new product / service technology is associated with existing products and services, the company can use existing channels of communication and distribution, significantly reducing the cost and risk of failure.

2.6. Product / service development

At the stage of product development / services selected concept of product / service is being transformed into a concrete product or service. Until this stage the products / services exist only as words, drawings and descriptions in the minds of the creators and consumers. The development of specific products and services mainly consist of information or a series of operational activities and includes determining the characteristics of individual products / services which contribute to creating the image of the product / service awareness, supporting procedures, software, assembly instructions for the use of this product. Three commonly used techniques for measuring consumer preferences are: ranking, comparing pairs and individual assessment. Suppose the consumer presents three versions (A, B and C) a new product. According to the technique of ranking, consumers are first presented all three versions of the product. They are asked to rank them by degree of attractiveness. The technique involves comparing the couples that consumers are pairs of products and they are required to declare that they are of two products in each pair more like.

2.7. Market Test

Market testing is the phase in which the product is offered in final form and gets its name. On the one hand, market testing is conditioned by the limited duration and cost of research, on the other side of the invested money and the risk of possible failure. The competitors can receive information about new products and services. This is the problem of the testing phase. Companies can reduce the risk of copying ideas about new products and services by competitors.

2.8. Commercialization

Commercialization is the final stage of the development of products and services and the start of their launch. Market testing will show whether the products and services will be launched in full or make specific improvements or corrections.

In the process of commercialization of products and services, the key question is timing when the market will be "fulfilled" product/service. Marketing research plays an important role in this phase of product development. In the commercialization phase (up to end of life products) marketing research is primarily tasked to monitor sales results.

In the process of adopting new products and services, there are five stages:

- Awareness - consumers become aware of innovations, but it lacks information about it.
- Inters - the consumer is stimulated to seek information about innovations.
- Evaluation- consumer considers whether to try the innovation.
- Test - test consumer innovation that would have a better assessment of its value.
- Adoption - the consumer decides to fully and regularly use a given innovation.

Companies can choose one of the following solutions:

- Introduced the first products to market and maximize the benefits of such decisions;
- Introduces a parallel product, waiting for response competition and then released to the market with a copy of its products;
- Decision on final version of the product, which allows learning to their own mistakes and omissions, then launch improved version of the product.

3. The success of new products and services

The speed at which products and services will be accepted by consumers depends on many factors. Some factors depend on the consumer, and some of the very nature of products and services. Businesses should be aware of the reasons why some consumers decide fairly quickly to use new products and services, while others abstain. Therefore, companies should identify and understand barriers to the acceptance of new products and services.

The speed of acceptance of new products and services, consumers are classified into:

- Innovators - those who first adopt new products and services; It is the most common category of "wealthy" young and well informed consumers.
- Early acquirer - those who embrace new products and services after the innovator; This category usually includes an above-average educated consumers.
- Early majority - made up of those who are extremely careful in accepting new products and services.
- Late majority - This category usually includes consumers who are very skeptical about the new products and services.
- Uncertain - the last to adopt new products and services; this category are traditionalists, consumers who look to the past, when they accept new products and services, they can already be replaced by newer products and services.

The development of any products and services is a risk, which is becoming more and more if the new products and services are designed to meet the needs and demands of consumers. Reasons for the failure of new products and services are integrated, indivisible and variable process that is often difficult to conceptualize, and sometimes they are very complex, dynamic and risky because of competition.

Successful products and services are those products and services that bring the company revenues and profits. Therefore, the measure of success for innovation:

- achieved sales,
- achieved by increasing sales,
- achieved market share,
- achieved by increasing market share,
- achieved profits,
- achieved by increasing profits.

In assessing the effectiveness and efficiency of innovation the company should ask the following questions:

1. Are the products or services offered by the new venture accepted in the market? If a new product (service) is accepted, the profits will probably be satisfactory. A successful innovation can be a guideline for future innovation.
2. Does the innovation add value to the company? If the innovation adds value to the company, the company will probably be able to strengthen existing resources and supplement internal knowledge and experience and improving ability of the company.
3. Whether the investment will maintain its competitive advantage? If the investment is maintained competitive advantage, the company will probably provide a stronger position over its competitors and create the basis on which it will build other advantages.

Successful innovation is characterized by [6, pp. 110-112]:

1. Relative advantage. Products and services, primarily, must have features that make them unique in terms of benefits provided by the consumer. Companies must devote full attention to even the smallest details in the design process to create a relative advantage, identify acceptable levels of differentiation and to ensure customer satisfaction.
2. Compatibility. Products and services that are market-oriented or that have been developed according to market demands, no doubt they have the property compatibility between the values and needs.
3. Complexity, which refers to the ease with which consumers understand the products and services. Indivisibility of products and services may cause difficulties in the mental conceptualization of products and services by consumers.

4. Severability. Companies must be oriented to the production and marketing when dealing with the creation of new products and services. Employees who come into contact with consumers must participate in the later stages to ensure the efficiency of products and services.
5. Portability – portability refers to the degree to which ideas can be transmitted to others.

Companies must be able to identify the specific factors contributing to the success of new products and services. These factors include:

- Promotion (planning, creating the image of new products and services, financial support for promotional activities);
- Internal marketing, which includes programs and procedures for staff training, promotional programs, etc.;
- Operating Procedures, which may be extended by testing products and services before launch, and training employees to better understand the new products and services, which will be presented and sold to consumers;
- Technical support;
- Compatibility of new products and services with the existing program of offering;
- The accuracy of identifying target groups of consumers, which is important because it used to be the most appropriate form of communication.
- The degree of differentiation of products and services.
- Marketing research and monitoring of consumer behaviour;

4. Conclusions

Innovation can take several forms, from the radical, revolutionary innovation to innovation resulting from the gradual improvement of products and services. Innovations are used to update and improve products and services or to improve procedures within the company. Innovation creates a risk venture, which becomes more and more if the new products and services are designed to meet the needs and demands of existing and potential customers. Innovative activities are quite expensive and risky, but no matter, they are a condition without which we can not provide long-term sustainable competitive advantage in the market.

The policy in the development and supply of products and services must be creative and of experimental and such that makes the constant discovery of new products and services in the future will replace those now in the stage of maturity or decline phase in its life cycle. Marketing research plays an important role in all stages of the development of new products and services. Lack of marketing research is leading cause the failure of products. New products and services introduced by the company shall be in accordance with its overall offering if the company wants to take advantage of the use of existing communication channels and distribution, and thus considerably reduce the cost and risk of possible failure.

Knowledge and Technology Transfer in Higher Education as support for Innovation: the case of University of Ljubljana

Slavko Dolinšek¹, Manca Poglajen²

¹*Institute for Innovation and Development of University of Ljubljana, Ljubljana, Slovenia, slavko.dolinsek@iri.uni-lj.si*

²*Institute for Innovation and Development of University of Ljubljana, Ljubljana, Slovenia, manca.poglajen@iri.uni-lj.si*

University technology transfer models have evolved significantly since the introduction of Bayh-Dole Act. However, the introduction of the knowledge and technology transfer concepts in the Central and Eastern Europe has its specificities, based on both different higher education systems as well as on the history of university-industry cooperation.

Copying of US or Western European innovation models and mechanisms, more specifically of the technology transfer organization, in national innovation system of CEE has lead to smaller effects than foreseen. An example of the situation is also Slovenia, where new strategies for supporting innovation and the exploitation of scientific research results from public research organizations are being reconsidered. The article presents the current situation and the challenges in knowledge and technology transfer in CEE from the point of view of technology transfer offices, and underlines the case of Slovenian public research institutions, most notably the University of Ljubljana. An analysis of the effects of the newly proposed strategies for Research and Innovation Strategy of Slovenia 2011-2020 and the complementary National Program of Higher Education 2011-2020 with regards to TTO services is provided. Legal and infrastructural framework is considered, continued by the specificities of the University of Ljubljana on national and regional level, and the description of its innovation system. Special attention is given to the institutions at the university that together perform classical TTO functions.

The article partially builds on experience gained in the CERIM (Central Europe Research to Innovation Model) project.

Central Europe, Innovation, Knowledge and Technology Transfer, Technology Transfer Organization, University of Ljubljana

1. Introduction

Support for innovation processes and improvement of knowledge and technology transfer is vital if the European Union wants to keep up with the competition. The paper aims to present the case of knowledge and technology transfer (KTT) system in Slovenia's biggest university, i.e. University of Ljubljana (UL), from the view point of technology transfer office (TTO) services. It builds on the results of the analysis of the innovation systems in regions in Central Europe, as provided by the CERIM (Central Europe Research to Innovation Model), where IRI UL is a partner.

In the first part of the article, the definition of knowledge and technology transfer through a TTO is provided and the framework conditions for it in the CERIM participating regions are described. In the second part, situation in Slovenia is presented with the emphasis on the proposed drafts for the national research and innovation policy in the period 2011 – 2020. Lastly, the example of KTT system

at the UL is described with the emphasis on the mission of the UL's Institute for Innovation and Development (IRI UL).

The article partially builds on experience gained in the CERIM project which is co-funded by the Central Europe Program of the European Union.

2. Knowledge and technology transfer – the case of Central Europe

2.1 Knowledge Commercialization

Though there is abundant literature on the concept of technology transfer, no single or prevailing definition of the term exists [1], [2]. By considering technology in its broadest sense as know-how, we understand technology transfer beyond the mere transfer of products and commodities [3], namely as a knowledge transfer process [4]. As we are interested in the transfer of innovations and associated research results and knowledge from a public university (and other public research institutions) to final research users, we use the term "knowledge and technology transfer", where we are interested especially in the commercialization (i.e. the end user being a company). The KTT which could be described as pedagogical activity and thus not commercialized (mentoring schemes, invited lectures etc.) is not considered here, nor is the KTT where end user is non-profit organization.

Ever since the Bayh-Dole Act in the 1980s in the USA lay rules for commercializing of results from publicly financed research, governments in the industrialized countries have been underlining the need to improve the ability of research organizations to commercialize their results. University KTT models which were first created in the USA and the UK have gained ground also in the EU countries and evolved significantly, resulting in the "triple helix" or mutual responsibility of university-government-industry for KTT [5]. Most notably, the KTT is managed by the university-established TTOs, who are in charge primarily (but not only) of the questions of intellectual property rights (IPR), licensing, and networking with the potential investors. First established in the US, the TTOs are created as specialized and decentralized unit within the university, which enables them a certain level of autonomy when creating connections with the industry and thus enable KTT. Yet the TTOs with the focus on patenting and similar type of IPR protection are not the sole KTT commercialization activities. Various links with industry are created also through forms of consulting services for companies, thus diversifying the risk on depending on patents and licences [6]. From the organizational point of view, a system that supports university KTT commercialization is thus a mix of decentralized units which provide services to university and industry for protection and transfer of researcher's knowledge in various mechanisms. The main fields of these services are:

- *knowledge valorisation and related protection* (e.g. IPR, patenting, licensing),
- *business development* (e.g. spin-offs),
- *cooperation with industry* (e.g. consulting services),
- *training* and informing the university staff on the commercialization issues.

2.2 CERIM project

Central Europe Research to Innovation Models (CERIM) project unites KTT organizations from regions of Austria, Germany, Hungary, Italy, Poland, Slovakia and Slovenia. The project mission is to develop adapted valorisation models for a more effective and efficient KTT from the universities and research institutes in Central Europe to the companies. Co-financed by the EU Central Europe programme, the project aims to contribute to a stronger sector of knowledge intensive European companies and a revitalisation of markets through innovative companies, especially in the participating regions (Table 1).

Table 1 CERIM project regions, selected data [7]

<i>Country / Region</i>	<i>Population (mio)</i>	<i>GDP pc (EUR)</i>	<i>Patents per mio inhabitants</i>
Austria, Salzburg	0,5	NA	NA
Germany, Baden - Wuerttemberg	10,7	33.876	385,0
Germany, Mecklenburg – Vorpommern	1,7	21.439	26,1
Germany, Saxony	4,2	22.620	68,6
Hungary, Budapest	2,9	14 800	38,6
Italy, Lombardia	9,64	32.326	113
Poland, Szczecin	1,7	NA	2,36
Slovakia, Bratislava	0,6	26 400 (USD)	NA
Slovakia, Žilina	0,7	12 145 (USD)	NA
Slovenia, Ljubljana	0,5	22.286	NA

Within the project, an analysis of the regional knowledge and technology transfer situation was performed in 2009. Among other, units providing services traditionally linked to TTOs were examined.

2.2.1 The policy context for KTT in CERIM regions

The introduction of the KTT and TTO concepts in the Central and Eastern Europe has its specificities, based on different higher education systems as well as on the history of university-industry cooperation. At the national and at regional level, the governments set the parameters for the effectiveness of the commercialization of academic research and the resulting impacts on economic growth [8]. Though partner countries differ on the approaches towards KTT, all have developed policies on the issue area. Most have seen an increase in this activity after year 2000 with the changes in legislation which allowed for the university (and not state) ownership of results issuing from publicly funded research. The universities and other public research organizations are thus *obliged* to protect the intellectual property created.

Austria, Germany, and Italy have a well developed structure of national and regional systems for KTT. Poland and Hungary, also Slovakia, have managed to develop regional innovation systems, too, yet their performance does not score high on the European Innovation Scoreboard. Centralization, which is the result of building predominantly national (and not regional) institutions in innovation system, may prevent actors from realizing potential advantages associated with KTT; however, fragmentation into smaller dimensions is not good if it lacks support and contact with other levels. Italy, with a strong regional autonomy, is an example of country where even the municipal level of innovation system is important, as institutions from this dimension are considered as relevant partners at setting policies.

2.2.2 Types of institutions providing TTOs services in CERIM regions

According to CERIM RTT overview [9], the new EU members have copied the form of successful KTT organizational structures from the USA and UK – this especially being evident with the number of newly created TTOs at universities and the springing of incubators, technology/science parks and other mechanisms –, but failed to implement also the content of these mechanisms. In the partner countries, there is no single understanding of a KTT-model mix. The identified KTT-models vary, as there are also different legal and policy backgrounds for their creation. Three types of units that provide above-mentioned TTOs services exist in these regions of Central Europe (more in Table 2):

- TTOs as *units inside* the university,
- TTOs as *independent public-private-partnership (PPP) agencies*, and
- *private* institutions (mainly companies).

Table 2 Types of institutions providing TTOs services

	TTO as unit within university	TTO as independent institution in the form of PPP	TTO as private institution
<i>Target group</i>	Researchers, university	Researchers, region	Investors (market)
<i>Aim</i>	Protect academic research results (IPR)	Market university research results to benefit the region	Develop ideas with market potential & respond to industry needs
<i>Important Services according to mission</i>	Knowledge valorisation (IPR, patents) Business development Training Other cooperation with the industry (consulting)	Knowledge valorisation (IPR, patents) Business development Other cooperation with industry (consulting) Training	Other cooperation with industry (consulting) Knowledge valorisation Business development
<i>Founders</i>	university	(regional) government + universities + regional business association	various (companies, individuals, public non-profit and private for-profit institutions)
<i>Strengths</i>	Knowledge of the academia Proximity to the university management	Support of (regional) governing institutions Pooling of innovations from several universities and achieving critical mass	Fast response to industry proposals Good understanding of market drive
<i>Weaknesses</i>	Little autonomy Slow response on industry demand or proposals Huge costs for small universities Focus on patents	Competition between universities	Lack of support from government and/or academia Perceived as competition to university-based TTOs

Regardless their variety, they all serve for promotion of research results and their commercialization. Yet, the first focus on the IPR (especially patenting) and business creation, the second on the immediate market availability of results through commercialization in form of patenting and licensing, whereas the third tend to focus more on the market itself and the expressed needs of industry. Herein lie also their strengths and weaknesses. Namely, university TTOs (especially in new member states) are often bureaucratic units inside the university structure, with inhibitions coming from the slowly responsive universities with rarely institutionalized cooperation with industry, the administrative red tape and unsupportive legal framework, inadequate rewards for entrepreneurial researchers, and with lack of KTT experts. On the other hand, a form of PPP between the universities, (regional) government and individual innovation management companies (typical of Germany and Austria) has proven to be successful especially at creating a critical mass of innovations and innovation experts who can provide adequate service to the researchers. Important fact is that as government is one of the founders, this reflects also in the related (regional) policy on innovation and KTT. For example, in the case of studied German regions, several universities and institutes in the region would establish a joint patenting and valorisation agency, whereas new EU members tend to create TTOs at the universities. Such TTOs, similarly to the German agencies, provide services of patenting, valorisations, licensing and other types of commercialization. A third type, the private institution performing KTT services, is focused on the needs of the industry, and is typically present in the new member states where university TTOs are new and still have to establish themselves as relevant partner to the industry. An example of this is IRI UL within the system of University of Ljubljana.

3. IRI as part of UL TTO system

3.1 University KTT in Slovenia

There are four public universities in Slovenia, namely in Koper, Ljubljana, Maribor and Nova Gorica. The UL is the oldest and the largest in terms of enrolled students, staff, as well as research and development investments. Koper, Ljubljana and Maribor universities cover all fields of science, whereas the most recent Nova Gorica has been built upon the basis set by a strong natural sciences departments and applicative research. Traditionally, the contact with companies was established by each faculty, and usually not on the university level.

Table 3 Slovene universities

	<i>University of Ljubljana</i>	<i>University of Maribor</i>	<i>University of Primorska Koper</i>	<i>University of Nova Gorica</i>
Established	1919	1975	2003	2006
Enlisted students (total) 2008/09	60.284	23.363	6.490	725

On the policy level, Slovenian Development Strategy for the period 2006-2013 and the Resolution on National Research and Development Program had defined R&D as the main factor for development and competition of Slovenia. Within this, the linkage of business with academia, the restructuring of public R&D system (increased investment, efficiency, strengthening the human resources and focus on high-tech and innovative companies, definition of key research areas) and the mobility of researchers between the two sectors were underlined. The policy documents also enabled the creation and funding of innovation system mechanisms such as technology/science parks and incubators. All universities except for Nova Gorica created their own university incubators aimed at creating student- and/or professor- start-ups, as well as units that are in charge of IPR protection. TTOs within research organizations (patent offices) have been established at all four universities as well as at the Chemical Institute and Institute Jožef Stefan [10]. As these institutions can and do provide also for training of academics and students on IPR and entrepreneurship, there was little focus on providing special services to companies. The situation is mirrored in the national legislation in the field of university KTT services in Slovenia. It is namely most elaborated on the issues of IPR. The Industrial Property Act was adopted in 2006, whereas the following year saw the adoption of Job Related Inventions Act. The main change is in the concept of IPR – now the innovations created by employees in publicly financed institutions (such as university) are owned by employer who also has to decide about the patenting. There are no fixed rules about the share in the profits between inventors and the institution. University remains autonomous in the ways it collaborates with firms.

Slovenian policy documents for 2011-2020 for the national innovation programme and the national higher education programme, reveal the desire to strengthen university TTOs, predominantly by improving the legal framework for enabling public research institutions to collaborate in industrial research and by simplifying the creation of university spin-offs. The financing of university TTOs unit should aim to "reach the entrepreneurial effects of KTT within a few years and to turn the unit more entrepreneurial every year" [10]. Thus, new innovation policy moves from the innovation support mechanisms which were successfully established, to a more entrepreneurial, market-oriented KTT.

3.2 University of Ljubljana KTT system

The UL has more than 63,000 graduate and postgraduate students, approximately 4.000 higher education teachers, and 3 arts academies and 23 faculties. It practices basic, applied and development research, in all fields of science and arts, such as the humanities, social sciences, linguistics, arts, medicine, natural sciences and technology. The University co-operates with various economic institutions in both the public and private sectors, with the government and local authorities as well as other civil institutions [12].

In 2004, UL founded its incubator (Ljubljana University Incubator – LUI), aimed at providing environment for developing professor or student starts-ups. LUI thus offers business development

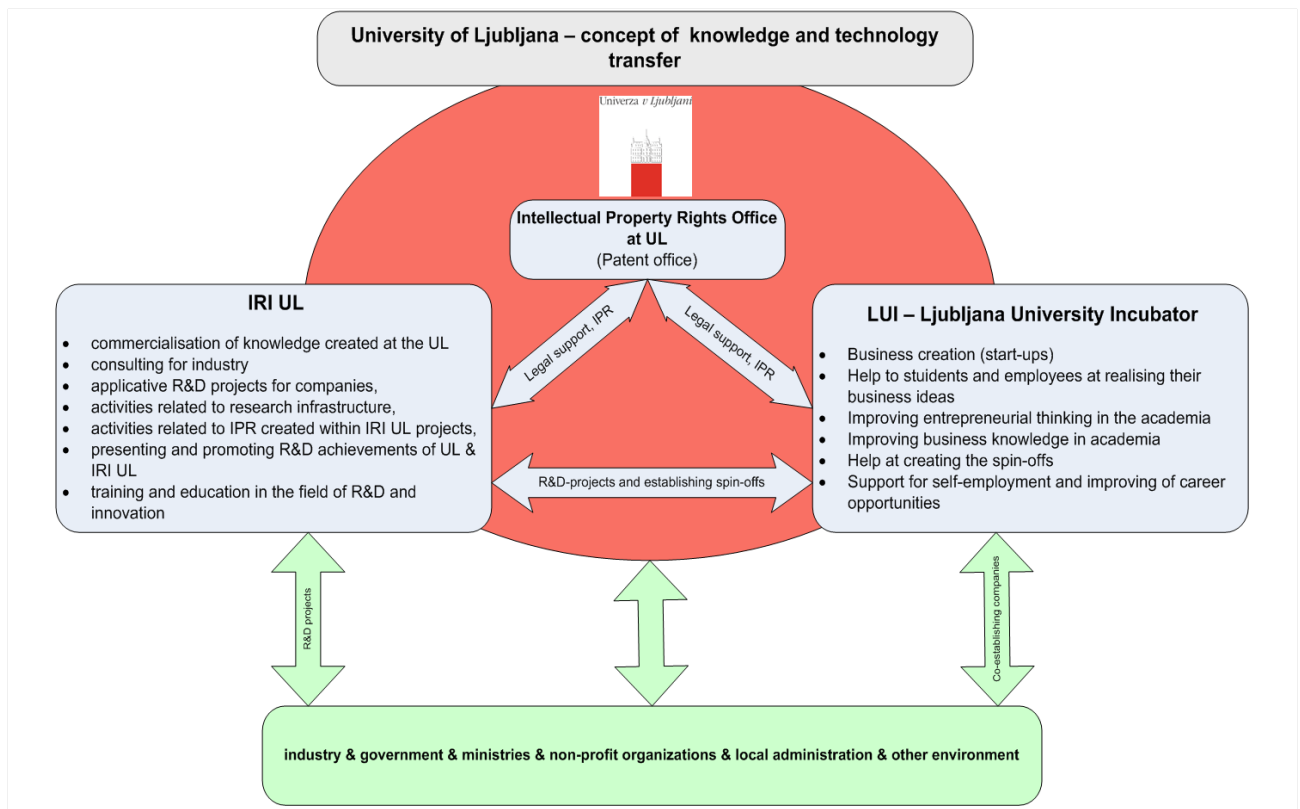

services and training services, and some IPR services. With the new IPR law in 2006, the university needed to create a special unit (patent office) for IPR. Having noted that there is no centralized institution to provide for the requests of the companies which would like to commission research or consulting on the university level, the university also decided to create the Institute for innovation and development (IRI UL). In its 2006-2009 strategy, the UL [13] defined KTT as one of its goals, comprised of a TTO as a unit within the university, of LUI which would continue functioning as a limited company, and of an independent IRI UL (more in Table 4).

Table 4 TTOs services as performed by the elements of University of Ljubljana KTT system

	IPR Office (Patent office)	LUI	IRI UL
<i>Target group</i>	Researchers, university	Researchers, students	Industry, research labs
<i>Aim</i>	Protect academic research results (IPR) and comply with 2006 IPR law	Create start-ups and spin-offs on the basis of student or professor's ideas	Develop multidisciplinary projects with market potential & respond to industry needs
<i>Important Services according to mission</i>	Knowledge valorisation (IPR, patents, licensing) Training and educating on IPR	Knowledge valorisation (IPR, patents) Business development Training (entrepreneurship classes for students)	Other cooperation with industry (consulting) Knowledge valorisation Business development Training (industry representatives, researchers)
<i>Legal form</i>	Part of the university administration	Independent company (ltd)	Independent private non-profit institute
<i>Founders</i>	University (obliged by law)	University of Ljubljana	University of Ljubljana + 10 Slovene companies
<i>Strengths</i>	Initial financial and staff support of Slovene intellectual property organization Establishing of the IPR system at university	Support of governing institutions Established and recognizable programme for students Incubator facilities (rooms, services)	Fast response to industry proposals in form of consulting or industry research projects Freedom from university bureaucracy Centralized service for all faculties Non-profit institute in public interest (University can veto potentially harmful decisions)
<i>Weaknesses</i>	Little autonomy Focus on patents Unrealistic expectations to create income in short term only established in 2006	focus of student ideas some companies remain in the incubator longer than 2 years	Lack of support from government Lack of recognisability

As Debackere [14] noted, decentralization of the organizational structure is important for successful KTT. Various units have several types of autonomy and can create different responses (thus provide different service) to the needs of their primary target groups.

Figure 1 the UL system scheme

3.3 IRI UL as part of University of Ljubljana KTT system

IRI UL is the innovation and development institute and service for KTT commercialization of the UL. It was established in 2007 by the UL and 10 leading Slovenian companies. It is a non-profit research and development institution whose aim is to establish a long-run and reciprocal partnership between the UL, Slovene industry and public institutions in order to foster research and development activities. Though private institute, it is in public interest as the UL has veto on any decision of the board that would harm the research mission of the university as an independent publicly financed organization. The mission of the IRI UL is to identify the research and development needs of the Slovene industry and competencies of researchers at the UL. The main aim is to enable the university staff to participate in commercial research projects and to enable researchers to consult companies.

IRI UL is the institution that is to be the intermediary between the demands of the industry and the potential of university researchers. IRI's main type of collaboration with industry is to create interdisciplinary teams of experts from UL to serve as consultants on a given issue or to perform industry research. For this purpose, IRI UL has created and is updating a network of all researchers at the university. Other activities consist of business development for ideas that do not qualify in the LUI (e.g. elaborating on the ideas and further development with international partners by applying for EU projects) or where patenting is not a viable option. As such, IRI is partner with university researchers in two EU Framework Programme 7 projects. Independent status of non-profit company enables IRI to participate with UL researchers in projects where the University or the LUI cannot be a partner, either because of the administrative constraints or because of the for-profit form.

All three institutions are to cooperate, yet so far, this has been more the case for the IPR office and LUI, as they have similar main preoccupation: protection of IPR and valorisation. On the other hand, IRI UL is more focused in the needs of Slovene industry and thus primarily searches for experts who could collaborate on research projects. Potential IPR questions are solved within the contract with company, and real IPR protection issues arise only in joint R&D projects. The UL has thus created a system, where it provides service which meets the legal demands, the needs of the researchers and students, as well as provides a new, centralized contractual collaboration for companies.

4. Conclusion

The transfer of researcher's know-how and research results from the university to commercial users (companies) can be named *knowledge and technology transfer*. For these purposes, traditionally a TTO unit within university was created, providing services of IPR protection and knowledge valorisation, business development, training for academic researchers and other services for companies. Today the focus in CEE has moved from the researcher to the needs of the industry and the society. In order to provide a more flexible service, the innovation system must consist of institutions which are autonomous and can respond to the needs of the market. In the KTT system of Ljubljana University such an institution was created the last and is the only one primarily aimed at the needs of industry.

Given the proposed changes in Slovene innovation and higher education policy documents for 2011-2020, it seems the patenting and valorisation activities will increase, with more impact on the applicability (market pull) of the research results. Though UL seems to be prepared for it on paper, it should be aware the institutions are very young and are unlikely to bring immediate and very tangible financial results soon.

Entrepreneurial Learning from the Support Organizations and Associations for Entrepreneurs: A Case of Turkey

*Dilek Donmez*¹

¹*Canakkale Onsekiz Mart University, Gokceada Vocational School, Gokceada, Turkey, ddonmez@comu.edu.tr*

The support organizations and associations for entrepreneurs have emerged as important agencies which work to change policy and provide services and networks to members. These organizations and associations help the entrepreneurs to develop themselves in many aspects. On the other hand these organizations and associations will serve and guide entrepreneurs through mentoring, equipping and networking them both spiritually and professionally so that the entrepreneurs can be successful on their job. Some examples of the support organizations and association for entrepreneurs are “Anatolia Businessmen's Association of Entrepreneurs”, “Association of Young Leaders and Entrepreneurs”, “Turkey Young Businessmen Association”, and “Association of Women Entrepreneurs” in Turkey. With a literature review, an empirical study had been conducted on SMEs in Turkey 1207 questionnaires were sent out, and of which 158 were usable. The purpose of this paper is to explore what are the learning needs of entrepreneurs, what do entrepreneurs want to learn about five ‘business dimensions’ in ensuring the success of their enterprises from the support organizations and association for entrepreneurs, what are the specific areas of learning needs and preferred way of learning of entrepreneurs. The empirical results of this study show that entrepreneurs want to have information in five business units as “strategy and policy” and “information technology”. They also need specific knowledge like solutions of problems for business growth. On the other hand, entrepreneurs want to learn from who have experienced the same situation before and professionals. One of the important results of the study is the entrepreneur want to see private consultants in learning process. An empirical verification of the links between learning needs of entrepreneurs and entrepreneur association in the context of Turkey's emerging economy. This paper provides some implications for the support organizations and association for entrepreneurs in presenting the right way to serve learning facilities for their members.

Keywords: Entrepreneurial learning, Learning Need, SME's, Support organizations and association for entrepreneurs, Turkey.

1. Introduction

Several authors have studied the entrepreneurial learning in entrepreneurship research (Rae, 2000). The importance of learning to small business survival and growth is beyond reasonable doubt in ever changing dynamic market places (Sullivan, 2000). The best training provision often comes from the organisations like Association of Young Entrepreneurs and Businessmen who best understand your business. Those associations are close to their members and fully understand the current training needs of businesses in their sector as well as those skills likely to be needed for future success. They will often recommend approved private training providers or offer tips on finding reputable ones. Sometimes they offer their own training courses.

A survey has shown that in the UK over 40,000 small businesses have failed annually for the last six years. In contrast the number of start-ups has been falling each year and in the last year start-ups have fallen by 26 percent. As a consequence the overall number of small businesses is decreasing (Bank of England, 2002). Beaver and Jennings (2001) updated earlier thinking on the reasons why businesses fail by compiling a list as: inadequate accounting systems; poor location; lack of marketing skills; lack of capital budget; inadequate provision for contingencies; lack of management skills; incompetence; lack of experience; neglect; fraud; disaster; poor record keeping; reckless money management; lack of formal planning; insufficient marketing talents; indifferent employees; inability to cope with growth; and excessive inventory. Deakins (1998) noted a link between the ability of an entrepreneur to learn and small firm failure. For entrepreneurs to deal with the unknown, they must be comfortable with uncertainty and manage risk (Schindehutte and Morris, 2001). To be successful an entrepreneur must think less about entrepreneurial activities and more about a set of qualities influencing behaviour and enabling flexibility and creativity (Henderson and Robertson, 1999). There are some researches defining the learning needs of entrepreneurs (John and Hides, 2002). Smilor (1997, p. 344) states, "effective entrepreneurs are exceptional learners. They learn from everything. They learn from customers, suppliers, and especially competitors. They learn from employees and associates. They learn from other entrepreneurs.

2. Entrepreneurial Learning

Learning is considered central to the process of entrepreneurial development (Deakins et al., 2000). This is particularly critical in an ever-changing dynamic marketplace (Sullivan, 2000). There is a close relationship between learning and entrepreneurial achievement in which learning is the dynamic process which enables entrepreneurial behaviour to be enacted. Entrepreneurial learning is concerned with how people construct new meaning in the process of recognising and acting on opportunities, and of organising and managing ventures (Rae and Carswell, 2000: 150-158). The entrepreneur must learn how to react to incidents, to changes and learn from problems encountered (Deakins, O'Neill and Mileham, 2000). Learning is critical to entrepreneurial effectiveness (Rae and Carswell). Entrepreneurial learning has become an important area of enquiry in relation to the academic study of entrepreneurship and the development of new entrepreneurs, yet it is an area that is not well understood (Gorman et al., 1997). The understanding of the learning process relating to entrepreneurs is of great importance. Deakins (1996, pp.21-22) states that "It is accepted that there is a learning experience from merely establishing a new enterprise. The learning process that is involved in business and enterprise development is poorly understood, yet programmes have been devised and interventions are made in business development. There is now a need for re-focusing research away from the emphasis on picking successful entrepreneurs or picking winners, to identifying key issues in the learning and developmental processes of entrepreneurship. Having briefly defined what is meant by the term "learning" time to consider how learning can be supported in the context of entrepreneurs. Entrepreneurial learning motivating on the expert knowledge and use of memory (Young and Sexton, 1997; Mitchell, 1997). Cox and Jennings (1995) suggest that it is this ability to learn from mistakes that makes successful entrepreneurs. Theoretically, external directors could have a critical role in the executive learning process. For example, they may be expected to bring experience, knowledge, discipline and rigour to strategic planning; they may also bring contacts, planning skills and a number of other intangible benefits to the entrepreneurial company (Deakins, O'Neil and Milaham, 2000). If entrepreneurs learn, what do they learn about? According to Minniti and Bygrave (2001), entrepreneurial decisions are a function of two types of knowledge. The first relates to market conditions, opportunities, technologies and/or new business ideas. Previous studies have outlined owner-managers' learning tasks in five broad areas: learning about oneself, about the business, about the environment and networks, about small business management and about the nature and management of relationship (Cope, 2005). For the entrepreneur, developing and transferring knowledge for better performance in product development requires a concerted effort across business processes. Across industries, pivotal knowledge is generated by highly specialized entities whose expertise lies in different areas. In an entrepreneurial arena facing increasing resource constraints, knowledge workers must not only be cognizant of their specific expertise, but also be able to synthesize and transfer their knowledge to other groups (Burns, Acar and Data). Therefore, the paper asks: What are the learning needs of entrepreneurs managing their businesses from the Associations of Entrepreneurs and Businessmen? The entrepreneurs around the world must be on the lookout for an entrepreneur organization to assist them in their own respective business ventures. There could be a notion that establishing one is impossible given the condition that there is a

competition among them and that there is fear of letting others learn of their respective secrets to entrepreneurial success. It also has the mission of letting these entrepreneurs learn and grow at the same time in their own fields of businesses. EO, like any other solid and well-founded organization, has a layout of its objectives. These are to nurture the entrepreneurship, to give support to the members, to present resources for new business ideas, and to have a sharing of success stories that would allow others to gain business principle insights. A free exchange of entrepreneurial ideas is fostered by the organization in order to make room for its objectives (www.bookfresh.com, 2009). In addition to the above-mentioned research, there are other studies showing that lead to this research. One of them is Schepers' study. Actually in Schepers' (2002) adaptation of the model, the following five 'business dimensions' are crucial parts of every organization that need to be integrated: strategy and policy; monitoring and control; organization and processes; people and culture; information technology. Basically, Schepers' model is that leveling of the five dimensions will significantly contribute to the performance of an organization (Schepers, 2002). Based on Schepers' model, this paper argues that member entrepreneurs of support organizations and association for entrepreneurs want to learn about five 'business dimensions' in ensuring the success of their enterprises.

3. The Support Organizations and Associations for Entrepreneurs in Turkey

An entrepreneur is never really alone unless he chooses to be. There are dozens of support organizations and professional associations specifically for entrepreneurs in Turkey. The support organizations and association for entrepreneurs are aware of their responsibility to create the entrepreneurial vision. The support organizations and association for entrepreneurs aim at maintaining a dialogue with policy makers and other stakeholders in pursuit of the public interest, enhancing the capacities of its members through continuous learning and training about entrepreneurship; creating business development and networking opportunities for its members in Turkey and abroad. The support organizations and association for entrepreneurs organize various meetings, panel discussions, and workshops with its strategic study groups or permanent commissions founded with the aim of forming the entrepreneurial vision in current, economical, social, political, and cultural issues. This organizations and associations have mission to inform their members about all kinds of studies carried out within the framework of our transparent leadership style and to encourage them to participate (Turkey Young Businessmen Association of Turkey, 2011). On the other hand Association of Young Businessmen provides its members with a variety of monthly programs designed to educate and inform, provide leadership opportunities, and develop a strong business and social network within the community.

4. Methodology

4.1 Research Questions

The specific research questions addressed in this research are; What are the learning needs of entrepreneurs managing their businesses from the Associations of Entrepreneurs and Businessmen? What do entrepreneurs want to learn about five 'business dimensions' in ensuring the success of their enterprises from the support organizations and association for entrepreneurs? What are the specific areas of learning needs of entrepreneurs? What is the preferred way of learning of entrepreneurs?

4.2 Sample and Response Rates

The survey was designed to explore the entrepreneurial learning needs of entrepreneurs and their expectations from support organizations and associations for entrepreneurs. A cross-sectional survey-based method is suitable for testing the study hypotheses because data on a large number of organizations can be collected systematically via this method (Babbie, 1973). The survey method is the least susceptible to researcher bias in data collection, analysis, and interpretation (Busha and Harter, 1980). Using the widely accepted definition of SMEs in Turkey as companies with 1-100 employees (Gungen, 2001) but excluding micro firms with 1-9 employees (Storey, 1994) from this set and considering the database of the members of governmental Network of Small and Medium Sized

Enterprises published on Internet (Kobinet, 2011), the population of the study was found to be 6322. There are 7 geographical regions in Turkey and total of 81 cities in these 7 regions. In order to collect adequate cross-sectional data for SMEs, the questionnaires were mailed by a systematic sampling that is used in previous study (Kutlu and Ozturan, 2008). In this way, total of 1207 questionnaires were mailed, informed of the nature of the study, and asked to complete a survey questionnaire. Research was conducted between September 2010 and December 2010. Follow-up reminder e-mails were sent periodically . 121 were returned as undeliverable. 207 respondents returned the completed survey questionnaires (49 of them is not member of support organizations and associations for entrepreneurs). Four survey questionnaires were deleted due to a large amount of missing data. The survey, therefore, yielded 158 usable responses, representing an 13 percent response rate. The survey was divided into sections that recorded personal demographics, the entrepreneur's perceptions of the entrepreneurial learning from the support organizations and association for entrepreneurs. The companies in the study are ranked all in the IT, tele-communication, other services, government and education, manufacturing, trade, transport and logistics.

4.3 Survey Instrument

As noted earlier, the survey instrument was developed based on a search of the literature. The questionnaire used in the research were adapted from previous studies (Sexton, Upton, Walcholtz and Mcdougall, 1997; Burns, Acar and Data, Kutlu and Özturan, 2008). SPSS Version 13 was used for statistical analysis. Conformingly, the reliability test done for this research shows an alpha values of which indicates a high reliability.

4.4 Results

4.4.1 The descriptive statistics of the enterprises

Table-1 shows the descriptive statistics of SMEs group by number of employees and industry. As shown in Table 1 the majority of enterprises are from manufacturing sector (41%). Services-based enterprises made up the largest percentage of the firms surveyed (21%,16%, 22%). 38% of the enterprises have 10-19 and 50-59 employees.

Table 1 The Descriptive Statistics of the Enterprises

Sector	Number of Employees					Total	%
	10-19	20-29	30-39	40-49	50-99		
IT, Tele-communications and Other services	15	7	10	-	1	33	0,21
Government and Education	11	3	-	12	-	26	0,16
Manufacturing	11	4	16	12	22	65	0,41
Trade, Transport and Logistics	1	7	2	9	15	34	0,22
Total	38	21	28	□□□□□□□□		158	100

4.4.2 Demographics Profile of the Entrepreneurs

There are more male (78%; 123) respondents than female respondents (22%; 35). Almost (75%; 118) of the sample are age of 30 and above. Almost half of the sample (55%; 87) indicates collage or university level of education. The majority of respondents are married (65%; 102).

4.4.3 Learning Needs of Entrepreneurs

This was measured with a 25-item grouped into 5 sections, five-point Likert scale based on the work of Scheper (2002) and Sexton, Upton, Walcholtz and Mcdougall (1997). The items were designed to identify entrepreneurial learning needs of entrepreneurs based on five 'business dimensions; "strategy and policy", "organization and processes", "monitoring and control", "people and culture" and "information technology". For validity purposes an exploratory factor analysis was conducted for 25-item scale. At first, values from the KMO and Barlett tests were taken into account in order to carry out

a factor analysis. Since KMO test suggested a variance of .83 and Barlett Sphericity test a meaningful variation ($\chi^2=470.54$, $p=.000$), it was decided that it would be appropriate to conduct a factor analysis for the scale. Firstly, factor analysis is applied to reduce the number of variables and to detect structure in the relationships between variables, that is to classify variables in the study. The scale was divided into five dimensions as mentioned previously in the literature, namely “strategy and policy” showed an eigenvalue of 3,12 and accounted for 77.0% of the total variance, which is a good value; “organization and processes” showed an eigenvalue of 3,45 and accounted for 70.0% of the total variance, which is a good value; “monitoring and control” showed an eigenvalue of 4,62 and accounted for 81.0% of the total variance, which is a good value; “people and culture” showed an eigenvalue of 4,00 and accounted for 76.0% of the total variance, which is a good value; and “information technology” showed an eigenvalue of 5,12 and accounted for 84.0% of the total variance, which is a good value. Entrepreneurs respond to items using a 5-point Likert-style that ranges from strongly disagree (1) to strongly agree (5). In this study reliability was measured by the Cronbach Alpha. Cronbach alpha values ranged from 0,67 to 0,96. Specifically, dimensions such as “strategy and policy” $\alpha=0,67$, “organization and processes” $\alpha=0,77$, “people and culture” $\alpha=0,79$, “information technology” $\alpha=0,84$, “monitoring and control” $\alpha=0,96$ had either excellent or acceptable alpha values (George and Mallery, 1995). As shown in Table 2, entrepreneurs have learning needs about “Strategy and Policy” ($M=4,55$) and “Information Technology” ($M=4,10$).

Table 2 Learning Needs of Entrepreneurs About Five ‘Business Dimensions’

Variables	M	SD	N
Strategy and Policy	4,55	0,76	158
Organization and Processes	2,16	1,35	158
Monitoring and Control	3,39	1,99	158
People and Culture	2,63	1,06	158
Information Technology	4,10	1,13	158

Notes: M=Mean, SD= Standard deviation, N=number of respondents

Based on this finding, support organizations and associations for entrepreneurs recommended that presenting strategy and policy and information technology-oriented learning activities. On the other hand, entrepreneurs reported a negative opinion on having support about “organization and processes” ($M=2,16$). Entrepreneurs remains undecided about “monitoring and control” ($M=3,39$) and “people and culture” ($M=2,63$).

4.4.4 Differences between the business about learning needs

In addition, study try to find out whether there are differences between the groups about learning needs of about five business dimensions according to industry and number of employess. One Way Anova test was applied for this purpose. Table 3 shows the results of One Way ANOVA test according to industry. The results reveal there is no significant difference between any pair of the four groups about learning needs on five business units of entrepreneurs based on industry ($p=.085 > 0,05$).

Table 3 The Results of One Way ANOVA Test According to Industry

		Sum of Squares	df	Mean Square	F	Sig. (p)
Learning Need of Entrepreneurs	Between Groups	4,322	3	1,541	3,852	,085
	Within Groups	133,039	237	1,461		
	Total	137,361	240			

Table 4 shows the results of One Way ANOVA test according to number of employees.

Table 4 The Results of One Way ANOVA Test According to Number of Employees

		Sum of Squares	df	Mean Square	F	Sig. (p)
Learning Need of Entrepreneurs	Between Groups	4,690	3	1,430	4,002	,120
	Within Groups	40,638	237	,176		

	Total	44,328	240			
--	-------	--------	-----	--	--	--

The results reveal that there is no significant difference between any pair of the five groups about learning needs on five business units of entrepreneurs in terms of number of employees ($p = 0,120 > 0,05$).

4.4.5 Specific Areas of Learning Needs of Entrepreneurs

Respondents were asked to rate the need of entrepreneurial learning about specific areas as with other similar studies (Sexton, Upton, Walcholtz and Mcdougall, 1997, Sullivan, 2000). As these studies the learning needs area were ranked as below: using cash flow to make operational and financial decisions; financing growth; increasing the value of the business; harvesting value from the business; successful selling via helping customers buy; hiring, training, and motivating a dynamic sales force; value-added advertising topics; sales and marketing strategies for growth; creative management of human resources; hiring, training, and motivating for growth; compensation for self and associates; equity-based compensation as a business strategy; building the entrepreneurial culture within the organization; problems and pitfalls of growth; succeeding in a rapidly changing world; and management succession. Respondents were also asked to identify any other topics not included in the list. Table 5 below presents the results of this question; the figures are in frekans and percentages. As it can be seen in the Table 5, the vast majority of entrepreneurs want to be informed about hiring, training and motivating for growth (91%), equity-based compensation as a business strategy (84%), financing growth (77%) and succeeding in a rapidly changing world (68%). Looking at these results it can be said that entrepreneurs seem to have problems related to the growth of their businesses. They need learning to plan for the success of the organization and to anticipate upcoming problems for growth. Entrepreneurs stated that their training needs of in some other titles like using cash flow to make operational and financial decisions (37%), increasing the value of the business (24%), successful selling via helping customers buy (42%), creative management of human resources (25%), compensation for self and associates (41%). One of the important results of the study entrepreneurs stated that they want to learn about the some issues not mentioned in the list. These are "e-commerce" (34%), "effective leadership" (43%), and "new approaches to productivity" (26%).

Table 5 Specific Areas of Learning Needs of Entrepreneurs

Specific Areas of Learning Needs	Frekans	Percent
using cash flow to make operational and financial decisions	60	0,37
financing growth;	123	0,77
increasing the value of the business	38	0,24
harvesting value from the business	49	0,31
successful selling via helping customers buy	67	0,42
hiring, training, and motivating a dynamic sales force	40	0,25
value-added advertising topics	15	0,09
sales and marketing strategies for growth	55	0,34
creative management of human resources	48	0,25
hiring, training, and motivating for growth	145	0,91
compensation for self and associates	65	0,41
equity-based compensation as a business strategy	134	0,84
building the entrepreneurial culture within the organization	13	0,08
problems and pitfalls of growth	53	0,33
succeeding in a rapidly changing world	109	0,68
management succession	12	0,07
Other (e-commerce)	55	0,34
Other (effective leadership)	68	0,43
Other (new approaches to productivity)	41	0,26

Specific Areas of Learning Needs	Frekans	Percent
Total	158	100

4.4.6 Preferred Way of Learning of Entrepreneurs

Respondents were also asked to indicate their preferred way of learning from a list of: nothing, do not need; read a computer bulletin board; listen to an audio tape or CD; watch a video tape; attend a roundtable discussion, attend a seminar; hire a private consultant; or other. Table 6 shows preferred way of learning of entrepreneurs.

Table 6 Preferred Way of Learning of Entrepreneurs

Way of Learning	Frekans	Percent
Nothing, dont need	-	0,00
Read a computer bulletin board	33	0,20
Listen to an audio tape or CD	28	0,17
Watch a video tape	79	0,50
Attend a roundtable discussion	97	0,61
Attend a seminar	148	0,93
Hire a private consultant	115	0,72
Other	-	0,00
Total	158	100

When asked if respondents preferred way of learning, the majority (93%, n=148) reported they want to attend a seminar, hire a private consultant (72%, n=115) and attend a roundtable discussion (61%, n=97). Of the 79 (43.4%) respondents who reported that they preferred watch a video tape about the topic that they want to learn. Only 28 (17%) and 33 (20%) respondents reported that they want to learn by reading a bulletin or listening an audio tape or CD.

5. Conclusions

As firms increase in size and complexities, the entrepreneurs managing them face a number of unique problems. Most of the time the entrepreneurs lack the experience to address these problems. At this point, support organizations and association for entrepreneurs come into for entrepreneurs. The results of this study conducted with 158 businesses show that entrepreneurs want to learn from these organizations and associations. This study also identifies the learning needs and preferred delivery ways of entrepreneurs. In the study the following preliminary findings also emerged: Entrepreneurs need to learn about "Strategy and Policy" and "Information Technology". Support organizations and associations for entrepreneurs share more detailed information about these business dimensions with their members. Managers and executives of companies who are becoming more strategic, more reliant on information technology because today entrepreneurs need information to do their work and support organizations and association for entrepreneurs can offer this service to them. Entrepreneurs want specific knowledge about financing growth, hiring, training, and motivating for growth, equity-based compensation as a business strategy, succeeding in a rapidly changing world, e-commerce, effective leadership and new approaches to productivity. Entrepreneurs have a better understanding of what they want to learn in complex business world. They want information that primarily about business strategies and growth of their businesses. These findings show the entrepreneurs may need to solve problems of growth in their businesses. Actually entrepreneurs tend to be growth-oriented, reach this finding is not surprising for this study. These findings could be used to develop a series of courses or modules that could enhance the success of entrepreneurs and efficiency and effectiveness of support organizations and association for entrepreneurs. Entrepreneurs want to learn the topics in an interactive way like attend a seminar or roundtable discussion. Based on this finding, roundtable discussions and seminars seem to be solution for learning activities of entrepreneurs. This finding also shows that today's entrepreneur want to find out by questioning, consultanting and discussing. Finally, they want to learn from those who have experienced the situation, i.e. private consultant. According to this finding, entrepreneurs believe that experience have effectively prepared them to compete in the

business world. Especially private consultants are preferred by entrepreneurs. Consultants and professionals can offer advice on all aspects of business. Thus, associations should focus on making this service. The results show there is no significant difference between groups about learning needs on five business units of entrepreneurs based on industry and number of employees. Accordingly, it can be said that learning needs of all businesses within the scope of research are the same. In conclusion, this study has contributed towards understanding entrepreneurs' learning need. An empirical verification of the links between learning need of entrepreneurs and support organizations and association for entrepreneurs in the context of Turkey's emerging economy. This paper provides some implications for the support organizations and association for entrepreneurs in presenting information needed and the right way to serve learning facilities for their members. Readers should be aware of possible limitations with the data source and measures used in this analysis. This study also raises a number of other important questions to be addressed in future research. A qualitative research can be done on the same subject. One big limitation was that the sample of the Turkish businesses obtained was only 158 participants. To be a representative sample it would have been needed more, but the resources, and limits of time to make this study didn't make possible to have a higher one. It would be interesting to make this type of study in different countries and societies to see the cross-cultural differences.

Strategies, the use of information technologies and competitiveness of companies in Serbia

Zdenka Dudić¹

¹Faculty of Technical Sciences, Novi Sad, Serbia, zdenkadudic@yahoo.com

The research paper "*Strategies, the use of information technologies and competitiveness of companies in Serbia*" deals with the subject that has been very important in recent years, not only for Serbian economy, but also for the country itself. Of course, the state is in search of the best solution for overcoming this situation; it tries to solve the problem in the fastest, most favourable and most efficient way. It should take advantage of good geographical position of the country, stimulate economic development, improve competitiveness and restore the former success and a good economy. What is the structure of enterprises in Serbia now? Recently we have often come across the term „strategy“ and competitiveness. The question is how and what to change. We must decide what strategies to use in order to increase the competitiveness of Serbian companies, what to do with the companies which have fallen into difficulties... Where is Serbia on the WEF's list now? How to achieve better position on this list? To be competitive means to be successful and to take a better position on the WEF's list. Do new technologies affect the productivity? Will they be the solution for the Serbian companies? What matters should we pay attention to? How should we invest our financial resources? Would this solution moderate the current crisis and the transition period? The information technologies have taken on a new significance. They influence the development and competitiveness of companies. The change of thinking, restructuring and investment in education are vital for the recovery of Serbian economy and bringing it back to European market. It also means making a bigger profit. The use of foreign funds, which are issued for the EU candidate countries, can be one of numerous sources for financing new companies, as well as for presenting the new high-quality products.

Keywords

Serbian economy, Serbia on the WEF's list, strategy, information technologies, competitiveness

1. Introduction

In recent years there has been a number of discussions about what a strategy is and what the elements of a successful strategy are. The main controversy is over the question of how to formulate a successful long-term strategy which would enable a company to survive and develop. The word "strategy" is widely used, but often misinterpreted. Companies need to know what they want and then they can create a strategy. The advantage is to do the same as the competition, but to do it better! The ultimate goal of a strategy is to be above average when compared to others, the competition. A strategy is therefore both science and skill. There is only one strategy in a system - it is related to the whole and it is always defined in relation to certain competitive company. The „strategic theory“ is important for every strategy. A strategy formulates system functioning under all circumstances, and it refers to a longer period of time. Thus it dictates the quality of the managers. A strategic management deals with a strategy. Different strategies lead to different results. The introduction of electronic commerce involves many changes. It changes business strategies. The Internet is the infrastructure for many jobs that did not exist before. Many companies adapt to new business conditions and introduce many novelties. More companies are now implementing ERP systems in their business, in order to improve their competitiveness and to survive in the market in the era of information technology.

Various authors define a strategy differently. One author defines a strategy in five different ways, such as: a plan, a procedure, a position, a perspective and discernment. Another author states that a strategy is defined by at least two aspects: what the company intends to do and what company does regardless of whether its actions have been planned or not. Every author sees the essence of a strategy in his own way, just as every company has its own strategy, which for some may be successful and for others not. Not every decision is good for every company. A strategic plan helps a company to make its dreams come true and to make correct decisions. It allows the organization to have a structure and to know what to do in order to achieve its goal, whether that is the survival in the market or circumvention of the competition. Therefore, most organizations attach great importance to strategic planning for a long-term growth and welfare of the company.

2. Strategic planning now and then

Strategic planning is helpful to managers because it allows them to prepare for the changing environment in which their organizations operate. Nowadays, things change so quickly that the managers' experience cannot be their only reliable guide. They are forced to develop new strategies that correspond to problems and future opportunities. The main drawback of strategic planning is danger of creating a huge amount of paperwork, which can lead to the loss of contact with business products and consumers. Some organizations have overly invested in the consultants, planning staff and sophisticated planning models and programs. Those investments cost greatly, because the planning staff may usurp the initiative and power of the operational managers. It is necessary to make strategic plans and concepts closer to the actual needs of an organization.

Another disadvantage of strategic planning is that it sometimes tries to limit a company i.e. it makes it use the most rational and less risky options. In order to be successful, there should not be too much planning, but more application. The most important thing is to apply the strategy, and convert it into action. This is the basic competency of today's enterprises. However, this is not so easily achievable in practice. Modern technology (mobile phones, internet, email ...) has completely altered the way of organization managing. Once the geographical distance was a problem, and today it is the smallest obstacle, since managers can now negotiate over the videophone, or enter into contracts electronically. The development of technologies has enabled managers to get in touch with anyone anywhere.

2.1 Decision-making in companies

In modern business managers are the main carriers of success, stability and development of a company. As many authors state, the main characteristic of a successful manager is his organizational skill which enables solving business activities efficiently. Based on this, decision-making is defined as solving various problems which occur in a company and its management. Problems may present not only the dangers but also the opportunities for a company. Some decisions are of great importance to the organization and the consequences of those decisions can have a long-time effect. Other decisions are not so important and their consequences are felt only for several days or even hours. Depending on the time dimension, decisions can be strategic, tactical and operational. Strategic decisions are made in high levels in the organizational structure of a company and they are related to the improvement of the future strategic position of the company. These decisions concern new technologies, new products, target markets, the manner of achieving competitive advantages, survivals in the market, stability of the company and others. According to the degree of structure, they are classified into:

1. structured - made on the basis of sufficient information, clearly defined rules and criteria.
2. non-structured - there is a lack of information as well as previous similar experiences and thus creativity and intuition are required.
3. half-structured - a combination of the previous two types.

The changes that are introduced and decisions that are made i.e. decision-making can be:

1. decision - making under conditions of certainty - it is not very difficult because all the facts and the situation are known. There is no risk so this kind of a situation is more of the confirmation than decision-making.

2. decision - making under conditions of partial uncertainty (risk). In this case, the situation is only partially known and the way how the situation will evolve can only be speculated.

3. decision-making under conditions of complete uncertainty. The situation and its possible development are completely unknown.

2.2 Competitiveness of enterprises in Serbia

The word competitiveness is often heard, along with the word strategy. Competitiveness is now an important element of any development strategy[1]. Some authors state that competitiveness is the ability of the economy to attract companies and keep them active by a growing market share and a steady increase in living standards in their communities. It is important for every country since it determines the level of productivity and development. Therefore, competitiveness is defined as a number of institutions, policies and factors that determine the level of productivity of the country. The level of productivity, on the other hand, defines a sustainable level of prosperity that an economy can create. More competitive economy will be able to produce a higher level of income to its citizens. The level of productivity determines the rate of return. Since the rate of return is vital for the economic growth, competitive economy is the one that achieves a faster growth in a long period. The concept of competitiveness includes both static and dynamic components: although the productivity of a country is clearly determined by its ability to maintain a high level of income, it is also one of the key determinants of realized investment returns. Competitiveness strategy now occupies a central place in numerous studies. The essence of competition is not in the rivalry. Companies in Serbia deal little with the matters of internal economy, increasing productivity, improving work organization, increasing profitability, introduction of information technology into their work and personnel training - and these are very important factors for increasing the competitiveness. Human resources and adoption of new technologies and technical facilities are two very important, perhaps the key factors in this era of extremely rapid development of information technology. World Economic Forum – WEF[2] shows twelve pillars of competitiveness i.e. it classifies a wide range of competitiveness factors into 12 categories, and each year it publishes a list of countries based on their competitiveness. The first phase - the initial phase of development - is a policy dealing with basic factors (institutions, infrastructure, macroeconomic stability, health and primary education) and it is of crucial importance, i.e. I - 60% - II - 35% - III - 5%. The second phase - the more mature phase - after reaching the primary factors of competitiveness, efficiency factors are important for future progress (higher education and training, market efficiency, labor market efficiency, financial market sophistication, knowledge and the use of technology, market size), i.e. I - 40% - II - 50% - III - 10%. The third phase - the most mature phase - is characterized by the factors related to innovation and the economy driven by innovation (business sophistication, innovation), i.e. I - 20% - II - 50% - III - 30%. According to the World Economic Forum[2], which shows the ranking of countries by competitiveness in 2009-2010 and compares them with the ranking in 2008-2009, Serbia is ranked the 93rd among 133 countries, which is very worrying. Only Albania and Bosnia and Herzegovina are below Serbia on this list. Serbian neighbors, Montenegro (62nd), Croatia (72nd), Macedonia (84th) are far ahead of Serbia. According to WEF's rankings for 2010/2011 in September 2010 Switzerland is the most competitive country, because its economy is characterized by innovation and sophisticated business culture. It is followed by Sweden, Singapore and the USA. At the bottom of this list, which comprises 139 countries around the world, are Burundi, Angola and Chile. The weak competitiveness of these countries is explained by inefficient bureaucracy, corruption in the country, restrictive labor regulations, policy instability, tax laws, insufficient education, access to finance ... On this new list for 2010/2011 Serbia is on the 96th place. The only countries in the same region that are below Serbia are Albania and BiH, which have recorded a slight rise on the list when compared to the last ranging. Montenegro has moved from the 62nd to the 49th place and entered the 50 most competitive countries, while Croatia reflects a small fall from the 72nd to the 77th place. Macedonia has moved from the 84th to the 79th place on the list. Regarding the adoption of new technologies in companies, Serbia is ranked 125th. Information about the departure of young talents from Serbia is also devastating: the 132nd place on the list of World Economic Forum. These data indicate the fact which is not openly discussed - it is frightening and alarming that one of the European economies is the worst ranked. The productivity of a country is determined by the productivity of its companies. Obviously, Serbian economy must pay greater attention to economic reforms and transition. The companies should actively participate in strengthening their own competitiveness. Entry to the investment-driven phase imposes new challenges on Serbia in terms of improving competitiveness. The future innovative phase will impose fulfilling of more requirements. In Serbia, small and medium-size enterprises (SMEs) employ 2 / 3 of workers. They are the most vital part of Serbian economy, which has achieved 40% of export and 60% of import. Furthermore, there is a great number of companies which produce products that cannot be exported, and are more expensive compared to imported products. Thus, they are non-competitive

and operate at a loss. The solution can be found in the change of thinking, in innovation. The key factor in initiating innovation is human capital. This confirms that the knowledge embodied in a number of competencies, and skills, is crucial for defining the company's competitive position. Strong need for specialized knowledge and skills is one of the dominant characteristics of modern business environment. In this sense, companies need human resources trained to conduct the expertise, to think critically and analytically, and to have the power of synthesis. Therefore, the management of human resources is the direct source of quality and productivity improvement, as well as competitiveness. At the same time, the resource must be continuously developed and perfected. In that sense, in every company, professional training, consultancy support and development of special skills of managers and employees must be of great importance. Production and technological innovation are important but not sufficient for achieving a successful strategy - innovation is necessary. In February 2010 National Agency for Regional Development and the Serbian Chamber of Commerce signed the Protocol on cooperation in the project of Enterprise European Network. This protocol is expected to increase the competitiveness of Serbian economy. The main objective of the Enterprise European Network in Serbia is to put Serbian small and medium-size enterprises in the same position with the European ones and to allow them access to various funds. Serbian small and medium-size enterprises are given way to the EU and their technologies and funds worth several hundred million euros. Thus Serbian small and medium-size enterprises are placed in the same position with the ones in the rest of Europe. Automatically, their competitiveness is increased as well as a greater participation in domestic and international markets. This is a good sign, because in Serbia 2 / 3 of the total number of enterprises are small and medium-size. They are the pillar of the national economy and they employ most people. Enterprise European Network allows companies to gain in one place different types of services, such as assistance in finding partners and establishing business cooperation, participation in tenders, easier access to information on the EU business regulations, support programs, legislation and results related to innovation.

2.3 Application of technology in decision-making

Inclusion of technology in the process of strategic management is an essential prerequisite for efficient and effective business operations. Technology creates new industries, transforms existing ones or destroys them. The increasing impact of technological progress and shorter life expectancy of primary technological changes require companies' continuous adaptation to new technological styles. Life expectancy of the basic technological equipment today is 5-7 years. In younger non-traditional sectors such as air industry, missile industry, electronic industry, electrical – mechanical construction industry, measuring instruments industry, pharmaceutical industry, chemical industry and others, life expectancy is 3-5 years, which requires adequate offensive response.[4]

Thus, companies are forced to be trendy, to change in order to survive and to be stable and thus more competitive in the market. Dynamism of change, globalization of the market, outstanding technological development lead to the acceptance of technology as a means of achieving and improving competitive advantage. An important element of strategic management is management technology and therefore, adaptation to changes in business environment. Management information systems are systems of collection, storage, organization and dissemination of information useful to managers. It should not be doubtful that most jobs today are based on managing a number of information generated from business. Computerization of information management has numerous effects on the organizations. The most important effects are: the ability of processing and creating documents with a high accuracy and high speed. Along with the emergence and development of decision theory, Information Systems evolved. Their development has changed everyday life and work of men. Computers, networks, databases, computer-based models are used in decision-making. The most important benefit derived from computerization of management system is a continuous progress in performance improvement. The biggest risk or threat associated with greater management information is security and protection of confidentiality and integrity of data and information. For most organizations, it is not easy to achieve profitable growth in today's business climate. They are faced with global competition, consolidation of the market, lack of talents, demands for coordination, increased expectations of customers and shareholders, as well as increased profitability. Constant changes in the industry make these challenges even more complex. To respond to these challenges, companies must be able to react and transform their business quickly and economically, without having to sacrifice profitability, transparency and internal control. Flexible, functional and reliable information technologies are required. A company also needs software that efficiently manages the entire process of the industry that the company deals with. The term ERP is often heard today. Almost every business magazine writes about it. ERP is an abbreviation for "Enterprise Resource Planning. ERP in general does not

plan anything and one will not be exempt from liability for one's decisions. It provides information based on which one can plan and make the right decisions. Solutions for enterprise resource planning (ERP) play a significant role in the success of the company. The appropriate ERP software can increase the productivity of corporations. It enables easier management of complex corporate structures, market channels and business scenarios, as well as modernization of business processes and operations, optimization of important corporate resources and assets. Implementation of appropriate ERP software can reduce the time for placing products on the market and returning of the investment, deliver individual products and services to existing and future markets, improve services and satisfaction of employees and customers in all aspects of business operations.

2.4 The research on application of information technology in Serbia

The research results of the Republic Bureau of Statistics[5] show that more than 90% of the companies in Republic of Serbia use computers in their work, which is a slight increase of 0.1% compared to 2008. 100% of large and medium-size enterprises use computers, whereas slightly over 90% of small ones do the same (see figure 1).

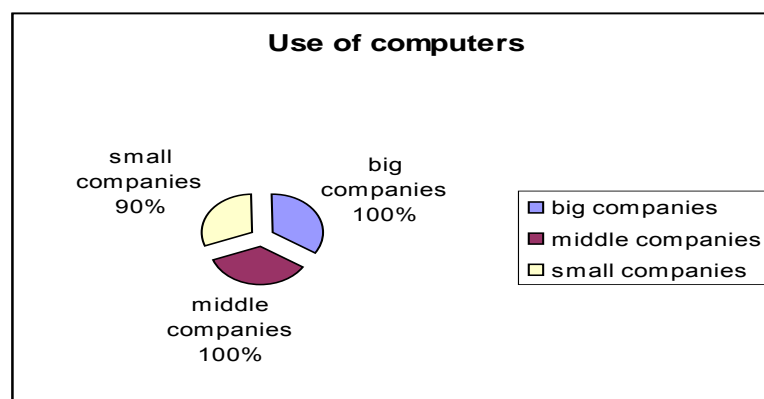

Figure 1 Use of computers

Regarding the representation of information and communication technology, the survey shows that 68.9% of the companies have Wire based LAN, 43.7% Intranet, 34.7% Wireless LAN, while 12.2% of the companies have Extranet. During 2009 11.3% of the companies used ERP system. Analysis of the companies by size shows that 49.2% of the large companies have ERP system, 21.6% of the medium-size, while only 7% of the small companies have ERP systems (see figure 2).

Figure 2 Use of ERP system

Banks and insurance companies use ERP system most (41.9%). They are followed by the companies providing transport, storage and communication services (15.7%). In 2009 CRM system was used by 14.1% of the surveyed companies. In January 2009 10.1% of the companies in Serbia used a CRM system which allows analysis of customer information for marketing purposes. 12.9% of the companies used CRM for entry and storage of customer information, making it available for other business services. Of the total number of analyzed companies, 36.8% of the large companies have a CRM system, as well as 26.1% of the medium-size and 10.2% of the small ones (see figure 3).

Figure 3 Use of CRM system

This system has the biggest application in the banks and insurance companies (71%), and then transport, storage and communication companies (24.8%). In Serbia, 94.5% of the companies have Internet access (large companies 100%, medium-size 97.7%, small 93.4%), which is 3% more compared to the data from 2008. The answers to the question whether the company has its own web page vary. In Belgrade 78.2% of the companies have their own web sites, in Vojvodina 66.3%, while in Central Serbia only 55.3%. The research shows that only 19.9% of the companies which have Internet access received orders via the Internet in 2008 (e-mail orders excluded) which is a slight increase of 2.9% compared to the data from 2007.

In Republic of Serbia only 20.2% of the companies have rules that normatively regulate the issues of information security. Regarding the knowledge of information security measures, 16.8% of the companies test their employees, while 83.2% have not yet introduced this kind of a test.[6]

3. Conclusion

ERP enables a company to integrate data and organizational processes into a single system. The company can design its own information system if its business processes are specific, or if it uses one of the ready-made solutions (Panthéon, SAP, MS Dynamics). In the surrounding region business solutions are used on a greater scale, and it is inevitable that in the coming years more and more companies will come to realize the need for such solutions. Companies in Serbia are not aware of what a standard internationally-recognized ERP represents and what its advantages are. The situation is better than it was last year, and it is expected to improve. The foreign companies on the Serbian market also have a positive impact. Statistics show that the ERP market in Serbia will have expansion in the next few years. Standard expectations of the companies after the process of implementing software solutions are certain benefits gained after the installation itself. This approach is not applied to the ERP solution because returns on investment come from improving business processes by ERP, not just from the new applications. Today's companies that use this software worth more and have higher value. It is possible that the world's financial crisis has slowed down the course of implementation of these systems in the companies in Serbia. One source of income are funds that are little used in Serbia and which are intended for the candidate countries for the membership in the European Union.

Over time the European Union has developed a whole range of external assistance programs, which has resulted in the creation of over 30 different legal instruments based on which these aid programs are implemented. The European Commission has proposed a simpler framework for the provision of external assistance in the budget period 2007-2013. To that end, in September 2004 the European Commission proposed the establishment of a new instrument for Pre-Accession Assistance (Instrument for Pre-Accession Assistance - IPA 2007-2013), which is designed for supporting the candidate countries as well as potential candidates for EU membership[7]. IPA 2007-2013 has two main priorities: helping countries in meeting the political and economic criteria as well as those related to the adoption of EU legislation; building and strengthening the judiciary and helping the countries get prepared for the use of EU structural cohesion funds after accession to the European Union. The components of the IPA for the period 2007-2013 are: transition assistance and institution building, cross-border cooperation, regional development, human resource development and rural development.

Visual Analysis of Economical Ratios in Du Pont Model Using Topic Maps

Helena Dudycz¹

¹ Department of Information Technologies, Faculty of Management, Computer Science and Finance Institute of Business Informatics, Wroclaw University of Economics, Wroclaw, Poland, helena.dudycz@ue.wroc.pl

Economical ratios provide much information concerning functioning of an enterprise. These ratios are essential on condition that they are well calculated and interpreted. Their usefulness depends also on comprehension by decision-makers existing between indicators structural and semantic connections. One of suggested solutions, which allow presenting various associations between economical ratios, is the standard of topic map. This standard can be easily used for representation of financial knowledge about financial measures. In this paper, an approach to analysis of economical ratios in Du Pont model based on topic maps is presented. The managerial staff can be supported by easy-to-use tools that facilitate access to a wide range of relevant data resources. Graphical expressions can assure semantic information search and interpretation for non-technically-minded users. Thanks to visualization users can more swiftly notice and understand various structural and semantic relations. In this paper, case studies illustrating the process of designing topic maps and concept of visual data analysis are discussed. The presented topic map for return on investment (ROI) indicator has been developed in the authoring environment TM4L (Topic Maps for e-Learning). The TM4L provides support in conceptual structure design and maintenance through its editing functionality, browsing and ability to link topics to resources. This article is continuation of carried out researches on possibility of adaptation and verification the standard of topic map as method of presenting semantic associations between different economical ratios.

Economical ratios, Ontology, Topic map, Visual Analysis, Visualization

1. Introduction

In business environment, where quick and reliable access to knowledge is crucial factor of success, efficient processing of data and information resulting in acquiring new knowledge concerning enterprise becomes essential. Hence organizations are more and more interested in supporting processes of knowledge management by using information technology allowing appropriately integrating and searching it [1, p. 169].

Essential information concerning functioning of enterprise is conclusions resulting from analysis of economical ratios. Relations between analyzed indicators can be both structural and semantic. In addition knowledge of semantic connections and resulting from them information concerning functioning of enterprise is often possessed only by experienced financial analysts. Research carried out by E. Awad i H. Ghaziri, published in 2004, confirms formulated in 1995 by I. Nonaka and H. Takeuchi statement, that as much as 95 percent of information is preserved as tacit knowledge [2, p. 209]. Therefore the problems still demanding solution is the way of acquiring and representing experts' knowledge to on the one hand support searching essential information in the analysis of economical ratios, but also by appropriate processing data allows discovering new knowledge. That requires connection of two essential issues: knowledge representation in information system that would also enable to change tacit knowledge to explicit knowledge, and using besides traditional

Information searching methods solutions allowing contextual searching. More and more attention is paid on using in this scope semantic technologies such as topic map as solution that can be used to search and acquire unique information [1].

In this article a topic maps application is discussed to show the ease of analysis of economical ratios in Du Pont model. The article is structured as follows. In the next section the state-of-the-art in topic map, visualization of business information and visual data analysis is presented. Section 3 illustrates a concept of application topic map for ROI indicator in Du Pont model and case study of visual analysis of economical ratios. A number of examples of visual interpretation are presented and discussed. Finally in the last section, a summary of this work is given and a future research projects are indicated.

2. Related work

2.1 Topic map as knowledge representation standard

Topic map is ISO standard (13250:2003) for knowledge representation, which main aim is to organize information by semantic connections of topics. Origin of its inception was need of creating technology allowing organizing big number of information sources as part of their semantic index. Towards the end of 2001 this standard was changed to ISO 13250:2003 and is based on *eXtensible Markup Language* (XML). Topic map is abstract structure, allowing mapping knowledge from given field and enabling to look through sources connected with it [3]. Topic map can represent complex structures of knowledge bases [4], becoming useful model of knowledge representation [5, p. 174], where multiple contextual indexing can be used. That results from the structure of topic map that contains three elements: topics, associations (that is relations existing between topics) and occurrences (that is indexed sources related to given topic).

Context search is very helpful in data exploration, as well as in targeting on searching information needed at the moment. In literature new paradigm for accessing and organizing information, consisting in integration and context classification of all information from different systems is written in [1, p. 172]. Context search is more efficient than the one basic only on simple hierarchic structure (see [6, pp. 1898-1911]). Latest research point out also, that searching information basing on semantic connections in topic map have positive influence on discovering essential information [7, p. 301].

As part of one, well defined topic map application there is possibility of merging various structures, diagrams, metadata, taxonomy etc. In this way semantic net can be built above information sources, that allows to easily navigate through scattered data sources (see [8], [9]), basing only on context of information. Topic map application can in a way function as interface between user and different data sources. Such approach allows, by one data model, to access different sources, that are in organizational information systems.

Topic map standard is well fit to map ontology, which is crucial element in many practical appliances of knowledge representation. Creating topic map application allows to map ontology prepared by one as well as several experts from particular field. Essential feature, especially in the context of mapping ontology of economical ratios is possibility – without unnecessary outlays – to modify already existing topic map application. Among advantages should also be mentioned, on what L. M. Garshol pays attention, that as ISO standard it is solution independent of producer and platform, what allows organization to choose any tool to create topic map application regardless of implemented in enterprise information system [10, p. 120].

Ability to connect topics with information sources corresponding to their context that are anywhere and organizing these sources according to given ontology causes, that topic map can be “a key component of the new generation of Web-aware knowledge management solutions” [5, p. 174].

2.2 Visualization of business information

Visualization is the process of representing data as a visual image (see [11, p. 24]), and is defined as “the use of computer-supported, interactive, visual representations of abstract data to amplify cognition” [12, p. 477]. In other words, visualization allows decision-makers to use their natural spatial/visual abilities to determine where further exploration should be done [13, p. 13]. Visualization techniques may help to solve the problem, because “visualization offers a link between the human eye and the computer, helping to identify patterns and to extract insights from large amounts of information” [14, p. 139].

Visualization technologies have been used in many areas of business because graphical representation of the data makes analysis easy and aids the user to make informed and quick decisions. Visualization enables to easily identify oddities in detail data, isolate them, and investigate their source much faster than with traditional analytical methods. Business information has been visualized in the form of tables, outlines, pie charts, line graphs, and bar charts for a very long time (see [15, p. 61]). Mentioned graphic methods do not meet all expectations of users of information systems because [13, p. 13]:

- today business information is typically abstract, discrete, multi-dimensional and can be either historical or generated in real-time,
- today's enterprise data is a mix of structured, unstructured, and semi-structured content, whereas users need access to it all,
- users need semantic information depicting relations between facts.

The important direction of researches concerning business information is verification of graphic methods enabling visual data exploration (see [13]). The basic idea of visual data exploration is "to present the data in some visual form, allowing the human to get insight into the data, draw conclusions, and directly interact with the data" [16, p. 100]. In this interactive process, the user is able to subsequently concentrate on the interesting data elements by filtering uninteresting data, and focusing (zooming in) on the interesting elements, until final details are available for an interesting subset of the analyzed elements (see also [17, p. 1756]). Important stage in this process is use of appropriate solutions, which allow filtering and zooming in (zoom out).

2.3 Visual data analysis

In literature increasingly often visual data analysis (called also as visual analysis or visual analytics) is distinguished as part of visual data exploration. Visualization technologies are interface between user (by using his perceptual abilities) and information system. Visual analysis and visualization techniques have been proven – as said Keim and Schneidewind [18, p. 1767] – "to be of great value in analyzing and exploring such large data sets, since presenting data in an interactive, graphical form often fosters new insights, encouraging the formation and validation of new hypotheses to the end of better problem solving and gaining deeper domain knowledge". It is possible, because visualization [14, p. 170]:

- could support interaction between users and data-the exploration of an unknown data set,
- could support interaction with the analytical process and output of a data mining system.

The process of visual data analysis consists of the following stage [19, p. 15]:

- analyze first,
- show the important,
- zoom, filter, and analyze further,
- details-on-demand.

In this interactive visual process, the user is able to subsequently concentrate on the interesting data elements by filtering uninteresting data, and focusing (zooming in) on the interesting elements, until finally details are available for an interesting subset of the analyzed elements (e.g. [17, p. 1756]). Important stage in this process is use of appropriate solutions, which allow filtering and zooming in (zoom out).

One of these visualization methods enabling visual data analysis is the topic map. It allows displaying the whole semantic network (topics and associations) efficiently, as it is essential to select the relevant information. Fundamental factors for good visualization interface of application of topic map are: the overview of the structure for the global understanding of the structure and of the relationships within the hierarchy; the ability to zoom and to select some nodes; and dynamic requests in order to filter data in real time [20]. The topic maps can be easily used to represent financial knowledge about financial measures, where graphical expressions can assure semantic information search and interpretation for non-technically-minded users. Analysis of potential possibilities of use of standard topic map for representation of financial knowledge was described in: [4], [8]. Topic map is a relatively new visualization form of the presentation of knowledge, which puts emphasis on data semantics and ease of finding desired information (see [21, p. 4]).

3. Case study: topic map application for ROI indicator

3.1 Creating ontology of economical ratios – research problem

Essence of examining and assessing functioning of enterprise consists in appropriate calculating and using economical ratios and/or financial coming from various financial reports. Economical ratios can be an useful tool to analyze results achieved by enterprise and to plan its activity. They are also information basis in the process of decision making, but only when they are appropriately selected, counted and interpreted. Information usefulness of indicators depends on accurate understanding by decision makers logic of counting these indicators and both structural and semantic relations between them. Analysis of economical ratios is the area, in which we deal with acquiring unique knowledge that results from combination of expert's experience and tacit knowledge data processing and obtained ad hoc essential information. In general, business data contains a lot of hidden relationships and dependencies that make their usage difficult. While creating ontology for chosen fragment of analysis of economical ratios it is necessary to include to this process experts from this field, not only to agree on vocabulary and semantic structure, but also to be able to represent their tacit knowledge, which their experience [2] is from repeatedly carried out analyses of economical ratios related to decision making process.

N. Noy and D. L. McGuinness pay attention, that during creating ontology of economical ratios it is necessary of being aware, that: „There is no single correct ontology for any domain. Ontology design is a creative process and no two ontologies designed by different people would be the same” [22]. However, B. Smith notes, that “information systems ontologists have thus far not been able to develop an algorithm for the automatic conversion of income statements and balance sheets prepared on the basis of the two sets of standards” [23]. Despite these problems, it is necessary to undertake researches connected with building ontology of economical ratios in order to create topic map application for them.

Conception of usage topic map as model of knowledge concerning indicators has such advantage that created model of ontology can be relatively easily modified and simultaneously it is possible to use multiple applications based on different ontologies of particular area. This is essential, because there is no single universal system of economical ratios, which would be used in all enterprises (see [24]).

3.2 The conceptualization of ontology of ROI indicator

One of stages of creating ontology of ROI indicator is conceptualization stage (procedure of creating ontology of economical ratios is described in [21]). During this stage occurs enumeration of important terms in the ontology, defining the classes and the class hierarchy, modelling of associations and indicating occurrence. It is not only important, but also difficult stage for constructing topic map application for ontology of economical ratios in Du Pont model.

During creating ontology of ROI approach middle-out was used. Firstly, most detailed terms, and then general terms were identified. At the end by repeated iteration terms acting as subclasses were assigned. Among identified terms following classes were set apart: *Total assets*, *Fixed assets*, *Current assets*, *General costs*, *Total income* and *Indicators*. Next stage of creating ontology is identification of semantic associations (b-ary and n-ary relations). Seven different types of associations are identified. Conceptualization stage of ontology of ROI indicator is wider described in [21], [24].

3.3 Creating topic map application for ROI indicator

To carry out researches concerning verification of the standard of topic map as method of presenting semantic associations between different economical ratios use of program TM4L was planned. The TM4L provides support in topic maps design and maintenance through its functionality for editing, browsing and combining such structures, coupled with support for relating concepts, linking concepts to resources, external searching for resources etc. The TM4L environment consists of a TM Editor and a TM Viewer. The presented application topic map for ROI indicator in Du Pont model (Figure 1) has been developed in the authoring environment TM4L.

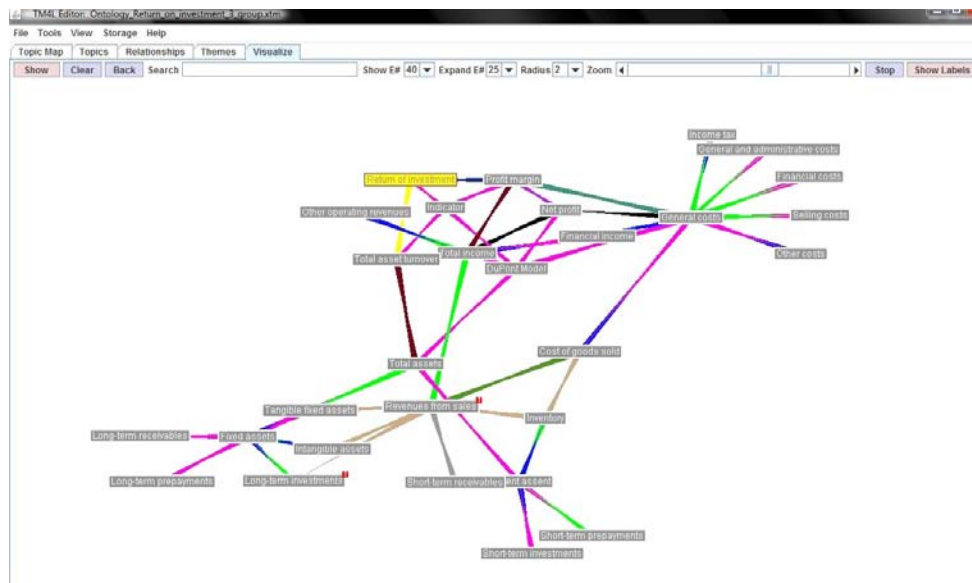

Figure 1 Example of visualization of the topic map for ROI

Source: own presentation based on TM4L Editor.

3.4 Visual analysis of ROI indicator

Topic maps may contain a large number of concepts and associations. Filtering techniques are needed in order to select and display only relevant information. For example in the software TM4L Viewer there are three possible manners of interrogations (see [8, p. 95]):

- searching by topic name and/or type,
- selecting topics from a hierarchy (tree view),
- using a custom query to display a list of valid choices (this option can make use of the current context as a part of the query).

Decision-makers by using created topic map application for ROI indicator have possibility to search data sources on account of context, where occurrences of topics refer to additional information sources. In this way they can find relations between data and on this basis get conclusions that can be for them new, unique knowledge.

In Figure 1 a screenshot presents visualization of the semantic network of the indicator *Return of investment*. Manager starts visual analysis of ROI indicator. He wants to see the report of the data; therefore he selects the link with instance. He notices that the value of indicator decreased compared with the previous year. Managers begin the analysis of the indicators that influence the value of the ROI. After choosing the topic *Profit margin* the user receives information about this indicator and its associations. The user executing operations zoom, filter and analyze further shows *Total income* with associations. During analysis of these relations, he observes that if *Cost of goods sold* is increasing *Revenue from sales* should also increase (associations: *Proportional positive/negative change* - Figure 2 and Figure 3). User selects and browses the reports, which show that indeed *Cost of goods sold* increased, while *Revenue from sales* hasn't changed. In this way, by performing the operation zoom, filter, and details-on-demand manager finds the reason of a lower ROI compared with the previous year. In the analogous way, the user may analyze other indicators.

Created topic map application for analysis of ROI indicator according to Du Pont model allows inter alia dynamic and interactive visualization of semantic connections between indicators. Thanks to that decision-makers can use user-friendly solution facilitating obtaining information from existing in enterprise databases. In literature studies concerning using topic map to search information are elaborated. They show, that users pointed out usefulness of topic map application and its support in finding unique information (see [7]).

Described solution has shown that topic maps can be adapted to new applications and managers' needs. The managerial staff can be supported by easy-to-use tools that facilitate access to a wide range of relevant data resources. Important advantages of this application are an easy and intuitive graphical user interface.

4. Conclusion and future work

Analysis of built topic map application representing Du Pont model results in statement that it serves to integrate data that are in many information systems functioning in the enterprise, often structured in a varied manner, according to logically consistent ontology. Through occurrences of topics (that is references to different data sources) decision makers have access into current information, reports presenting current enterprise's condition. In the context of carrying out analysis of functioning of enterprise it is important, that without necessity of modifying existing information system companies can create many topic map application for different models of analysis of ROI indicator, which can refer to the same information sources. Research carried out on using topic map to reproduce knowledge concerning economical ratios point out, that created model of ontology can be relatively easily modified. It is essential, a there is no single universal system of economical ratios, which would be used in all enterprises. Besides, many firms use many models of assessment of run activity basing

on analysis of various indicators. the topic maps can be easily used for representation of financial knowledge about financial measures.

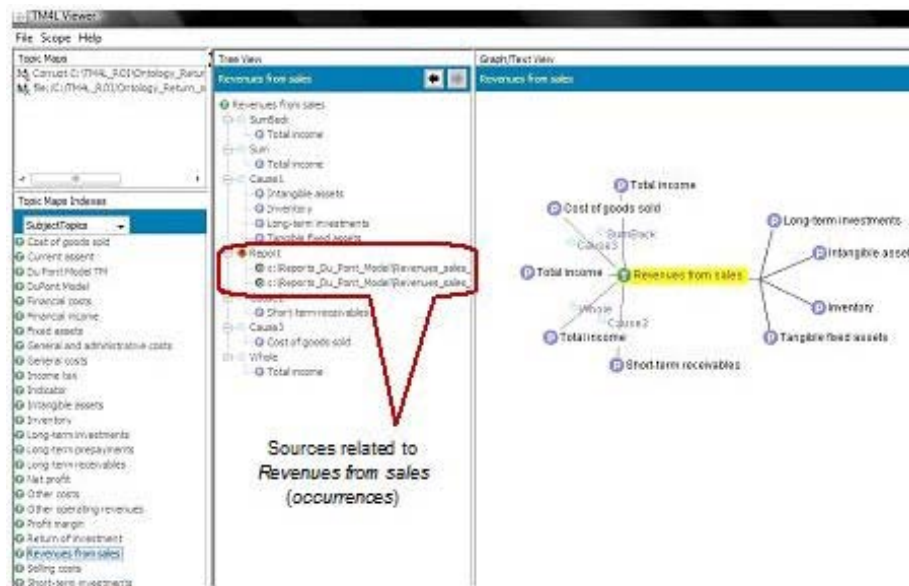

Figure 3 Visualization of the indicator ROI

Source: own presentation based on TM4L Viewer.

Information systems using field knowledge mapped basing on created will be created and developed. That will be caused by following factors: easier understanding of content by their users, common logical platform for different languages and applications, relatively easy adaptation of content and additional possibilities of searching and filtering information.

Future works will involve studying for using topic map as data model of knowledge of economical ratios will be continued in order to verify usefulness of such application allowing visualizing semantic associations for particular area of economical analysis and use of topic map application as a tool of visual exploration of data. Researches will be continued in order to verify ontology of ROI in formal and substantive respect testing created applications. Then research verifying usefulness of applying topic map standard as interface allowing to visually exploring data concerning indicators of assessment of functioning an enterprise and usefulness of application in economical analysis will be carried out.

Water distribution problem in the coastal region of Albania - The improvement for strategic changes - Regional development, possibilities and barriers.

Water plays an essential role in sanitation and public health. But while it helps to keep people, homes, and cities clean, water itself can also carry harmful microbial or chemical contaminants. In the United States, many water quality regulations help to ensure that drinking water is adequately treated, monitored, and managed to protect public health.

Democratic local governance is a prerequisite to the meaningful decentralization of infrastructure management. When people participate in defining visions for sustainable development for their communities, in formulating strategies for equitable access to services and resources and in setting priorities for action, they have endorsed. Participation also sharpens their awareness of the interrelations between economic, social and environmental issues.

This is a highly significant feature of infrastructure programs and carries important implications for local development. Almost everywhere problems of water scarcity can be considerably mitigated through metering, leakage detection and reduction, network improvements, disconnection of illegal connections, and optimization of storage and supply patterns.

The distribution problem also has a seasonal aspect: much more water is needed during the summer growing season; when rainfall is scarce, rural drinking water is often misused for irrigation; and the tourist resort areas use large amounts of water. On average, water is available only 3-4 hours per day, with certain areas receiving water only once in three days.

Urban areas have mostly combined sewage and storm water collection networks that discharge into near bay surface water bodies. In rural areas, only a small portion of the areas with piped water supply is equipped with sewer networks.

Most rural areas have individual household wastewater collection systems, principally simple pit-latrines with no drainage pipes. Upgrading of sewer networks has not kept pace with the general development of infrastructure, and the materials and technology used have not been improved. Presently, there is no treatment of wastewater in Albania; its discharge in water bodies, especially in coastal tourist areas and delicate ecosystems.

Keywords

Drinking water, Economic development, Social Leadership, Urban areas, Water distribution

Supported by donor assistance and international and local NGO's the city initiated a community-based development strategy in the informal settlement. The program brought together local government teams, NGO's and residents to formulate a development plan for the neighborhood define priorities for improvements and determine equitable cost-sharing formulas to finance infrastructure. This partnership led to the upgrading of roads and electrical networks, the construction of community buildings and schools, improved public spaces and programs. Clarifying the legal status of residential land and formalizing an urban plan resulted in the sufficient leveraging of community and household resources to provide infrastructure and build new housing.

1. Strength Local Government Leadership and Initiative

Decentralization has given local governments the discretion and scope they need to take a lead role in responding to the challenges of economic downturn , degradation of the urban environment, and social hardship. They institute bold initiatives and innovative practices. Western European nations have put in place sophisticated frameworks to provide local governments with technical and financial assistance. The European Union supplements these national programs with coordinated assistance aimed at promoting economic development, assisting distressed localities and fostering social inclusion. Infrastructure is an important component of these programs.

{ 2} Anthony, R. N. and Dearden, J. Management Control System, Irwin, Homewood, IL, 1980.

Despite its location in an industrialized province Jerez's economy relies on wine production which, in recent years has been declining. Weak community participation, inadequate infrastructure, poor accessibility to regional resources and an unskilled labor force compounded the effects of massive job cuts in the wine industry..

With regard to economic development the plan focuses on the development of cultural tourism and the promotion of entrepreneurial activities.

1.1 Oriented keys of success are seven key factors:

- A dynamic local government leadership
- A coherent strategy acted upon with determination
- A healthy climate of cooperation with business
- Local government's investment initiatives to jumpstart the stagnant economy
- Creative use EU funds to implement local policy
- Efficient municipal administration
- Coherent links among urban planning, infrastructure and economic development

2. Partnerships between Municipalities and NGOs

Partnerships with municipalities has provided the best channel for the participation of communities in the organized delivery of public services and paved the way for the growing role of NGO' s and CBO's in this sector in urban and rural areas and different regions of the world.

Albania, one of the smallest and poorest countries in Eastern Europe, has experienced a transition marked by sharp economic swings and periods of civil strife. The early phases of decentralization witnessed the transfer of political autonomy and limited administrative and fiscal authority, to local governments, inadequate legislation outlining central/local responsibilities, scarce financial resources and deficient infrastructure strained the capacity of local governments to manage urban services. In January 2000, the government promulgated a national Strategy for Decentralization and Local Autonomy which includes laws to strengthen the autonomy of local governments and increase their capacity to manage local infrastructure and services.

2.1 Supported by donor assistance and international and local NGO's the city initiated a community-based development strategy in the informal

The program brought together local government teams, NGO's and residents to formulate a development plan for the neighborhood define priorities for improvements and determine equitable cost-sharing formulas to finance infrastructure. This partnership led to the upgrading of roads and electrical networks, the construction of community buildings and schools, improved public spaces and programs for youth. Clarifying the legal status of residential land and formalizing an urban plan resulted in the sufficient leveraging of community and household resources to provide infrastructure and build new housing.

2.2 Finally, the engagement of senior government officials in the dissemination of project information secured commitment among communities and farmers.

- To work closely with Community- Based organizations so as to enhance their capacity to participate in development programs and strengthen the City Council's capacity to respond to requests from communities
- To adopt a new approach to Environmental Planning and Management based on capacity building. {1} Albania -Rural Water Supply and Sanitation Strategy 2009

The CIP upgraded infrastructure, enhanced participation and built the capacity of CBOs and stakeholders. CIP strengthened institutional capacity by establishing program offices in each community, forming steering committees made up of representatives from all stakeholder groups and formalizing institutional links between the relevant partners and information for decision-making and monitoring of performance among the stakeholders altered attitudes and understanding of roles and responsibilities. Communities have agreed to earmark part of stakeholders as partners in urban development ensures the sustainability of these assets.

3. Community-Based Approaches to Infrastructure Services and Neighborhood Revitalization

This is a highly significant feature of infrastructure programs and carries important implications for local development.

Sustained political pressure and the demonstrated capacity of municipalities to manage their responsibilities were the driving forces for local administrative and fiscal autonomy. Initial assessments suggested that decentralization did improve the quality of service delivery and foster a new, user oriented attitude, facilitating the transition from a centrally planned to a market economy.

3.1 The act for support of local investment committed the municipality to cover 50 percent of the cost of water, sewerage and power lines, 70 percent of the cost of roadbeds and sidewalks and 100 percent of the cost of drainage and street paving.

The cost sharing formula can be modulated to take into consideration issues of equity and cost burden. As an incentive to private rehabilitations of buildings, investors are granted a three year exemption from property taxes.

We recomanded these conclusions:

- Introducing participatory planning and community-based development processes through neighborhood development committees and street representatives working in partnership with the city
- Creating an enabling environment for private investment
- Empowering citizens to pursue their own self improvement
- promoting privatization of the housing a stock and fostering the development of micro- enterprises
- Ensuring the sustainability of activities initiated
- Promoting the reliability of successful initiatives.

Albanian government will be reality these points:

- A dynamic local government leadership
- A coherent strategy acted upon with determination
- A healthy climate of cooperation with business
- Local government's investment initiatives to jumpstart the stagnant economy
- Creative use EU funds to implement local policy
- Efficient municipal administration
- Coherent links among urban planning, infrastructure and economic development.

Economic Crisis and Informatisation Strategies of Enterprises in Poland. Selected Results of Comparative Surveys from Years 2009-2010

Mirosław Dyczkowski¹

¹Institute of Business Informatics, Wrocław University of Economics, Wrocław, Poland, miroslaw.dyczkowski@ue.wroc.pl

The last-year proceedings of the ICEIRD 2010 Conference contained results of a survey – carried out by the author of this paper in 2009 – which aimed at analyzing how the recent economic crisis had influenced informatisation strategies of enterprises (see [2]). In 2010 a comparative study was conducted, with an objective to determine whether any substantial differences in reference to the previously obtained results could be observed, and if yes, how intensive such changes were. This paper discusses results of the comparative surveys from years 2009-2010. The obtained results support a working hypothesis that the economic crisis affected – to smaller or greater extent – short- and long-range informatisation strategies in the majority of companies. Even if relative shares of identified variances and intensity of their visible symptoms changed from year to year, deviations were minor and referred only to selected elements of informatisation strategies or areas where IT was applied in business entities. The detailed information to that subject is included in this paper.

Keywords

economic crisis, statistical analysis, informatisation strategies, comparative survey results

1. Introduction

The global financial crisis, which have been affecting the Polish economy since the second half of 2008, resulted in deteriorating economic situation in majority of companies. Evidence was provided by: current business statistics, economic and social analyses, or by monitoring tendency changes in the

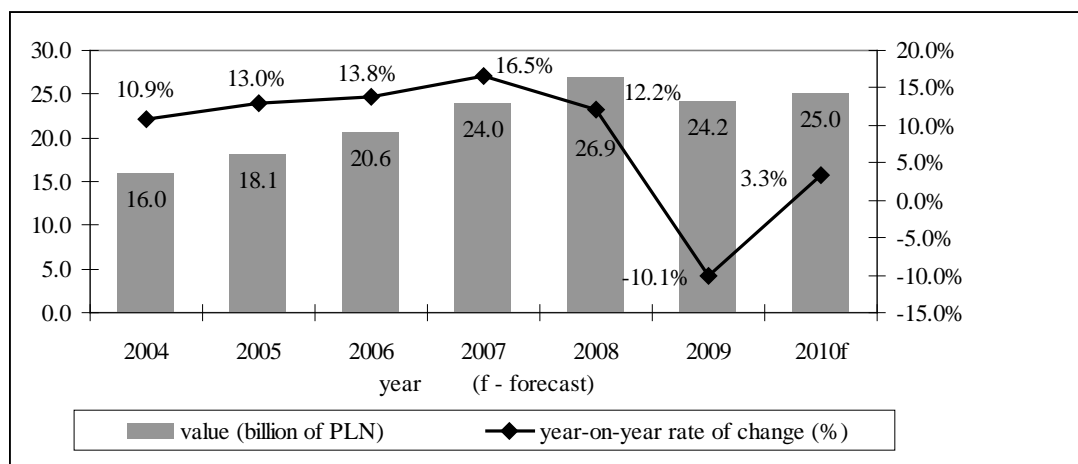

Figure 1 Value and year-on-year rate of change at IT market in Poland according to PMR data and forecasts from August 2010 (based on [9, p. 2]).

economy. Implications of the crisis were observed in information technology domain, as well. Clear signals came from producers and providers of IT products and services, and from their customers. They were also acknowledged by nearly all major companies monitoring IT industry, including: DiS, Gartner, Forrester Research, IDG or PMR. The last of the forgoing companies, for example, revised its forecasts for the Polish IT market twice in 2009, from the original 14.7% to 1.2%-growth only (see [2], [7] and [8]). The report published in August 2010 [9], which incorporated the most recent data on the value and dynamism of the Polish IT market, revealed that the situation was in fact much worse. For the first time in many years, instead of growth, a decrease (see figure 1) by 10.1% was observed (from 26.9 to 24.2 billion PLN). This situation made consulting companies examine quality and credibility of their projections and ultimately update them (see opinions and assessments included in e.g. [1], [5], [6] and [10]). All these confirmed the author's belief that it was necessary to continue the study initiated in 2009, which investigated an impact of the economic crisis on IT strategies and projects in selected companies. The same conclusion were drawn from presentation of the published outcomes of that study at several conferences where they earned marked attention ([2], [3] and [4]).

This paper will present various data breakdowns and analyses which help to assess an impact of the economic crisis on IT strategies and to detect changes observed in the two subsequent years.

2. Assumptions for the comparative study

Selection of the area for the comparative study followed the author's conviction that awareness of ways in which business organizations respond to the prolonging economic crisis (with the focus on IT-related activities) is important in order to counteract effects of the crisis more effectively. Such knowledge should enable the IT industry to get back on track of dynamic growth observed in recent years (see figure 1) much quicker, what is essential considering long-term strategies for developing e-society and e-economy in Poland.

The aforesaid study has an interregional reach, and reflects situation of companies located mostly in Warsaw and Mazovia or in Wroclaw and Lower Silesia. Both surveys, which provided data for the comparison, were carried out in April and May, the first in 2009 and the other in 2010. Selection of that period resulted from the author's conviction – substantiated by other sources – that at that time forecasts drawn up at the turn of 2008/2009 and 2009/2010 were modified, and already incorporated information on crisis development, figures from financial statements for years 2008 and 2009 along with data from closing reports for the first quarters of 2009 and 2010 respectively. The companies reflected the most recent data in their strategies, including those referring to IT area, by either sticking to or modifying prior plans.

The overall number of collected questionnaires amounted to 139 in 2009 and 109 in 2010. All answers formed a repository of 248 sets of data, each comprising: 38 quantitative and qualitative characteristics describing how the economic crisis affected IT strategies and what changes in strategies were adopted, 6 descriptive and typological features of the surveyed objects, and 5 other which allowed to verify collected data. The repository contains data on a very diverse group of companies, which differs from year to year. A detailed presentation of that group is, therefore, required.

3. General characteristics of the surveyed objects

Before selected results of the study are discussed, the surveyed objects will be presented in brief. The table 1 presents a breakdown of objects examined in 2009 and in 2010 by their areas of operations and sizes. It includes: importance of clusters in the whole samples, dominating values (cells with digits in bold), and substantial differences between the two examined years (cells shaded in grey).

The information presented in table 1 requires short comment. Considering areas of operation, the category "other" prevails (despite observed decrease of its share by 14.71%, from 53.24% of answers in 2009 to 38.53% in 2010), what was a consequence of professional profiles of students who carried out the surveys. This group included mostly IT companies (58.67% in 2009 and 48.84% in 2010) but also telecommunication ones (10.67% in 2009 and 13.95% in 2010). This means that the ICT industry amounted to 69.33% in 2009 and to 60.47% in 2010 of all objects belonging to the category "other sector". It should be noticed that distinct differences (exceeding 2.5% – see cells shaded in grey) between year 2009 and 2010 were observed – beside previously mentioned category "other" – in relation to the following groups: "public administration" (increase by 4.61% in 2010 in relation to 2009), "banking, finance, insurance" (growth by 5.85%) and "industry" (gain by 2.84%).

Table 1 Structures of the objects by sector and by size – the comparative analysis.

Sector	Object size* (percentage in surveyed objects)										Total	
	micro		small		medium		large		the largest		2009	2010

*Sizes of institutions were determined in a simplified manner, and considered number of employees only.

With regard to size, similar shares of objects belonging to: small-, medium-, large- and the largest-sized enterprises can be observed (18.35%÷27.52%). Some changes in composition of the samples should be noticed, though. They include both increases (the share of small objects went up by 3.71% and that of the largest ones by 6.66% in 2010) and declines (the number of medium sized entities went down by 4.28% and that of large ones by 4.67% within one year time). A number of microenterprises was relatively smaller (11.51% of the sample in 2009 and 10.09% in 2010). The situation differs slightly from sector to sector, in particular in case of financial institutions where the largest objects dominate (54.55% of that sector in 2009 and 53.33% in 2010). The author is aware that the samples reflect neither sector- nor size-related profiles of the Polish economy (in both years). Having considered basic characteristics of the surveyed objects, the following parts of the paper will analyze influence of the crisis on economic situation of these companies and institutions.

4. Assessing influence of the crisis on economic situation of the surveyed objects

The table 2 compares industrial profiles of the examined objects with evaluation of an impact which the crisis had on their economic situation. The assessments were based on a 5-grade scale. Considering information presented in the table 2, it can be observed (see cells with bold digits) that the most frequent response was that a situation of an object became “slightly worse” (51.8% of all the answers in 2009 and 53.21% in 2010). Nevertheless, the significant share (32.37% in 2009 and

Table 2 Structures of the objects by sector and by impact of the crisis on their economic situation – the comparative analysis.

Sector	Impact of the crisis on economic situation of an object										Total	
	it is much worse		it is slightly worse		nothing has changed		it is slightly better		it is much better		2009	2010

other	2.88	2.75	25.90	20.18	16.55	8.26	7.91	5.50	0.00	1.83	53.24	38.53
Total	6.47	11.01	51.80	53.21	32.37	23.85	9.35	10.09	0.00	1.83	100.00	100.00

23.85% in 2010) of responses suggested a stable economic position. It is worth pointing out that in this last group a decrease of 8.52% in comparison to the previous year was observed. Considering

also a growing share (by 4.53%) of responses: “it is much worse”, it can be stated that the economic crises still affects the surveyed objects. In relation to sectors, the most acute deterioration of the economic situation was noticed in the following three domains: “public administration” (increased share of negative assessments by 18.75% to the previous year), “industry” (growth by 9.06%) and “other” (increase by 5.47%). The biggest increase in share of neutral or positive assessments was noted in the “banking, finance, insurance” cluster (by 10.23%).

Table 3 Structures of the objects by size and by impact of the crisis on their economic situation – the comparative analysis.

Object size	Impact of the crisis on economic situation of an object										Total	
	it is much worse		it is slightly worse		nothing has changed		it is slightly better		it is much better			
	2009	2010	2009	2010	2009	2010	2009	2010	2009	2010	2009	2010
micro	1.44	0.92	7.19	3.67	1.44	4.59	1.44	0.92	0.00	0.00	11.51	10.09

large	1.44	3.67	11.51	11.01	7.19	0.92	2.88	2.75	0.00	0.00	23.02	18.35
the largest	0.72	3.67	13.67	15.60	6.47	3.67	0.00	3.67	0.00	0.92	20.86	27.52

The table 3, in turn, compares size of the surveyed objects with assessments of an impact of the crisis on their economic situation. Considering information presented in that table, it can be noticed that the most acute deterioration of the economic situation was observed among “small” and “large” objects (increased share of negative assessments by 18.68% and by 23.75% respectively in relation to the previous year). On the other hand, the highest increase in share (by 29.55%) of neutral or positive assessments was observed in the “micro” cluster.

Having considered all basic characteristics of the impact of the crisis on economic situation of the surveyed objects, the following parts of the paper may focus on analyzing influence of the economic crisis on IT strategies – what is the major point of interest of this publication.

5. Assessing Influence of the crisis on informatisation strategies

Results of the analysis, showing how the economic crisis affected informatisation strategies, will be presented in the following sequence. In the beginning it will be examined whether – and, if yes, than to what extent – informatisation strategies were modified; firstly, in particular industries (table 4), secondly, in objects of certain sizes (table 5), and thirdly, in objects grouped according to informatisation levels (table 6). Subsequently, it will be analyzed in what ways changes in economic situation of companies influenced their informatisation strategies and ongoing IT projects (table 7). The following tables present: importance of clusters in the whole sample, dominating values (cells with bold digits), and important differences between the two years of the survey (cells shaded in grey).

Table 4 Influence of the economic crisis on informatisation strategies and projects in the objects according to sectors – the comparative analysis.

it is much worse	0.72	0.00	1.44	9.17	4.32	1.83	6.47	11.01
it is slightly worse	10.07	10.09	38.85	40.37	2.88	2.75	51.80	53.21
nothing has changed	20.83	13.76	10.79	9.17	0.72	0.92	32.37	23.85
it is slightly better	5.04	0.92	4.32	7.34	0.00	1.83	9.35	10.09
it is much better	0.00	1.83	0.00	0.00	0.00	0.00	0.00	1.83

The data presented in tables 4-7 requires explanation.

First of all, the study shows (see the cells with bold digits in the table 4) that as much as 63.31% (in 2009) and 73.39% (in 2010) of the surveyed objects adjusted their informatisation strategies and IT projects due to the crisis ("slightly": 55.40% in 2009 and 66.06% in 2010; "in a radical way": 7.91% in 2009 and 7.34% in 2010). This substantiates results of similar analyses carried out in 2009 and 2010 (see [2], [7] and [9]). Considering data from the table 5 (see shadowed cells in the 'Total' row) material changes in answers received in subsequent years can be noticed. On the one hand, the number of objects reporting "slight changes" increased in 2010 (by 10.66%), and on the other one, the share of answers indicating "no change" decreased at a similar rate (by 10.09%). Secondly, the data collected shows that influence of the crisis on informatisation strategies and IT projects was only partially related to sectors where the objects operated. Intensity and direction of observed changes differ between sectors and groups of answers (see shadowed cells in the table 4, depicting the biggest changes from year to year). Thirdly, a similar conclusion may be drawn in reference to the relation between the crisis and sizes of objects (see cells with bold digits and shaded cells in the table 5). The fourth conclusion is that an impact of the crisis on informatisation strategies and IT projects is more visible among objects characterized by higher level of informatisation (see shaded range in table 6). Nevertheless, the changes were recognized as "slight" both in 2009 and in 2010. Finally – as expected – a scope of adjustments in informatisation strategies and in IT projects was correlated with a magnitude of change in economic situation of an object. The growing tendency can be detected among objects declaring evolutionary ("slight") changes in their informatisation strategies and IT projects. It refers (see table 7)

both to deteriorating (“much worse” or “slightly worse” indications were more frequent by 9.25%) and to improving economic situation (the answer “slightly better” was more frequent by 3.02%).

The following parts of the paper will identify and depict the most important symptoms of changes in informatisation strategies in reference both to the whole analyzed group and to those object where IT strategies were modified.

6. Symptoms of changes in informatisation strategies and in IT projects

The data collected in both studies enabled to detect and structure major symptoms of changes in informatisation strategies and in IT projects, which resulted from the crisis. It should be added that these symptoms were identified by the surveyed objects with a help of a predefined list. The list was open, nevertheless, only 6 of all the objects (i.e. 139 in 2009 and 109 w 2010) presented other reasons than defined. By compiling the list of the symptoms (table 8, column 1), the author considered various studies (see [2, p. 85]). The surveyed objects were asked to select all relevant symptoms. The table 8 present structures of responses in the whole analyzed group (columns 2 and 3) and for those objects only where changes – either slight of radical – in IT strategies took place (columns 4 and 5). Dominating values (those exceeding 20% of indications) were marked – like in previous tables – in a bold type, and substantial changes (over 5%) between results from 2009 and 2010 were shaded.

Table 8 Structures of identified symptoms of changes in informatisation strategies for the entire group of objects – the comparative analysis.

Identified symptoms of changes in informatisation strategies	Percentage share of particular symptoms			
	all objects		objects which modified their strategies	
	2009	2010	2009	2010
a budget of an IT department was reduced	25.90	28.44	38.64	38.75
spendings related to IT investments decreased	30.94	30.28	48.86	41.25
new projects were abandoned	13.67	6.42	21.59	8.75
ongoing projects were stopped	7.19	7.34	11.36	10.00
a scope of projects was reduced	13.67	13.76	21.59	18.75
IT investments were postponed	20.86	38.53	32.95	52.50
IT services outsourcing was intensified	2.88	4.59	3.41	6.25
IT personnel was made redundant	15.83	16.51	23.86	22.50
IT seminars and trainings were cut	33.09	33.03	51.14	45.00
IT was financed with external sources	1.44	3.67	2.27	3.75
IT costs were streamlined (using TCO)	15.83	22.94	25.00	31.25
other, namely...	4.32	5.50	5.68	6.25

Referring to data depicted in table 8 (columns 2 and 3) it should be noticed that the surveyed objects declared the following symptoms of informatisation strategy changes the most frequently (they appeared in over 20% of questionnaires): reduced number of IT seminars and trainings (33.09% of questionnaires in 2009 and 33.03% in 2010), decreasing spendings on IT investments (30.94% in 2009 and 30.28% in 2010), reduced budgets of IT departments (25.90% in 2009 and 28.44% in 2010), postponed IT investments (20.86% in 2009 and 38.63% in 2010) and IT cost streamlining initiatives using TCO (22.94%-level, which exceeds the said 20%-threshold only in 2010). When the data are analyzed, and values from subsequent years compared, several facts become visible. Firstly, the biggest increase in indications (by as much as 17.67%) refers to the situation when “IT investments were postponed” – which was also the most frequently selected answer by the surveyed companies in 2010. Secondly, the biggest decrease (by 7.25%) in indications, in relation to the previous year, refers to the situation when “new projects were abandoned”. All these confirm observations of many researchers (see e.g. [1], [5], [9] and [10]), who pointed out significant reduction in number and value of new projects in all sectors except for “public administration”. Thirdly, an increased share (by 7.11%) of objects declaring that their “IT costs were streamlined (using TCO)” is also worth mentioning. This is a proof that awareness of this issue has grown recently. Finally, the low significance of IT services outsourcing (only 2.88% in 2009 and 4.59% in 2010) along with limited external financing (1.44% in

2009 and 3.67% in 2010) are unpleasant surprises. In particular the latter figure is disappointing, considering significant funds for fostering innovations (including ICT) available within EU and nationwide frameworks for financial support. The results obtained in the group of organizations which declared changes in their informatisation strategies were similar, and differed only – what is obvious – in percentage levels (see table 8, columns 4 and 5).

Table 9 Intensity of symptoms of IT strategy changes (quantitative and monetary assessments) for the objects which modified their strategies – the comparative analysis.

Symptoms of informatisation strategy changes in the objects which modified their IT strategies	„Intensity” of IT strategy changes (quantitative and monetary assessments)									
	substantial decrease		decrease		no changes		increase		substantial increase	
	2009	2010	2009	2010	2009	2010	2009	2010	2009	2010
IT investment budgets	7.95	8.75	53.41	53.75	31.82	21.25	6.82	13.75	0.00	2.50
current spendings on IT	2.27	6.25	48.86	45.00	43.18	28.75	5.68	16.25	0.00	3.75
purchases of equipment for IT department	18.18	8.75	35.23	33.75	39.77	42.50	4.55	12.50	2.27	2.50
purchases of equipment for end-users	10.23	6.25	32.95	18.75	50.00	63.75	4.55	8.75	2.27	2.50
software purchases	11.36	7.50	27.27	27.50	54.55	48.75	5.68	12.50	1.14	3.75
purchases of application software/systems	7.95	3.75	31.82	26.25	50.00	50.00	7.95	16.25	2.27	3.75
purchases of external services	5.68	1.25	27.27	28.75	61.36	47.50	4.55	20.00	1.14	2.50
own projects (carried out by IT department)	3.41	2.50	19.32	8.75	56.82	61.25	18.18	20.00	2.27	7.50
project implementation	5.68	0.00	27.27	21.25	56.82	57.50	9.09	20.00	1.14	1.25
outsourcing projects	5.68	0.00	21.59	15.00	63.64	63.75	9.09	18.75	0.00	2.50
IT seminars and trainings	18.18	20.00	40.91	33.75	38.64	31.25	2.27	11.25	0.00	3.75

Apart from identifying symptoms of IT strategy changes, the study covered also quantitative and monetary characteristics which reflected „intensity” of such changes. This part of the questionnaire used a 5-grade scale of quantitative and monetary assessments. The surveyed objects declared „intensity” of particular symptoms as: „substantial decrease”, „decrease”, „no changes”, „increase”, „substantial increase”. Among the objects which modified their IT strategies the most significant decreases were observed in (see table 9): IT investment budgets (61.36% of answers in 2009 and 62.50% in 2010 indicated „decrease” or „substantial decrease”), seminars and trainings (59.09% and 53.75% respectively), equipment purchases for IT departments (53.41% in 2009 and only 42.50% in 2010) and current spendings on IT (51.14% and 51.25% respectively). It should be emphasized that in 2010 a number of answers indicating „decrease” or „substantial decrease” went down in case of nearly all the symptoms, and the most significant changes in relation to the previous year included „purchases of equipment for end-users” (by 18.18%). On the other hand, in 2009 a noticeable growth (by 15%) could be observed only in case of projects carried out by own IT departments (20.45% of answers indicated „increase” or „substantial increase”), whereas in 2010 such growth was observed for 10 out of 11 symptoms. The most frequent indications of „increase” were related to the following options: „own projects, carried out by IT department” (27,50%), „purchases of external services” (22.50%), „project implementation” and „outsourcing projects” (21,25% each), „current spendings on IT” and „purchases of application software/systems” (20.00% each). It is worth mentioning that in 2010 shares of answers indicating „increase” or „substantial increase” went up for nearly all the symptoms in relation to the previous year. The most significant changes included: „purchases of external services” (by 16.82%), „current spendings on IT” (by 14.32%), „IT seminars and trainings” (by 12.73%), „outsourcing projects” (by 12.16%) and „project implementation” (by 11.02%).

7. Conclusions

The selected results from analyzing data collected in the comparative surveys carried out in April 2009 and May 2010, with a focus on an impact of the economic crisis on informatisation strategies and IT projects, entitle to formulate the following conclusions.

Firstly, the results supported the working hypothesis that the economic crises affected, to smaller or greater extent, long- and short-term informatisation strategies in most of the examined objects. Observed modifications in IT strategies (in 63.31% of all the surveyed objects in 2009 and 73.39% in 2010) are the most evident indicator of this situation.

Secondly, the observed frequency and magnitude of changes in IT strategies was – as expected – correlated with informatisation level (see table 6). It is worth mentioning that this correlation was stronger in 2010 than the year before. The major symptoms of IT strategy and projects modifications were similar in subsequent years (see table 8).

Thirdly, in 2010 the number of indications on negative changes, including “decreases” and “substantial decreases” went down in comparison to the previous year with regard to most of the symptoms for IT strategy modifications (see table 9). The aforementioned data substantiate observations included in other reports and analyses, and depicted by Jadczyk [5] in the title of his study: “The Polish IT market – 2009 debacle! 2010 – new hope”.

The author believes, that by monitoring behavior of companies and their responses to the economic crisis in IT domain, and observing changes in this respect in the two subsequent years, the following two objectives were achieved. On the one hand, the findings presented in other reports and analyses were confirmed and supplemented, and on the other one – due to new pieces of evidence gained – negative consequences of the crisis in IT area may be effectively counterbalanced.

Science-based Incubators Linked with Universities

Irini Efthimiadou¹, Theologos Prokopiou², Paris Kokorotsikos³

Key features of pre-incubation in higher education institutes are analysed, by examining good practices in supporting potential entrepreneurs to turn a science or technology-based business idea into a viable business. Recommendations for transferring good practice elements of pre-incubation are presented, focusing on environments with specific contextual characteristics of entrepreneurship, policy making and innovation system, as in the case of a Greek region.

Keywords

Entrepreneurship, Innovation, Pre-incubation, Start-ups, Spin-offs

1. Introduction

The higher education institutes are expected to play a new role in society, in addition to teaching and research, by applying a third mission of contributing to economic development. They can contribute to entrepreneurship both indirectly, through education of potential entrepreneurs, and directly by commercialization of research results. The research conducted at higher education institutes is a source of ideas with potential for commercialization that has not been fully utilised in most cases. Moreover, the traditional focus in entrepreneurship education is seen as inadequate. There is an increased focus on the context and learning by doing, which implies involvement of students in working on real business cases, from case-based teaching to real start-ups, and finally in starting their own company [1]. The pre-incubator model, linked with higher education institutes, is one mechanism that supports both commercialization of research and entrepreneurial education through learning by doing.

2. The Pre-incubation Concept

In the higher education environment, pre-incubators are seen as a necessary facility to fill the gap that exists between higher education establishments and science-based business incubators. As opposed to business incubators, which offer support to new enterprises already established, pre-incubators offer services and support at a very early stage of the start-up process until the establishment of the new start-up (Figure 1). The target groups of a pre-incubator are students, young graduates and researchers of higher education institutes. The objective of pre-incubation is to support future entrepreneurs from the academic environment to establish and manage a successful business, leading to the creation of viable start-ups, the increase of spin-offs from the academic environment and in general the creation of an entrepreneurial culture in higher education. A pre-incubation process is often part of the services offered by a science-based business incubator that is linked to a higher education institute.

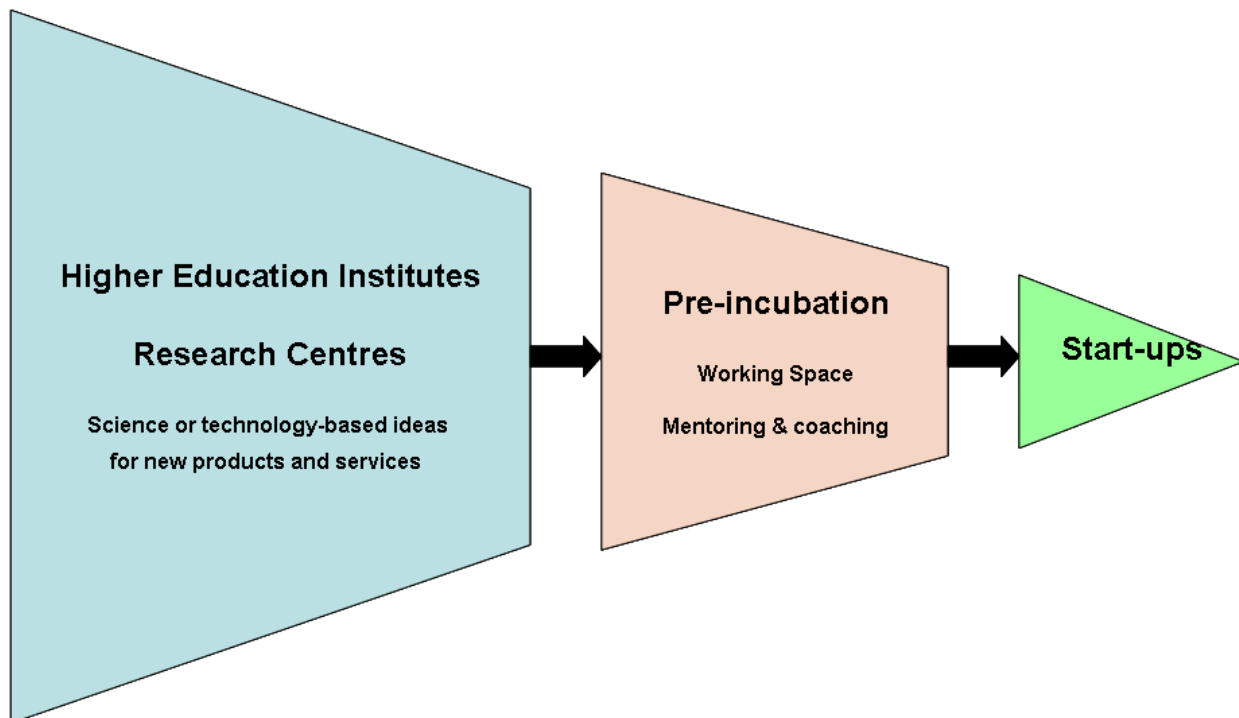

Figure 1 Following the Entrepreneurial Path in the Academic Environment

The first European pre-incubator was established in 1997 at the University of Bielefeld in Germany. The pre-incubator was designed to qualify and coach academic entrepreneurs, increase the number of sustainability of the spin-offs from the University of Bielefeld and to foster the entrepreneurial spirit at the university. The USINE project experimented in transferring the model of Bielefeld pre-incubation across national borders and led to the creation of two regional pre-incubators, one at the Universidad Politecnica de Valencia in Spain and the other at the Ecole Polytechnique in France [2].

In Finland, incubation activities seem to be well established too, including pre-incubation as part of a wider organization or process. Due to their special character as facilitators of start-ups from higher education pre-incubators are mainly located in the higher education institutes. Examples of pre-incubation in the Finish polytechnics and universities include the pre-incubators of Jyväskylä Polytechnic, Satakunta Polytechnic, Turku Polytechnic, University of Tampere, Helsinki University of Technology etc [3].

In Sweden, the interest for entrepreneurship has been significantly growing since the 1990s. A significant number of higher education institutes in Sweden offer entrepreneurship education, which does not focus on traditional teaching of individuals, but has increased the focus on active involvement of the students in commercializing research and new venture creation [1]. A specific example is the case of Jonköping University, which provides a course to all students, where teams of students can establish their own company, parallel to their study. The students get access to experienced mentors and relevant teaching activities during the study. Many activities are coordinated by Creative Center, which is a non-profit organization at the university that runs the Business Lab, a pre-incubator where persons get an environment to explore the potential of their ideas. With more than 200 student start-ups during a period of 5 years, it can be viewed as an implementation of a business generation model of entrepreneurship education, where learning by doing and student involvement is the core activity.

3. Key Elements of Good Practice in Pre-incubation

Key elements of good practice of pre-incubation in European higher education institutes have been identified, which can be transferred in other contexts and environments. The pre-incubation elements of good practice are focusing on strategic issues, such as stakeholders and benefits, intellectual property rights, facilities and services, and operational issues, such as legal status, management structure, cost, resources, selection procedures.

3.1 Stakeholders and benefits

The main stakeholders in the pre-incubation process are:

- The *higher education institutes* that are interested in supporting the commercialization process of science or technology-based ideas generated by students, young graduates and researchers
- *Potential entrepreneurs*, rising from the higher education environment, who need to be assisted to move from study into work by following the entrepreneurial path

Through the pre-incubation process, potential entrepreneurs are getting the opportunities and skills needed to grow and develop their business idea, aiming for their business to be successful and reach a state where they will not need the pre-incubator's support any longer. Moreover, the pre-incubation process can also be seen as a way of filtering out non-viable business ideas.

It should be noted that the pre-incubation process is a staging post in a long process starting from an idea for a science or technology-based product or service to the commercialization of that idea. Many cases that are suitable for pre-incubation may not generate significant returns for the higher education institute but there can be additional significant gains for the regional economy, such as giving rise to sustainable science or technology-based companies within the region.

For this reason, other regional stakeholders may be involved in the pre-incubation process, including:

- Regional authorities or regional development agencies
- Other relevant structures such as regional innovation or entrepreneurship centres that offer business support services or business incubators, publicly funded or commercially owned
- Other forms of private capital

3.2 Facilities and services

The added-value of pre-incubation is the capacity to test the market of a business idea before the company formation, by offering learning based on experience and therefore lowering the risk of market failure. For this reason, pre-incubation comprises a set of core features, including:

- *Space and facilities*, either real or virtual, that may include:
 - Working space for the potential entrepreneurs in order to develop their idea
 - Shared facilities, such as Information and Communication Technologies infrastructure, meeting room access, laboratory access etc
 - Information and communication tools allowing interaction with other entrepreneurs, experts and the pre-incubation management
 - Virtual space to provide advice and support
- *Support* for the potential entrepreneurs to develop their ideas into viable businesses, that may include:
 - Testing if there is a market for the idea
 - Linking into specialist networks and expertise
 - Producing prototypes
 - Forming a business plan
 - Training in business skills and requirements
 - Assistance with the formalities of establishing a new company

3.3 Intellectual property rights

There are several strategic issues surrounding intellectual property generated by research conducted using the facilities and resources of the higher education institute. A key issue is the chosen commercialization route, since there may be a potential conflict between the interests of the individual and those of the higher education institute. The academic may wish to start a company while his/ her institution may prefer another route to commercialization. The potential for conflict of interest is greater where there is intellectual property that belongs to the higher education institute.

Best practice suggests that the pre-incubator should gain experience in negotiating on behalf of the potential entrepreneur towards a position where both parties benefit. Intellectual property issues should be dealt at an early stage and negotiations should be based on mutual respect and trust, leading to the establishment of clear and detailed boundaries of the intellectual property.

3.4 Legal and management structure

Pre-incubators are usually established as part of bigger host organizations: higher education institutes, technology centres or business incubators. If the pre-incubator is established as a separate entity it has the ability to act as an autonomous organization, creating its own corporate identity. In most cases, the higher education institute seeks to build pre-incubator ownership models to share investment costs with regional authorities.

The management team should undertake the overall management and commercial activities of the pre-incubator. The core expertise of the management team should include company/ financial management and accounting expertise, transaction/ negotiating expertise and general marketing expertise. The pre-incubator should have the right networks to be able to access any specific expertise needed that the pre-incubator cannot have in-house.

3.5 Cost and resources

Regarding the cost of pre-incubation, flexible options are usually available so that pre-incubation space and support can be used in a way that best suits the potential entrepreneur.

The budget of the pre-incubator should cover staff expenses, including expert time, market research activities, hiring facilities for technology development, developing promotional material, buying supplies etc.

3.6 Selection procedures

The selection of the potential entrepreneurs to be supported by the pre-incubator is based on corresponding applications. Selection criteria should include the profile and commitment of the potential entrepreneur, the level of innovation and technology development, the potential market and the potential business model. The selection panel should include the manager of the pre-incubator and other stakeholders with relevant experience and expertise.

The pre-incubation has a clearly defined beginning and ending. The average time for pre-incubation is 6 months, but experiences have shown this period may be too short and it is recommended to be extended to one year. Entrance in the pre-incubation is sealed by a contract, which is ended when the pre-incubation time runs to an end or before, if a start-up company is established.

4. The Case of the Central Macedonia Region in Greece

Central Macedonia, situated in the centre of Northern Greece, has an important geographical position; it shares borders with two Balkan countries and its capital, Thessaloniki, is the second economic centre in the country with a metropolitan role in the Balkan / the Black Sea area. The population of the region is 1710000 (16.7% of the country's total) with a growing trend. The agricultural sector has a higher productivity rate than the country's average and contributes significantly to exports, but it is especially sensitive to changes over time. Industrial activity entails 23.5% of the regional Gross Domestic Product and is strongly specialized in certain branches (food-drinks, textile, footwear-clothing, non-metal minerals, building materials). Exporting activity is important and covers 30% of the country's total export value. The contribution of tourism in the economic development of the region is important in terms of employment, income, foreign exchange inflow [4].

As a result of national and regional policies supporting innovative entrepreneurship in Central Macedonia, there are a number of local initiatives for the establishment and development of networks and infrastructures that support entrepreneurship and innovation. Most of the established organisations supporting innovative entrepreneurship are situated in the Metropolitan area of Thessaloniki, the capital city of Central Macedonia, and act as incubators for innovative businesses, providing housing, business advisory services and access to venture capital.

The main regional stakeholders of the innovation system of Central Macedonia include four higher education institutes (Aristotle University of Thessaloniki, University of Macedonia, International Hellenic University and Technological Educational Institute of Thessaloniki), one research centre (Centre of Research and Technology Hellas), three business incubators, the Technology Park of Thessaloniki and more than 250 high-tech firms and their networks.

The Regional Innovation Pole of Central Macedonia, supported by the Operational Programme "Competitiveness" 2000-2006, has been planned as a regional system of institutions and partnerships

that reinforces innovation, firstly in the sector of Information and Communication Technologies and then in other sectors of industry and services, dealing with their shortcomings in the fields of research and development, patent acquisition, development of new products, and access to international markets. The Regional Innovation Pole of Central Macedonia aims at contributing to the reinforcement of the regional innovation system. In long-term, it aims at the creation of an innovation system in the field of Information and Communication Technologies, while its direct objective was the enhancement of the innovation of Information and Communication Technology firms of the Region of Central Macedonia.

Thessaloniki Technology Park is the structure established in Thessaloniki in order to link research to production. Today, Thessaloniki Technology Park includes the research facilities of the "Centre for Research and Technology Hellas" (CERTH), an incubator building which houses 10 companies, administration building containing a library and conference centre. The Management and Development Company of the Thessaloniki Technology Park (TTP / MDC) promotes and enriches the activities of the businesses housed in the Technology Park in collaboration with the Federation of Industries of Northern Greece and the Universities and Research Centres.

The Business Incubator "Incubation for Growth - i4G S.A." is one of the most significant and particularly successful business activities implemented within the framework of "ELEFTHO" Programme of Ministry of Development according to specifications set by other pertinent European programmes. The business incubator i4G S.A. mainly aims at both the stimulation and management of the knowledge and technology flow exchanged amongst universities, research institutions, companies and markets. It also provides value-added services along with high quality infrastructure, contributing thus, to the economic growth of the local community.

Similarly, Thermi S.A. has created an Integrated Corporate Support System in its Business Incubator, where recently established technologically innovative enterprises are hosted. In addition to the high quality installations and equipment provided by Thermi Incubators, its incubatees are also offered the support of the incubator's Integrated Corporate Support System based on the highly qualified human resources employed by Thermi S.A. and on the external support it receives through its network of consultants, comprising academics, university professors and researchers.

"Technopolis Thessaloniki SA" is a unique initiative taken by the Association of Information Technology Companies of Northern Greece. Its shareholders consist of:

- Social and educational institutions of Thessaloniki as well as companies belonging to the wider public sector
- Over 70 companies with a strong interest in information and new technologies, which employ a large number of scientists and researchers and are export - oriented with established presence in the neighbouring countries

The concept behind "Technopolis Thessaloniki" is to create a cross-regional, cross-Balkan operational base and a pole for innovation, research and cooperation in developing innovative solutions and in commercializing the innovative products and services. As a catalyst for commercial investments in the sector of Information and Communication Technologies, "Technopolis Thessaloniki" envisages its operation as a Centre of Excellence in the wider region of South East Europe and beyond. The vision is to become a hub of high-tech, entrepreneurial companies that attracts investments by Greek and foreign companies creating thus new opportunities for growth. Aiming to accelerate the existing knowledge capital in the region, "Technopolis Thessaloniki" will bridge research with business and will become the meeting point of local and regional innovators. Technopolis Incubator is an integral part of Technopolis Thessaloniki. The incubator has the aim to provide the necessary infrastructure, consulting support and investment funds to lead promising start-up companies to success. The incubator focuses on the fields of information and communication technologies as well as related areas, thus utilizing the dynamics and partnerships of the Technopolis Business Park. Through the incubator new business ideas and technologies can have access to Technopolis Thessaloniki, while the new companies enjoy all the advantages of being located in this thriving environment.

The business incubators in the region not only provide building and state-of-the-art equipment infrastructure to the incubator tenants, but they also support the firms by offering management consultancy and information provision, as well as access to capital in order to finance development concerning short-term operating needs and long-term investments. They have also established beneficial links among research and entrepreneurship, activating at the same time long-lasting mechanisms:

- Co-operation among scientists, researchers, entrepreneurs and investors
- Entrepreneurship encouragement by pointing out new ideas and supporting their business-wise utilization

However, the regional business incubators are not directly linked to the higher education institutes, and they do not provide permanent pre-incubation services, unless these are provided as part of a local project or initiative for a limited period. An example is a corresponding activity of the Regional Innovation Pole of Central Macedonia, aiming at providing specialized support and evaluation services prior to assuming the business risk, combined with the existing support and finance structures (incubators) of innovative ventures. Two cycles of stimulation activities for innovative entrepreneurship were conducted and proved to be a significant instrument in the empowerment and acceleration of the commercial exploitation of the research results. Parallel to this, the collaboration of all the incubators in the implementation of the task ensured the homogenization and complementarities of the services provided at the level of structures as well as at the level of the services rendered, creating a strong support cluster for new knowledge intensive businesses in the Region of Central Macedonia.

The strong networking relationships and past collaboration experience between the regional innovation structures and organisations in Central Macedonia, in collaboration with regional authorities and regional policy makers, can provide the perfect environment and suitable infrastructure to further develop and support pre-incubation activities in the region. In contrast to the incubators, which provide services for new businesses already operating, a pre-incubation program can provide employment, education and counselling at a very early stage of the start-up process until the establishment of the new start-up company.

The proposed pre-incubation program should provide the following services to the young scientists who will join the program:

- *Working space.* In collaboration with the existing incubators, the pre-incubation program should be able to provide a certain number of working spaces for the participants. Conference and meeting rooms will be available for the networking of the participants between themselves or with the management team during the training and personal guidance activities.
- *Training and personal guidance (coaching / mentoring).* Training activities should be organized for the participants in the pre-incubator program, including training courses and practical training in subjects related to business planning and development issues, sales and marketing, organization. Personal guidance should be also provided to each participant to design and develop the business idea in the form of a business plan for the establishment and development of a start-up company.

5. Conclusions

In the academic environment, pre-incubators have been developed to address the obstacles that academics often see regarding entrepreneurship, such as insufficient knowledge about economics, unknown market potential of the developed products and services, high financial risks, lack of personal skills on entrepreneurship, unawareness of the value of their intellectual property.

Particular emphasis is put on the following pre-incubation features that serve the main objective of the pre-incubation approach, which is to support a young entrepreneur to turn a business idea into a viable business:

- Providing efficient customized services, through coaching and mentoring of the young entrepreneurs, in setting out, monitoring and evaluating the development plan of their business idea
- Assisting the young entrepreneurs in defining and testing the market potential of their business idea, incorporating also user requirements into the design, configuration and price of their new product or service.
- Providing a shared environment for networking and sharing experiences

In the case of Central Macedonia, the business incubators in collaboration with the higher education institutes should build on the successful experience of the pilot pre-incubation activities in order to establish permanent pre-incubation facilities and services with the aim of supporting entrepreneurship emerging from the academic and research environment. Current and future pre-incubation activities should have the support of national and regional authorities, within the broad innovation policy framework that has been developed in Central Macedonia. Regional funds for innovation and entrepreneurship should be directed towards the pre-incubation approach for supporting academic entrepreneurs in the initial stages of their development.

Entrepreneurship and innovation in Russia: local and international perspective

Artem Egorenkov¹

¹Faculty of Economics, National Research University – Higher School of Economics, Moscow, Russia, artemegorenkov@mail.ru

Promoting innovations is one of the hottest topics in the Russian political and economical life at the moment. Vital necessity to upgrade manufacturing facilities and diversify economics through production of high-tech goods with significant value added makes analysis of innovation process and diffusion of innovations in the economy actual as never before. However, deficiencies of the data, collected by the official statistics, due to relatively short history of innovation surveys in Russia, mostly cost-based approach, and situation, when most of the forms on innovation activities results are turned in blank, stimulate search of alternative ways to data collection and analysis. One of the possibilities provides Global Entrepreneurship Monitor, conducted worldwide on a longitude basis for a quite significant period of time already. Overall, this methodology, as shown in the article, lies within the requirements stipulated in international statistics manuals on innovations (such as, for example, OSLO manual). Additionally, they provide an opportunity to include small and medium enterprises, and even those businesses, that are currently being at the planning stage (nascent entrepreneurs), in the scope of the research, to conduct a cross-national comparison and explore indicators in dynamics. Even initial results obtained from such an analysis provide quite unexpected results and facilitate further thorough study of the problem.

Keywords

GEM, innovations, innovative entrepreneurship, product innovations, technological innovations

1. Introduction

Research on innovation activity of entrepreneurs is probably one of the most promising and asked-for areas of economic study at present. It is also one of the least developed topics in the field. Xheneti and Blackburn [1] in their analysis of publications on Small Business and Entrepreneurship in 696 articles from 6 major ISI journals on entrepreneurship identified that articles on innovative aspects of entrepreneurship amounted for only 17. Many scientists admit the leading role of innovations though in economic development, as it is innovation that appears to be “carrying out of new combinations” – activity, seen as the primary function of entrepreneurship by J. Schumpeter [2]. Innovations are also the key to understanding economic growth – conclusion that has been reached by different economists at different points of time: K. Marx in the law on the tendency of rate of profit to fall told about the exhaustion of economic growth unless the so-called “switch of technologies” occurs or production methods change. Soviet economist N. Kondratiev showed that the slowdown in development without implementing changes in the production process – innovations – is inevitable [3]. Breakthroughs in technological development of industry were identified as the main factors of long cycles of economic development [4]. Technological progress is the key factor of economic growth in popular and well-known Solow model [5] and later and more complicated models of economic growth.

In spite of thorough proof by economic theory of the key role of innovations in many economic processes at the macro- and micro-level (including success of the entrepreneur and his firm), categories of innovation and innovation activity are often mentioned in relation to absolutely different in its substance processes and phenomena. Besides that very often the meaning of these categories is

unreasonably broadened or, on the contrary, narrowed. That is why empirical research of innovation activity of entrepreneurs, study on possibilities of innovation development, especially pressing in view of the proclaimed course towards modernization of Russia through innovations, requires statistically correct and unambiguous specification of the scope of innovation activity. Only finding an answer to the statistical specification of innovation category, methodologically consistent with the definitions and concepts of SNA UN 2008 will provide for the adequate measure of innovation activity and create conditions for the empirical study of factors and obstacles on the way towards increase of innovativeness of Russian economy, including the context of international comparisons.

2. Problems with measuring innovative activity in official statistics and possible solutions

The official methodology currently implemented for the purpose of innovation data collection out through the European Union and in many other, including OECD, countries all over the world is best described by the special manual developed by experts of both European Union and OECD: Oslo Manual [6]. The thorough outlook of the methodology can be found in many works including another work of the author [7].

The Russian Federal State Statistics Service (Rosstat) monitors innovation processes based on the same OECD–Eurostat methodology. During the past few decades, surveying principles at Rosstat have undergone the same changes as principles of Community Innovation Surveys.

As of now, official statistics on innovations in Russia is collected in compliance with the standard form No. 4-Innovation, and it is not empirical facts that are covered therein, but individual outlooks on innovation activity of business organizations responsible for the respective course of their business in terms of qualitative and quantitative estimates. In theory, it is supposed that opinion expressed by an organization that fills the form is by itself an expert judgment. Considered from the standpoint of reporting practice organization principles, this means that such opinion is expressed in good faith and can be effectively used to describe the actual state of affairs at a company and make effective management decisions (in abroad books, such opinion of usually referred to as ‘true and fair view’). Nevertheless, it would be logical, when setting up a survey, to take into account the biased nature of the valuation and make the category of innovation as defined in respective items of the questionnaire or reporting form, as statistically specific and clear to a potential respondent as possible.

The other important factor in this regard is responder’s trust in statistical observation and his/her readiness to cooperate. For example, a survey of industrial enterprises with respect to the quality of filling the Form 4-Innovation conducted in 2008 at the request of St. Petersburg Territorial Statistics Service (Petrostat) and led by Irina Eliseyeva, Ph.D. Econ. and associate member of the Russian Academy of Sciences, showed that enterprises that were unapt to disclose information or had doubts about the privacy of information put in the questionnaire by contrast with when such data is published in an annual survey, would return the forms almost unfilled. In particular, even sections with the largest number of questions answered still were filled out for less than 73%. It is noteworthy that, even if a responder leaves an entire section of the questionnaire unfilled, it cannot actually lead to any adverse consequences [8]. Probably, so large a number of unanswered questions was due to the unreasonably high statistical load on respondents, which had to fill an extra reporting form immediately after the annual survey. Nevertheless, we have to acknowledge that the problem of empty answers and incompleteness of collected data do exists in the course of statistical measurement of innovation activity, and even more so is aggravated by the inaccuracy of given valuations.

The fundamental need for the resolution of both the aforementioned and other problems related to the credibility and integrity of data collected for the purpose of official government statistics on innovation data encourages alternative statistics to search for, and use, additional sources of empirical evidence for interpreting innovation activity.

One of such sources is the Global Entrepreneurship Monitor (GEM) database. GEM is an international scientific and research project, which involves more than 50 member states. Within the GEM project, adult working population is interviewed, with an eye to make up a statistical characteristic of activity and qualitative structure of entrepreneurship in a country. The survey allows for a chance to group entrepreneurs by phases of business development, from potential entrepreneurs, i.e. individuals that are only trying to start their business, to owners of established businesses, i.e. entrepreneurs that have received a hard gross mixed income for at least 3.5 years [9]. The GEM program pays special attention to the monitoring of early entrepreneurship, represented by the most active, mobile and unreliable strata of nascent entrepreneurs and owners of new business; official statistics, however,

provide almost no coverage of the above groups [10]. Entrepreneurship characteristics, covered by the GEM on a permanent basis, also include indicators of product and technological innovations. Since 2006, information on innovation activity of Russian entrepreneurs, obtained through the polling of adult working population of the Russian Federation, is handled by the research group of the Higher School of Economics. Under the GEM survey, entrepreneurs answer questions about their businesses' innovation activities, which make it possible to spot product and technological innovations. The wording of questions is linked to the standard international definition of innovation, but responders can supplement their personal assessment of novelty by several additional qualifying characteristics. For example, a responder can additionally specify whether the product or service offered by his/her company is new to all, some, or none of consumers. The question about product innovations is worded so as to define product innovation by the 'new-to-market' criterion, which implies a greater degree of novelty and a much more precise valuation by contrast with the OECD–Eurostat methodology, which defines the scope of innovation by the 'new-to-firm' criterion. The identification of technological innovation in surveys under the GEM methodology is also largely particularized: a respondent must not only define whether a used technology is 'new-to-firm', but also specify its age, i.e. for what time it has been available to market producers: less than 12 months, from 12 months to 5 years, or more than 5 years. Therefore, data on innovation in Russia collected under the GEM methodology make it possible to analyze the innovation activity of Russian entrepreneurs at various phases of business development for a period since 2006, including in the context of international collations, based upon objective criteria that make the specifications of international innovation measurement standards more precise.

3. Empirical study of innovation activity of Russian entrepreneurs: GEM survey

Official statistics show Russia's growing retard in the innovation sphere from countries with developed economies. For reference, the World Bank estimates Russia's share of global exports of science intensive civilian products at 0.5%. At the same time, the US controls a 36% share, Japan has 30%, Germany 16% and China 6%. Based on the above data, we may assume that the most economically developed states are characterized by businesses' heightened innovation activity. This can be reasoned by the fact that developed economies have more preconditions for the usage of new, more technically and technologically complex methods of product manufacturing and service providing. In addition, such states have a more developed resource base for innovation development. However, as we have stated hereinabove, the impact of some statistical causes on the above-described results cannot be ruled out either.

It is therefore appears as appropriate that a comparative analysis of market innovation activity should be carried out based on an alternative source of empirical information, preferably in a detailed form, as company's market position can change markedly at every phase of entrepreneurial activity.

The need for a reliable resource base for any investment, including in the innovative development of enterprises, suggests a hypothesis about the influence of economic recession on entrepreneurs' innovation activity.

H1. Financial crisis causes entrepreneurs to cut capital expenditures, including investments in the development of new products and technologies.

An analysis of literature on the theory of entrepreneurship makes it possible to suggest that the degree of innovation varies greatly among various entrepreneurial strata. Early entrepreneurs are just coming to the market and are trying to take a specific niche by means of a competitive struggle. According to the Schumpeterian concept, the manufacture of an innovative product, new to all customers, and the product supply to the market is the only way to introduce a nascent or new firm to the market [2], [5]. This puts forward the second hypothesis about the innovation activity of Russian entrepreneurs.

H2. Early entrepreneurs are more active in fostering innovation than owners of established businesses.

The statistical verification of the hypotheses was made based upon the international GEM database, available, as it has been noted above, for Russia for the period from 2006 to 2010. To study into the dynamics and place-to-place collations for 2006-2009, a database was formed that covered innovation activity of entrepreneurs from 24 states which have been members of the GEM project over the entire period of its existence. Under the terms of national teams' participation in the GEM consortium, data for 2010 is presently available only for Russia.

As is seen on figure 1 below, the percentage share of Russian entrepreneurs that offer products that are new to all consumers rose by 10% y-o-y in 2007, which was primarily due to a decreased number of entrepreneurs that offered services to many consumers. In 2008, the share grew even higher, up to 23.3%, but came down slightly in 2009 and 2010.

The verification by the Student criterion showed that a change in the percentage of products new to the entire market was statistically significant (5% sig., Student's test) only in 2006-2007. Economists consider this period as the time when global crisis processes emerged: the mortgage crisis in the US outraged in 2006. The absence of data on Russia for the preceding periods does not suggest a compelling reason to say that year 2007 was critical, i.e. the share of entrepreneurs that offered innovative products increased sharply that year, or that 2006 was abnormal, and the product innovation indicator came sharply down.

Figure 1 Share of entrepreneurs, offering product, new to all customers, to many and to nobody (%)

The situation with technological innovations is much more oppressing (see figure 2): here, the statistically significant positive dynamics for absolutely new technologies (5% sig., Student's test) was only registered in 2010. This was probably the result of resource restrictions after the economic recession. The reduction in the share of entrepreneurs using new technologies, i.e. those that had only been available to market producers for less than 12 months, can be reasoned by the overall drop in investments in new technology and economic insecurity, especially given the crisis was still in full play in 2009. In 2010, the Russian economy followed a steady upward trend, and the society generally considered the crisis to have come to end. As a result, the share of entrepreneurs that implemented technological innovations increased and even exceeded pre-crisis level (12% vs. 7%).

Figure 2 Share of entrepreneurs, using technology available for less than 12 months, from 12 months to 5 years and more than 5 years

Therefore, the H1 hypothesis was proved wrong: the crisis does not necessarily bring forth any statistically significant reduction in entrepreneurs' innovation activity in either the sphere of product innovations or technological innovations. This is probably due to the fact that higher resource restrictions make competition among small and medium businesses more intense amid the crisis. This encourages entrepreneurs to apply more state-of-the-art technological production processes on one hand and master new product niches on the other. As a result, the limited access to financial resources, caused by the financial crisis, did not give rise to any grave negative consequences, e.g. new forms of competition, in the innovation sphere.

The difference among innovation activity levels for various phases of business development, i.e. for early and established entrepreneurs, is of particular analytical interest, too. The chart 3 below shows that early entrepreneurs were more active in an attempt to deploy product innovations in all the years, except 2007 and 2008. The statistically significant gap was registered in 2009 and 2010 (15% sig., χ^2

test), when is amounted 11% and 8%, respectively. Therefore, the H2 hypothesis proves out amid economic stabilization: early entrepreneurs, when put in more or less secure conditions, are indeed more active in the deployment of product innovations.

Figure 3 Share of entrepreneurs, offering product, new to ALL customers

This can be reasoned by new entrepreneurs' ambition to market the innovative product with a view to occupy a specific market niche, get a competitive advantage over other firms and entrepreneurs and "carry out a new combination", i.e. perform their primary entrepreneurial function, according to Schumpeter. The dominating share of established businesses in the marketing of product innovations in 2007-2008 can be attributed to their larger financial, social and institutional resources by contrast with early entrepreneurs, especially amidst stronger resource restrictions when exposed to the financial crisis. For the same reason, established businesses are less inclined to conserve their economic activities in anticipation of better economic conditions. This is the reason why established businesses actively search for opportunities to offset crisis-driven market contractions through the extension of their market positions, if not by upgrading profits, but at last by keeping them at pre-crisis levels, including by supplying customers with innovative products.

In case of technological innovations, implemented by entrepreneurs at various phases of business development, the leading role of early entrepreneurship is even more significant (see figure 4). In 2007-2008, established businesses made almost no implementations of technical innovations. On the contrary, early businesses showed quite robust results in the sphere of technological innovations.

Figure 4 Share of entrepreneurs, using technologies, available for less than 12 months

The benefit of GEM data from an analytical viewpoint is their longitude character and convenience for making place-on-place collations. In 2006-2009, a panel of 24 countries was made up, which permitted to not only monitor entrepreneurs' innovative activity in Russia, but make comparisons with other countries. Figure 5 below depicts the curves of average and median percentage numbers for entrepreneurs that classify their products as new to all customers on the domestic market.

Figure 5 Median and mean evolution: share of entrepreneurs, offering products new to ALL customers (24 countries)

Figure 6 Median and mean evolution: share of entrepreneurs, using technologies, available for less than 12 months (24 countries)

Analysis of the available data shows that, since 2006, product innovation in Russia has been much above the average level of other monitored countries. At the same time, the situation with technological innovations is polar: technological innovation in Russia is below the average level of the 24 GEM member states that have been project members in the course of the observation period.

Table 1 Russia's rating in the made-up panel for a period from 2006 to 2009.

Indicator	2006	2007	2008	2009
Product innovations	18	3	5	6
Technological innovations	20	14	15	20

Global data on innovation activity among early and established businesses makes it possible to carry out a bi-dimensional clustering of countries by the product and technological innovation for 2009. A total of four such clusters were distinguished: countries with low level of product and technological innovations, high level of product and technological innovations and countries with high level of one type of innovations and low level of the other. The distinction between high and low levels has been made based on the mean values of entrepreneurs implementing product and technological innovations for the populations. The obtained results appear to be quite interesting and may serve as a clear illustration for the fact that innovation on developed markets is more of technological nature. At the same time, innovation on less developed, and hence less competitive markets, is largely of product type. Figure 7 shows that the countries with the highest product innovation numbers are Chile, Peru and Uruguay. The leading technological innovators are France and Croatia. At the same time, the US, Japan, the UK and the Netherlands were classified as states with the least intense technological and product innovation activity among entrepreneurs. Russia, together with Argentina,

Peru and Columbia, was put in the cluster of states with quite a large amount of product innovation and a relatively low level of technological innovation.

Figure 7 Country clusters

All in all, we may assume there is an interrelation between the level of economic development of a country in general and the innovativeness of its entrepreneurs. For reference, the most economically developed states according to GEM data entrepreneurs show the weakest production and technological innovation levels. The cluster that includes France, Croatia, Finland, Greece, Spain and other countries also covers states with relatively high living standards, but which still are the leading technological innovators. The least economically developed states, on the contrary, show the highest level of product innovation.

4. Conclusions

Data collected within the GEM survey open up tremendous opportunities for the further observations and are an appropriate supplement to information covered by official government statistics, as they monitor entrepreneur's innovative activity at the earliest phases of business development. The sphere of innovations still has more questions than answers, and the continuous development of the pool of empirical evidence will soon permit to resolve problems, which might seem almost insoluble under a statistical system available just 10 or 15 years ago. For example, one may conclude even now that early entrepreneurs, at least in Russia, are more dynamic innovators than established businesses, which are crustier, more stagnant, and far less dynamic when it comes to innovation. In addition, we may arrive at a conclusion that product innovation in Russia is presently at a relatively stable level. Technological innovation in this country has followed a steady upward trend, except in crisis-shaken years. On the back of economic recession, entrepreneurs do their best to curtail expenses, and consider switching to new, more efficient and resource-saving technologies and production schemes.

The survey showed innovation activity of small and medium business was in non-linear dependence on the level of economic development. It is noteworthy that, in spite of initial assumptions and results of official statistical surveys, this relationship is inverse. Contrary to expectations, such countries as the US, Japan and the UK show lackluster product and technological innovation performances. At the same time, Chili, Peru, Uruguay and Argentina have the largest product innovation numbers. Countries with more developed economies, such as Belgium, France and Croatia, have greater technological innovation numbers. Moreover, small, medium and large businesses play different roles in the innovation sphere in different countries: in developed states, innovators are medium and huge businesses. In emerging economies, innovators are small and medium businesses.

Finally, we would like to underline that we regard the achieved results as a precursor to a new extended general survey of entrepreneurs' innovative activity. The way the GEM monitoring is organized implies that data is collected primarily for small and medium businesses. The study covers business activity of the entire population, and there is almost no chance any large entrepreneur or monopolist could be covered in the survey. Official statistics, on the contrary, monitors medium and

large businesses. In more economically developed countries, innovation activity, or at least the marketing of new products and the initial implementation of new technologies, is the task of medium and large, and not small businesses. In emerging countries, the situation is polar: innovation is pioneered by small businesses. For this reason, one of the most important aspects that should be covered in future surveys is the detailed monitoring of innovations at various entrepreneurial strata.

Entrepreneurship orientations before and during the global economic crises

Tiit Elenurm¹

¹Entrepreneurship Department, Estonian Business School, Tallinn, Estonia
tiit.elenurm@ebs.ee

The objective of this paper is to explain the implications of economic boom and economic crises on entrepreneurship orientations. Survey results of 1075 experienced entrepreneurs and business and entrepreneurship students in Estonia during the years 2005-2010 are presented and discussed. Theoretical foundations for analyzing imitative, innovative and co-creative entrepreneurship orientations are presented. The paper explains, why studying three different entrepreneurship orientations is essential in rapidly changing business environments of catch-up economies. Combinations of co-creative and innovative entrepreneurship orientations are more popular than the imitative entrepreneurship orientation even during the economic crises. When comparing survey answers that were given during the boom period 2005-2007 and later in the economic crises period 2008-2010, there is some evidence of trends towards innovative and co-creative orientations and diminishing support for the imitative orientation. In 2005-2007, 28.7% of the respondents supported the co-creative view of being entrepreneurial because it enabled others to be innovative and 36.2% were focused on imitation. In 2008-2010, imitative orientation on implementing proven ideas from other places received only 28.1% support, but support for the co-creative view had increased to 43.6%. Support for the co-creative statement that customers should participate in business development more openly increased from 26.1% to 35.8%. An action research that involved some survey participants in a training setting revealed that participants with some entrepreneurship experience mainly focused on opportunities for locating new export markets for existing products and on taking over local enterprises that face bankruptcy or opportunities to acquire cheap resources available in depressed markets. At the same time both students that lacked entrepreneurship experience and serial entrepreneurs were open to the “blue ocean” thinking and were focused on more innovative entrepreneurship opportunities. Research results can be used as an input for training that takes into consideration differences in entrepreneurship orientations and changing business opportunities in the business cycle.

Keywords

Entrepreneurship education, Entrepreneurship orientations, Innovation, Networking

1. Introduction

In the discourse about business development and innovation, the crucial role of entrepreneurs in recognising new business opportunities, in developing, expanding, restructuring and sometimes down-sizing or even closing businesses deserves special attention. Innovative business ideas facilitate organisational changes. Peter Drucker [1] has stressed that entrepreneurs play an important role in building and nurturing organisational learning and initiating organisational change. Initiatives that focus on innovation and regional development have to take into consideration preferences of the entrepreneurs in charge of the business and their ability to rely on their own old and new ideas and competences of business partners in entrepreneurial ventures. Preferences of entrepreneurs to use innovative or more traditional business opportunities may change during an economic crises.

This paper addresses two main research questions: How do imitative, innovative and co-creative entrepreneurship orientations appear before and during the economic crises? Which differences between entrepreneurship orientations of respondents with entrepreneurship experience and without such experience are relevant to developing innovative entrepreneurship and entrepreneurship education?

In order to answer these questions, the paper at first provides an overview of some key concepts of entrepreneurship and entrepreneurship orientations in the context of change and innovation managements. The next section of the paper presents the logic of the self-assessment tool applied in order to assess preferences of respondents, when they have to choose between different entrepreneurship orientations. Survey results are then analyzed by comparing surveys conducted before and during the economic crises. The last section focuses on some learning experience and highlights opportunities to align training of present and potential entrepreneurs to their orientations.

2. Entrepreneurship orientations and innovation

Innovative entrepreneurs have to understand new opportunities that in the long run cause economic growth. Developing the skills involved in identifying business opportunities has an important role in the entrepreneurial effort [2]; [3]. Recognition of new opportunities is one of the most important outcomes of entrepreneurial learning [4]. The right balance between the opportunity-driven entrepreneurial domain and the resource-driven managerial domain [5] has to be found taking into consideration limited resources.

Schumpeter [6] linked the role of the entrepreneur to creative destruction by transforming existing production systems. Kirzner [7] in his theory of entrepreneurship concluded that the entrepreneur is a driving force in the market due to his or her role in discovering unused opportunities in the marketplace, and the competitive behaviour of entrepreneurs is operational in restoring the equilibrium of the market. The innovative entrepreneur described by Schumpeter is more related to introducing creative business ideas that may change the nature of markets, whereas the entrepreneur described by Kirzner is more an opportunity seeker able to perceive market gaps and mistakes made by other entrepreneurs in the situation of incomplete information supply. Shane [8] links Kirznerian entrepreneurial opportunities to equilibrating forces, to limited discovery of common and less innovative solutions that do not require radically new information, whereas Schumpeterian opportunities are disequilibrating, rare, innovative, involve creation and require new information and organisational learning. Scarce resources are not limited to finances, but often include human resources, who are essential for core competence development.

Entrepreneurs have also been characterised as individuals that believe something that nobody else believes [9]. Such differential beliefs allow them to use new business opportunities. Unique beliefs, at the same time, create the challenge of aligning the vision of the entrepreneur and his/her team with business partners and other stakeholders in the process of identifying, developing and implementing new business ideas. Ireland et. al. [5] pointed out that entrepreneurial opportunity-seeking may be at the same time also strategic behaviour with the aim of value creation. Strategic choices of individual are influenced by their more general orientations.

Entrepreneurship researchers Tom Lumpkin and Gregory Dess developed the entrepreneurial orientation construct that integrates five dimensions: innovation, proactiveness, risk-taking, autonomy and competitive aggressiveness [10]. The founders of the enterprise try to lead it in a direction that is consistent with their personal tendencies [11]. The behaviour of the firm and that of the entrepreneur are likely to follow the same orientation in entrepreneur-led firms [12].

The construct of the single entrepreneurial orientation however does not address some crucial choices that are driven by the basic attitudes of the entrepreneur concerning preferable ways of value creation and the nature of the core competence needed for successful business development. The construct of a single entrepreneurial orientation has been further developed by differentiating several entrepreneurship orientations: imitative entrepreneurship, individual innovative entrepreneurship and co-creative entrepreneurship [13].

The dynamic capability school developed by Barney [14] links business success to developing distinctive organisational capabilities and core competences that are difficult to imitate. Prahalad and Hamel [15] treat core competence as an outcome of collective learning in an organisation by integrating and co-ordinating diverse skills and multiple technologies to deliver unique value to customers. In the rapidly changing business environment of an emerging market, an entrepreneurial person can, however, gain business success by imitating business ideas and technologies that have already been used by other entrepreneurs. Imitation in a non-saturated market of a catch-up economy

can support market pro-activeness and the competitive aggressiveness of a fast mover in recognising business opportunities that can be exploited by transferring business models from more advanced markets without “reinventing the wheel”. Such business behaviour does not assume core competence for delivering unique value based on entrepreneur’s own product or process innovation development efforts. Successful imitation, however, assumes not only an understanding of product life cycles, but also of economic boom and crisis cycles in order to follow the right business ideas at the right time and to sell the business before the business opportunity becomes unprofitable and exhausted. Imitative orientation may sometimes mean illegal copying of products, but alternatively it can be applied in the legal framework of representing some well-known trade mark, importing goods or taking a franchise. As the imitator is not offering a unique product or service, the long-term success of the imitative orientation assumes the core competence for retaining the cost advantage or changing the object of imitation when the competitive situation becomes unfavourable.

Individual innovative orientation is a good basis for entrepreneurial ventures in a business environment, where creative differentiation is the main prerequisite for creating and retaining local or international competitive advantage. This orientation will work for business growth if core competence of the entrepreneur is sufficient to manage the change starting from the creative idea until commercialization of the innovation. Entrepreneur has to be able to protect his/her innovative solution and to individually control human resources and investments that are needed in order to implement an innovative product or technology. Start-up ventures in a catch-up economy often lack capital for long-term new product development and credibility for commercializing their innovation at international markets. Innovative entrepreneurs have to understand if their new business idea corresponds to the business opportunity at the marketplace that they are able to access. An important feature of innovator’s core competence is to understand if markets are ready for commercializing their innovative solutions. Innovative orientation can be supported by the core competence in the field of new product and/or technology development or by creative ways to re-define business boundaries and to combine existing business ideas in a new way. The “blue ocean” concept of Kim and Mauborgne [16] explains business opportunities of value innovations that focus on new markets and on new ways of satisfying client needs not yet discovered by competitors stacked in fierce competition in existing “red oceans”. The innovative entrepreneur faces the choice of developing in his/her entrepreneurial venture core competences sufficient for implementing a value innovation or relying on complementary core competences of business partners and customers as co-creators of new business solutions.

The co-creative orientation is a reflection of the emerging network economy of the 21st century. Entrepreneurs that choose to follow this orientation can co-operate as members of regional or global value chains. Software development projects that are based on open source code and communities of practice are examples of co-creative environments that may generate synergetic entrepreneurial ideas. Co-creation is also linked to the rise of business services [17]. Co-creative orientation in the pure mode assumes knowledge sharing readiness and mutual trust in a business environment where, as in a brainstorming session, it is not always possible to fix and protect the authorship of the idea. Co-creative orientation means a readiness to share business opportunities and business gains with partners. Co-creative entrepreneurship is based on social networks and clusters as information dissemination mechanisms that facilitate entrepreneurship [18]. Business networks mean continuous information exchange and the other co-operative relationships that a business organisation is engaged in with other organisations. Core competence development and open innovation management become inter-organisational processes that are supported by networking. At the same time, networking assumes readiness to overcome individualistic attitudes of traditional entrepreneurs. It may be difficult to align co-creative orientation with such dimensions of the traditional concept of entrepreneurial orientation [10] as autonomy and competitive aggressiveness.

Understanding imitative, innovative and co-creative entrepreneurship orientations of entrepreneurs helps to understand attitudes and priorities of entrepreneurs at the changing business landscape. Entrepreneurs that prefer one of these entrepreneurship orientations need to develop the core competence of their business venture in accordance with this entrepreneurship orientation.

3. Self-assessment tool for studying entrepreneurship orientations

Elenurm and Moisala [13] created a self-assessment tool for studying imitative, individual innovative and co-creative entrepreneurship orientations of entrepreneurs and potential entrepreneurs. Fifteen questions were developed to cover guiding principles and priorities in these main phases of the entrepreneurial process: business opportunity identification, business idea development and implementation. Sources of entrepreneurial ideas, interaction with customers and partners and risk

management in the entrepreneurial activity are reflected in the questionnaire. These issues were, however, not separate questionnaire sections, but presented through alternative statements that had a mixed sequence in order not to disclose the questionnaire pattern in the process of self-assessment.

Respondents were asked to compare three statements under each question and to choose only one statement that is most suitable for describing his/her preferences in the role of an entrepreneur. Table 1 gives a brief overview of the key issues of statements. The full statements are sentences that describe entrepreneurial action priorities and principles such as: "The best way to succeed in business is not to "invent a bicycle", but to introduce an existing product that will best serve the market need" that had to be compared with statements such as, "The best way to succeed in business is to trust your own intuition every time you have a creative business insight" and "The best way to succeed in business is to develop new business ideas with other people, although there is never a guarantee of success if you match people with different visions." Additional questions about entrepreneurial experience, age and gender were included in the questionnaire.

Surveys were mainly conducted in the business and entrepreneurship training environment in order to discuss survey results with participants. In this paper we analyse the results of 1075 respondents from two periods, 2005-2007 and 2008-2010. The respondents comprised 51% females and 49% males. Among the respondents, 32% (98 females and 245 males) had practical entrepreneurship experience. Of the survey participants, 49% represented the age group 18-24 years, followed by 21% in the age 25-29, 12% in the age 30-34, 8% in the age 34-39. Just 10% of the respondents were older than 40 years. The age composition of the sample represents well such age groups where young people involved in business studies should consider entrepreneurship as an option for their business career.

This sample also includes 105 Finnish students who participated in 2005-2006 surveys. The comparison of Estonian and Finnish business students indicated that in both countries there are two preferred entrepreneurship orientations among the business students: individual innovative orientation and co-creative innovative orientation. The imitative orientation was less popular among the business students in both countries. However, in Finland more students had followed a combined pattern of different orientations [19].

Table 1 Issues for the self-assessment of entrepreneurship orientations

	Key points of alternative statements reflecting entrepreneurship orientations		
	Imitative	Individual innovative	Co-creative
<p><u>I</u> questionnaire issue</p> <p>Sources of entrepreneurial ideas</p>	<ul style="list-style-type: none"> • Ideas proved elsewhere • Brands from other markets • Do not invent "bicycle" • Follow best practices • Flexibility to make profits like others 	<ul style="list-style-type: none"> • Own original ideas • First in the marketplace • Trust intuition • Change existing practices • Flexibility to develop own innovation further 	<ul style="list-style-type: none"> • Supporting ideas of others • Social impact • Develop ideas with others • Combine solutions of partners • Open to cooperation that reshapes existing business

4. Survey results before and during the economic crises

In the total sample of 1075 respondents, 40% gave priority to statements that correspond to the co-creative entrepreneurship orientation. Individual innovative orientation in the business creation and development process was supported by 35% and imitative orientation by 25% of respondents. Support for the imitative entrepreneurship statement of keeping one's eyes open to implement ideas that have already proved workable in other places is 31.5% among respondents that do not have entrepreneurship experience, and marginally higher (34.6%) among experienced entrepreneurs. Among experienced entrepreneurs, 51.9% are ready to combine good business solutions of partners in a new way, while 45.3% of inexperienced respondents prefer the same statement. Experienced respondents have higher readiness to share even negative information with customers (42%) than inexperienced respondents (30.8%). Among experienced entrepreneurs 53% support the view that the business vision of the entrepreneur will define the focus of the employee initiative while 39% of inexperienced respondents prefer the same statement. Instead of this statement, 50% of inexperienced respondents limit the initiative of employees to quality assurance in the established production process. These results indicate a potential challenge that some students and trainees without entrepreneurship experience may behave in a more directive and less participative way in the business creation and development process than experienced entrepreneurs with their own business practice reflections. Encouraging participation of employees in business development is an important challenge during the economic crises, where many enterprises have to restructure their operations.

On comparing survey answers that were given during the period 2005-2007 and 2008-2010, there is some evidence of trends towards innovative and co-creative orientations and diminishing support for the imitative orientation. In 2005-2007, 28.7% of the respondents supported the co-creative view of being entrepreneurial because it enabled others to be innovative and 36.2% considered themselves entrepreneurial because it kept their eyes open to implement ideas that have already proved workable in other places. In 2008-2010, imitative orientation on implementing proven ideas from other places received only 28.1% support, but support for the co-creative view had increased to 43.6%. Support for the co-creative statement that customers should participate in business development more openly increased from 26.1% to 35.8%.

Evidence of increasing support for the individual innovative orientation from 2005-2007 to 2008-2010 is reflected in the desire to be the first to launch a new product that has not been introduced before (from 29% to 39.4%) and in stressing the individual innovative view that the business vision of the entrepreneur will define the focus of employee initiative (from 36.8% to 57.2%). Support for the statement that the entrepreneur has to own the innovation that is used in a business activity has

increased from 32.4% to 41.4%. These trends can be explained as a result of the transition towards a more advanced market economy, where innovation has become more essential in international competition. During the economic crises some innovative entrepreneurs see a business opportunity in acquiring ownership in companies that face financial difficulties but can be restructured on the basis of their innovative vision. Ownership of the innovation as a feature of the individual innovative orientation, which can decrease the risk of imitating rare and valuable components of the core competence, assumes however more awareness about intellectual property protection.

5. Implications for entrepreneurship training

In 2009-2010 we used in the Entrepreneurship MBA programme entrepreneurship orientation self-assessment and business opportunity identification exercises in order to understand business development priorities and action patterns of real and potential entrepreneurs in recognizing business opportunities and in following different entrepreneurial orientations in the economic crisis situation. The training process involved developing written descriptions of individual short- and long-term entrepreneurship visions, specifying individual high priority business opportunities for 2009–2010, followed by discussing and reflecting business opportunity descriptions in teams during the entrepreneurial life cycle training programme and the development programme for entrepreneurs in 2009.

Managers and course participants that had some entrepreneurship experience mainly focused on opportunities for locating new export markets for existing products and on opportunities for taking over local enterprises that face bankruptcy or opportunities to acquire cheap resources available in the current depressed markets for industrial goods. They found such opportunities in real estate development projects that have run into difficulties and have been taken over by banks. Among actual entrepreneurs, there was evidence of the arbitrage logic that corresponds to Kirzner's [7] interpretation that the entrepreneur is the actor that restores the equilibrium in a non-perfect market. The business ideas of this group assume certain core competence to receive just in time information, flexible access to risk capital and good business contacts in order to exploit "window of opportunity" profitably. This reflects some kind of combination between the imitative and co-creative entrepreneurship orientations taking into consideration the limited capital base of these individuals that forces them to find business partners.

Participants that lacked entrepreneurship experience were in fact more focused on innovative business opportunities in the field of green products and alternative energy production. They also described life style entrepreneurship opportunities such as arranging cost efficient tourist trips to new destinations chosen in line with their own travelling interests. Some serial entrepreneurs with extensive business start-up experience, were, however, also inspired by business opportunities that correspond to the "blue ocean" thinking. From the point of view of imitative versus innovative entrepreneurship orientations, these entrepreneurial business ideas cannot, however, be interpreted as completely innovative. Their authors to some extent imitated green ideas and related business development practices of more advanced market economies. In fact they did not have a precise understanding of the extent to which their business opportunities can be exploited by transferring already existing business concepts and technologies from other countries, and what is the exact scope and resource base of their innovative development work in the Estonian context. Co-creative entrepreneurship orientation, in such cases, can be implemented through involvement in international virtual networks that use social software for discussing ideas related to alternative energy sources, green products and ethical entrepreneurship. Involvement in such networks can enhance a more realistic assessment of one's own core competences in following global trends and reveal differences between regional and global business opportunities. Entrepreneurship education can support networking by offering e-learning platforms that help cross-border teams to develop co-creative entrepreneurship skills.

6. Conclusions

Survey results indicate that during the period 2005-2010 innovative and co-creative entrepreneurship orientations have gained more popularity, and support for the imitative orientation has diminished.

Combining individual innovative efforts and the co-creative entrepreneurship orientation is a logical way to adapt to the changing business environment. The survey gives evidence that such combinations of orientations are perceived to be successful also during economic crises.

When developing core competences for managing global changes in the emerging network economy of the 21st century, cross-border networking is a crucial factor for discovering new business opportunities that can be used by combining ideas and resources of entrepreneurs in different regions. In order to anticipate potential opportunities and problems in such business co-operation, entrepreneurs have to be conscious, consistent and ethical in their choices between imitation, individual and co-creative innovation. Applying the tool for self-analysis of entrepreneurship orientations when discussing new business opportunities in the entrepreneurship education framework can empower present and future entrepreneurs for combining innovative and co-creative orientations.

The LifeLong Learning (LLL) paradigm supports the idea that learning should occur throughout a person's lifetime. Its purpose is to integrate education and work in a continuous process in which all citizens should be able to access knowledge and perform work at 20, 40 or 60 years old or even older. To support this valuable paradigm, following a "student-centred approach", students have to be equipped with their attitudes and skills to learn both in formal education and long after they have graduated. Strikingly, though, this student-centred approach is inappropriate for an increasing number of students, who are supposed to benefit from this paradigm, but in fact have to face social, physical and cognitive barriers because they have special needs and do not meet "standard ways of doing things".

To tackle this problem, the Integrated Project EU4All (European Unified Approach for Accessible Lifelong Learning) focuses on developing a flexible, open, standard-based architecture of services to support the LLL paradigm in Higher Education Institutions for people with special needs, giving a special attention to elderly people and those with disabilities. The project is based on the idea that in a knowledge-based economy, education and work are integrated throughout people's lives. All citizens need ongoing access to learning to enable them to work. Technology is playing an increasing role in mediating this learning. However, if this technology is inappropriate and introduced with insufficient support, disabled people will face even further exclusion from the interlinked worlds of education and work.

Furthermore EU4ALL contributes to a more general objective of "eInclusion" by ensuring equal access, independent living and participation in the Information Society for everyone and developing next generation assistive systems to empower persons with disabilities and ageing citizens playing a role in society, increasing their autonomy and realising their potential.

In EU4ALL, the R&D main aim is to provide full access to Lifelong Learning to users (adult learners and professionals) with impairments, allowing them to fully benefit of all the learning content and support facilities, including assessment and guidance, in a high education context.

The project now faces the challenges of promoting adoption, use and exploitation of the EU4ALL outcomes.

Keywords

accessibility, innovation, lifelong learning, special needs.

1. Introduction

The LifeLong Learning (LLL) paradigm supports the idea that learning should occur throughout a person's lifetime. Its purpose is to integrate education and work in a continuous process in which all citizens should be able to access knowledge and perform work at 20, 40 or 60 years old or even older. To support this valuable paradigm students have to be equipped, following a student-centred approach, with their attitudes and skills to learn both in formal education and long after they have graduated. Strikingly, though, this student-centred approach is inappropriate for an increasing number of students, who are supposed to benefit from this paradigm, but in fact have to face social, physical and cognitive barriers because they have special needs and do not meet "standard ways of doing things". This issue is palpable for those involved in providing assistance to learners with special needs in educational institutions, where the mere lack of information or access to pre-established procedures, not to mention the difficulties in providing the required infrastructure, may become insurmountable barriers for students interested in making this paradigm come true.

Furthermore, students and professionals with special needs have problems in accessing LLL due to what can become a crooked path of barriers that many times are involved in the various stages required to realise their learning goals. From enrolment to assessment, students have to negotiate a pre-established general procedures, which are intended to fulfil a "standard" set of needs but are far from considering their individual needs and preferences. Nonetheless, learning should be a personalised and adaptive process for all, which from the start to the end should consider the learner's needs. In fact, it is disturbing to note that most service providers, educational institutions and corporations as well, do not meet properly the most basic requirements of people with special needs. In particular, this problem is even more urgent in the so called mega-universities where an increasing number of students with special needs have to be assisted.

To tackle this problem, the a Sixth Framework Programme Research and Development Integrated Project EU4All (European Unified Approach for Accessible Lifelong Learning) focused on developing a flexible, open, standard-based architecture of services to support the LLL paradigm in higher education institutions for people with special needs, giving a special attention to elderly people and those with disabilities. Thus, the scope of EU4ALL is a subset of the general concept of "Assisted Living", namely Assisted Lifelong Learning (ALL).

The project is based on the idea that in a knowledge based economy, in which education and work are integrated throughout people's lives, all citizens need ongoing access to learning to enable them to work. Technology is playing an increasing role in mediating this learning. However, if this technology is inappropriate and introduced with insufficient support, disabled people will face even further exclusion from the interlinked worlds of education and work.

To address this, the EU4ALL project sets forward the concept of Accessible Lifelong Learning uniting 3 key strategies:

- That the technology mediating lifelong learning does so in accommodating the diversity of ways people interact with technology and the content and services it delivers.
- That this technology is used to bring support services to disabled learners.
- That provides support services and technical infrastructure enabling teaching, technical and administrative staff of educational institutions to offer their teaching and services in a way that is accessible to disabled learners.

2. LifeLong Learning (LLL) paradigm and technology

LifeLong Learning, also known as LLL, is the continuous building of skills and knowledge throughout the life of an individual. It occurs through experiences encountered in the course of a lifetime. These experiences could be formal (training, counseling, tutoring, mentorship, apprenticeship, higher education, etc.) or informal (experiences, situations, etc.) LLL is the "lifelong, voluntary, and self-motivated" pursuit of knowledge for either personal or professional reasons. As such, it not only enhances social inclusion, active citizenship and personal development, but also competitiveness and employability.

In the early 21st century new processes for education delivery and learner support mechanisms advanced to meet the dynamic needs of the adult learner marketplace. Today's depressed economic environment and challenged workforce have dramatically increased the needs and demands of learners to retool their capabilities and acquire new competencies. LLL definition is based on Jacques Delors' [1] four 'pillars' of education for the future. Learning to know - mastering learning tools rather than acquisition of structured knowledge.

Learning to do – equipping people for the types of work needed now and in the future including innovation and adaptation of learning to future work environments.

Learning to live together, and with others – peacefully resolving conflict, discovering other people and their cultures, fostering community capability, individual competence and capacity, economic resilience, and social inclusion.

Learning to be – education contributing to a person's complete development: mind and body, intelligence, sensitivity, aesthetic appreciation and spirituality.

European policy, also through the Bologna Process, aims to drive for a Europe of knowledge which includes lifelong learning and development. In the Leuven Communiqué of 2009 the Ministers identified among the priorities for the coming decade: lifelong learning, student-centred learning and social dimension as an equitable access to learn. To establish synergies between the Bologna process and the Copenhagen process, which concerns vocational education and training, in co-operation with Member States, the European Commission has established a European Qualifications Framework for lifelong learning (EQF) [2], applying it to all types of education, training and qualifications, from school education to academic, professional and vocational. This approach shifts the focus from the traditional system which emphasises 'learning inputs', such as the length of a learning experience, or type of institution, to the reference levels describing what a learner knows, understands and is able to do – 'learning outcomes'. It also encourages lifelong learning by promoting the validation of non-formal and informal learning [3].

To support LLL paradigm and to follow a necessary student-centred approach students have to be equipped, with their attitudes and skills to learn both in formal education and long after they have graduated. This approach needs an emphasis on the reformulation of access and equity priorities in a lifelong context, by looking at the opportunities that are available to individuals across their life-cycle and in the different settings where learning can occur. It is argued that knowledge-based economies and societies cannot afford to exclude a large part of their population from access to education and learning resources.

One of the pillar of Bologna Process, the so called “social dimension” aims at equality of opportunities in higher education, in terms of access, participation and successful completion of studies; at studying and living conditions; at guidance and counselling; at financial support, and student participation in higher education governance.

Nowadays technology is playing an increasing role in mediating LLL. The introduction of computing technology into higher and further education could have a large impact on how people participate in learning activities. From the retrieval of learning resources, such as lecture notes or presentation slides, to being able to engage with teachers and tutors in virtual environments, nowadays there are more available opportunities to learn than ever before. Technology has a strong potential to provide a personalized education experience to students and staff with disabilities in higher and further education institutions. While there are definitions for accessibility in both the physical and digital domains, it is unclear what are the current barriers to participation for people with disabilities in higher and further education environments. Furthermore it is unclear if the current technology is being leveraged in addressing the needs and preferences of people with disabilities in their environments. EU4All project worked on a large-scale user requirements elicitation activities undertaken in international higher and further educational institution, and on activities behind the development of the prototypes technology improved to promote accessibility and usability of virtual learning environments.

3. EU4ALL aims, framework, and services

The EU4ALL-project created an open architecture systems (OAS) focused on providing flexible and standard-based set of components and services for higher education institutions in order to solve issues that are hindering the individual access to learning content or support. The components and the services as well as third party authoring tools can easily be integrated in existing learning environments (actually with Moodle [4], .LRN [5], and SAKAI [6]).

In a wide sense EU4ALL is a framework to build up adaptive eLearning systems, if we consider it a conceptual and tool-based infrastructure providing generic functionality which can be use to solve groups of similar problems in order to offer a set of theoretical and practical tools that can be adopted by educational institutions to increase the quality and coverage of the accessibility services that are offered to students with disabilities [7]. In particular EU4ALL framework aims to offer theoretical and practical guidance to educational institutions in order to enable them to effectively offer support to students who make use of tools such as virtual learning environment (VLE) systems. VLEs are often described as web-based systems that enable educational institutions to disseminate learning

resources to students and facilitate the provision of on-line learning activities [8]. Through the use of VLE systems, students can contribute to their learning by participating in on-line discussions, writing reflective blog posts or diary entries, or working collaboratively with other students to create useful resources using tools such as wikis or ePortfolios. VLE systems enable educational institutions to increase face to face teaching.

The main areas the EU4ALL framework aims to address include [7]:

- Enhancing the learning experience by presenting learning materials that are appropriate for and matched to modality and end-user devices preferences, such as mobile devices or assistive technologies used with a desktop computer.
- Providing a wide range of services that an institution can adopt to ensure that the needs of learners with disabilities are most appropriately supported.
- Providing practical advice and guidance from domain experts to ensure that educators are in a position to ensure that their use of technology encourages inclusion.

The first two areas represent functional components of the architecture that can be practically implemented using a service-oriented architecture. The third area, in EU4ALL is entitled Guidance 4 All (G4All). This is a set of complementary training resources providing practical advice on inclusive teaching practice and technology use. G4All is also associated to a wider part of the EU4ALL project to explore how best to offer psychological and pedagogical support for students with disabilities.

The EU4ALL OAS is built up in order to allow institutions to create (or modify their current traditional eLearning systems in) adaptive systems. While the traditional eLearning systems create an accessible course allowing all the users to access to all the contents adapting themselves, in the EU4ALL systems the contents of the course are presented to the users by an adaptation to the user's needs (see figure 1).

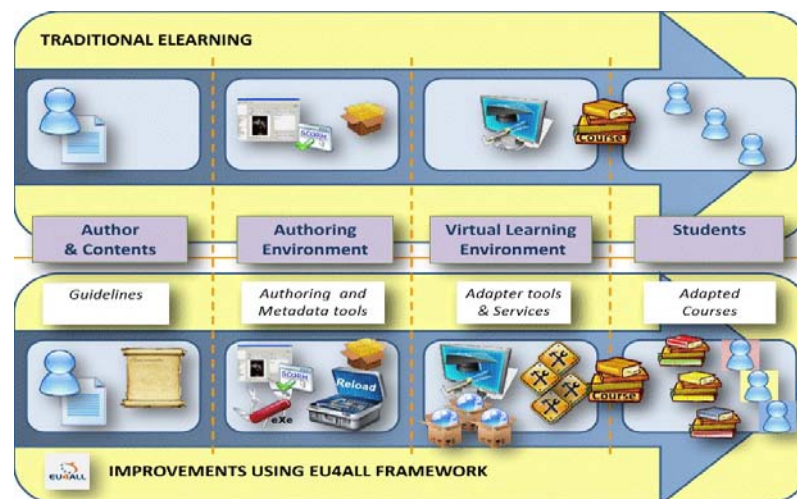

Figure 1 Shows the difference between traditional eLearning systems and the EU4ALL systems[1]

The key components of the EU4ALL system include a content delivery system, such as a virtual learning environment (VLE), a user modelling service (UM), a content personalisation system (CP), metadata repository system (MR), a recommender system (RS) and a device modelling system (DM). The eServices server (ESS) is an institution facing component aiming to provide ways to manage the delivery of accessibility services. This component can be used to guide the development of new digital resources that can be consumed by learners. It also offers a framework for the development of accessibility support systems. Such systems can present information about effectiveness of accessibility support and gather information about changing levels of support demands (see figure 2).

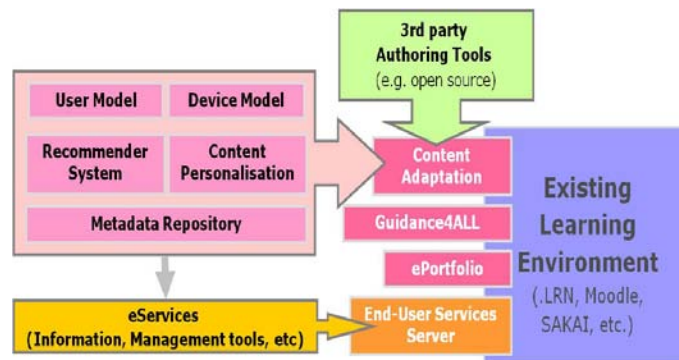

Figure 2 Shows the relation among the EU4ALL components and the VLE in order to create an adaptive eLearning systems[2].

The components represented in figure 2 are the core of the EU4ALL AOS. Those functions of those components can be summarized as follow [7]:

- *User Modeling (UM)*: It is a software system that stores information about the functional needs and preferences of learners. The notion of 'needs and preferences' refers to a combination of media preferences, such as whether a learner would prefer to receive learning resources in a textual as opposed to a visual format. The UM component provides a web service interface that facilitates the storage and retrieval of user preferences. A VLE system can make calls to the UM component to allow either administrators or users to create and modify user preferences. Learner preferences are specified using a controlled language. The UM data held is used alongside data that is held by a component called the Metadata Repository (MR) to permit the delivery of material that has been selected for the needs of an individual learner.
- *Metadata Repository (MR)*: Whilst the UM component stores information about the accessibility preferences of the user, the MR stores descriptions of the accessibility properties of individual resources. It has been designed with the intention of holding information about whether a digital resource can be perceived through a particular modality. A digital video resource that does not contain an appropriate level of supplementary audio descriptions may not be able to be perceived by learners with visual impairments. By way of an example, given two digital resources, one which presents material in a visual form (such as a diagram), and another resource which presents the material in a textual form (such as an equivalent description of a diagram); the MR enables course creators or administrators to indicate that different digital media items are semantically equivalent in terms of the learning material they present to a user.
- *Content Personalisation (CP)*: This component selects materials that are most appropriate for an individual user, given what is known about their needs and preferences, and the device that was used to request the materials. The VLE acts as a mediator. When a user requests a content that can be personalised, the VLE sends a request to the CP content to ask it what material or digital resource is best suited to the needs of an individual learner. It does this by sending information about the user, device and content item. This information is presented in terms of identifiers, which are represented in the form of character strings or numbers. A similar action occurs in relation to the MR component: the CP component asks the MR component for all the accessibility metadata that is associated to a particular content item (or learning resource). The CP system then converts the metadata descriptions from each of the EU4ALL components into an internal representation. The internal representation is then used by a rule based system, where a matching process takes place to ensure the most appropriate content alternative is selected. At the end of the selection process, an address or an identifier that references the most appropriate resource is returned to the VLE. This resource is then delivered to the learner through the VLE.
- *E-Services Server (ESS)*: Although providing accessible personalised content can alleviate some of the challenges that learners may face, an educational institution is necessarily required to offer a range of services to support all its students, especially to those with disabilities. These services may be embedded within mainstream educational services, or be managed through a dedicated organisational unit for disabled which co-operate with different departments throughout a university structure. The ESS within the EU4ALL Framework represents a workflow and information system that can be used by different stakeholders within a university. Its underlying intention is to offer functionality that directly supports an institution in the provision of services, which directly support learners. The provision of services can be thought of in terms of 'what' can

be done to help learners, 'how' can a particular service be carried out, 'who' provides appropriate support, and even 'where' the support is offered.

- *Associated Services:*
 - *The G4ALL package:* can be used in association with another EU4ALL component called the Recommender Service (RS) [9]. Drawing on the information that can be obtained from the UM, the RS component aims to provide a user with useful information and links that have been drawn from previous interactions with the system or a set of suggestions that have been prepared by a tutor. The notion of user modelling and recommendation systems is one that is familiar to users of e-commerce sites [10]. In the context of a learning management system the RS presents information about what activities, content or learning material a student may potentially benefit from. This may include a link to a recent forum post that has been made by a fellow student, or a reference to some learning material in response to recent learning activities. In the case of the G4ALL system, the 'student' G4ALL will often be a member of academic staff.
 - *The ePortfolio:* that has been developed as a part of the EU4ALL has been designed to make use of the user accessibility information that is held within the user modelling (UM) component. The accessibility of ePortfolios is particularly important, because unlike most web applications it is designed to enable many authors to publish for few readers. Further work on ePortfolio accessibility needs to consider how best to address the creation and deployment of accessible authoring tools. Such an issue is beyond the planned scope of the EU4ALL project.
 - *Device Model (DM):* DM component, has been briefly presented earlier. Due to the availability of increasingly powerful mobile devices and the changes in the way that web-based applications can be consumed, the DM component aims to provide a way to manage the storage and delivery of information relating to mobile devices, desktop computers, browsing software and presence of assistive technologies. By gathering the information that describes the capabilities of a device [11] and presenting this information to the applications which deliver materials to a device, it is envisaged, through content personalisation, that the users can be presented with materials that are most effectively adapted to changing personal circumstances. This component of the framework is the subject of on-going research and evolution due to the increasing availability of widening internet access. Further work is necessary to ensure that the CP module can select the optimal resource for an individual given both their stated personal requirements (as held by the UM) and the capabilities of a particular device (as detected by the DM) that is being used at the time when a resource is requested.

The EU4ALL prototypes are now running and are being integrated in four different settings for the launch of a large scale pilots. Two major distance training universities and two small educational institutions will evaluate the developed system with the help of disable professionals, course developers, tutors and students. The evaluation will include different kind of disability categories: on one hand visual, hearing and other physical impairments, and on the other specific learning disabilities, in particular dyslexic and dyscalculia and general cognitive impairments.

4. Accessibility and “eInclusion”

The connection between educational and social exclusion, especially labour market exclusion, emerges as a major theme for development.

In the framework of EU policy several are in the last year the Communications adapted by European Commission (EC) stressing active strategies to improve e-accessibility to the Information Society for all potentially disadvantaged groups, in particular [12]:

- pursuing standardization efforts, financial support for research and deployment of technology solutions for people with disabilities and for elderly persons, and
- enhancing cooperation with Member States and other stakeholders towards a common European approach for e-accessibility, including through a new EU high-level e-accessibility expert group to provide strategic guidance.

The EC is also running the ICT Policy Support Programme in which eAccessibility is considered a key priority [13].

At the level of Member States the awareness of this strict connection between education and social exclusion is still often not clear. The Academic Network of European Disability (ANED) conducted in 2008 an analysis within 14 European Countries. By the results of the National Strategy Reports for Social Protection and Social Inclusion emerged that only in few countries the disabled people's risk of exclusion from education is specifically identified, or related to consequent labour market risk. In general, disabled people's labour market skills are more likely to be addressed by Member States in

terms of special vocational rehabilitation programmes than by tackling access to lifelong learning in the mainstream [14].

EU4ALL project contributes to a more general objective of “eInclusion” by:

- mainstreaming accessibility in consumer goods and services, including public services through the applied research and development of advanced technologies. This will help ensure equal access, independent living and participation in the Information Society for everyone.
- developing next generation assistive systems that allow persons with (in particular cognitive) disabilities and ageing citizens playing a role in society, increasing their autonomy and realising their potential.

5. Conclusion

The EU4ALL-project created an open architecture systems (OAS) focused on providing flexible and standard-based set of components and service for higher education institutions in order to solve issues that are hindering the individual access to learning content or support. The EU4ALL AOS is built up in order to allow institutions to create (or modify their current traditional eLearning systems in) adaptive systems. In EU4ALL R&D main aim is to provide full access to Lifelong Learning to users (adult learners) with impairments, allowing them to fully benefit of all the learning content and support facilities, including assessment and guidance, in a high education context.

EU4ALL also contributes to a more general objective of “eInclusion” by mainstreaming accessibility in consumer goods and services through the applied research and development of advanced technologies and developing next generation assistive systems that empower persons playing a role in society, increasing their autonomy and realising their potential.

The project now faces the challenges of the future adoption, use and exploitation of the EU4ALL outcomes. Most organisations in the sector are not yet ready to offer accessible education to their students and to implement part or the whole framework. The readiness of institutions is not only related to technical aspects, but depends principally on social, political, organisational and management issues.

A social innovation perspective needs to be introduced to make sure that the EU4ALL outcomes have a chance to be adopted. Rogers theory of Diffusion of Innovation and the social innovation perspective outline the importance to find a strategy to approach organisations taking advantage of their potential for adoption and offer a progressive and modular implementation of the solution, depending on institutions accessibility preparedness [15]. Consequently, as “social innovation refers to new ideas that work in meeting social goals” [16], in addition to technology transfer, a social innovation perspective needs to be introduced to make sure that the EU4ALL outcomes have a chance to be adopted. Effectively, the market study realised in the context of the project [17] reveals that most organisations in the sector are not yet ready to offer accessible education to their students and to implement part or the whole framework. The readiness of institutions is not only related to technical aspects, but depends principally on social, political, organisational and management issues. Warford [18] sustains that individual decisions are incomplete without recognising the impact of socio-organisational aspects (e.g. management level decisions).

The EU4ALL outcomes present three kinds of innovations: technological innovation, the so called “practice-based innovation” (guidelines, support materials), and organisational innovation or “principle-based innovation” (e.g. new approaches, new staff structures, to support disabled and elderly students). Consequently, the EU4ALL innovation nature is complex. On the one hand, we should take advantage of the fact that, according to Rogers (1995), technological innovation, as well as practice-based innovation, which are easy to be employed, have the best chance of success. On the other hand, we should pay attention to the fact that idea- and principle-based innovations are the most difficult to implement.

However, for EU4ALL outcomes to be implemented and used by potential adopters, not only technology transfer is needed, but social innovation has also to take place. Factors such as institution accessibility preparedness, as well as their ability to change, are crucial when considering the potential adoption of the EU4ALL innovation. The legal and political frameworks are additional factors of influence. Therefore it will be very important to outline a strategy to approach organisations taking advantage of their potential for adoption and offer a progressive and modular implementation of the solution, depending on institutions accessibility preparedness. Actually, due to the changing political, social, technological and educational context regarding Students with Disabilities (SWD), institutions increase the need to “becoming a learning organisation by opening up to disability. Whatever the country and whatever the institution, the way in which disabled students are admitted depends on the

attitude of the institution to diversity” [18]. Opening up to needs of learners with disabilities is seen as a source of innovation and modernisation of HEI [19]. Consequently, it will be crucial to check the attitude and dimension of target adopters. If the contacted organisations are open to social changes, they might be more likely to adopt.

Earlier organizations were usually closed and focused on their own internal resource base (their “core competencies”), today they have to engage into interaction processes with many and changing actors and to involve external resources if they want to be innovative (Open Innovation). On the other hand reflexive modernization deeply manipulates the context for innovations. This paper will discuss ‘reflexive open innovation’ for Central European Region.

Closed Innovation, Open Innovation, Reflexive Open Innovation, Reflexive Modernization

1. Reflexive Modernization and Uncertainty

Sociologist Ulrich Beck has defined time diagnosis in terms of so called Reflexive Modernization [1], [2], [3], [4]. He indicates a thoughtful transformation in the character of the modernization process itself. This transformation is typified as a changeover from uncomplicated/simple/first modernity to reflexive/automatic/late modernity. First modernity represents the progress from a conventional, undeveloped social order to a modern, developed social order. In this period of transformation, reasonableness stays over convention and false notion. Methodical reasonableness functions as a perfect source of authentic and purposeful awareness. The societal group dissimilarity has replaced the previous dissimilarity between the 3 feudal domains. However this ‘classical’ modernity is a ‘semi-modern condition’. The manufacturing, developed background intrinsically encloses more than a few anti-modern essentials which stay resistant to additional modernization. It means that the contemporary institutional prototypes of social group and sexual category are reasoning novel social disparities. These contemporary disparities actually substitute the conventional hierarchy. The methodical fascination with development produces significant hazards that are no more controllable. However, these unmanageable risks stay unseen behind a contemporary frontage of lucid dominance and ideal managing systems. Knowledge and expertise reach therefore a self-disagreement with the as yet uncontrolled increase of dangerous side-effects of their success [5], [6], [7], [8].

The *Theory of Reflexive Modernization* argues that industrial civilization threatens itself throughout its imperfect structural design. Through the disagreement with its partially contemporary restrictions, developed civilization becomes the energetic power of its own alteration progression. Reflexive Modernization thus represents a transformation of the developed civilization itself. From the wrecks of developed civilization, first-order modernity occurs. This essential transformation breaks through the semi-modern nature of the ordinary contemporary developed period. Away from the charts of developed civilization, it produces a dissimilar and not unavoidably better, institutional form, so called hazard social order full of risks. This novel institutional circumstance is typified by a basic insight into the critical and repeatedly increasing consequences that are methodically shaped together with the rising accessibility of well-being. The hazard social order refers to the mixture of stability and instability. While in traditional developed civilization the sense of prosperity creation prevails, transformation does not just mean prosperity growth, but also the methodical creation of increasing and universal hazards like nuclear risks, which can’t be understood as simply handy consequences of a smooth transformation progression. On the opposite, they more and more come into view as intrinsic products of additional transformation. Furthermore hazard social order refers to the far-reaching societal transformations that are reasoned by the transformation progression. These split as ordinary

characteristic the immanent disagreements flanked by modernity and anti-modernity within developed civilization and indicates the progressions of globalization and individualization, to altering relations among men and women, within the family etc. to progresses in the area of employment, economical development and political affairs. Consequently, the development of automatic, reflexive transformation and modernization deeply manipulates the social surroundings. The developed dynamism of improvement also challenges the philosophy of social groups and categories, qualified employment, family, sexual category roles, church, manufacturing, political affairs etc. which are extremely entrenched in individual life. Novel and radical structures are taking forms alongside the environment of the outstanding but collapsing mature ways of life. In these unfinished and opposing circumstances among departed and upcoming conditions, life obtains some novel attribute appearances as uncertainty, randomness, temporality and doubt linked with the loss of identity [9]. In a first step, the Field of Action *Management of Uncertainty* developed problem-oriented expertises. They show how new ways of dealing with uncertainty become necessary in various practical fields of economy and labor and how new approaches can already be found in scientific discussion. The expertises relate to the fields (1) people, (2) organizations and (3) technology and highlight changes in dealing with uncertainty (1) in vitas, biographies and learning, (2) in project organization and product **innovation** and (3) in complex technological systems. New approaches on dealing with uncertainty emerge in science and practice [10], [11]. *Managing of Uncertainty* can be regarded as a core practice of successful **innovation management**. Firms face various sources of uncertainty with regard to their technological and managerial capabilities and the target markets [12], [13].

2. Reflexive Open Innovation

More and more organizations are confronted with highly dynamic external organizational environments. The drivers of change are globalization, sustainable development, new technologies and the aged population. The pressure on organizations forces them to continuously adapt to the environmental shifts [14] and to create organizational forms able to provide faster and innovative response to market threats and opportunities [15]. Innovation is a key-factor of business success [16], but in “many organizations, especially those with a traditional approach, innovation is often only seen as valid when it is completely ‘homemade’”. This traditional view of innovation – *Closed Innovation* - completely disregards the growth market of demand-driven innovation” [17] or *Open Innovation* (Figure 1).

Figure 1 The innovation continuum [18]

Open Innovation is “the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation [20]. Open Innovation should use external ideas as well as internal ideas, and internal and external paths to market, as the firms look to advance their technology” [19], [20]. Research activities has been focused on the notion of Open Innovation, business models, organizational design and boundaries of the firm, leadership and culture, tools and technologies, IP, patenting and appropriation, industrial dynamics and manufacturing [17]. This paper affects the themes leadership and culture. Alliances and Open Innovation systems might facilitate the diffusion of knowledge over firms and within firms much better, adding to the chances of recombining mature and emergent knowledge [21]. Open Innovation today has a much broader application than first proposed by Chesbrough [22], e.g. the “Lead User Concept” or “User-Centred-Innovation” [23], or “Interactive value chain” [24]. The emerging research field of Open Innovation is in a phase that is still very fluid with many national/global [25] and regional [26] Open Innovation activities.

A new nature of innovation is emerging within companies as well as in the public sector. There are 9 innovation principles. Each of the innovation principles are based on evidence of new innovation behaviour: (1) Co-creating values with customers, (2) Users' Involvement, (3) Accessing and combining globally-dispersed knowledge, (4) Forming collaborative networks and partnerships, (5) Dynamics between large companies and entrepreneurs, (6) Environmental concerns drive innovation, (7) Needs in developing countries drive innovation, (8) Welfare system concerns drive innovation, (9) Technology's role as an enabler of innovation. The 9th principle of innovation is not considered a new principle in itself. What is new? It is the future role of technology [27].

Open Innovation systems are characterized by complexity, long-time completion and high risk initial capital. In the aftermath, the solution could be to facilitate innovation systems by stimulating learning of how to change the way of thinking and acting in new environments [28]. The modern system innovations must be reflexive, namely that people must adore the challenging and changing the presumptions, current practices, methods and techniques and sometimes selecting the pathway of improvisation. Reflexive institutions and enterprises such as state, science, society and entrepreneurship, should not behave as stable and strict functions but as leaders of change and reflexive learning [30]. According with the literature there are some problems:

1. System innovations are made by many different social and technical parts that cannot be identified in advance. The results of such innovation projects are completely unknown and cannot be pre-defined, due to the fact that they are perplexed without a linear path of progress [29].
2. Entrepreneurial paths, business strategies, innovation activities, research directions and routes, solutions and many other features of system innovations have to be able to change. The adjustability sometimes means intelligence. The managers need to be more flexible with their decisions in order to choose new directions, according to their environment [19].
3. Reflexive innovation faces a lack of standard implementation tools and techniques. Upon this situation, reflexive innovation projects can use evaluation methodologies that support and enhance such reflexivity [30]. Such methodologies must be able to support complex projects without predefined and ambitious outcomes, facilitate by questioning participants in project and contribute to collective and institutional change. At the end, these methodologies must self-evaluate the project, comparing the changes that have occurred from past till present situation.

Reflexive Innovation Systems is a term to denote dynamic systems that produce innovation, while evolving in parallel with the technology that is innovated. Reflexive Innovation is the process where growth is created by positive feedback, while at the same time guided by anticipatory negative and positive feedback [31] [32]. Feedback loops are included to describe systems that grow and at the same time change the dynamics of their own growth [33]. The functions are not only influenced by endogenous growth, but also by exogenous actions, events and structures. The positive feedback could lead to a close system insensitive to less forceful signals of negative feedback. Negative feedback may slow down growth or cause abandonment of technology that would like to evolve. Negative feedback could be positive feedback for exogenous factors. Thoughts for democratizing innovation process could transform negative feedback into positive for other actors. Two paradigms are stated below.

1. Health Technology is a good example of continuous innovation and it is also a result of health policy from the government. Health Technology Assessment could be an approach to reflexive innovation, through surveillance, audit, measuring and evaluating [31]. Many innovation projects try to use standardized measures of technologies which are the key dimension of technical and socio-political ordering and control, but technical developments simultaneously undermine these standards [34]. Nowadays, innovation findings abolish conventional boundaries among species, machines and humans. It is recorded a continuous shifting from the incumbent, technocratic innovation system of the 1950s and 1960s to the current situation of the knowledge-based society that creates proper conditions for reflexive innovation systems [35]. Health Technology Assessment is also a good example of the way that social actors develop new tools and also new institutions that enable reflexive innovation systems. This can be standardized into a common evaluation of cost-benefit and risk-benefit analysis, known as systemic reflexivity [36].
2. An approach for reflexivity on system nanotechnology innovations was occurred in Sweden which analyse three crucial spheres of Swedish society: science, industry and politics. At the end, the study came up with the following results. The missing system components within national boundaries do not imply that the system itself does not work properly, but simply that the system transcends national boundaries. The conclusions for the spheres are negative marks of influence on the meaning and engagement of society into the system innovation outcomes, so the number and the type of actors are reduced. The key negative mark is the lack of interconnectivity within

the nanosystem. A more reflexive system of innovation would be able to alter continuously its direction and content of growth, during growth [31]. The term of *Reflexive Open Innovation* could be the solution to the non-linearity of a system innovation for abandoned ideas, while fluctuations in risk indicators could be decreased by opening innovation system to modern society.

3. Reflexive Open Innovation in Central Europe

We can look at the future of Open Innovation from the spatial, structural, user, supplier, leveraging, process, tool, institutional or cultural perspective. Creating a culture that values outside competence and know-how is crucial for open innovation practice. This culture is influenced by many factors: besides being influenced by the values of the company, it is also influenced by concrete artifacts such as incentive systems, management information systems, communication platforms, project decision criteria, supplier evaluation lists and its handling and so on [37].

Beyond recognized drivers of innovation in other policy domains, such as education and entrepreneurship, some countries in the EU and beyond have started looking at drivers of innovation not previously looked at in a policy context. Notably, some of Europe's leading innovation nations such as Finland, Denmark and the UK have included *user-driven* or *user-centred* innovation as cornerstones of their national innovation strategies [38]. The small country Denmark has five dedicated University Chair Professorships on „User-led Innovation” or „Open Innovation” (while Germany or the US has none” and spend 160 million kroner a year for these activities [12]

Examples of good Open Innovation practices in Western Europe are all very interesting, but only callow people would believe that the answer is to copy these practices and to emulate them in Central European Region [39]. Several studies suggest that there are cultural and ethnical factors influencing the acceptance and diffusion of Open Innovation among customers in different countries [25]. Finally, the acceptance and diffusion of Open Innovation related phenomena is contingent on customers' cultural orientation, specifically their interdependent or collectivistic tendencies [40], which is important for implementing Open Innovation in the special cultural context of Central Europe. Because of these cultural differences in Central European Region, not only traditional management practices differ across countries [45], but also Management of Uncertainty in Open Innovation Processes differ in Central Europe. Individuals, groups, organizations, networks and institutions should think of Open Innovation from the reflexive point of view.

4. Conclusions and further research

Reflexive Modernization leads to the Field of Action *Management of Uncertainty*, which can be regarded as a core practice of successful innovation management. *Reflexive Open Innovation* could be the solution to the non-linearity of a system innovation for abandoned ideas, while fluctuations in risk indicators could be decreased by opening the innovation system in modern society. Central European Region with its cultural diversity should find their own way to make profit from *Reflexive Open Innovation* and should not copy Western European best practices on Open Innovation.

Government should assist and support new infrastructures where individuals, users, companies etc. can meet and interact to each other. In order to understand and feel the influence of all those aspects on Reflexive Open Innovation culture in Central European Region further research should gain more from the psychological field, in order to find and outreach the cultural limits which handicap the openness of innovation process.

Reflexive Open Innovation can be supported by foundations, similar to Living Labs. The interconnection among the actors is the most crucial brick piece of Reflexive Open Innovation structure. Every actor can shape the preferences of its character and their mechanisms of reflexivity, too. Preferences and mechanisms should demand for interconnectivity in order to be more flexible and agile on continuous non-linear changeable conditions. Living Lab is a good paradigm of flexibility and accuracy into an interconnected system of actors. Infrastructures of Living Lab concept could support and engage Reflexive Open Innovation in a Reflexive Modern Society.

Quality of employee hotels in Novi Sad - system of continuing education as a measure to enhance development

Tamara Gajić¹, Nina Đurica², Nenad Đokić³

^{1,2,3} Higher School of Professional Studies, Novi Sad, Serbia

Consideration of the needs of tourist consumers during the implementation of service delivery can be understood as a full appreciation of consumers. The way of communication with travel consumers is only part of the realization of quality of service providers. In terms of major changes and increasing international competition, which is a direct result of flows of globalization and internationalization, quality has become an imperative for survival, growth and development. The leading problem of modern tourist business is certainly the quality of employees in the tourism and hospitality facilities. The burning issue of quality human resources in tourism imposed itself in preparation of this study, which presents the data obtained by survey of secondary publications, and survey made by the authors in the hotel facilities in Novi Sad. Among the issues that are in major focus for theorists is how to reduce the impact of existing problems and the increasing quality of employees as key segments of each of the tourist business. The study was primarily to point out the increasing importance of education in the tourism sector and intensive application of measures for permanent education in this field.

Keywords

Quality, employees, hotels, education, Novi Sad.

1. Introductory discussion and literature review

In the modern world needs of people become more diverse and are not satisfied with anything and in any way (any product or service). Today's more demanding tourists insist that the services which settled their needs have exactly certain quality, which level is growing up with the development of society and the material standard [8]. However, the problem of quality is not only directly related to the services and products, but also to those who are in direct contact with the direct consumers of services concerned [16]. In this work the problem of the quality of employees has the special place and importance [12]. Education is not just a positive activity from the human aspect but it is a pure business activity and probably the most profitable investment, which has long been not just a question of individuals but a matter of people and the wider society because the dimensions of these investments often exceed the capabilities of a nation. It is known that many companies spend a lot for training their staff and they spend only for the management team more than 10% of the total earnings of all employees [5]. Poor quality is actually a consequence of poor regulation, technical, technological, organizational, but the main factor in setting the criteria and the implementation of discipline is finally the man himself [17]. Man is the only factors that in the whole process work with the mind and creates a logical base for all, more than any other factor. Only man is able to react and if he cannot remove he can at least give information on the negative.

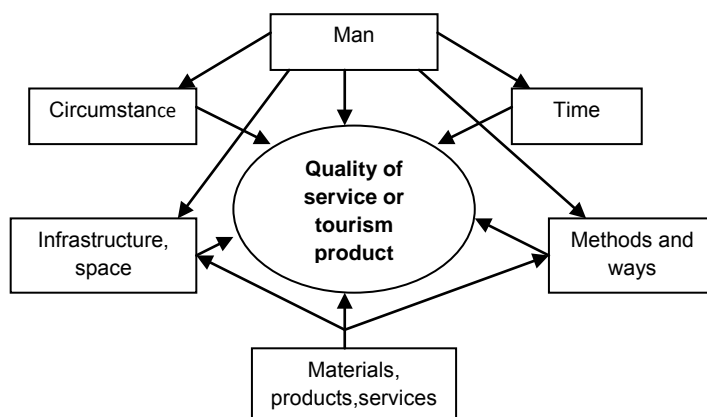

Figure 1 The influence of certain components on the quality of tourism products and services

That quality has a huge importance and that it is a segment of business that every organization needs to have tells the example from 1987. When the Malcolm Baldrige Award was established for the quality (Malcolm Baldrige National Quality Awards) [9]. The winner of this award is the Ritz Carlton hotel for the quality of its services and offers where the quality of employees is included of course. In order to receive the European Quality Award these are the criteria: customer satisfaction, human resources and leadership [3]. It can be assumed that the improvement of service quality will increase the satisfaction of tourists, which will result in increased sales and profits. The key to providing quality services is understanding and meeting the expectations of tourists. To achieve this it is necessary to create a clear picture of the criteria on which to form expectations, whereas we need to bear in mind that tourists do not only evaluate the outcome of service but also the experience of participating in it. It is clear that research of tourist market is an important and vital aspect of management. This is the main weapon to improve the ability of suppliers to understand and comprehend the dynamics of markets and effective decision making [13]. Model of tourism development of Novi Sad is based on the approaches and principles of total quality assurance, whereas we need to take into account the need to ensure the satisfaction of tourists quantitative and qualitative factors of offer, the satisfaction of participants in local tourism expressed through opportunities for professional development and productive employment, satisfaction with local population, always taking into account the quality of the environment by pointing to the positive and negative impacts of tourism on the environment and the like.

2. Analysis of survey results obtained in the hotels of Novi Sad

Tourism is a special branch of the economy at all but also for the fact that some studies range from the simplest to the carefully planned empirical research. Today the survey is the most commonly used method because tourism organizations have much more to know about your end-users and their satisfaction with services provided in certain tourist destinations [6]. In survey that was conducted the human factor was included as one of the most important elements in managing the development of tourism. Tourists evaluated some of the features that employees in the tourist restaurants should have. Issues are mainly related to training personnel and their attitude towards work and guests. Survey had a broader significance and the main goal of this research was to show how the tourists are satisfied with certain service and thus come to know whether and to what extent their demands and expectations are met on one hand and how it is possible to make any corrective action consistent with the results on the other hand in order to achieve positive results in the tourism industry and survival of the destinations on the tourist market in general [7].

Table 1 Data of a survey

Total questionnaires 450		Total respondents	%
Total answered questionnaires 280			
Tourists	domestic	189	67,6%
	foreign	91	32,5%
Sex structure	male	167	59,4%

Total questionnaires 450 Total answered questionnaires 280		Total respondents	%
	female	113	40,35%
Age structure	< = 40	149	53,21%
	41-55	119	42,5%
	>55	12	4,28%
Educational structure	High school	91	32,5%
	University	189	67,5%

The survey was conducted in May 2010 in three hotels in Novi Sad: Park Hotel (5 *), Ile de France (3 *), Hotel Novi Sad (3 *). The totals of 450 questionnaires were given of which only 280 were taken in processing. Survey data can be seen in Table 1. However, due to poor response and return of the questionnaires and the objective difficulties in the access to hotel facilities, only indicative data were obtained which should serve as a good example and a possible starting point for a representative survey of service quality in tourism. Based on the answers given and processed, it can be concluded on the degree of the quality of certain segments of offer and of course the possibilities for their improvement.

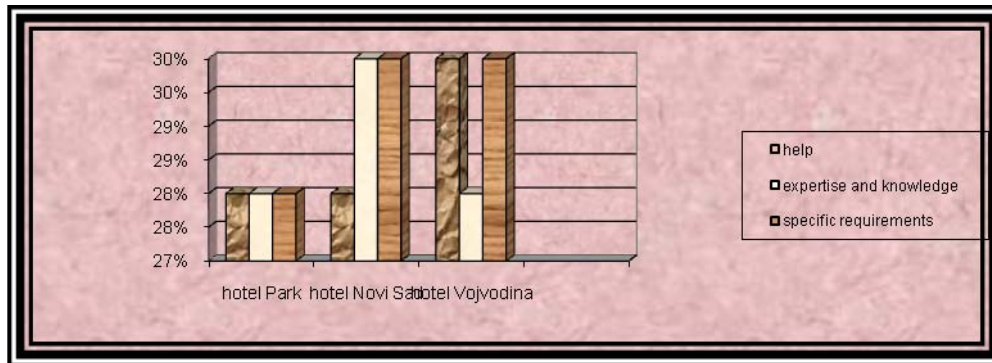

Figure 1 Percentage display of very satisfied tourists with dress code, language skills and responsibility of personnel employed in hotels

Done by survey data obtained

Hotel Park is a facility that has been completely renovated. Management of the hotel did his best to all work according to European standards and it is logical that the management of human resources is at a high level of development too. Tourists have assessed a dress code positively, 64% were satisfied with the dress of employees and of course this only further highlights the professionalism of business of the hotel. Hotel Novi Sad is also similar to the situation where 52% is satisfied, and in the Ile de France 50%. This data shows quality of the management of employed personnel but looking back a number of years dress code was always there especially in the tourism and hospitality facilities. As far as knowledge of foreign languages, it refers primarily to speaking English and German. The largest part of the employees does not know sufficiently and does not speak English. When it comes to accountability and conscientiousness of the employees it can be seen that in all three hotels have just a little over 30% of satisfied tourists, and it must be noted that there was even a few tourists who gave negative ratings to this issue: exceptions are always present because the structure of the guests are different with regard to age and emitting area. In Graph 1 we can see the percentage value of tourist satisfaction with offered segments of professional skills of staff. The lowest rated knows foreign languages as we have already mentioned. Characteristic of people from the province is hospitality and friendliness and it is logical that the question of the willingness of employees to help at any time will bring a positive evaluation or pleasure of the visitors. In all hotels there is the largest percentage of satisfied and the minimum degree and those who are partially satisfied: 12% Hotel Park, Hotel Novi Sad 2% and 6% Hotel Vojvodina. The professional skills of tourists have also got satisfactory grades (4) and yet it is noted that the employment structure changed significantly as well as education and skills requirement for the commencement of employment in the tourism and hospitality industry. In the Park 28% were very satisfied with prominent expertise of employees, then at the Novi Sad 30% of them and at Vojvodina 28% of tourists from the whole number of people who were taken into analysis. On the question of whether the employees could respond to specific demands of tourists who stayed and were surveyed in a given hotel most of them gave a satisfactory rating. Figure 2 reveals the percentage of estimated value of services in all three hotels.

Figure 2 Percentage display of very satisfied tourists with the willingness to help, expertise and knowledge of staff employed

Done by survey data obtained

As for the staff employed in tourism-hotel services based on a survey it is also possible to note that the situation is relatively good or satisfactory. The highest average rating took a part which was related to adequate training of employees 4.16. This can best be seen from the data in a chart obtained by descriptive analysis of the survey. As for the responsibility, the willingness of employees to help at any time has been evaluated with an average grade above 3.9. The lowest ratings were given in terms of knowledge of foreign languages (3.76) and understanding the specific demands of tourists (3.86). Training of personnel in the field of tourism is of great importance for the development of this activity and to increase the service quality in tourism. Implementation of the system of continuing education which will be shown later will affect the increase in the level of knowledge as well as other specific characteristics of personnel which they must have in their work and relationship with tourists.

Figure 3 Average scores of individual parts of the tourist offer in the hotels in Novi Sad

Done by survey data obtained

It can be said that the main characteristics of today's tourism market is dynamics because of the appearance of technical development as well as competitive pressure and continuing increase of the expectations and demands of tourism consumers. Of course the introduction of new products and services and new strategies creates instability in the tourism market because companies are constantly struggling not only to accept the papers but also to maintain the position they occupied. However, in the constant struggle to survive or maintain a solid position in the market quality is definitely a key part of success.

3. Continuing education as a restrictive measure to improve tourist business

Education is an activity within the social division of labor which improves the knowledge of man and improve his skills and which contributes to the formation of human personality. It must be pointed out that education has an economic function as educators are one of the important factors for the development of productive forces and increase the productivity of labor in society and thus also to

promote social development. The accumulation of knowledge understood as the production of knowledge in educational research and knowledge transfer as well as in education has been given the quality in contemporary society. According to recent research it points out that primary education increases working capacity for 30-40%, medium for 100%, and higher education up to 300%. Russian experts have calculated that each ruble invested in expanded production increases national income for 0.39 rubles while a ruble invested in knowledge and education increases income for 1.45 rubles. It can be concluded that education is the most important factor in success of each development and consequently the tourism industry, too [15]. According to some research knowledge can for period of 8 years drop almost by half. The development changes the structure of personnel employed in tourism. On one side it happens that the staffs with new experiences and education are looked for and yet on the other hand in certain sectors of the economy there is a surplus of such labor. In some countries a large number of occupations disappear completely and yet on the other side entirely new profession are created. Obsolescence of acquired knowledge requires renewal, updating, acquiring new ones [1]. Content of permanent education may be gaining a new education or professional training and development of existing tourism personnel who already have some degree of education. Some of the principles of continuing education may include: ensuring continuity of education, prevent leakage, the linking of various forms of action and goals and ways of education, adapting education systems to social systems which they refer to, use of a large number of funds of education and information and to prepare people at all levels of education for a way of life and work in constant change. Tourism and Hotel Management are business areas where the dynamics of education is of particular importance. The development of modern tourism and tourist traffic in the national and international level increase the need for quality services provided in different shapes, kinds and types of economic organizations that deal with the service and using the achievements of modern science and technology. In this way they adapt to the growing and more various demand for these services. These tourism businesses are once again connected or associated with other business and nonprofit organizations where the role of the staff who must have certain qualifications, skills, and the quality of their work is also emphasized which still requires continuous training and education. Also, It is emphasized the need for new staff profiles, their specialization, broadening knowledge, training for new kinds of jobs. In this way we recognize the importance of education in tourism and hospitality industry because it must provide employees to adjust to new personnel and the ever increasing demands in terms of education and provision of services [14]. What is really needed is to determine the main problems of education taking into account the faster transformation of this economic activity from the classical, local tourism and hospitality in one industry. We should start with the following questions: What is the main goal of training? What kind of education will give the best results in terms of the tasks? What profile of participants should educational programs include? Education must aim at improving knowledge of tourist-hospitality workers in specific places. Seminars should last only three to five days depending on the subject because every course should be completed as a whole. The form of the seminar depends on the subject that is treated and experts must take part in. Training required extensive preparation and consultation in connection with the curriculum that were referred for consideration to renowned scientists in the field of tourism and hospitality and other directors and management of work organizations. The curriculum must provide the expertise needed to operate [10]. According to a survey in 12 tourism businesses in Novi Sad, out of 60 of them interviewed 88% said they were satisfied with their jobs but do not specify many details about why they are satisfied and whether they are satisfied with the external (salary) or internal aspects of the work. It must be pointed out that tourism organizations are looking to achieve top tourist market and condition to achieve this is that they provide quality service to tourists which in turn depend directly on the staff. Average income per capita and wages in the tourism sector in Novi Sad was 15,610 dinars in March 2009. Year. In the same period the highest average salaries and wages was recorded in the municipality Beočin with an average of 36,030 dinars, after that in Novi Sad with an average salary of 34,930 dinars. The highest average salary for the period from March 2009. was registered in the sectors of financial intermediation and mining and quarrying with more than 56,554 dinars. The key to happy work force is in several business steps: motivation and involvement in communication with managers, disclosure of awards based on positive feedback from tourists, to make jobs more interesting by rotating jobs, affect the perception of the importance of teamwork and a sense of belonging to an organization, conversion of work into a career and so on [4]. According to ILO (2002) employment is the effect of quality education and training. It includes the knowledge, expertise and ability that people get and keep a job if laid off, career progress or enter the job market in various seasons of their life and duty cycle [11]. However, there are exceptions to the rules, since the current education of employees is very often not the safety of competitiveness and economic development. The workforce may be inadequately trained, educated; it may not have the necessary knowledge and the like. The main task of managers

is to create an agile, capable person, willing to take risks and solve problems, think independently and who are willing to work in a team. According to data from the Statistical Office of Serbia, the largest number of unemployed is among the persons with first degree qualification (33.81%), and least of unemployed is among PhDs or those who have the eighth level of education, a total of nine in the Province of Vojvodina. There is also evident that the majority of employees in hotels of Novi Sad is with secondary education, namely 72.72%. A small part of the staff has high (22.72%) and higher vocational education (4.54%). Statistical data show that the employment is in favor of women is 69.09% and 30.91% of employed men. Development of hotels and other tourism enterprises in Novi Sad requires the acquisition of knowledge through continuous training of management and other personnel, but also in the field of learning about new management skills, which should contribute to the overall development of the hotel's destination as a whole. It is necessary to motivate all employees to participate in the education system, and reward their contribution to raising the quality of offer and achieving better physical and financial results. The importance of the qualitative development of tourism highlights the need for personnel who possess superior knowledge and continuous education and training of all employees, instead of the now present trend of inflow of human resources, which lead to changes in social structure at the level of destination.

Educational center of this type would provide introducing the international standards of education and a high degree of comparability between national and the leading European and international programs, and thus the smooth integration into the European Credit Transfer System (ECTS) as a form of cooperation in the European academic community and references to international positioning in tourism. In these frameworks it will be possible to ensure the acquisition of various forms of continuing education and training, and otherwise ensure the possibility of improving knowledge, skills and abilities. Educational tourism is acceptable form of bids for the younger population who are involved in tourist movements; they then become active participants in the attractive educational programs (particularly school trips). Besides it is the best way to get to know the value of this destination, and their family members become customers of other tourist services.

This raises the key issue in human resource management in tourism:

Does intensive tourism development requires inflow of labor force, whether it is acceptable or not?

Figure 4 Opinion of the management of hotels in Novi Sad on the impact of tourism on the influx of labor force

Done according to the survey data obtained through interviews, 2010.

At Graph 4 information are given about what management thinks of influx of labor force in Novi Sad in developing large-scale forms of tourism trends. For the most part the responses were positive in the sense that influx of seasonal workers will not happen (67.2%), because tourism itself has no seasonal nature of business in Novi Sad.

4. Conclusion

In recent years the study of tourism as an important socio-economic phenomenon has been given a great consideration, and primarily it has been studied service quality as the imperative of success in the market. Quality of supply is a key segment that dictates the direction and intensity of tourism development. It is generally accepted assessment and conclusion that in the last period tourist services in Serbia developed in an extremely unfavorable environment. The last decade of the

twentieth century is characterized by well-known events (economic isolation, the war in the former republics, Kosovo issue, bombing, etc..) that are deformed relations in the economic and social development of Serbia, and thus in the tourism sector. A new stage in economic development began in late 2000 with the cancellation of the process of economic and political sanctions and involvement in world economic developments. These changes were especially significant for the development of tourism, which by nature of its activities operates difficult in conditions of isolation of the national economy. Stagnation and decline of Serbia in the international tourist trade comes just at a time when other European countries generally recorded high growth rates of foreign tourists and foreign exchange revenues. Quality of services is newer dimension in the contemporary market conditions and the quality policy inevitably the main segment of each business in the tourism and hospitality. Profit is not an adequate measure of success in today's competitive arena, and certainly is pointless, if we look at it static, that is not parallel to assess the changes of position in the market. Expanding markets and achieving a solid position in mind of the perspective certainly has the closest correlation with quality not only of products and services, but also employed people in tourist restaurants. The modern tourist business started investing in the quality of human resources, because it provides a quick and sure success. This paper presents data of a research on the issue of tourist satisfaction with personnel employed in hotels in Novi Sad. The aim was to see what degree of quality human resources meets in terms of the various segments of the supply, from clothing to expertise and knowledge. The data obtained suggest that there is a need to take a lot of corrective measures and actions to improve the quality of workers, because they are key to secure the success of the tourism market. In fact, already mentioned situation or the conditions of developing tourism in Serbia, led to poor quality offer in services and products as well as employees themselves. Unfavorable situation that affected the entire economy has affected the education of employees, and a large number of unskilled labor are employed in tourism, which must be recognized as the leading problem today. It takes many years to change things and take corrective measures to employ in this sector more professional and skilled people, because it is the only sector of the economy where human labor is most responsible for achieving quality and success. For all activities related to improving the quality and reliability the human factor is certainly always present as a prerequisite for the implementation of all activities and to achieve optimal efficiency of activities, especially in tourism, where a man is a direct consumer of services and products. In Novi Sad there are a number of educational institutions that are slowly being introduced more directions for education of personnel for the tourism and hospitality industry. It must be pointed out that apart from education it is necessary to conduct a series of other measures and activities to improve situation, starting with the economic situation. Many people believe that working in tourism is actually one of the easiest tasks, and in recent years there has been an appreciable inflow of labor from the primary sector to the secondary. The conclusion is that the basic condition for ensuring the viability of tourism and hospitality businesses actually is the quality of services and products, and at the first place staff personnel. In order for services received the epithet of a complex tourism services it is necessary to meet the expectations of tourists in all areas of offer. This will of course be achieved only with quality as the imperative of survival of each company.

Product Lifecycle Management (PLM) is recognized as one of the most effective approaches for better, fast and cheaper product development and management. Mass customization is one of the key technologies in PLM to provide tailored product to end customers with the cost of mass production. In the modern global economy, companies are facing ever-increasing challenges for short time-to-market to enter into the market early, for reduced time-to-volume to occupy the market quickly, and for decreased time-to-profit to get return from market shortly. Product lifecycle management (PLM) is recognized as one of the key leading technologies to facilitate companies to overcome these challenges, which will offer companies a new way to rapidly plan, organize, manage, measure, and deliver new products or services much faster, better, and cheaper in an integrated way. Following this trend, this study proposes a full scenario of technology solutions for PLM based on the complete analysis of business drivers, industry requirements, limit of current solution, and recent state-of-the-art review in the domain related to PLM. Potential industrial impact of the developed PLM technology solutions is analyzed. It is hoped that the proposed PLM technology solutions will form the frontier basis for further research, development, and application of PLM systems to quickly adapt to the dynamic changing market for industry companies to pursue the most advanced competitiveness.

Keywords

Product Lifecycle Management (PLM), Business strategy, Technology requirements.

1. Introduction

In today's highly competitive environment, business requirements always drive technology solutions. In response to increasing customer demand and dynamic competition, companies are under high pressure to shorten time-to-market by providing tailored products to the customer for the economy of scope, to reduce time-to-volume via mass production for the economy of scale, and to decrease time-to-profit by increasing the efficiency of the entire lifecycle for the economy of service. These business requirements drive technology needs: (1) to speed up product development, (2) to enhance manufacturing and supply capability and capacity and (3) to improve revenue from lifecycle efficiency. To tackle such challenges, in past decades, with the support of advanced manufacturing technologies, manufacturing industry has shifted from mass production, which takes the advantage of scale of production, to concurrent engineering, which optimizes internal enterprise processes, and virtual enterprise, which leverages intellectual capital via collaborative innovation [1]. In such a virtual enterprise environment, companies need to closely collaborate with customers, manufacturers, and suppliers in a real time manner so as to quickly respond to dynamic market changes.

Accordingly, the business model in the manufacturing industry has shifted from make-to-order, to build-to-order, to engineering-to-order, to configure-to-order, to design-to-order, and in near future to innovate-to-order.

Key technologies to support these business models have changed as well from mass production, to a flexible manufacturing system, to manufacturing knowledge management, to product customization, to product knowledge management, and to product lifecycle management (PLM) [1,2,3,4,5]. As such, PLM is recognized by world's leading universities, institutes, and solution vendors as the next big wave in enterprise application software market.

Product lifecycle includes the processes of portfolio management, product design, process design, supply, production, launch, service, and recycle. Throughout the entire product lifecycle [6], there exist three major objectives, which are:

- customer benefit such as product quality and serviceability,
- company benefit such as product cost and profit, and
- society benefit such as clean and green environment.

These benefits become the 'WHY' aspect of product lifecycle. Bearing these benefits in mind, the 'WHAT' aspect of product lifecycle can be created, which is to model product specification, function, behaviour, structure, geometry, topology, machining process, schedule, supply chain, operation service, recycling, and disposal. The next step is 'HOW' to model the product lifecycle, which are lifecycle processes including specification management, conceptual design, detailed design, process design, production, supply, service, and recycle.

To reach customer benefits, mass customization, time-to-innovation, product quality, and reliability are recognized as the key approaches enabled with technologies e.g., product family design, platform based design, modular product design, design process modelling and management, design knowledge management, collaborative design engineering, function/ behaviour/ structure design, etc.

To achieve company benefits, time-to-market, time-to-volume, and time-to-profit are known as the key approaches enabled with technologies, e.g., collaborative product service, product lifecycle process management, product lifecycle information and knowledge management, etc.

To obtain society benefits, design for service, design for reuse, design for recycle are justified as the key approaches enabled with technologies, e.g. product/ service co-design, collaborative early design for lifecycle efficiency, environmentally conscious design, etc.

This article will focus on the discussion of technology solutions to achieve company benefits in product lifecycle, namely, product lifecycle management (PLM), which is also the dominant direction in the current market of enterprise software application. PLM provides customers, developers, manufacturers, and suppliers with the most effective means by collaboratively managing business activities throughout entire product lifecycle [4,6]. PLM supports the capability of collaborative creation, management, dissemination and use of product assets (including data, information and knowledge) in virtual enterprise integrating people, processes, and technology [1,2,3]. PLM systems manage a portfolio of products, processes, and services from initial concept, through design, engineering, to final disposal. As such, PLM offers companies a new way to rapidly plan, organize, manage, measure, and deliver new products or services much faster, better, and cheaper in an integrated way.

Following this trend, in this article, ever-increasing business drivers and industrial requirements are analyzed. PLM is proposed as a new weapon to satisfy modern needs for new business model of innovation-to-order. A recent state-of-the-art review for PLM, including both academe and industry is done.

To effectively manage these product lifecycle processes for competitive advantages via efficient collaboration, technology solutions for PLM are proposed as the future trend. Accordingly, the impacts of PLM technology solutions to industry are analyzed.

2. Challenges in Product Lifecycle

2.1 Business Driver

The current business environment faces new business challenges for effective management of whole product lifecycle [3], e.g., shorter product lifecycles, increased outsourcing, mass customization demands, more complex products, geographically dispersed design teams, inventories subject to rapid depreciation, and rapid fulfilment needs. In general, these challenges include increased speed, increased demand; increased outsourcing, and the use of Internet.

To effectively tackle the above challenges in a modern collaborative enterprise environment [1,6], new industrial capabilities are required in order to obtain business success in today's Internet economy:

1. Geographically scattered design teams and supply chain partners need to collaboratively design products on a virtual basis.
2. Static designs need to be replaced by mass customization often using predefined modules or building blocks to rapidly configure new product platforms that can be flexibly managed through lifecycle.
3. A new approach needs to be created to leverage net centric technology to liberate the inherent value in today's extended business model.
4. Such a new approach should enable business to use and leverage information needed by each partner to accelerate and enhance product development predictability.
5. That approach should provide a system to exchange and control product information and to perform real-time program/project management.
6. A system needs to emerge as the dominant technology for managing inter-enterprise data, information and knowledge.

To meet these requirements, a new system is imperatively required:

- to provide an information continuum in order to deliver pervasive, real-time analytics, querying, and reporting throughout the entire product lifecycle,
- to provide a collaborative environment bringing together multiple roles, constituents, and stakeholders in threaded discussions beyond four walls of enterprise,
- to enable interactive viewing upon product development through multiple devices, channels, and systems involved with the product lifecycle,
- to be an open but integrated solution supporting key enterprise value disciplines of product leadership, customer intimacy, and operational excellence.

Such a new system will provide customers, developers, manufacturers, suppliers, and partners with the following capabilities:

- product lifecycle collaboration across virtual enterprises,
- common product lifecycle processes management,
- effective management of product lifecycle activities, convenient integration with other enterprise systems.

3. Review of PLM Approach

3.1 PLM Concept

As companies move towards providing better customer-centric products and services quickly to maximally satisfy customer requirements, to improve market share and market size with continuously growing revenue, the efficiency and effectiveness of product lifecycle management becomes much more important in modern enterprise application systems [1,7]. To address these needs, PLM has recently been recognized as a new strategic business approach in support of collaborative creation, management, dissemination, and use of product assets, including data, information, knowledge, etc., across extended enterprise from concept to end of life – integrating people, processes, and technology. PLM systems support the management of a portfolio of products, processes, and services from the initial concept, through the design, engineering, launch, production, and use to final disposal. They coordinate and collaborate products, project and process information throughout the product value chain among various players, internal and external to enterprise. They also support a product-centric business solution that unifies product lifecycle by enabling online sharing of product knowledge and business applications [2,3,4].

As such, PLM enables manufacturing organizations to obtain the greatest competitive advantages by creating better products in less time, at a lower cost, and with fewer defects than ever before. In summary, PLM not only provides service throughout the entire product lifecycle, but also enables effective collaboration among networked participants in product value chain, which differentiates it from traditional enterprise application systems, such as Enterprise Resource Planning (ERP), Manufacturing Execution System (MES), etc.

3.3 Gap Analysis

However, to get the most competitive advantages in the modern dynamic global manufacturing era, there is still a big gap between increasing demands from industrial companies and available solutions from vendors. The gaps in PLM include:

1. CAD/CAPP/CAM integration versus collaboration product development and real time design to manufacturing collaboration;
2. Product structure and configuration management versus collaborative product family design for mass customization;
3. Design for manufacturing versus design for supply chain and lifecycle efficiency;
4. Product planning versus product portfolio management;
5. Design workflow management versus product lifecycle process management;
7. Product and part maintenance versus extended product service.

Therefore, it is imperatively required that new technology needs to be identified and further developed to enable current commercial PLM solutions to satisfy increasing industrial requirements.

4. Collaborative PLM Strategy

4.1. PLM Strategy

As a business strategy [2,3,4], PLM lets distributed organizations innovate, produce, develop, support, and retire products. It captures best practices creating a storehouse of valuable intellectual capital for systematic and repeatable re-use.

As an information technology strategy, PLM establishes a coherent data structure that enables real-time collaboration and data sharing among geographically distributed teams. PLM lets companies consolidate multiple application systems while leveraging existing legacy investments during their useful lives. Through adherence to industry standards, PLM minimizes data translation issues while providing users with information access and process visibility at every stage of the product's life.

PLM systems support the management of a portfolio of products, processes and services from initial concept, through design, launch, production and use to final disposal [8]. They coordinate products, project and process information throughout new product introduction, production, service and retirement among the various players, internal and external, who must collaborate to bring the concept to fruition.

The PLM concept gives the strategies to organize and to manage product information the entire life cycle, from concept to re-cycling of the product through:

- Share the updated product information's within the organization to design, manufacturing, marketing and procurement divisions,
- Collaborate internal team with external users, suppliers and customers for iterating new designs,
- Maintain a repository of product information for design reuse and to reduce part redundancy,
- Systematically gather and analyze customer or market product requirements,
- Streamline sourcing team to identify a list of preferred suppliers for purchasing custom and standard parts,
- Streamline resource management and analyze the cost-benefits of allocating resources for specific projects.

Management and distribution of enterprise information by PLM system is realized on different data levels, as:

- ICT
 - Compliance with existing legacy system
 - Integration of PLM and ERP/CAD systems
- Processes
 - Fragmented and unalterable
 - Modeling, controlling, improving
- Data & Objects
 - Different data formats; Standard data representation (IGES, STEP...)
 - Preserving data integrity along the time; Supporting data evolution
- Methods & Tools

- Specific tools (CAD, CAE)
- New development methodologies (Six Sigma, Axiomatic design...)
- People & Organization
 - Functional organization promotes incommu-nicability
 - Supply chain approach

4.2. Establishing PLM

There are companies that supply software to support the PLM process. That software itself is just a tool and cannot make many contributions if the PLM process is not defined first and understood by its users whom it should contribute to at the end. Setting up PLM within the company is a process and project itself [6].

Select operations that should be managed as a part of the PLM across the company business would be:

- Customer relationship management (CRM) system for managing customer record,
- Enterprise resource planning (ERP) system for managing financial records,
- Supply chain management (SCM) system for managing supplier support,
- Human resource management (HRM) system to manage the employee record,
- Requirement management (RM) system for managing of requirements,
- Project management (PM) system for managing capabilities provide project scheduling, tracking, and resource management while the change management is driving the execution of these projects via the process workflows and part/document management capabilities.
- Product data Management (PDM) system for managing product data and workflows.

Fist step in establishing PLM would be understanding and analyzing the company way of work, organizational structure, roles and responsibilities within the organization. Each of the PLM operational systems should be defined to specify who is contributing to the system, how the information is shared and responsible person appointed for each of the systems. It is not necessary that all those operation systems are integrated within one software tool, and usually for small and medium companies they won't be, while on the other side big companies might need to adopt available software and tools to their specific needs.

4.3. Application of PLM in medium to large enterprises

In the current economic climate, addressing global business challenges is the top priority of most medium and large enterprises. Whether they want to expand their customer base in new markets, or to leverage more cost competitive resources, conducting their business globally is a necessity [1,7]. To sustain an advantage, they have to overcome the challenges of a dispersed organization, while still empowering individual team members.

PLM concept offers comprehensive solutions to help enterprises address their challenges and create competitive advantage. Five areas where medium and large enterprise should have achieved success include:

- Managing new product introduction, to create a winning product portfolio.
 - Achieving concurrent engineering globally, to be faster to market.
 - Creating platforms for reuse, to reduce cost and speed product customization.
 - Managing product and manufacturing complexity, to avoid program problems.
- Supporting products currently in-service, to ensure they are available for use at minimum cost.

4.4. Application of PLM in small to medium enterprises

Small and medium enterprises have special needs and limited resources. PLM concept brings a complete solutions designed specifically for them; solutions that help them respond better to their customer's needs.

Small businesses need a product lifecycle management solution designed from the ground-up –one that is pre-configured with the industry's best practices, and offers fast and affordable deployment. Fully integrated PLM solutions are designed to provide what small and medium enterprises need to maximize their innovation strategy, and easily scale to meet their needs tomorrow.

One producer of that type of PLM software solutions is Siemens PLM software [8]. It helps mid-sized

manufacturing companies to transform their process of innovation by applying preconfigured best practices to everyday engineering tasks and processes. Companies using PLM software benefit from:

- Securing their corporate design data while facilitating access by authorized personnel
- A more successful move from 2D to 3D
- Increasing their design reuse, facilitated by a powerful and flexible search capability
- Streamlining their engineering process with simple design review and release workflows and effective change management
- Error reduction through more effective collaboration between their departments and the elimination of mistake manual handoffs to manufacturing
- Rapid deployment of a full-featured product data management (PDM) solution
- Low total cost of ownership.

5. PLM Metrics Development Process

The questions often asked in business and commerce are how well do we know we're doing, and how do we know what we're doing is working? There is important to find out the metrics process for measuring what is important and meaningful [3,5,7]. The only way to find out answers to these questions is to measure the processes and outcomes of these processes. As PLM transforms the way companies do business, it is important that companies understand how well they are doing. To determine the effectiveness of PLM implementation within any context, PLM processes and outcomes need to be measured. Measurement of PLM requires the development of metrics that are important and meaningful to the process. It is essential that what is identified as a metric is relevant, appropriate and important, since typically what gets measured gets done.

The objective of the metrics development process is to identify, develop, and articulate PLM metrics that would help companies implementing PLM determine the extent to which their PLM efforts are paying off. The PLM assessment process model shown at the Figure 1, conceptually presents the metrics development process.

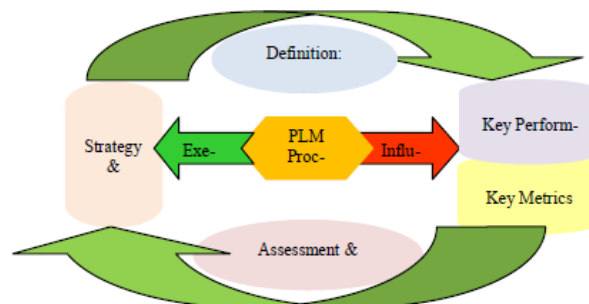

Figure 1 PLM Assessment Process Model

The PLM processes, including ideation, design, build, service, disposal, and recycling, on one hand influence the determination the key performance indicators of success on the other hand the execution of the strategies and initiatives depends on them. The key performance indicators are directly impacted by the organizational strategies and initiatives. In other words, the organizational goals and objectives define what the organization considers success which should determine the key performance indicators. Key metrics are derived from the performance indicators. The key metrics measure what is relevant and important to the organization as outlined by the organizational strategic plan. Outcomes of the assessment and analysis using the key metrics impact the organizational strategic plan. These metrics are all tied to business objectives related to growth, revenue, and profitability.

PLM metrics can be applied at various levels of complexity.

- At the very basic Level 1 Input metrics are measured. At this level, the question is whether the organization is applying appropriate resources to the PLM process, i.e. investments.
- At Level 2, metrics are used to determine if the appropriate PLM processes were implemented, e.g., Requirements Management, Sourcing and procurement, Distribution Quote/order generation.
- Level 3 focuses on customers being reached.
- Level 4 and 5 metrics examine the efficiency whether the outputs meet the needs of customers are being met (e.g., requirements traceability, visualization, concepts, design capture & accessibility, change control & change capacity, configuration management, commercial cost of risk, product

quality) and effectiveness, if desirable results are being achieved (e.g., generation of new business, software integration, cost performance, market share, cost reduction, design reuse).

- At the highest Level 6 metrics are used to measure the impact of the implementation of PLM by measuring the extent to which procedures and controls have been integrated and the return on investment. Level 6 metrics are the most complex and difficult to measure. These include waste reduction, innovation/ new products, continuous improvement, and sustainable green manufacturing.

6. PLM Business Value

When the enterprise implements the PLM concept in work, than it can move forward strategically while achieving near-term results and can establish a platform for innovation. As the enterprise address specific business issues and builds a solid foundation for future success through PLM platform, it will be able to realize measurable innovation benefits both immediately and over the long term, shown on the Figure 2.

Traditionally, companies brought their products to market in time-consuming serial processes that delayed the participation of downstream contributors, such as suppliers, manufacturing experts and service/maintenance providers. By allowing to the enterprise to execute as many lifecycle tasks as possible in parallel processes, PLM enables to the enterprise to streamline and collapse critical stages in the product lifecycle. PLM delivers aligned, accurate, and highly synchronized product knowledge to multiple disciplines early in product lifecycle – thereby avoiding the cost and scheduling impact that comes when late suggestions and unexpected concerns arise from downstream players. PLM enables to the enterprise to beat the competition to market with innovative product content that carries first-to-market advantages and drives early product sales.

Figure 2 PLM business value

6.1 Increase profitable growth

PLM allows the enterprise to create, capture and share the product-related requirements, expectations and preferences of targeted customers and markets and align these requirements with specific innovative content that customers want for a price they can afford at the time when it is needed. PLM concept gives new product ideas against quickly rising customer requirements and cost effective manufacturability. Global cross-functional teams collaborate in real time on the development process, each contributing their unique experience and perspective. Knowledge and “lessons learned” are captured for potential re-use in a process of continual innovation. PLM facilitates mass customization by enabling to rapidly and costs effectively deliver customized product offerings that satisfy the needs of individual customers and targeted market segments. PLM combines the advantages of configuration management with option and variant management. These state-of-the-market capabilities allow the enterprise to perform portfolio planning in as flexible and continuous a process as possible.

6.2 Reduce build costs

PLM allows the enterprise to reduce cost across all of the stages in the product lifecycle – which in turn, enables to minimize the cost of the product offerings that plan, develop, manufacture, and support.

For example, by leveraging PLM to understand the time and resource impacts of proposed design changes and requirements changes, the enterprise's team can make decisions that minimize lifecycle and product costs. By using PLM to catch design flaws up front in the lifecycle, the team can avoid the cascading rework and cost associated with changing the products during the manufacturing stages of the product lifecycle. Also, the enterprise's team can use PLM to incorporate the concerns of the maintenance and service groups into the product designs and minimize warranty costs. By digitally creating and re-using the manufacturing plans, plant information and manufacturing processes, the enterprise can reduce the overall operational costs. The enterprise can also use PLM to implement virtual prototyping that enables to reduce the validation costs associated with physical prototyping.

Implementation of the PLM concept in the enterprise enables to cost effectively deliver product enhancements, derivatives, niche offerings and add-ons that extend the profitable duration of the product lifecycle. PLM facilitates this objective by enabling to create product platforms that accelerate start up processes, minimize take to market cost and maximize the revenue generated by a product's initial release.

PLM enables the enterprise to maximize the re-use of the best-practice processes, intellectual capital, human resources, product plans, production plans, production facilities and value chains across a continuing set of take-to-market programs and complete set of product and production management capabilities.

7. Idea for Joint Programme of PLM Master Studies

The basic principles for offer the master study programme in PLM in the Western Balkan region are that the curriculum of joint PLM master programme is committed to excellence in European-wide PLM interdisciplinary education and training of engineers to deliver and manage high quality and trustworthy systems for all phases of PLM that meet the local industrial, economical, environmental and social needs. The knowledge in PLM offers an approach complete and comprehensive to the most acute problems of economic development on the whole, as well as the competitive positioning of the individual company.

The intention of this joint programme is to promote a new type of expert who will have all the necessary theoretical and practical knowledge, not just engineering, but business, economical and environmental as well, covered by new ICT techniques. That kind of expert needs to have the ability for research in those disciplines, also as specific skills in product development and management in all phases of its lifecycle with environmental sustainability and corporate social responsibility view. They need to be prepared to apply the learnt methods for product and process management in different areas, such as production, services, and public activities in practice, all of this supported by latest information technologies.

The beneficiary partner institutions from Western Balkan (WB) made needs analysis in order to improve the higher education curricula, to develop and to offer new one, based on the experiences of Italian partner institution, in the field of competitive Product Lifecycle Management (PLM) by integrated Sustainable Development (SD) view. Partner institutions developed Joint Programme of Master Studies in PLM under coordination of Technical University of Turin from Italy and University from Maribor, Slovenia established at the universities from WB region: Macedonia, Serbia and Croatia.

Joint Programme of Master Studies in PLM is established in continued process during two years of development the structure, the teaching contents, the teaching methodologies adopted for blended learning, new teaching ICT environment and implementation of new programme at the postgraduate university level in accordance with Bologna Declaration principles.

This new introduced Joint Master studies programme in Product Lifecycle Management is new offer on postgraduate level in WB countries with interdisciplinary and contemporary contents in fields of industrial engineering, management and sustainable development with business and management subjects, ICT technology driven subjects and environmental sustainability subjects. Development and implementation of the joint programme of master studies in PLM is realized in frame of the Tempus IV MAS-PLM project: Master studies and continuing education network for Product Lifecycle Management with Sustainable Production, funded by EC with the Agreement No.144959-TEMPUS-2008-IT-JPCR (2009-2012) (www.master-plm.net).

7. Conclusion

Although a quite new method with short history PLM has proven itself to be useful for all management levels within the company in both vertical and horizontal organization. By making relevant historical information structured and available PLM is used both for those who are doing execution and decision makers within the organization answering to the rapid changes in the business environment. A business approach for coordinating design process through the implementation of PLM systems is proposed for improving design coordination in SMEs. Firstly, this business approach is based on a method for analysing informal collaborative practices and modelling detailed design processes. Secondly, these processes are implemented by using PLM technologies. Multi-level workflows are implemented to control progress of design schedule from project management level to document lifecycle management level.

Towards the Development of Web-based Business intelligence Tools: Co-creation Strategy Components in Technology-driven Firms

Lachezar Georgiev¹, Hristo Milyakov¹, Petko Ruskov¹, Lars Eriksen², Stoyan Tanev²

¹Faculty of Mathematics and Informatics, Sofia University, Bulgaria

²Institute of Technology and Innovation, University of Southern Denmark, Odense M, tan@iti.sdu.dk

This paper focuses on using web search techniques in examining the co-creation strategies of technology driven firms. It does not focus on the co-creation results but describes the implementation of a software tool using data mining techniques to analyze the content on firms' websites. The tool was used in other research projects to identify the ways firms engage in value co-creation with customers.

Keywords

Business intelligence tools, search engine, value co-creation, quantitative analysis, qualitative analysis

1. Introduction

This paper describes the results from a research project focusing on using web search techniques in examining the co-creation strategies of technology driven firms. The research methodology was first developed by Hicks et al. (2006) and then introduced to the study of value co-creation by Steve Allen et al. (2009) and by Tanev et al. (2010). It is based on using data mining techniques and principal component analysis to analyze the content on firms' websites in identifying the ways firms engage in value co-creation with customers. A key component in the methodology is the use of a search engine and all the works so far have focused on using Google. The research methodology is visualized in the figure below.

Figure 1 A step-by-step description of the research methodology

The present study will extend the above methodology by using data from multiple search engines. This approach will validate the research methodology and will attempt to provide valuable insights on the coherence of the results from the different search engines. The focus however will be on the enhancement of the functionality of the search tool. The main deliverable therefore is the development of a user friendly search tool. In order to be able to validate and further expand the methodology, the present study will be based on the same keywords and the same sample of firms as in Allen et al, 2009 and Tanev et al., 2010. The key difference in our approach can be summarized as follows. First, a new data collection was done by three different web search engines (Google, Yahoo, Bing) to measure the frequency of the keywords on firms' websites. Second, the data was collected by newly developed multi-functional search tool.

2. Development of the Search Tool ‘LuckySearch’

This section will focus on the details of the development and the functionality of the search tool.

2.1 Description of the functionality of the LuckySearch tool

The application is developed as a Windows Desktop program. It executes searches on Google, Yahoo! Search and Bing. The search queries are constructed for each keyword and each company's web site. Also one additional search is executed only with the company's web site, to get the count of the pages in the web site. The output of the application is one (287x30) matrix (corresponding to # of firms X # of keywords) saved in Microsoft Excel file with the results of the searches executed against one of the search engines. The results are structured in a table with columns – the selected 29 keywords entered as an input + one column for the pages size of the web site; and rows – the 287 companies' web sites. The data in the table is normalized: the number of pages beneath the site and the keyword counts normalized by the number of pages beneath the site. The application is able to execute simultaneous searches against one of the three search engines. The number of the simultaneously executed search may be preconfigured by the user of the application. The application is constructed in a way that supposes further development and integration with the SPSS software. The user interface is shown in Fig. 2.

Figure 2 Preview of the LuckySearch user interface

To use the software application, the following steps must be executed:

- Import a text file that contains the predesigned keywords. Each keyword should be placed in a new line in the file or in the “**Keywords**” text area in the keyword application window.
- Import a text file that contains the web sites. Each web site should be placed in a new line in the file or in the “**Websites**” text area in the application window.

- Select a folder in the field “**Output directory**”, to specify the output directory where the excel file and the text files results should be collected.
- Choose the “**Number of threads**”, which specifies the parallel web searches executed at a given moment. It is recommended that this value is preset to 2, otherwise the search engine may reject the request to execute the web searches.
- To save the text content from the first found web pages should be parsed and saved in the specified output directory, check the field “**Save text results**”.
- To specify the number of the first found web pages, from the search engines, which are going to be parsed and their text content saved, choose the number from “**Number of links**” field.
- Click the “**Search**” button to start web search executions.

2.2 Technical description of the LuckySearch Tool

1. **Development platform.** As the Bing and the .NET platforms have a common owner - Microsoft, there is plenty of documentation, articles and examples how the Bing API can be used with the .NET development platform. There is an available Bing library written in .NET that can be used for the execution of web search requests. Yahoo! Search has its own .NET Developer Center with HOWTO articles and Community Resources where one can join mailing list and discuss the Yahoo! APIs (as well as OAuth Authorization class source in C# and VB.NET). The OAuth Authorization source saves a significant development tie and is appropriate to be used in this project. For Google there is an available .NET Client Library Developer’s Guide, which includes many tutorials and examples in .NET. From version 14 onwards SPSS can be driven externally by a Python, R and .NET program using supplied "plug-ins". So for the sake of convenience for the further development and integration with SPSS, one should focus on using development platforms such as: Python, R or .NET. Since the application uses Microsoft Excel file as the output of the application, the development platform should have integration and possibility for output Excel files with filled results in it. Microsoft distributes MS Office libraries that can be used by external sources. They support almost all Windows development platforms including .NET. One advantage of .NET over Python is the possibility to use integrated modules for Windows Forms and the nice compatibility between .NET and Windows’ Desktop. Having in mind all of the above, it was found to be most appropriate using the .NET platform and its most popular language C#. As a coding convention for the development we have chosen the one recommended by Microsoft.

2. **Software application design.** All the search engines’ API supports a web response in XML, JSON and SOAP protocols. In this software XML responses are chosen to be used, as this is the most affirmative method today. For the development of the Bing part in the application, Bing API SDK was used. It provides automatic authentication and search query construction. It is recommended to be used by Microsoft MSDN. The application - "LuckySearch" is developed with three subprojects:

- The user interface is separated in individual sub-project. It contains the user settings, the windows forms interface and the class that outputs the Excel data file with the matrix results. This project manages the executed simultaneous threads.
- Module responsible for extracting the text from the web site content. It parses the web page and removes its HTML, Javascript and Flash code.
- Module responsible for executing web requests to the Google, Yahoo and Bing. It is also responsible for parsing the results from the Search engines. It determines the total number of results for a given requests, and also gathers the returned links in a lists.

3. **Application process flow.** The diagram shown in Fig. are described the process actions steps that the application LuckySearch must execute to gather the search engines Excel data results and the text data results from the sites linked by the search engines.

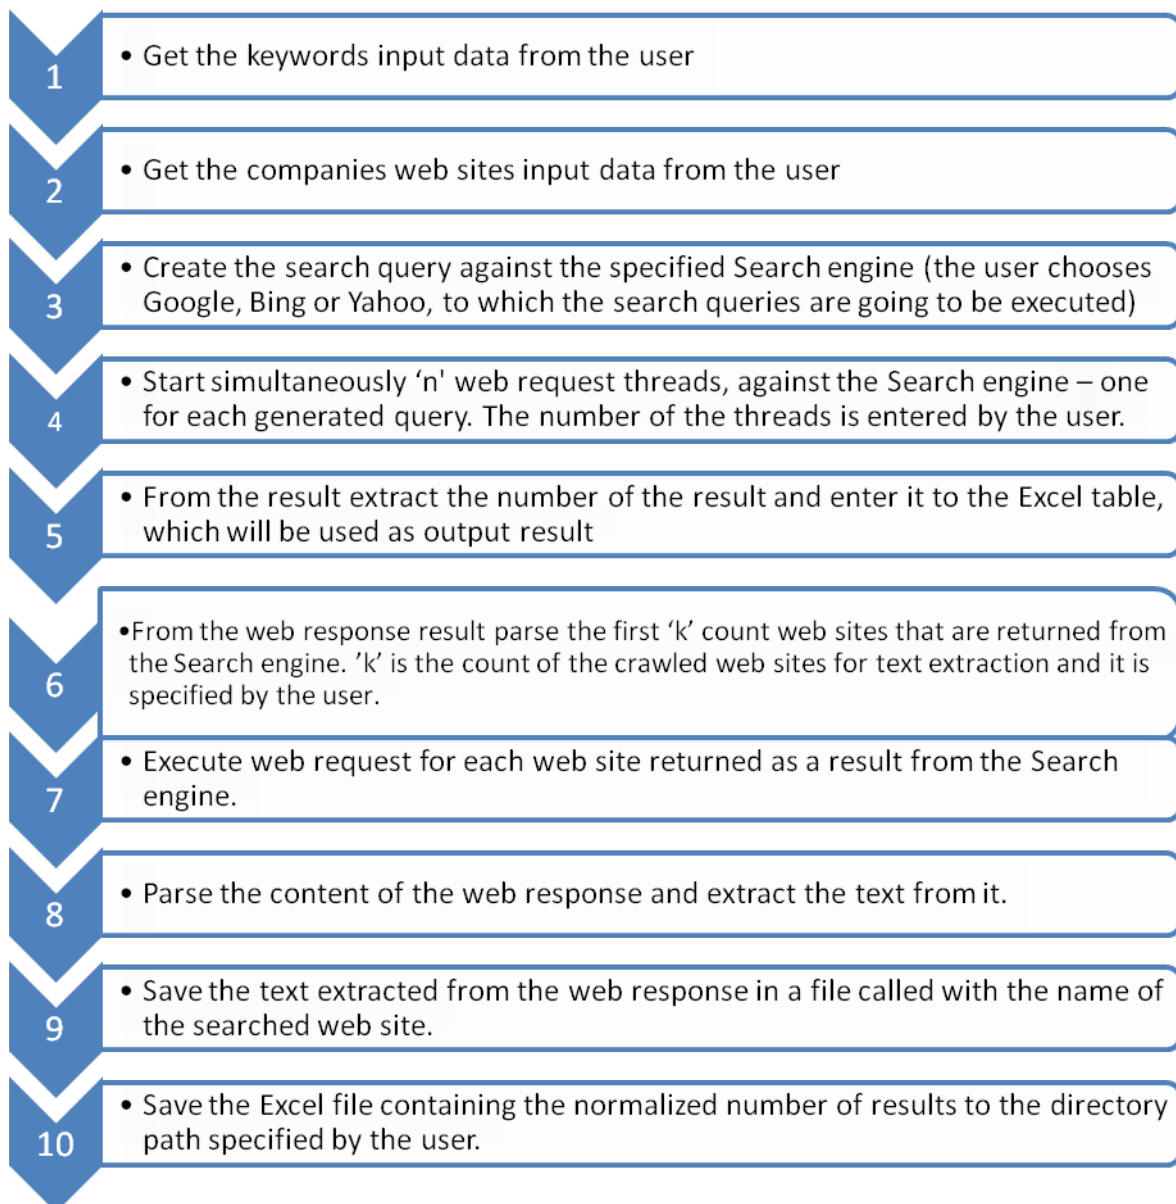

Figure 3 Process diagram of the LuckySearch application

4. **Constructing the search queries.** Before executing the search requests, the application must be registered in the search engine's web site:

- Yahoo: <http://developer.yahoo.com/bbauth/appreg.html>;
- Bing: <http://www.bing.com/developers/appids.aspx>;
- Google: <http://code.google.com/apis/accounts/docs/RegistrationForWebAppsAuto.html>.

Before filling any of these registration forms one must have an account for the corresponding search engine. After the registration is done, specific keys and passwords given during the registration must be used for authentication when creating the web requests to the search engines.

5. **Technical challenges.** One of the most serious problems when using the tool came from the fact that, if there is a bigger web request load from one single place to their API, the connection is rejected without the possibility to open a new one for an unpredictable period of time. This can be resolved by executing the requests with a lower flooding and smaller amount of threads used in the application. The number of threads can be predefined in the application, but it must not increase three threads at one time. Also if the problem occurs again, the search requests for all web sites can be executed at two, three or more parts with a gap of, for example, 20 min. When using the Google API, the maximum simultaneous threads must be no more than two. Also the group of 287 company's web sites was loaded and executed in groups of four with group of 70 companies each. When using the Yahoo! Search API it is suggested that the threads must be no more than 3 and for Bing they must be no more than 5. Even with these precautions, because of using the application very often or because

of any other reason, the Search engine can decide to block the web requests for a period of time. Than LuckySearch receives error 403 from the server and waits for 30 seconds. If the error occurs again it shows message box shown on figure 11 that stops the thread until the user doesn't click OK.

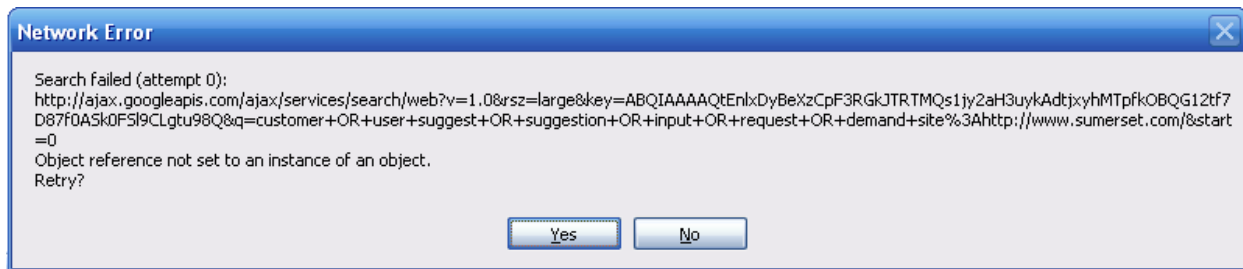

Figure 4 Error window shown when LuckySearch is blocked

When searching for a keyword in Google, Yahoo and Bing, the engine could show millions web pages. Actually, it shows only ten results on the first page and when you click on the next twenty pages the number of results decreases. It can decrease, for example, from 1 600 000 results down to 450. Most of the results are claimed to be in the “Invisible Web”. The Search engines calculation of the total number of search results is an estimate. As this makes one uncertain about the validity of the results, one can assume that it will be proportional for each search result and, thus, empirically correct. For Bing there is specifically developed tool “Bing Sharp”. It calculates the total number of search result not as estimation, but as a sharp value. It is not used in the current thesis, but is suggestion for further research. Although the results are not as many as the first totals search estimation, it is still a large amount of data. Therefore in the application will be available text box, by which the user can configure what number of web sites to be parsed.

Another challenge was related to the question how to remove the useless content of the web sites and be able to extract only the text. The approach that was undertaken can be summarized as follows.

- All the html code must be removed. To be properly removed, the HTML must be a valid xml. This helps the code to find, for each opened xml tag, the closing one. The html removal can be applied by depth first search algorithm for the XML tree, also each opening and closing XML tag will be removed, as it is not valid text (in HTML, the < class is < and > is >). Exception from the removal of each XML tag is, if it is not included in <pre> tag that stands for preformatted text and excludes all other inner tags.
- The script code must be removed. All the js and vb files are ignored. Rare there is a text in these files. All the scripts are enclosed in <script> tag and that's the way it can be found and removed, as it is useless code.
- The style sheets must be removed. All the .css files are ignored too. All the styles in the html file is enclosed in <style> tag and that's the way it can be removed.
- The video and flash animations are removed while removing the html tags, because in the HTML files they are presented only as one <object> tag. The Flash and Silverlight only sites (that doesn't use HTML) are ignored by the Search engines too, so they are not problem for gathering its text.

Another smaller challenge was that there were lots of symbols (more than 250) of the text in the HTML document, which are presented as encoded ones. As an example < stands for <, > stands for > and & stands for &. They must be decoded, to be entered properly as text results in the data storage that will save the text results. The extracted text from the web sites must be stored in files, to be available for further data mining provided by external tools or further developed in LuckySearch. For each company there must be created a text file, to which the text must be added. After the LuckySearch is finished with the web site text gathering, there must be 287 files with extracted text data for each keyword. If needed later the LuckySearch might be easily redeveloped to store the extracted text for each keyword in separate file.

3. Conclusions

The paper focused on the description of the implantation of LuckySearch – a software business intelligence tool using online data to study the customer interactive behaviour of technology driven firms. The focus on the technical description was intentional. The reader could find more details on using the tool for value co-creation research in related research publications (Allen, 2009; Tanev et al,

2009). The implementation of the tool opens the possibility to explore other areas of research including competitive strategy, online cooperation etc.

Knowledge Transfer Flows in the Life Sciences

Ani Gerbin¹, Mateja Drnovsek²

¹Faculty of Medicine, University of Rijeka, Rijeka, Croatia, agerbin@medri.hr

²Faculty of Economics, University of Ljubljana, Ljubljana, Slovenia, mateja.drnovsek@ef.uni-lj.si

This paper investigates knowledge transfer process in the life sciences. We analyze traditional knowledge transfer activities, contingent on industrial funding of academia, and “new-type” knowledge transfer activities, including patenting, licensing and the creation of spin-off companies. Previous studies of the impact of knowledge transfer on knowledge flows in life science communities have produced equivocal findings. While some authors supported modest evidence of the restrictions in knowledge diffusion due to patenting and exclusive licensing of basic technologies, others pointed to significant limitations in the dissemination of research inputs and results, particularly in genetics. The key research question of this paper is: How does the involvement of researchers in different forms of knowledge transfer with the industry influence the particular forms of knowledge flows among researchers? Based on the literature review we established the theoretical framework of knowledge transfer process from an individual researcher perspective. Our research model included two dependent variables, formal and informal collaboration, and predictor variables, that refer to involvement in “traditional” and “new-type” knowledge transfer activities as well as to scientists’ human and social capital. The model developed within this research should be the first seeking to identify the influences of different types of knowledge transfer on the extent of particular forms of collaboration between fellow researchers. As such, it represents an original contribution to the existing literature dealing with the complex problem of withholding of research results and limitations in formal collaboration among the members of the scientific community, which may derive from their involvement in knowledge transfer. This is relevant because of potentially detrimental effect of knowledge transfer on the progress of fundamental science. The empirical findings on knowledge flows in the academic community, the norms of sharing practices and causes of such behaviors have important implications for researchers, managers and policy makers.

Keywords

Formal knowledge flows, Informal knowledge flows, New-type knowledge transfer, Traditional knowledge transfer

1. Introduction

The adoption of the Patent and Trademark Amendments of 1980 in the USA, known as the Bayh-Dole Act, is historically viewed as an event that marked the beginning of the global upsurge of knowledge and technology transfer activities from academic and other non-profit research institutions to the business sector. The Bayh-Dole Act gave non-profit institutions the privilege to retain the property rights to inventions deriving from the state-funded research. Prior literature on the subject matter examined how links between academia and industry enable the realization of complementarities between applied and basic research, the generation of new research ideas and the overcoming of the shortage of funding of basic research through the private sector [1]. Other stream of researchers explored how engagement of individual researchers into knowledge transfer activities could undermine their commitment to the norms of open science, in that way leading to secrecy and publication delays

[2, 3]. The most often examined challenges of the Bayh-Dole Act include: threat to scientific progress due to increasing disclosure restrictions; declining patents' and publications' quality, biasing research efforts toward commercial priorities and crowding-out between patents and publications [4]. These issues have been examined on the individual and institutional levels of analysis, taking into account either the academic or the industry perspective [5]. Recently the level of analysis shifted to an individual's perspective to fully capture the predictors, characteristics and effects of knowledge transfer process, particularly in relation to scientific knowledge diffusion [6].

Drawing from this body of literature we identified several gaps. First, empirical studies have for the most part dealt with the impact of patenting on the open science environment, without paying specific attention to other knowledge transfer activities [7, 8]. Second, the studies that did consider the impact of different forms of knowledge transfer on knowledge flows among researchers have mostly examined only one aspect of knowledge diffusion - informal cooperation between researchers [9-11]. Third, the empirical findings with reference to formal knowledge flows have typically been restricted to investigations of the relationship between knowledge transfer and quantity and quality of the researchers' scientific output [12]. Thus, only few studies attempted so far to consider the determinants of other forms of formal collaboration among researchers, such as collaborative research projects or personnel exchange between laboratories.

In this study we first seek to provide a broad perspective on knowledge flows in the life science community, by considering both the individual and the environmental determinants of different forms of collaborative efforts among researchers. Second, we plan to extend the work of other scholars that discuss the conflicts between the norms of free circulation of knowledge and the rules of market competition [13], arisen following the expansion of patenting in the life sciences. Specifically, our research aims to investigate a wide range of knowledge transfer activities in assessing their role in the diffusion of formal and informal scientific knowledge. By separately evaluating different forms of knowledge transfer we intend to account for their diverse characteristics and consequently, their potentially diverse impact on knowledge flows. Moreover, we suggest that it is possible to draw generalized conclusions regarding the actual extent of impact of knowledge transfer process on knowledge flows in the life sciences only by considering a full spectrum of available knowledge transfer activities on one side, and a variety of knowledge flows among researchers on the other.

In so doing we propose a comprehensive conceptual model of knowledge transfer process from the perspective of an individual researcher. This model and the related key propositions will capture the relationship between particular forms of knowledge transfer activities and particular forms of dissemination of research inputs and research results among researchers. The propositions will be tested by combining personal interviews with researchers and questionnaire surveys. Based on our findings we will estimate whether the present concerns of scholars and policy makers over increasing secrecy in biomedicine and biotechnology fields have been targeting the factual cause of problems.

2. Literature Review

A significant fraction of the articles published in the field focused on the impact of patenting, as one form of knowledge transfer, on knowledge diffusion among researchers. On one hand, patenting in biomedicine is viewed as a means of providing investment incentives, essentially due to long product development time horizons and high associated risks. On the other hand, the expansion of proprietary interests to life sciences is assumed to have the strongest influence on endangering free knowledge flows among academic researchers. It seems that patenting and exclusive licensing of fundamental technologies could in fact restrict future innovation, by increasing costs and hindering the access to technologies and the free flow of scientific knowledge needed for subsequent research and even redirecting the research [14, 15]. This concern has been captured in the phrase "*the tragedy of the anti-commons*", which has been used extensively to point to the problem of existence of multiple holders of rights to separately patentable inputs which combined from one product or resource [7, 16].

In a qualitative study of the impact of patenting of research tools in biomedicine on innovation, Walsh and colleagues [16] find that university research has not been substantially impeded by an increase in patenting; with an exception of patented genetic diagnostics. Relying on the analysis of citation rates of scientific publications before and after the grant of associated patents, Murray and Stern [8] test the anti-commons hypothesis and find a modest evidence of the restrictive impact of patents on knowledge diffusion. Furthermore, Caulfield and colleagues [17] show that even though researchers view patents negatively in terms of their impact on research environment by increasing secrecy, there is little evidence that patenting in reality interferes with the research process through increased withholding of protected materials. Academic competitiveness, and not patents, is viewed as a principal reason for the denials. Only a limited number of studies have considered the heterogeneity in

university-industry interactions when assessing their relationship with knowledge diffusion. In a study aimed to reveal the reasons behind two forms of data withholding, publication delays and refusals to share biomaterials and data, Blumenthal and colleagues [9] find that involvement in academic-industry research relationship and engagement in the commercialization of university research are both associated with publication delays, whereas only the latter is associated with refusal to share research results upon request. Shibayama [18] on a sample of Japanese natural scientists finds that not all entrepreneurial activities discourage cooperative relationships between scientists: while commercial activity facilitates secretive publications and non-compliant behaviors in material transfer, no significant effects are shown for collaboration with industry and funding from industry. These findings are particularly interesting because they point to the need for distinguishing between particular forms of knowledge transfer in investigating their impact on knowledge flows in the life science communities. Thus, some authors report modest or no evidence of increasing restrictions in knowledge sharing due to involvement of researchers in knowledge transfer activities. Instead, they attribute the limitations in knowledge flows to reasons such as academic competition or logistical difficulties. On the other hand, others point to significant limitations in sharing resulting from knowledge transfer activities. Next, the published articles only to a certain extent take into account other forms of knowledge transfer in addition to patenting. Moreover, informal knowledge flows, such as sharing of materials and data, are mostly in the focus of attention of such studies; the empirical findings with reference to formal knowledge flows have been poorly represented in the literature. Existing gaps could be addressed by integrating the effects of involvement of researchers in different forms of knowledge transfer with the industry on particular forms of knowledge flows among researchers in one theoretical model. This approach arises from the assumption that the lack of consideration of diversity of knowledge transfer activities or concentration on only one aspect of knowledge diffusion obscures drawing general conclusions regarding the real scope of impact of knowledge transfer on knowledge flows.

3. Theory and Hypotheses

Knowledge transfer activities may take various forms. In this paper we categorize knowledge transfer activities from the academia to industry in two distinct groups and separately analyze the impact on knowledge flows of (1) “traditional” knowledge transfer activities, which are contingent on industrial funding of researchers and research institutions, such as consulting, sponsored research or university-industry joint research projects, and (2) “new-type” knowledge transfer activities, which erect from the value of intellectual property rights, including patenting, licensing and the creation of spin-off companies [19, 20]. When discussing the knowledge diffusion pathways between members of the scientific community, we recognize that informal collaboration between researchers, in the form of exchange of research information and research materials, is as important for the continued existence of the open science paradigm as formal collaboration due to creation of “learning intensive” opportunities [21]. The latter can be realized through joint research projects, personnel exchange, co-authorships on publications and dissemination of results in scientific journals, books and at professional conferences.

3.1 “Traditional” Knowledge Transfer Activities as Determinants of Knowledge Flows

Government funding of research has been declining during the last two decades. This change has forced the researchers to diversify the sources of their finance, either through applying for competitive supranational funds or by chasing different sources of funding of industrial origin [3, 19]. Different forms of university–industry collaboration have increased in magnitude also due to the emergence of the biotechnology industry, which relied heavily on the expertise and social capital of basic academic researchers [22]. These may include collaborative research projects, sponsored research, consulting, equity holding in companies, personnel exchange, joint supervision of PhD students or joint publishing and can be called “traditional” knowledge transfer activities [adapted from 20] as the consideration of intellectual property rights, although possible, is not of primary concern.

“Traditional” knowledge transfer activities and formal knowledge flows

This research focuses on publication contents and timing dimensions of formal knowledge diffusion in scientific journals. Shibayama [18] shows that collaboration with industry and funding from industry has no significant effect on secretive publications or intentional exclusion of information from a publication. On the other hand, Blumenthal and colleagues [23] show that involvement in various forms of research relationships with industry is associated with publishing data sharing restrictions or

publication delays. Haeussler and colleagues [24] find that consulting is negatively related to dissemination of findings at scientific conferences and publishing timing. Davis and colleagues [25] show that the award of an industry research grant is positively associated with the likelihood that the scientist would be skeptical about the impact of academic patenting on the norms of open science. All in all, there is a considerable amount of previous findings showing that academia-industry relationships have to a certain extent adversely influenced the adherence of researchers to the norms of open science with respect to formal knowledge diffusion. This leads us to argue:

Proposition 1 The extent of an academic researcher's involvement in "traditional" knowledge transfer activities will be negatively related to the extent s(he) formally collaborates with members of the scientific community.

"Traditional" knowledge transfer activities and informal knowledge flows

Concerning the impact of "traditional" knowledge transfer activities on informal knowledge flows, the evidence is more straightforward. In general, biomedical researchers with connections to industry seem to be more likely to engage in data and materials withholding than their colleagues without such connections [26]. Hong and Walsh [27] obtain diverse results when assessing the impact of industry-related activity of mathematicians, physicists and experimental biologists on secrecy with respect to discussing ongoing research with other researchers: industry funding is related to greater secrecy, while having industry collaborators is associated with less secrecy. This hypothesis however, is confirmed only for the overall sample, whereas none of the industry-related activities is shown to have a significant impact on secrecy in the experimental biology community [see also 11, 18]. We propose:

Proposition 2 The extent of an academic researcher's involvement in "traditional" knowledge transfer activities will be negatively related to the extent s(he) informally collaborates with members of the scientific community.

3.2 "New-Type" Knowledge Transfer Activities as Determinants of Knowledge Flows

"New-type" knowledge transfer activities have its focus in the value of intellectual property rights, although there are many historical examples of consideration of commercial value of knowledge generated from non-profit organizations' research [19, 20]. The expansion of proprietary interests to a broader range of scientific findings in the life sciences and biotechnology as well as to new parties, academic and other non-profit institutions, created various new opportunities for scientific development [22] with the help of activities such as patenting, licensing, spin-off companies founding and marketing of new products and services generated through the use of academic-based resources.

"New-type" knowledge transfer activities and formal knowledge flows

In this research timing and contents of scientific papers dimensions of publishing knowledge flows are considered. Blumenthal and colleagues [9, 23] show that university research commercialization endeavors are associated with publication delays, whereas Shibayama [18] finds that commercial activity facilitates secretive publications. Haeussler and colleagues [24] confirm a negative relationship between the number and importance of patents and general sharing among academic researchers, in the shape of conference presentations to the broader community or publishing timing. Despite limited and often disagreeing evidence with respect to the impact of commercialization on other formal collaboration forms, such as personnel exchange or collaborative research projects we propose:

Proposition 3 The extent of an academic researcher's involvement in "new-type" knowledge transfer activities will be negatively related to the extent s(he) formally collaborates with members of the scientific community.

"New-type" knowledge transfer activities and informal knowledge flows

Several empirical studies focus on different forms of commercialization activity: while some authors assess merely the impact of patenting [24], others include a range of business activities, from invention disclosing and licensing, to business planning, spinning-off or product placing on the market [10, 11, 18, 28, 29]. In practically all examined cases the authors reach consensus with respect to the adverse impact of commercialization activities on research materials and information sharing between researchers. Based on this rationale we hypothesize that:

Proposition 4 The extent of an academic researcher's involvement in "new-type" knowledge transfer activities will be negatively related to the extent s(he) informally collaborates with members of the scientific community.

3.3 Human and Social Capital Determinants of Knowledge Flows

Academic rank and formal knowledge flows

Previous studies have mostly found no significant effect of academic rank on formal knowledge sharing [18, 24]. Yet, Blumenthal and colleagues [9] find that higher academic rank is associated with publication delays. Since these studies produced mixed results and only partially examined different formal knowledge diffusion forms, we recognize the need for further empirical studies, which will take into account a wider range of components of formal collaboration between researchers. Our assumption is that the higher up a researcher is on the academic ladder, the better the sign that one has shown capacity to attract resources and a broader range of collaborative and disseminative endeavors. We propose that:

Proposition 5 The academic researcher's academic rank will be positively related to the extent (s)he formally collaborates with members of the scientific community.

Academic rank and informal knowledge flows

While some studies indicate that untenured faculty is less likely to share materials and data than tenured faculty [24], other studies find no significant associations between research results or materials sharing restrictions and respondents' academic rank [9, 10]. In contrast, Shibayama [18] finds that full professors are more likely than associate professors to deny material transfer to colleague researchers. We explain this conflicting evidence by considering the differences in sample sizes, scientific fields examined and cultural settings in each of these studies. One can argue that researchers of higher academic rank will have more professional experience and thus deeper and more extensive contacts with fellow researchers. We hypothesize that:

Proposition 6 The academic researcher's academic rank will be positively related to the extent (s)he informally collaborates with members of the scientific community.

Scientific values and formal and informal knowledge flows

Scientific openness or unimpeded access to research results [30] have been traditionally considered to be the most important norms of the scientists' profession. The outcomes of academic prestige such as publications, citations and peer status emerge from adherence to this system. Merton observed more than 40 years ago that "the communism of the scientific ethos is abstractly incompatible with the definition of technology as 'private property' in a capitalistic economy." Evidently, the attitude of the majority of scientists towards commercial involvement has in the meantime changed, i.e. evolved from resistance to compliance to acceptance, primarily thanks to the departmental and institutional norms and policies, such as academic workload reduction and part-time appointments. Yet, a significant concern, perceived as an obstacle, has remained present with some researchers concerning the delay and secrecy in the dissemination of results and possible interference with academic pursuits and freedom to select collaborators or enter informal modes of cooperation, which could arise from knowledge transfer activities [31]. Based on this reasoning and prior findings we propose that:

Proposition 7 The more inclined is the academic researcher to the concepts of open science, the extent (s)he formally collaborates with members of the scientific community will be more intensive.

Proposition 8 The more inclined is the academic researcher to the concepts of open science, the extent (s)he informally collaborates with members of the scientific community will be more intensive.

Research productivity and quality and formal knowledge flows

Overall, we expect that researchers who publish and receive many citations will have more ongoing research projects, personnel exchange programs and publications in co-authorship with other laboratories than the researchers of lower scientific productivity and quality. The same refers to the extent of dissemination of knowledge at scientific conferences. When it comes to publications timing and contents, it is expected that researchers with high scientific quality will publish their results without delays once the research project is completed. Also, we argue that they will be less likely to conceal information from the publication than their less productive colleagues [24]. We propose:

Proposition 9 The extent of an academic researcher's research productivity and quality will be positively related to the extent (s)he formally collaborates with members of the scientific community.

Research productivity and quality and informal knowledge flows

Interestingly, prior research has shown that those researchers who publish more are more likely to refuse requests for data and materials to other researchers. The justification lies in the increase of the opportunity cost of compliance; namely, it is probable that more eminent scientists are less likely to respond to requests due to time limitations [9-11, 16, 18, 27, 28]. Based on this argumentation we presume that:

Proposition 10 The extent of an academic researcher's research productivity and quality will be negatively related to the extent (s)he informally collaborates with members of the scientific community.

Based on the evidence presented above we have identified the conceptual model of knowledge transfer process from the perspective of an individual researcher (Figure 1). The model is controlled

for certain demographic, professional, institutional and environmental traits relating to individual researchers. It is expected that the results of the empirical study will vary depending on the researchers' gender, ethnicity, country of work, affiliation, life science field, type of research conducted, size and sources of funding. Moreover, it is expected that the degree of aggressiveness of university technology transfer policy as well as the intensity of scientific competition in the area will also affect the extent of knowledge diffusion in the life science communities. This framework should provide a useful outline of the existing literature; explain the determinants of knowledge flows in the life science community as well as direct future empirical studies on this topic.

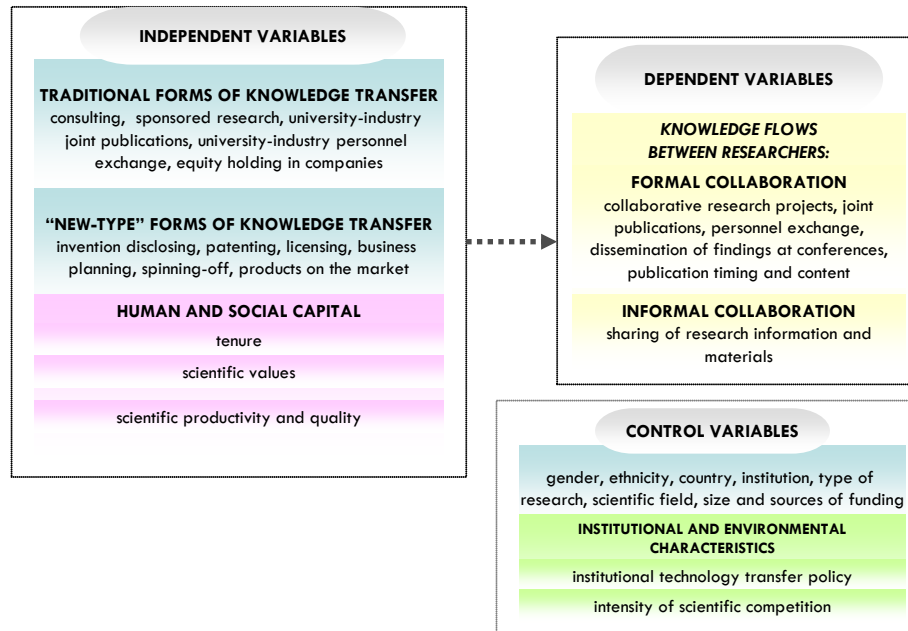

Figure 1 The theoretical model of knowledge transfer process from the perspective of an individual researcher, with dependent, independent and control variables shown.

4. Conclusion and Implications for Future Research

Researchers, public institutions managers and policy makers are increasingly interested in the impact of knowledge transfer activities on knowledge diffusion in science. Knowledge transfer has become widely understood as desirable and appropriate activity for research universities. In the same time concerns over potential negative impacts of these activities on the norms of open science have arisen, particularly because of high-profile patenting controversies regarding patenting of research tools or inputs for subsequent research as well as expansion of proprietary rights to life forms. Encouraged by increasing debates, scholars have sought to investigate whether the information flows have truly been compromised due to knowledge transfer activities, and if so, to explore the consequences of these limitations on the progress of science. The evidence from the conducted studies is mixed; thus, the majority of the questions still remains open and calls for further research.

In this paper we provided a broad overview of knowledge flows in the life science community, in which we considered both the individual and the environmental determinants of different forms of collaborative efforts among researchers. Furthermore, we expanded the existing research on knowledge transfer from academia to industry by taking into account a wide range of such activities in assessing their role in the diffusion of formal and informal scientific knowledge. Through recognizing the heterogeneity in knowledge transfer activities in a comprehensive individual-level conceptual model, we invoked the assumption that the extent of impact of knowledge transfer process on knowledge flows cannot be fully measured if the studies neglect the diversity of knowledge transfer activities or concentrate on only one aspect of knowledge diffusion. Thus, the framework developed within this research offers some new insights that should help increase our understanding of determinants of formal and informal knowledge flows in the life sciences in relation to knowledge transfer activities as well as guide prospective empirical studies.

The pilot empirical analysis is currently being conducted in frame of this study. It should result in seventy in-depth interviews with researchers from the academia and the biotechnology industry, conducted with the aim of revealing their experiences, attitudes and predictions regarding the problem of restrictions in the access to research information and research materials as well as restrictions in their formal interaction with other researchers due to their engagement in knowledge transfer activities. The in-depth interviews will also help with the pre-testing of the questionnaire developed for the purposes of empirical testing of the model. In addition, the study will be put in a cross-national context, to check whether there are significant differences in the results when researchers from ten different countries, including Croatia, Slovenia, Germany, Italy, Israel and USA, are taken into account. This represents an important contribution because so far, the majority of the published articles in the field have focused only on one country, predominantly the USA [4]. The final results of the study will shed light on the determinants, both positive and negative, of knowledge sharing in the life science communities. Previous studies have produced mixed results, with the sharing restricting factors ranging from scientific competition and logistical difficulties, to patents. Based on the obtained findings it will be possible to estimate whether the present concerns of scholars and policy makers over increasing secrecy in the life sciences have been targeting the real cause of problems.

Food Innovation - A Regional Cluster Approach

Mr. Nikos Giannoulidis¹

¹Senior Consultant, Euroconsultants S.A., Technology and Development Consultants, Thessaloniki, GREECE

Networks and clusters of innovation are frequently promoted as effective means of facilitating regional economic development. The European Commission has launched the 7th Framework Programme (FP7) initiative “Regions of Knowledge” in order to increase the overall capacity of regional players in enhancing science and technology based development.

Euroconsultants S.A. coordinated the FP7 Regions of Knowledge project RAF Regions, (www.rafreions.eu) which focused on Food Innovation in the Regions of Central Macedonia in Greece, Puglia in Italy and Pazardzhik in Bulgaria. The overarching objective of RAF- Regions was to increase the capacity of the Regions in enhancing science and technology based economic development, focusing on the Food Sector. The RAF Regions consortium comprised Regional Authorities, SME Associations, Research Entities (the “triple helix of innovation”) and Technology Consultants. The main project results were as follows:

- Identification of Food Research and Technological Development (RTD) actors and Small and Medium Sized Enterprises (SMEs) from the food sector, capable of adopting new technologies;
- Mapping and analysis of policies and initiatives for food RTD; Strengths, Weaknesses, Opportunities and Threats (SWOT) analysis of RTD capacity;
- FP7 Training regional workshops of SMEs and RTD entities; Conference “Mind your Food!”; Review of funding mechanisms available for Food research;
- Joint Action Plan for Food RTD adopted by the 3 regional clusters;
- Awareness raising about the potential that innovation proposes to the food sector; organization of 3 Joints events for SMEs and RTD actors; organization of European Conference “Mind your Food!” in Thessaloniki with more than 200 participants;
- Capacity building of Bulgarian partners: organisation of Training trips to Central Macedonia and Puglia and Follow- Up Workshop in Pazardzhik and Plovdiv;
- Dissemination of project objectives & results: Project website; Partner Search Database with ~150 registrants; Project Publications;
- Cooperation with other EU projects & initiatives; participation in Food Cluster Initiative;
- Developing partnerships with a view to furthering food RTD and innovation cooperation [new proposals submitted under FP7, Mediterranean (MED), South East Europe (SEE) and Interreg IVC programmes].

This paper discusses the RAF Regions project which provided to the regional stakeholders the opportunity to make the first steps for the development of innovation clusters with a focus on the Food sector. The main characteristics and results of this initiative are discussed and particular recommendations for similar future activities are presented.

Keywords

Clusters, Food, Innovation, Regional, SMEs.

1. Challenges for the European Food Industry

The Food Industry is the largest manufacturing sector in the European Union in terms of both turnover (approx. €965 Bn) and the number of active companies (approx. 310,000). It is also the leading employer in the EU with 4.4 million employees. Research and Development (R&D) investment of food and drink manufacturers has traditionally been relatively low in comparison to other industries. R&D expenditure (R&D investment as a percentage of output) in EU-15 has been the lowest when compared to a majority of developed countries (see Figure 1). The R&D expenditure levels are higher and continue to increase in Japan, the USA, Australia and South Korea, while EU-15 countries experienced marked levels of stagnation of approximately 0.37% in 2006, close to 2005 levels (0.38%).

R&D investment in EU and non-EU countries (€ billion)

Source: The 2009 EU Industrial R&D Investment Scoreboard, European Commission, JRC and DG RTD

Figure 1 R&D investment in EU and non- EU countries (€ billion) by productive sector (Source: The 2009 EU Industrial R&D Investment Scoreboard, European Commission, JRC and DG RTD)

European food sector SMEs face significant challenges in terms of their participation in the pan-European and global commercial competition, a trend expected to increase. Additionally, changing attitudes and behaviour in society, as well as new and emerging consumer trends necessitate constant renewal of food products and product concepts at an ever increasing pace. The food industry must, therefore, constantly innovate its processes and products in order to remain competitive and SMEs need to invest towards the adoption of new technologies, developed through research.

The European Food industry is dominated by SMEs which, in most cases, do not invest the necessary financial, human and other resources to ensure increased uptake of R&D outputs into their processes. Furthermore, the SMEs in question often lack the inherent capacity to develop their own R&D activities. Many Food SMEs confront difficulties in making the most of the existing opportunities, their awareness of the technological solutions is low or they are not well positioned to adopt R&D results.

According to the European Technology Platform Food for Life (an initiative that aims to strengthen the European-wide innovation processes, improve knowledge transfer and stimulate European competitiveness across the food chain), research in the AgroFood sector should address the following issues in order to ensure that the market and consumer needs are met:

1. Ensuring that the healthy choice is the easy choice for consumers,
2. Delivering a healthy diet,
3. Developing value-added food products with superior quality, convenience, availability and affordability,
4. Assuring safe foods that consumers can trust,
5. Achieving sustainable food production,
6. Managing the food chain, and

7. Communication, training and technology transfer, competitiveness and consumer interaction

Several trends guide food innovation in Europe. They can be divided into 15 trends, grouped together in 5 axes: Pleasure, Health, Physical, Convenience and Ethics (see Figure 2 below). At a global level, the pleasure axis continues to drive innovation all over the world. At a European level, the two leading trends are sophistication and variety of senses. The health category is equally composed of medical and natural trends.

<i>Axis</i>	<i>Trend</i>
Health	Medical
	Natural
	Vegetal
Pleasure	Sophistication
	Exoticism
	Variety of senses
	Fun
Physical	Slimness
	Cosmetic
	Energy, well-being
Convenience	Time saving
	Easy to handle
Ethics	Nomadism
	Ecology
	Solidarity

2. Innovation in the Food Industry in Central Macedonia, Puglia and Pazardzhik

The Food industry is a major manufacturing sector for the Regions of Central Macedonia (Greece), Puglia (Italy) and the district of Pazardzhik (Bulgaria), and local economies heavily depend on it for their development and prosperity. Indicatively, in the Region of Central Macedonia, Food industries constitute around 20% of the total number of industries, provide around 28% of the employment and around 30% of the gross and value added production of the overall industries in the region. This makes Central Macedonia the main producer of Food and Beverages in Greece. The food sector is of equal importance for the Regions of Puglia and Pazardzhik.

It is, nonetheless, evident that the Food sector in the participating regions is slow in the adoption of new and innovative technologies and the introduction of suitable research results in their processes (from the selection of the raw material to processing and marketing their products). There is a need to identify the needs of the Food Industry, to employ innovative actions, exploit the research results and introduce new technologies in their processes.

Initiatives have been implemented in recent years at a regional, national and European level in order to bring together R&D entities, regional and local authorities and enterprises in the Regions of Central Macedonia (Greece), Puglia (Italy) and the district of Pazardzhik (Bulgaria). However, levels of success remained low when it came to efficient uptake of research benefits by private sector entities, especially in terms of sustainable initiatives ensuring the basis for long-term and fruitful cooperation between Industry and the R&D partners. In most cases breakthrough science was not supported for the food sector because the focus has been largely centred on food quality and safety.

Furthermore, in most cases regional initiatives undertaken in view of promoting innovation and research development focused on support and development of domains such as the Information and Communication Technologies. The Food sector, although a significant contributor within the local

economies, and despite evident room for improvement in terms of the introduction of research-based benefits into operations, remained out of the spotlight.

3. The objectives of RAF Regions

The goal of RAF Regions was to increase the overall capacity of the targeted Regions of Central Macedonia (Greece), Puglia (Italy) and Pazardzhik (Bulgaria) in enhancing science and technology based economic development, focusing on the AgroFood Sector. This was to be achieved by targeting the following specific objectives:

- Supporting the development of innovative “Research-driven Clusters” in the AgroFood sector;
- Promoting synergies between regional and research policies in each participating Region, primarily by producing regional research strategies for the AgroFood sector,;
- Fostering transnational cooperation in the AgroFood sector;
- Assisting the Food sector SMEs of the 3 Regions in becoming more competitive, by adopting new technologies and solutions;
- Facilitating the exchange of best practices between the partners;
- Mentoring of the participating partners through mutual exchange of experience and best practices;
- Cooperating with respective projects in other European Regions in order to increase regional economic competitiveness through research and technological development activities in the AgroFood sector;
- Increasing the capacity of the 3 Regions to participate in the RTD Framework Programme and the Competitiveness and Innovation Programme.

4. Activities and results of RAF Regions

The project objectives met to a significant degree; the main project results were as follows:

- Identification of Food RTD actors with research potential and food SMEs capable to adopt technologies & research results: 56 RTD actors from the 3 regions were profiled and 47 food SMEs were technologically assessed;
- Mapping, analysis and assessment of policies, strategies and initiatives for food RTD in each region;
- Identification of strengths, weaknesses, threats and opportunities (SWOT analysis) of the 3 regions concerning their Food RTD capacity;
- Training of SMEs and RTD entities to enhance the participation in FP7; networking and exchange of ideas and best practices: Organisation of 3 regional workshops in Central Macedonia (Greece), Puglia (Italy) and Pazardzhik (Bulgaria), October to November '09; Conference “Mind your Food!” in Thessaloniki; Study and analysis of the funding mechanisms available for Food research;
- Regional plans for AgroFood RTD: a Joint Action Plan was adopted by the 3 regional clusters;
- Raising awareness on the project, the potential that innovation proposes for the food sector and the RTD funding opportunities available: 3 Joins events for SMEs and RTD actors; Organization of 2-day Conference “Mind your Food!”, 5 & 6 March 2010, Thessaloniki with more than 200 participants;
- Enhancing the research profile and increasing the capacity of Bulgarian partners: Organisation of Training trips to C. Macedonia and Puglia and Follow- Up Workshop in Pazardzhik and Plovdiv;
- Dissemination of project objectives & results: Development and Operation of Project website, www.rafregions.eu with more than 4246 hits; Partner Search Database with more than 150 registrants; Project Publications (brochures and flyers);
- Cooperation with other EU projects & initiatives funded by FP7, Structural Funds (SFs), Competitiveness and Innovation Programme (CIP), etc.: participation in all Food Cluster Initiative meetings, links with other projects, links with the European Technology Platform (ETP) Food for Life, etc.
- Developing partnerships with a view to furthering food RTD and innovation cooperation (proposals submitted for funding under FP7, MED, SEE and Interreg IVC programmes).

Pictures from selected activities of RAF Regions are presented below:

Figure 3 Visit to the Institute of Agrobiotechnology- CERTH during the 1st training trip in Thessaloniki, 23 November 2009.

Figure 4 Visit to PELOPAC S.A. food industry during the 1st training trip in Thessaloniki, 24 November 2009.

Figure 5 Opening of the “Mind your Food!” Conference in Thessaloniki, 5- 6 March 2010.

5. The European Food- Cluster Initiative

In order to enhance its scope and operational links with other food clusters from other European regions, RAF Regions actively participated in the Food - Cluster initiative (<http://www.foodclusterinitiative.eu/>). The Food-Cluster initiative has been launched with the ambition of involving different European Commission (EC) funded research projects within an exchange of knowledge and experiences, learning about each other's strengths and weaknesses, defining regional strategies and investing in the strengths through integral use of national and regional funding (Research Framework Programmes, Structural Funds, Competitiveness and Innovation Framework Programme, etc.) as a basis for establishing EU consortia in food science - in fact building the European Research Area (ERA) in Food. This EC initiative currently brings together 14 EC funded projects and initiatives in the field of "food science" in order to strengthen this scientific area and increase its competitive advantage.

6. Follow- up activities

Five of the RAF Regions partners will expand their cooperation in the framework of the Inno- Food SEE project which will start its operation in the next months and will be funded by the South- East Europe Programme, (<http://www.southeast-europe.net/en/>). The project is coordinated by the Institute of Agrobiotechnology of the Centre for Research and Technological Development Hellas (INA- CERTH) and includes partners from Greece, Italy, Bulgaria, Romania, Hungary, Slovenia, Serbia, Moldova and Ukraine. The Inno- Food SEE objective is to set up the appropriate mechanisms to facilitate the exchange and coordination of innovation approaches and policies for the food sector and to increase awareness on the importance of food innovation for the wider SEE area. The partnership comprises key players from the RTD and Innovation Cycle (RTD entities, industry and SME support entities, regional authorities, etc.) which have the capacity to influence the development of support mechanisms and raise awareness on the potential of food innovation.

It is also worthwhile mentioning that INA- CERTH is coordinating a regional initiative for the establishment of a Bio- Agro- Food Cluster in Central Macedonia with the objectives of improving the added value of the agricultural and the processed food products and the fulfilment of the consumer needs of specific population groups (diabetics, celiac disease patients, pregnant women, etc.). The Cluster brings together food companies, RTD institutes, technology providers, consumer associations and other interested groups and will seek funding from the national structural funds. The Cluster activities will comprise support of entrepreneurship and innovation; support of development of spin- off & spin- out companies; provision of access to high end technologies and RTD infrastructure for SMEs; RTD project funding; international dissemination and networking; marketing and branding of companies and products.

7. Main findings- Conclusions

The readiness of the regional authorities to adopt food clustering measures is considered a critical factor for success. The 3 Regions that participated in RAF Regions shared a common objective, namely the development of effective strategies and action plans to boost science and technology based economic development, focusing on the Food Sector. Although the Regions utilized a common methodology to develop their activities, their approaches were redefined, in line with individual particularities present in each region. For example, the different levels of regional integration and autonomy in decision making at the 3 Regions necessitated a different approach in the involvement of the public stakeholders. Particular SWOT and Strategic Orientation Rounds (SOR) methodologies with wide participation of stakeholders were employed to cater for this need.

RAF Regions benefited considerably from its participation in the FOOD CLUSTER Initiative. It provided a wide and systematic framework for enriching and validating the project methodologies. In addition the examples set by some of the most important and successful food clusters in Europe (e.g. the Dutch Food Valley, <http://www.foodvalley.nl> and the German Food- Processing Initiative, <http://www.foodprocessing.de/>) were valuable as an exchange of knowledge and experiences. The FOOD CLUSTER Initiative was and will continue to serve as a solid and relevant basis for establishing EU consortia in food science. It is therefore highly recommended that any clustering efforts aim to benefit from more mature schemes and network with international key players.

Securing the commitment and availability of the different stakeholders is of critical importance. A clear vision and benefit for everyone involved should be communicated from the start. The introduction of pilot actions that could bear tangible and early results may provide a good incentive for the activation of stakeholders.

The sustainability of the food cluster should be in the centre of its activities. It is important that all stakeholders (industry, RTD entities and regional authorities) invest resources in a permanent management body that would coordinate the activities beyond the limited timeframe of any EC funded project.

Innovativeness of enterprises in Kujawsko-Pomorskie voivodship as an object of interest of the Kujawsko-Pomorskie Regional Research Centre

Wiesława Gierańczyk¹

¹ Head of Kujawsko-Pomorskie Regional Research Centre, Statistical Office in Bydgoszcz, Poland, W.Gieranczyk@stat.gov.pl

Innovation and innovativeness are considered to be one of the most progressive factors in the development of the economy in XXI century, in which knowledge and the resulting technological progress are gaining significance, and the dominant factors (land, natural resources and large reserves of low-qualified manpower resources) move into further positions. This causes a change of the existing social, economic and cultural order in the world. Owing to the technological revolution, the existing barriers related to the necessity of overcoming considerable distance (sometimes the following costs), no longer have essential significance. The processes of globalization, which are one of the effects of these changes, have contributed to the transition in thinking about development from the national to the global level and simultaneously reinforced the importance of actions taken at the regional or even local level.

Innovativeness of the region is shaped by the innovativeness of the entities operating on its territory and their willingness to cooperate in the range of innovative activity. Among these entities enterprises have a special role, because in the process of producing and providing services, they introduce products, services, technologies and organizational solutions, that is to say what may signify of innovation. Above-mentioned issue is an object of interest of the Kujawsko-Pomorskie Regional Research Centre founded in Statistical Office in Bydgoszcz. The conducted researches of the dependencies between the potential for innovation and demographic and economic potential show that Kujawsko-Pomorskie voivodship belongs to regions with low potential of development, average dynamics of socio-economic changes and low tendency to create innovation. The experience of developed countries allow to claim that the regions in which ideas for supporting innovative activities of enterprises cannot be found, have no chance to be called an innovative region. Thus, the idea of Kujawsko-Pomorskie Regional Research Centre is to create a knowledge center for the region, which would help to shape the long-term development strategy for Kujawsko-Pomorskie voivodship tending to create regional innovation systems.

Keywords

innovation, industry

1. Introduction

Innovations are considered as one of the most progressive factors in the development of the economy in the XXI century, in which the importance is gained by knowledge and technological progress, followed by: land, natural resources and large reserves of low-qualified workforce. This causes a change in the existing social, economic and cultural world. Thanks to the technological revolution, the existing barriers associated with space, time and costs arising do not play such an important role as it used to be. The globalization as one of the effects of these changes have

contributed to the transition in thinking about development from the national to the global level, while reinforced the importance of action taken at regional or even local level.

Regional innovation is shaped by innovation of the transistors located there as well as their willingness to cooperate in the innovative area. Among these entities special role is played by the company because of producing and providing services, introduce products, services, technologies and organizational solutions.

Mentioned problems are the subject of research activity in Kujawsko-Pomorskie Regional Research Center, which is the part of the Statistical Office in Bydgoszcz. Analyses indicate that, kujawsko-pomorskie province is regions with low development potential, the average dynamics of socio-economic changes and a low propensity to innovate. The experience of developed countries show that the regions in which ideas cannot be found to support innovative activities of enterprises, they have no chance to be called an innovative region. Thus, the idea of Kujawsko-Pomorskie Regional Research Center is to create a knowledge center for the region, which would help shape the long-term development strategy for Kujawsko-Pomorskie province to create a context of regional innovation systems.

2. Definitions and origins of research innovation

The ideas of innovation and innovativeness were introduced to the world economic literature by J. A. Schumpeter. In his writings he pointed that, besides traditional exogenic factors, the increase in productiveness is boosted by entrepreneurs who in the face of competitors and decreasing income show inclination to innovativeness. Schumpeter's ideas, not very popular in his times, were continued by economists in the latter half of the 20th century as it was then that the shift of techno-economic paradigm took place. Innovations became specific tools and actions of entrepreneurship which gave the resources new economic opportunities (Drucker 1992). The specialist literature contains a number of definitions of innovativeness which differ in their substantive range. In most cases the definitions refer to the changes of ideas, practices or objects with which innovations or creativity based on human ingenuity are connected, as well as their successful application (Grandstrand 1999). Generally, it can be accepted that innovation is a change in products and the methods of production connected with application of some technical knowledge in the production process, which in turn leads to increase in effectiveness of using economic resources available to a given economic system (company). Thus, according to this most general definition, innovation is a successful exploitation of new ideas (Porter 1990). Seen as a continuation of techno-organizational changes, innovation includes activities from simple modifications of the existing products, processes and practices, which can be new for a given company but not necessarily for industry, to fundamentally new products and processes. Innovativeness remains a sign of implementation of new ideas into economic practice. Some authors identify innovativeness with technical progress, while others relate it to the actions which use the results of research or processes leading to applying an invention in a product or a method of production (Zarys...2006). In a classical form of definition, innovativeness means undertaking new economic activity or providing new services as a result of a new combination of production factors, new goods or new ways of distribution of goods and services (Sundbo 1998).

Similarly to classical functions of production, the main determinants of economic innovation include capital and labour. The capital means funds spent on research and development (R&D), while the labour factor means human resources connected with the R&D sector. Both innovative actions and actions which support innovation also refer to upgrading the level of education, development of infrastructure, especially of the ICT sector which increases growth and transfer of information, knowledge and skills, and increase in synergy between science, technology, economy and society. An important area which is responsible for creating positive conditions for innovativeness is the activities undertaken to protect industrial and intellectual property which supports patenting. In the international scale, the effectiveness of innovation is represented by the share of advanced technologies in foreign trade.

3. Company innovations of the kujawsko-pomorskie province

Launching the region's innovative potential is one of the biggest challenges faced by all participants in socio-economic life in Poland. The relationships between innovation and regional development are interdependent due to nowadays, regions are becoming one of the most important common ground supporting the processes of creating, absorption and diffusion of innovation. It should be noted that,

possibility of creation innovation not only depend on business but also on an organized network of cooperation which become more regional than trade (Parteka 2002). On the other hand, regional development and it's competition strongly dependent on the innovation of its resources, which gives an opportunity to generate permanent competitive advantage. As existing possibilities for economic growth such as: relatively low labor costs, the availability of cheap raw materials, favorable geographical location are exhausting, the new sources of competitive advantage must be sought. Growth's tendencies of high developed countries show that permanent development in the short and medium term could provide advantage build on the knowledge and innovation.

Figure 1 Expenditures on the 1 employed in the industry section (in thousand zł) in Poland and in Kujawsko - Pomorskie in (K - P) in 2002-2008.

Kujawsko–Pomorskie, both in terms of economic and innovative potential, do not belong to the leading regions in Poland, it is noted that in 2002-2008 the share of the region in the economic potential decreased, while the value of resources spent on innovation increased (Figure 1). As a result, the average value of inputs on one worker in 2002-2008 was about 1/3 higher than the average in Poland. The interest of Kujawsko – Pomorskie business section in introducing the innovation was shaped below the national average. In Kujawsko – Pomorskie in 2008 the percentage of enterprises that have made the expenditures on innovation was 16,9 % and was by 3.4 p.p. lower than the average in Poland. The level of innovation in this region mostly was determined by industrial enterprises. Their expenditures (expenses) on innovation activity was accounted for 98,8% of total expenditures on innovation activities in the province, but as it is noted by Domański (2001) the changes in industrys' structures, rapprochement to the consumer, less standard and more flexible production during postfordyzm time, have made the innovative activity in the industry similar to the innovative activity in the services sector. Accordig to Cappelin (2004) industrial innovations has its own characteristics, which unlike to "scientific" innovation are not a formal and intended effect of the planned research process conducted to develop new product or services. It stems rather from the informal "searching" or the long-term knowledge exchange between interdependent entities.

Figure 2 The participation(share) of industrial enterprises, which have introduced technological innovations in Poland and in Kujawsko – Pomorskie in 2002 and 2007.

The studies indicates that in the first decade of XXI century industrial enterprises in Kujawsko – Pomorskie, as in Poland, more often introduced process innovation rather than product innovation, but the share of industrial enterprises which have introduced technological innovations in Kujawsko – Pomorskie decreased as well as in Poland (Figure 2). During the study period primary there was a limitation in introducing innovation, which were new from the point of view of the market. In 2008 this type of innovative activity showed only one in ten company, which seems to be insufficient , because the necessary condition for the development of every company operating in a saturated and demanding market is a successful introduction of new and very modern products. Their creation is the essence of today's business innovation activities and guide their development, and knowledge that arises in innovation process became crucial to achieving and maintaining competitive advantage by business (Żmigrodzki 2006). Results of tests which were carried out in two hundred U.S. companies indicate that the benefits generated by new products in the years 1976 – 1995 XXI century have doubled and are getting higher (Zimonik 2003). However, the introduction of a new product is expensive. Costs are mainly generated by research and development, where in result the ideas are materialized. Meanwhile, in Kujawsko – Pomorskie the expenditures spent on innovation were mostly located in fixed assets (91,5% - Figure 3.) which, like the average in Poland, were mainly earmarked for the purchase of machinery and equipment.

Figure 3 The structure of use the expenditure on innovative activities in industrial enterprises in Kujawsko- Pomorskie and in Poland in 2008 (a-research and development (R&D), b - acquisition of knowledge from external sources, c - the purchase of software, d - investment in fixed assets in general, e - staff training, f - marketing associated with the introduction of new or significantly improved products).

Such a structure of use the resources intended for innovative activity indicate that companies try to reduce “the technological gap” by using the external material technology, which allow them to modernize machinery and introduce the innovation process (Gaczek, Stryjakiewicz 2008), wherein Kuyavian – Pomeranian entrepreneurs more often than average in Poland have benefited from the technical achievements, which were developed abroad. In 2008 the value of imported machinery and equipment was accounted for almost 60% of the total funds allocated for this purpose. An important group of expenses on innovation in Kujawsko – Pomorskie were connected with buildings and lands. For that purpose allocated 33,1% resources for innovation, ie. 5 pp. more than average in Poland.

In the province Kujawsko – Pomorskie invested in the purchase of new technology in the form of documentation and rights in a lesser extent than the average in Poland, marketing for new and improved products and personnel training related to innovation activities, although spending on the latter two positions have increased significantly.

There should be paid a special attention that since 1999 in the structure of the expenditures on innovative activity in industrial enterprises, both in Poland and in Kujawsko – Pomorskie, the share of expenditures on R&D in overall expenditures on innovative activities is small and steadily decrease. Small share of expenses on R&D and large share of expenses on investments in total expenditures in investing activity indicates that generally Kujawsko – Pomorskie does not create innovation, but adapt already existing solutions. Observed tendency to reducing the share of expenditures on R&D is a negative phenomenon, because it is generally recognized that the most effective way to economic progress are skillfully directed and used in development of technology science researches. The stimulations of scientific research are the subject of any modern innovation policy in every region and state. On one hand scientific and technical achievements are a valuable and south-after commodity in the world, which can be a source of significant incomes such as sales of licenses, know-how and technology, on the other hand material products produced by industry, and incorporating modern technological thought, are among the most attractive products on the market, especially in the foreign trade. The ability of companies to use the results of research and development works in the form of introducing new and modern goods and at the same time improving the products already produced provides a competitiveness of the economies in the international arena. This ability, as it says Bossak (1998), largely depends on the level of development the innovation system, that is mechanisms, structures and connections between public and private institutions, domestic and foreign, which

guarantees the rapid flow of information and capital needed to implement new technical and organizational solutions.

The most commonly used measuring instruments of the effectiveness innovative activities are patents and sales of new and improved goods. Patent statistic is used to measure the results of innovative activity that create the most desirable innovation, which are new in the world. Kujawsko – Pomorskie in the field of industrial property protection is rather at the end of the list of provinces. Patent applications, patent designs, patent obtained and given protective rights are around 5% of their total number in the scale of Poland, and there is no clear trend to change this situation. In 2005 from Kujawsko – Pomorskie reported on average 36,3 inventions per 1 million inhabitants, while in Poland reported on average 53,1 inventions per 1 million inhabitants.

Figure 4 The share of net revenues from sales of innovative products in the net revenue from sales of industrial enterprises in the total in kujawsko-pomorskie province and Poland in 2008 (a - total b - innovative products for the market, c - just innovative products for the enterprise, d - innovative products for export, e - innovative products for the export market.)

Analysis of the economic impact of innovation, measured as a share of revenues from sales of innovative products in industry in kujawsko-pomorskie province indicates that, in 2008 there were more innovative than the average in Poland but mainly decided by the only innovative products for the enterprise (Figure 4). This means, that innovative activity was only a consequence of emulating existing ideas and solutions. Revenues from sales of innovative products for the export market accounted for less than 2% of sales.

Beside low activity in R&D, shortcoming of industry in kujawsko-pomorskie province is, low tendency to cooperation in innovation area. In 2008 innovation's cooperation indicated less than 7.3% companies', including 3% small's and 39.1% of large's'. Lack of developed networking cooperation as well as communication and interaction in the triangle: education, business and administration are the conditions without which it is difficult to start a mechanisms of competitiveness based on innovation.

4. Summary

Regional innovation is shaped by innovation of the transistors located there as well as their willingness to cooperate in the innovative area. In time of knowledge-based economy region ceases to be associated only with physical space, regarded in traditional economic theories of location in terms of

cost of land, capital, labor and transportation costs. It is started to be perceived as a form of organization, reducing uncertainty and risk, which constitutes a source of innovation, accumulation and transfer of knowledge and skills (Pietrzyk 2003). Numerous studies indicate that the ability of regions to assimilate and transform local resources, including knowledge in effective economy is varied. Also, the creation of innovative capacity of the region is complicated and lengthy process, requiring a comprehensive and dynamic view, depends on a number of the social, cultural, economic and organizational conditions. The research Rodriguez-Pose'a (1999) shows that absorption of innovation is inhibited by factors as: the gap between economic and social sphere of life, rigid labor markets, lack of high-skilled, low participation of women, or aging of the economically active population.

The studies of the relationships between innovation, demographic and economic potential indicate that Kujawsko-Pomorskie province belongs to regions with low development potential, the average dynamics of socio-economic changes and a low propensity to create innovations. Referring to the typology of the results presented by A. Kuklinski, and supplemented by Z. Rykiel, we can conclude that Kujawsko-Pomorskie province is imitated region to which the innovation reaches with a considerable delay, and in which are rarely adapted to local peculiarity. The main centers of innovation are the foreign companies that generate the import of foreign machinery and equipment. They also bear the highest spending on R&D. In other companies the resources devoted to R&D are far too low in relation to the needs of an innovative economy and constitute a serious barrier to improve innovations in the region. Kujawsko-Pomorski Centre for Regional Studies in the Statistical Office in Bydgoszcz in the face of the situation presented indicates the need to create a platform for cooperation and information exchange between the sphere of administrative, scientific and economic situation in the Kujawsko-Pomorskie province, which will contribute to strengthening the innovative capacity of the region based on their specific circumstances and supremacy.

ICT System re-engineering as a change initiative

Ljupco Gruevski¹

¹Pro grupad.o.o., Bitola, Macedonia, pro_grupa@t-home.mk

In the beginning, a long, long time ago, almost 20 fiscal years before the present day, three types of companies existed: those making things possible, those just looking around, and, those asking what is happening. Nowadays, only two types exist: those changing themselves and those that disappear. In this way, even “the future isn’t what it used to be”!

Most Macedonian SMBs, both successful and disappearing, have ICT systems built over the course of many years, with solutions based on procedures and rules established by the owners in the very early days. Also, a bunch of equipment and software is present, de-organized and broken up in islands of data and applications.

The lack of managerial knowledge and structure results in managers tired of working both as executives and as decision makers on all levels, or concurrently filling the roles of general manager, general engineer, secretary, driver and many others.

Today companies focus on streamlining operations, acquiring customers, increasing revenues and profitability and outpacing the competition. And while your company has continued to improve its operating efficiency (sometimes by quickly learning from past mistakes), you feel it should be spending more time analyzing what’s going on and predicting and planning for the future, rather than having employees constantly run around trying to solve operational problems based on past experience and putting out fires. In a world where business agility – the ability to quickly and efficiently adapt to changing markets, competitive actions, regulatory and legislative mandates, or other challenges – is a hallmark of successful organizations, information technology plays a critical role. In fact, the role of IT systems has become interwoven with how organizations operate, enabling significant productivity and efficiency improvements.

The re-engineering of ICT systems is a revolution – at some point companies must change many (or all) of their components (hardware, system software and applications) because of technological advances. Even though the computers (or other devices) themselves are working fine, the requirements of Internet, e-banking, e-business and all other e-things, are an absolute necessity. Even in the situation of a malfunction or breakdown, replacing hardware or software with an identical part is almost an impossible mission. Each project for re-engineering of an ICT system involves all business processes. Creating new hardware, software and communication solutions requires the participation of not only top management, but all levels of management, and, more importantly, the intimate knowledge of all processes, procedures, reports, etc. The first checkpoint is here – companies have two choices:

- the new system will be an exact replica of the old system, i.e. will follow the already established workflow in the company, or
- the new system’s solutions will provoke changes in business processes, procedures, reporting systems, etc., which means synchronized changes in the company structure.

These choices are the same regardless of whether the change of the ICT system is done at once or gradually during some period. In this paper, we are going to present a few cases from our portfolio. There are both successful and unsuccessful projects. In addition, an analysis of success factors and reasons for refusal is provided.

Many of our SMBs are eager to change themselves, to find an escape route from the current situation. They all know that change is not only initiated by the market – each company must change itself during its natural period of growth – it is change by evolution. However, many of them also do not know how or do not have enough

internal power to do these changes. ICT system re-engineering could really be the right way for most of them to do the necessary changes. Innovation could start here.

Keywords

re-engineering, ICT system

1. Introduction

In today's fast-paced, highly competitive world, change is inevitable. Organizations must respond to change to remain competitive and customer focused. Change is not only driven by forces outside the company, from enhancement requests to bug reports. It is also driven by economic, organizational and regulatory changes.

It pays to work smarter, not harder. According to a recent study of the IBM Institute for Business Value, organizations that are significantly outperforming their industry peers also happen to be making more headway on newer approaches to work. They are using dynamic, collaborative and connected ways of working to get things done effectively within a constantly changing environment. However, most organizations are not yet meeting their ambitions in these areas. For those at the forefront and those lagging behind, this research offers insights into the critical practices and technologies that are fundamentally changing the nature of work.

Organizations today have no shortage of data, but many lack integrated information and insights they can easily use to execute their business processes. Even more information is produced as processes and systems – both natural and manmade – become increasingly instrumented with billions of sensors and smart devices at work. Businesses need a strategy for making sense of it all. Information must be delivered in context to the people and processes that need it.

2. Why changes in the IT system mean business model changes?

Visibility into IT is no longer an IT thing. It is a business thing. Accurate, up-to-date, easily accessible insight into the inner workings of the IT environment yields improvements across a wide range of IT functions that have a direct impact on business success.

Almost every function of every business subject exists thanks to IT system support.

According to this, all changes applied on IT system mean changes in the company's business model. That's why we stressed that even a simple request for IT system enhancement, should (or will) cause big structural changes in the company model – changes requested by a "new reality" present on the market, changes which management and the company itself could not have initiated or done.

Internal IT systems must also fulfill necessary standards and provide the level of flexibility and adaptability to change that are required by new technologies.

The problem is that the communications for implementing change often come from various sources and in many different formats, including change requests, defects, bug reports, enhancements requests and problem reports.

Change data is generally managed using standard tools (such Excel sheets), but, even more frequently, the data is described in e-mail threads, phone conversations and staff meeting minutes.

In addition, many organizations lack a common process and supporting products for handling change requests because they appear to be overly expensive. Some change management systems are costly to maintain – you must implement processes, document workflows, automate reporting and integrate the change management system with other IT systems.

With an enterprise change management (ECM) solution, organizations have a major opportunity to reduce operating costs while managing change effectively and efficiently.

3. Re-engineering instead of consolidation?

IT systems, if we could even talk about systems, at our SMBs are built during long periods according only to the current need and budget. Most of them do not have system architecture, dedicated server, backup or security procedures, etc. Usually, there are few, sometime tens of PC desktops and

laptops, a local network, a file server computer and some resource sharing. According to our experience, most of this equipment is usually more than 5 years old.

IT systems consolidation is a process of resource optimization, replacement of ineffective components with new, sophisticated ones. This process often aims to obtain better ROI, system usability and efficiency, and, of course, lower maintenance and support costs.

Re-engineering is a process of designing from scratch: completely new hardware, network and system software configuration, new or enhanced applications, new working procedures, a new level of required knowledge and skills.

In natural language, consolidation is evolution, whereas re-engineering is a revolution.

The re-engineering process should promote a new dialogue between business itself and the IT system, striving to speed up deployment of mission-critical IT solutions while demanding that ongoing IT operations improve resource utilization and make staff more productive.

With the burgeoning availability of cloud computing services and enabling technologies, IT decision makers can take full advantage of these architectures both on premises and over the Internet, making the security, performance, and cost decisions that are the most appropriate for their specific performance, security, and business resilience requirements.

Today's business is conducted across highly connected environments where geographic borders and time zones blur and business transactions flow 24/7. To make informed decisions, executives need real-time access to accurate information about products, customers, markets, and competitors. They need to extract the utmost value from every investment by maximizing resource utilization and holding down cost.

A decade of IT-enabled innovation has significantly contributed to the establishment of highly fluid and dynamic business environments. The Internet and mobile computing allow employees, contractors, and partners to work as virtual teams – anywhere and anytime. Simultaneously, embedded computing and smart sensors permit organizations to track, route, and optimize types of resources on the fly.

For business to succeed in today's competitive real-time markets, senior executives need IT teams to speed up all aspects of IT solution provisioning, reporting and operations. In a recent IDC survey (Fig. 1), senior business leaders stated that the top messages they want to communicate to their own IT leaders are:

- increase speed of IT project delivery
- improve access to information
- develop more innovative ideas
- improve IT support

Most Important Messages That CEOs Want to Impart to CIOs and Senior IT Managers

Note: Multiple responses were allowed.
Source: IDC's Enterprise Panel, 2008

It goes without saying that senior business leaders want IT to ensure that the technologies, processes, and management tools used to deliver business services are secure, compliant, resilient and cost-effective. Those solution attributes are table stakes needed for any kind of IT investment to be considered in the current global economic environment.

4. What triggered these changes?

It is very important to find what the main reasons that triggered the changes are. Our analysis shows that the most common are:

- problem escalation (hardware or software malfunction is in more than half of all cases)
- software problems (unlicensed software, application changes or upgrades, data loss...)
- communication issues (accessing bank accounts, government institutions, distant locations, Internet....)
- legal obligations (personal data protection, data exchange, data storage....)

These conclusions are based on our more than 25 years' experience in IT systems design. During the last few years, we have been preparing case studies both for successful and not so successful projects. We intentionally do not use the term 'unsuccessful projects' because there is no such IT project - what is unsuccessful is the business itself. The IT system always works: sometimes fully supporting the business processes and sometimes failing and possibly causing damage or even total destruction.

Many years of mindset evolution was needed to reach today's situation described in the next chapter. Not so long ago, the major problem was to exclude the general manager or business owner from the design phase of the process. Our SMB's owners want to make the decisions in each step of every situation, ranging from core business process to buying hygienic supplies.

We (the IT business community in general) have spent a lot of time explaining that "finding solutions at the speed of light", ordering new products or services by mobile phone, because "business will stop" since "there is some main board failure" or something similar, is not the right way at all. However, many of us keep working this way, trying to make some profit in situations where business has problems. The truth is that nobody is satisfied after such deals.

Before any further action, we must slow down the whole process. Yes, there could be very urgent or very important matters, among which the above-mentioned reasons, that must be done in a few hours or during the working day. We should not ignore them and we must find a temporary (or sometimes final) solution. However, immediately afterward and no later than the next workday, we must approach the manager or owner with an offer for the right solution, following the process described below.

Slowing the process down does not mean that we want to ignore the customer's problem. Completely the opposite – this will show our devotion to find the right solution, because the business bottom line – the one that really counts – only benefits when money is invested productively in *doing* business, not proposing it.

5. Change process

The changes need to be implemented in several steps.

The first step is the appointment of a Change Advisory Team (CAT). The main duty of this team will be advising the company management (most often in our SMBs – the business owners) about the "new reality", and the changes that have to be made. This team should compensate for the lack of company IT manager and department, or a dedicated IT decision maker – role(s) that our SMBs usually outsourced, or which general managers (aka owners) used to "play".

The team should consist of three to five members: one top management individual (not the general manager or owner) as a team leader, representatives of major company parts, and mandatorily at least one external person in the role of technology and business consultant.

The role of this team will be to complete a system diagnostic process that will result in:

- an overview of the current situation in terms of hardware, software and human resources
- a detailed overview and analysis of the current needs of the IT system's users
- definition of the differences between the current and the desired state of the system
- a strategy to resolve these differences
- contact with suppliers in order to obtain information, budget offers and other data from the IT market
- a project solution containing a method, resources and a schedule of activities required
- a budget proposal complete with specifications of the required equipment and services
- an upgrade strategy detailing development of the IT system over the course of the next 3 to 5 years

The second step involves the presentation of the proposed solution to the firm's top management and a reality check to determine whether the solution really fixes the underlying problem. This step should entail several meetings in which all aspects of the solution must be considered in detail. The result of this activity is the creation of a Change Implementation Strategy – a document that will demonstrate the actual needs of the company. A mandatory section of the document is the Needs Specification, containing required equipment, services and everything which is to be outsourced: hardware, software, services.

The third step is the collection, presentation and evaluation of offers by the CAT. The CAT then needs to compile a short-list containing the best two or three offers that will earn the chance to be evaluated by the actual top management.

One very fresh approach is to create a case study for each of the preferred solutions and build a framework for measuring ROI. It is a multi-step process that will produce standardized reports and will ease the evaluation. To create a business case for any investment and select the right option, organizations should follow a 7-step process:

- Describe the business challenge
- Assess the potential benefits of the investment
- Assess the potential costs of each option
- Assess risks and issues that might arise during the implementation
- Recommend the preferred solution
- Describe the implementation approach
- Measure potential and actual ROI

By following this 7-step process, organizations have the tools they need to precisely measure the value of any investment to their operation and to compare all solution alternatives. They can also use this analysis as the basis for estimating potential ROI prior to the investment — and actual ROI results after implementation.

During the fourth, final step, the CAT needs to recommend the best solution using the conclusions drawn from the individual offer presentations. This recommendation should contain:

- a procedure and timeframe for the solution's implementation
- the required funds and method of payment
- a recommendation for the creation of a Steering Committee (SC) – a body which will take over the responsibility of implementing the chosen solution

In practice, it is common for two different companies to be involved in the realization of the project – one in charge of infrastructure (hardware, system software, network and other communication equipment) and the other in charge of the application software. In such a scenario, two SCs must be formed. No more than three individuals should take part in each SC: one or two representatives of the IT project customer and one representative of the IT company in charge of that part of the project. If the project solution is of significant value or if it is deemed necessary, the CAT consultant may be included in place of a second company representative. Considering that the basic task of the SC is to coordinate and control activities at the highest level, the members of the company may be the same in both SCs.

The SC has to insist from the very beginning that all activities undertaken as part of the project have to be defined by industry standards, procedures and timeframes in accordance with the chosen solution offer.

At a glance, the procedure detailed above may seem unnecessarily complex and overly bureaucratic. However, in reality both our SMBs and their IT service suppliers work at 'the speed of light' from the very beginning, discussing solutions over the phone and with no paper trail or signed contracts. In this situation, it is completely normal that neither party is satisfied with the end result – neither the customer has received what they actually asked for, nor the IT company made any profit, often ending up at a significant loss due to wrong assessments and the delivery of inadequate equipment as a cost-cutting strategy.

In this way, the main trend in the business world today – the use of complex IT solutions (such as ERP software) and their components could be integrated in current SMBs. Although this seemed impossible due to the low budget SMBs have at their disposal for IT projects, recent technology advances have brought prices down, opened the market to a number of "small" players and shifted the focus of large IT companies toward the huge number of SMBs in need of solutions. This is a completely logical and expected turn of events since large companies such as banks, enterprise

companies and corporations have not only already solved these problems, but in fact are not even thinking at this level.

High technology's availability (hardware, software and services) in terms of price does not automatically make it available for direct and simple implementation. Nothing has changed in the conditions necessary for deployment and use of such advanced solutions, but this is in fact the best part! Some of these conditions and requirements are:

- completion of a diagnostic process which will determine the current state of the system, current and future needs and the most suitable products and solutions
- well-defined company structure and existence of a decision hierarchy
- well-defined procedures
- delegation of authority

These and other conditions must be fulfilled in the everyday functioning of the SMB – some before using the new technology, but all during the implementation process.

The existence of an outside consultant – commonly regarded as a waste of money by SMB managers and owners alike – is actually a fundamental need for the success of the project. Although the cost of the project will probably increase by 5-10%, the benefits of having a consultant are numerous:

- takes the burden of boring market research for compliant solutions off company management;
- company management is no longer responsible for the numerous meetings and presentations by IT service providers and the evaluation of their offers;
- the consultant's neutrality will inject the necessary objectivity into the decision process, ignoring possible personal and business relationships between the company employees and the IT companies or their representatives

Apart from these roles, the consultant may also act as a catalyst. What does that mean?

No one likes change, neither in corporate America, nor in developing economies. However, change is sometimes necessary and the consultant may be brought in to "start rolling the ball". In other words, the consultant may make decisions without taking into account company culture, employee morale or other effects of changes in the company.

The consultant should be employed to bring the necessary objectivity, since who could better identify possible problems than an individual who has experience gained in numerous IT projects? A good consultant provides a new, objective viewpoint on the problem, without regard for employee opinions on the subject.

The consultant may be employed to train – especially if he or she is an IT consultant.

The consultant may also be employed to do the "dirty work". Let's be realistic: no one wants to be the person who imposes new, stricter rules, additional work or is responsible for firing employees or eliminating entire departments.

The existence of a consultant will be a replacement for mid-level management, which is generally missing in our SMBs. Successful SMBs have a huge need for the inclusion of this level of management, which will reduce or even eliminate the connection between workers and top management. When the consultant leaves the company, he will create a perfect situation for the implementation of such a management level, making his presence justified and beneficial both financially and in business terms.

7. Conclusions

Innovation is the only path out of a crisis. Large companies have an advantage over smaller ones in such a situation, since SMBs have neither the means nor the capacity to innovate. Even when a minor company has an idea for a new product or service, it will be easier for the large company to buy the idea or even the entire company than for the small company to materialize their idea.

A well-designed and functional IT system can provide SMBs with more time, better financial management, easier access to information and excellent opportunities to conduct market research and testing in order to easily commence and commit to the development of innovative solutions and products.

Change is inevitable, but refining the ways that your organization responds to change represents an opportunity for competitive advantage.

Poorly managed change is the main cause of more than 50% of all problems causing delays or decreased productivity. Only a structured and well-supported process of change management,

augmented with automation wherever possible, can enable a company to effectively slash costs and risk caused by change while increasing overall business performance.

In this study, the Entrepreneurship Activity Rate in Syria has been analysed, the related characteristic in general, and the distribution of the entrepreneurs across the five different regions of Syria. Additionally, the paper concentrated on the regional disparities in term of entrepreneurship since there is a vast imbalance regional development. The study analysed the main factors determining entrepreneurship in Syria.

The main results of the paper show that the age and level of education, training on starting a business during primary/ secondary schools or after completing education, household income and gender are the main determinants of entrepreneurship in Syria. When we control the above variables the region factors will be insignificant.

- 3- GEM, Global Entrepreneurship Monitor
- 4- TEA Rate, Total Entrepreneurship Activity Rate

1. Introduction

Syria is in the middle of the transformation situation toward social market economy. Part of this transformation process is to enhance the entrepreneurial spirit to lead to innovative and competitive economy.

In this regards, the government had adopted some initiatives to create an enabling environment for entrepreneurship to accelerating the capabilities of entrepreneurs. For instance, the entrepreneurial curriculum had been integrated into the official education curriculum of the Ministry of Education in vocational schools and intermediated institutes (2007 to present).

This study analyzed the Entrepreneurship Activity Rate in Syria, the related characteristic in general, and the distribution of the entrepreneurs across the five different regions of Syria. Additionally, the study concentrated on the regional disparities in term of entrepreneurship since there is a vast imbalance regional development. For example, most of poor people are living in East Region, and the industry is concentrated in the North and South Regions, etc.

The main two questions of the study are: 1) what are the main factors that determined the entrepreneurship in Syria? 2) Is there a significant difference of entrepreneurship among regions in Syria?

The study will use quantitative analysis to describe the current entrepreneurship characteristics among regions in Syria. This study depends on the available dataset of the Adult Population Survey (APS) of the Global Entrepreneurship Monitor (GEM) that was administered across the 52 GEM countries, in 2009. The researchers used the SPSS software to analyze the available datasets.

2. Literature Review

Schumpeter (1942) referred that entrepreneur "can no longer be seen as the sole vector of innovation" but innovation would in fact mainly be through managerial business owners who direct big companies, yet, their activities are restricted to routine work Wennekers and Thurik (1999). Accordingly, many studies show that innovative activities are affected by the size of firm. Some advocates that small and entrepreneurial firms contribute significantly to total innovation (Feldman and Audretsch 1999), others argued that large firms tend to have innovative activities than small businesses (Cohen, 1996). Other researchers underlined the role of institutions that direct ownership, knowledge production and knowledge diffusion and its interface with entrepreneurship (Braunerhjelm, 2010).

Other studies have shown the role of "traditional determinants" on decisions to innovate, such as the characteristics of firms, market structures (concentrated markets), the degree of openness to foreign trade, technology transfer and the degree of exposure to foreign competition in the domestic market, skills in, human resources have been identified in various studies (Baldwin and Johnson, 1995). Other studies assumed that "monopoly power" helps firms to acquire the products of innovation, while, others have supported competitiveness (Arrow, 1962).

The different entrepreneurship theory, explain entrepreneurs as the ability to recognize and utilize opportunities what and where these opportunities might exist. Regarding entrepreneurship that refers to a set of abilities embodied within an individual, rather than those who starting a new venture; self-employed consists of a very mixed group may involved in creative entrepreneurial activities, but it could just also be job creator, (Blanchower, 2000).

Alternatively, related measures of entrepreneurship are density of firms (Klapper et al 2008), or business ownership (Carré, van Stel and Thurik 2002). Net birth rate has also been suggested as an indicator of entrepreneurship (Dejardin 2008).

The most commonly defined determinants of entrepreneurship at the macro-level in the literature are the level and growth of GDP, unemployment, investments, cost levels, inflation and the interest rate level (Bosma et al, 2005). Also factors like government spending on education, infrastructure and health seems to be positively correlated with start-ups (Reynolds and Storey, 1993). Specifically, human capital (education) seems as one of the basic variable which explains entrepreneurship (Kim et al 2006), which is important for exploiting an opportunity. Human capital refers to qualified workers who rise above barriers such as getting credit, as well as improving network.

In addition to regional differences, Braunerhjelm and Feldman (2006), had presented positive effect of concentrated environment on the location of firms and entrepreneurs. This include, access to finance and services, better flow of new business ideas, larger markets and less fluctuating in demand, lower entry costs, access to knowledge, skills, density, opportunities, networks, (Nijkamp, 2003), low fixed cost industries (Glaeser and Kerr, 2009), which are very important for innovative and entrepreneurship.

In the previous literature there are many references to demand and supply side determinants of entrepreneurship (Koster and Karlsson, 2009) is likely to be a consequence of local norms, traditions, unexpected events, (Glaeser and Kerr 2009).

The aim of this paper is to find out the main determinants of the entrepreneurship activity rate in Syria and to investigate if there is a significant difference of entrepreneurship among regions in Syria.

The following section is a background about Syrian economy including demographic, employment, unemployment, education level and the economic activities among regions in Syria.

3. Background about Syria

The total number of the Syrian population (who live in Syria) had increased from 13.8 million in year 1994 to 20.4 million in year 2009 although the population growth rate was decreased from 3.3% between "1981 to 1994" to 2.45% between "2000 to 2009", yet it is considered as one of the highest growth rate worldwide. The increased population had associated with the increased population in urban areas out of total population (43.5% in year 1970, 47% in year 1981 to 53.5% in year 2009),

which indicate the internal immigration to big cities in Syria such as Damascus, rural Damascus and Aleppo (CBS, 2009).

The highest percent of employed population is in the southern region (30%), middle region (26%), and northern region. The employment status is varied by educational level. The highest percent of employed population in Syria is the elementary level of education 40% while university and more is 9% (per each). Among each region, the highest percentages of employed people with secondary, university and more are in the coastal region (17%, 14% respectively), compared to other regions.

Moreover, the disparity among regions is noticed regarding the percent of employed population with elementary level of education and less which is high among eastern region (74%) out of total educated population in this region, compared to the lowest which is among population in coastal region 37%.

Further regional distinction is observed regarding the distribution of employed population among sectors. Commonly, on national level, the distribution of employees is high among service sector (26%); then among the industry, building and construction, hotels and restaurants sector (16%, per each); agriculture (15%); transportation (8%) and the lowest is the insurance and real estate sectors (2%).

Among each region, the highest shares of employees in the north region are in the industrial sector (19%). While the highest share, in the eastern and the middle regions region is the agriculture sector (30%, 21% respectively). Whilst, among the coastal region the service sector is constitute the highest shares of employees (22%). Whereas, the south region represents the highest shares of employees in insurance and real estate sectors (19%).

We can conclude that the descriptive analysis of statistics among the five regions in Syria reflects clear differences regarding the population distribution, household expenditure, and employment concerning to education levels, unemployment rate, and the distribution of employed population based on the economic activity. In the following section the paper will illustrate further disparities in Syria concerning the characteristics of the Total Entrepreneurship Activity Rate (TEA Rate) based on analyzing the GEM APS data, 2009.

3.1 Entrepreneurship in Syria

The TEA rate in Syria (8.5%) is low compared to other factor-driven economies (FDE) (17.7%) and other MENA countries (12.6%) that include: Algeria, Jordan, Lebanon, Morocco, Palestine, Saudi Arabia, Tunisia, UAE and Yemen (GEM MENA Report, 2009).

TEA Rate is the sum of the Syrian adult population who were actively trying to start business (3.4%) and who were owners of new business (less than 42 months old) (5.1%) (GEM MENA Report, 2009). This rate is low compared to FDE (averaging 17.7%) and the comparison MENA countries (averaging 12.6%).

Furthermore, only 6.7% of adult Syrians were owners of an established business (more than 42 months old). This is a less than the average of FDE (8.9%) and the MENA comparison countries (average 7.8%), where Syria ranked sixth of the ten.

The Syrian business discontinuation rate (7.4%) is about average among factor-driven economies (6.9%), while higher than the average of both efficiency-driven (4.9%) and innovation-driven (2.5%) economies. Due to personal reasons, most of entrepreneurs discontinued their businesses in Syria; the second most common reason was due to the unprofitability of the business. Problems getting financing, often cited by Syrians as a main barrier to establishing a business, was the third most common reason (only 14%).

GEM data, reflects the entrepreneurial gender gap in Syria which mirror the employment gender gap in the labour force. Female participation rate in the labour force in Syria is relatively low, 14% in 2009 as compared to 71% among men (CBS, 2009). Similarly, the TEA rate for males was about 13.6% to 3.1% among females. This places Syria the country with the largest gender gap in TEA among the tenth MENA countries and FDE after Saudi Arabia (APS, GEM 2009).

There is little difference in the distribution of entrepreneurs between urban and rural areas (8.8% in urban areas compared to 8.0% in rural areas). While entrepreneurship activity in rural areas is more likely to be necessity-driven than in urban areas, these findings are not statistically significant. Moreover, on gender level, the difference is not significant among men, 13% in urban versus 14%; in rural areas. However, rural women are significantly less likely to be engaged in early-stage entrepreneurial activity than their urban counterparts (1.8% as compared to 4.2%). The findings might be due to any number of factors, including differences in business opportunities and more conservative attitudes towards women's work in rural areas. The findings should be examined further.

Syria is a fairly young society. The demographic distribution in Syria shows the highest share of the population to be the 25-34 year-old age group (CBS, 2009). Interestingly, the highest TEA rates in

Syria are among these same young adults aged 25-34 (10.8%). This rate is only slightly higher than among 18-24 year olds and 35-44 year olds. After age 40, entrepreneurial activity rates drop sharply to around 5%. TEA rates in factor-driven economies exhibit a similar pattern, with the highest rates among the 25-34 year-old age group. The main difference is that TEA rates do not drop as sharply after age 40-44.

In terms of gender, the correlation between age groups involved in entrepreneurship varies significantly. Young male Syrians aged 25-34 are more active entrepreneurs than males in older age group (35-64). The analysis indicates that the correlation is significant yet, this result indicates the existing of endogenous factors that impact the relation between the age group of males and their intention to start their own business.

The education level is yet another characteristic to be explored; the higher the educational level, the more likely adults are to engage in entrepreneurial activities. The share of entrepreneurs among those who graduated from college is twice as high as the share among non-educated Syrians.

The association between higher levels of educational attainment and entrepreneurial activity holds for both men and women. However, the difference in the TEA rates is especially high between women with lower than a secondary education and those with a secondary or post-secondary degree.

Consistent with overall GEM patterns, TEA rates in Syria increase with household income, from 4.1% in the lower-third income group to 12% in the upper-third income group. This pattern holds for men. For women, the TEA rate is highest in the middle-third income group.

To summarize, the preceding described activity components of entrepreneurship concludes that the TEA Rate is low compared to other similar economies and MENA countries; the low TEA among women compare to men mainly in rural areas; the higher educational level the more TEA Rate. Also it concludes that the low TEA Rate in Syria is likely due to institutions issue such as: the government policies and support, access to finance, awareness about the regulations related to business world.

In the following section, the paper report will illustrate the main determinants of TEA Rate in Syria and the innovation determinants depending on analysing GEM Syria APS 2009 survey.

4. Methodology

This paper analyses the data of the GEM Adult Population Survey carried out in 2009 in order to measure the level of Total Entrepreneurship Activity (TEA) Rate. It surveyed 2002 respondents aged between 18 to 99 years old. The sample has been weighted by population aged 18 to 64 years old.

4.1. Model specification

The paper tried to explain the main determinants of the TEA Rate using the following potential determinants: levels of education, received training about starting a business during primary or secondary education, or after completing education, income household level, age groups, and the gender of the respondent.

However, this study tried to investigate the main determinants of innovation based on some indices that were extracted from the following variables:

- How many (potential) customers consider product new/ unfamiliar? (1= all, 2= some, 3= none)
- How many businesses offer the same products? (1= many, 2= few, 3= none)
- Were the technologies or procedures available more than a year ago? [1= Very latest technology (newer than one year), 2= New technology (one to 5 years), 3= No new technology (more than 5 years)]
- Technology level of the sector: (1= No/low technology, 2= Medium technology, 3= high technology)
- Technology sector: (1= indication, 2= no indication)
- The analysis showed that innovation indices were not significantly correlated with the TEA Rate.

This result suggests the need to do deep investigation in order to study the main determinants of innovation and its relation with the TEA Rate in Syria.

The results showed the there is no significant correlation among the selected indices. Therefore the next part of this study will focus on determinants of the TEA Rate.

4.2. The dependent variable

This variable is the Total Early-stage Entrepreneurial Activity (TEA Rate), which indicates if the respondent involved in starting a business or not, (variable values, 0= No, 1= Yes).

4.3. The explanatory variables

The selected variables have the following values as follow:

- Gender= respondent gender, 0= Female, 1= Male
- Syhhinc= ranges best describes the total annual income of all the members of respondent's household, including income of the respondent in SYP, which includes: (1= less than SYP 60,000, 2= From 60,001 to 120,000, 3= From 120,001 to 240,000, 4= From 240,001 to 360,000, 5= From 360,001 to 600,000, 6= From 600,001 to 900,000, 7= From 900,001 to 1,200,000, 8= From 1,200,001 to 1,500,000, 9= From 1,500,001 to 1,800,000, 10= From 1,800,001 to 2,100,000, 11= From 2,100,001 to 2,400,000, 12= More than SYP 2,400,000,
- Age 0_to_6= The group which describe the respondent age, which include: (1= 18-24, 2= 25-34, 3= 35-44, 4= 45-54, 5= 55-64)
- entri_sec= the respondent had ever taken part in training on starting a business at primary or secondary school, (0= No, 1= Yes)
- etaftsch= the respondent had ever taken part in training on starting a business after completing education in school
- gemeduc= education attainment, which include: (1= Basic education, 2= some secondary, 3= Secondary degree, 4= Post secondary, 5= Post university.
- regions= the five regions in Syria, which include: (1= south region, 2= north region, 3= middle region, 4= east region, 5= coast region)

4.4. The Model

The analysis shows that the TEA Rate is associated with the set variables which illustrated in the following two models:

Model...1

$$TEA = \alpha_1 + \alpha_2 \text{ gender} + \alpha_3 \text{ syhhinc} + \alpha_4 \text{ Age 0}_{to_6} + \alpha_5 \text{ etpri}_{sec} + \alpha_6 \text{ gemeduc} + \varepsilon + \text{regions.}$$

Model...2

$$TEA = \alpha_1 + \alpha_2 \text{ gender} + \alpha_3 \text{ syhhinc} + \alpha_4 \text{ Age 0}_{to_6} + \alpha_5 \text{ etaftsch} + \alpha_6 \text{ gemeduc} + \varepsilon + \text{regions.}$$

The difference of the two models is regarding receiving training during school or after completing education in school. The results are illustrated in the table below (Table 1).

Table 1 Regression results of Model-1 and Model-2

Variables in the Equations	Model 2		Model 1	
	B	Exp(B)	B	Exp(B)
etpri_sec	0.938 (7.658)***	2.555	.	.
Etaftsch	.	.	0.969 (11.957)***	2.636
Syhhinc	0.155 (8.167)***	1.168	0.156 (8.187)***	1.168
Gemeduc	0.266 (9.083)***	1.304	0.242 (7.423)***	1.273
Gender	1.433 (41.123)***	4.191	1.414 (39.87)***	4.113

Variables in the Equations	Model 2		Model 1	
	B	Exp(B)	B	Exp(B)
Age_0_to_6	(10.494)**		(10.924)**	
Age_0_to_6(1)	0.645 (-2.073)	1.907	0.639 (-2.021)	1.894
Age_0_to_6(2)	0.857 (3.743)*	2.357	0.854 (3.699)*	2.35
Age_0_to_6(3)	0.51 (-1.221)	1.666	0.503 (-1.181)	1.653
Age_0_to_6(4)	-.159- (-0.089)	0.853	-.197- (-0.136)	0.821
regions_MH	0.044 (-0.438)	1.045	0.058 (-0.749)	1.06
Constant	-4.964- (83.64)***	0.007	-4.975- (83.243)***	0.007

- Between two brackets we put Wald value;

- (*) Significant at 1% level, (**) Significant at 5%, (***) significant at 10% level.

- Age_0_to_6 indicates the overall age is significant impact of TEA. Yet, category age 2 (25- 35) has significant impact compared to the others.

4.5. Robustness check

By using the Omnibus Test (Table 2) the two models are significant regarding the Chi-square value which means that the variables in the model are different from zero.

Table 2 Omnibus Tests to check robustness of the applied regression

Omnibus Tests of Model Coefficients				
	Model 1		Model 2	
	Chi-square	Sig.	Chi-square	Sig.
Step	(98.57)		(94.583)

a. Estimation terminated at iteration number 6 because parameter estimates changed by less than .001.

In addition, the models were test by Hosmer and Lemeshow Test (Table 3). The results show that we don't reject the null hypothesis, which indicates that there is no difference between the observed and expected results (goodness of fit).

Table 3 Goodness of fit test

Hosmer and Lemeshow Test	
Chi-square	
Model 1	Model 2
8.624	5.748

Moreover, the descriptive statistics (Table 4) show that the Cook's influence mean is close to zero.

Table 4 Descriptive Statistics of Cook's influence statistics and normal distribution

	Descriptive Statistics									
	Model 1					Model 2				
	N	Mini.	Max.	Mean	Std. Dev.	N	Mini.	Max.	Mean	Std. Dev.
Analog of Cook's influence statistics	1613	0.00001	0.2072	0.0063	0.0205	1613	0.00001	0.2038	0.0061	0.0202
Normalized residual	1613	-.91519-	9.0523	-.0017925-	0.9903	1613	-.87755-	8.7935	0.0004	0.9992
Valid N (listwise)	1613					1613				

a. Estimation terminated at iteration number 6 because parameter estimates changed by less than .001.

The interpretations of the results:

According to model above the main determinants of the entrepreneurship activity rate are:

- Education: the higher education level the more the probability of being entrepreneur, the relationship is positive and significant as expected.
- Household income: the higher income level the more the probability of being entrepreneur, the relationship is positive and significant which means that the entrepreneurs in Syria come from high economic class background.
- Training in starting a business after completing school: the training is playing positive role in increasing the probability in entrepreneurship.
- Age: the results show that the young people between 25 and 34 years old are more likely to start their own business than other age groups in Syria.
- Gender: the gender gap is clear in Syria in terms of entrepreneurship since female are less likely to start their own business.
- Regions: the difference between the entrepreneurship between regions in Syria is not significant in terms of entrepreneurship after we control for household income, age, training and gender.

5. Conclusions and recommendations

This paper concludes that the Total-Entrepreneurship Activity Rate (TEA Rate) in Syrian is low comparing to the countries in the same development. The paper tried to explain the determinants of TEA rate in Syria to understand the main reasons behind this low rate.

Additionally the paper compared TEA cross regions to investigate if there is a regional disparities. From the descriptive cross region analysis it appears that there is a difference between regions in terms of entrepreneurship, education, unemployment, level of education among employed population, and economic activities.

The main results of the paper show that the age and level of education, training on starting a business during primary/ secondary schools or after completing education, Household income and gender are the main determinants of entrepreneurship in Syria. When we control the above variables the region factors will be insignificant.

The main recommendations: The government, private sector and civil society should support young people and to increase the TEA Rate more we need further investigations about elder people or middle age people how don't significantly hesitate to start their own business.

Moreover, education and training seems to play an important role in entrepreneurship which means more investment in education and expanding of training programs is crucial for supporting entrepreneurship in Syria.

The strong correlation between high Houshol income and entrepreneurship in Syia raise the issue of access to finance since the results refer to dependency of entrepreneurs on the family standard of living. More facilities for entrepreneurs for access to finance is an important issue for improving business in Syria.

Finally the large gender gap needs more attention to support females in terms of training and access to finance.

National policy on entrepreneurship and innovation – Serbian case

Miroљjub Hadžić¹, Petar Pavlović²

¹ *Professor, Singidunum University, Belgrade, Serbia, Faculty of Business and Faculty for Economics, Finance and Administration, mhadzic@singidunum.ac.rs*

² *Senior Advisor, Republic Development Bureau, Republic of Serbia, petarpavlebgd@gmail.com*

Serbia has started late transition after political changes in 2000. It was successful in creating encouraging climate for overall business and especially for SME operating, mainly through legal changes and institutional development. Those measures have resulted in increasing number of new SME each year. Global economic crisis influenced Serbian economy more than expected. Global crisis in fact enforced growth limits of the national economy, as the development during previous decade was non sustainable in medium - term. Serbian companies are not competitive on the world market. Foreign trade deficit is huge. In order to be more competitive SME are seen as key factor. At the same time it is right time to transform policy for SME support from quantitative into more qualitative one. The subject of this policy would be fast growing SME and the fastest one – so called gazelles. Innovative companies and innovative entrepreneurs are essentially important for fast growth, but they are not strong enough. Those companies need financial support, institutional support, encouraging legal framework, training, project approach, clusters creation, from bought governmental and local level, as well. It is not less important fact that this qualitative shift should be in line with EU2020 development agenda.

The aim of the paper is threefold: firstly, to illuminate SME supportive policy framework to day, secondly, to analyze influence of economic crisis and thirdly, to envisage new, more qualitative set of supportive measures for future SME development.

Keywords

Entrepreneurship, innovation, national policy, SME

1. Introduction

In the transition period 2000-2010, Serbia finished the first phase of transition toward market economy. Great deal of measures was introduced, from legal and institutional framework market oriented establishment, to restructuring on the firm level and opening to the world market. Generally speaking reform was better performed in financial then in real sector.

During the period under consideration fast GDP increase was realized. It was partially due to fast than average increase in SME and entrepreneurship development. Small and medium scale enterprises became important agents for the whole economy and their share in total figures increased considerably. It was possible as more encouraging business climate was created and supportive set of measures for fast SME development were introduced. From year to year number of new companies increased, which partially absorbed surpluses of workers from companies in restructuring.

Last two years (2009 and 2010) Serbian economy suffered as others because of Global economic crisis. Companies faced great deal of problems: from liquidity, scarce and more expensive bank credits to decrease in foreign and domestic demand. Among others, SME and shops suffered a lot and their numbers for the first time during transition period started to increase slowly and lastly decreased.

During 2010 there were the first signs of the recovery of Serbian economy and one can expect increase in GDP in 2011. For the period of economic recovery SME become important factor for speeding up economic development.

One can say that importance of SME and entrepreneurs, as factor of a positive destruction, become even more influential than before. Considering that Serbian SME are less efficient and less competitive than European it is right moment to change attitude of policy supportive to SME development to improve their efficiency. Moreover these measures would be in line with EU 2020 Agenda [1]

2. The First phase – improvement of overall business climate

Real encouraging climate for strengthening entrepreneurship and supportive measures for SME and shops was introduced after political changes in late 2000. Serbia has started transformation toward fully market economy as the last among Eastern and Central European countries. On the basis of others experience it was chance to avoid mistakes and define better mix of macro economic policies and market reforms. At the same time in Serbia after overall political and economic crisis during the 1990s a consensus of influential social groups was achieved about need for market reform, but atmosphere was pretty hectic because of great expectations.

During the period under consideration (2000-2010) Serbia has introduced a number of market reforms, achieved macroeconomic stability and high rate of economic growth, privatized majority of (socially owned) companies, started process of joining EU, with harmonization of number of laws and other adjustments. In the period before Global economic crisis Serbian GDP increased 5.4% per year on average, with peak in 2004 (9.3%) and industrial production increased 1.3% per year (see table below).

Table 1 Serbia Key Macroeconomic Indicators (Increase %)

	2001	2002	2003	2004	2005	2006	2007	2008	2009
GDP	5.1	4.5	2.5	8.4	6.2	5.7	7.5	5.5	-2.8
Industry	0.1	1.8	-3.0	7.1	0.8	4.7	4.6	1.1	-12.6
Trade	19.8	23.9	13.8	18.0	26.5	7.7	22.8	6.6	-11.7
Traffic	9.6	6.9	5.0	4.8	4.4	10.4	1.7	0.4	-14.9
Export	10.5	20.6	32.8	27.8	27.2	43.4	38.1	24.3	-26
Import	28.0	31.8	33.2	43.8	-2.7	25.9	41.5	23.3	-34.7
Inflation	40.7	14.8	7.8	13.7	17.7	6.6	10.1	6.8	6.6

Source: Ministry of Finance of Serbia

Macroeconomic stability was improved considerably, as retail prices index decreased from 92% in 2000 to 6.8% in 2008, with exchange rate stability and increasing foreign exchange reserves (Foreign direct investment reached maximum of 4.4 billion € in 2006, mainly due to privatization of banks and companies)[1]. It was partially due to public finance reform and introduction of hard budget constraint, as public finance deficit in the period 2001-2003 was transformed into surplus (of 2% of GDP), for the first time after years.

Although unemployment is still very high (20%), employment started to rise in 2004 (0.4%) and 2005 (0.9%). Free formation of wages resulted in their high increase – over 10% per year in real terms. At the same time average monthly salary per employee increased from 102€ in 2001 to 320€ in 2008.

Market reforms in Serbia improved overall business climate for all economic agents, including SME and entrepreneurs. For example Serbia was labeled as a leader of reforms in 2005 and improved its place from 95th to 68th position worldwide [1]. Time necessary for company foundation was shortened, for registration, as well, for license issuing and tax payment also. Time period for custom declaration (export and import) issuing was shortened. Investment climate was improved. The liquidation of enterprise was easier then before.

Overall market reforms slow down considerably during the last several years. The World Bank examination for 2008 proved worsening business climate in Serbia recently [2]. Serbia was ranked as 86th, although it was 84th in 2006. Comparing to other countries within the region it was better ranked than Croatia (97), Bosnia and Herzegovina (105) and Albania (136), but was worse ranked than Hungary (45), Romania (48), Slovenia (55), Macedonia (75) and Montenegro (81).

During the last decade institutional conditions for SME and entrepreneurship development and their strengthening were considerably improved. Increasing number of SME and shops was result of improvement of overall business climate and, at the same time even more important, encouraging measures oriented toward SME especially. A number of measures were introduced from governmental

to local level, as well. One can summarize those supportive measures, as follows [3]: 1) Improvement in overall business climate – although reforms lost momentum in the second half of previous decade, business climate was encouraging especially in comparison to the 1990s, when Serbia was faced with overall sanctions of International community; 2) Establishment of institution responsible for SME support - Ministry for economy and regional development is responsible for strategic and policy definition. Republican Agency for SME and entrepreneurship development was founded and broad network of local and regional agencies, as well. Council for SME and entrepreneurs was formed as inter – ministerial body responsible for dialog with representatives of SME sector; 3) Legal infrastructure for SME strengthening – as a part of the process of law changes toward recognizable market legal environment – encouraging for business – a number of laws was changed and set of completely new one was enacted. This was partially due to harmonization with EU legal framework for business, considering Serbian will to join EU; 4) Financial supportive measures were introduced – financial sources for SME support were established within Republican development fund and Republican employment service, as well. Important factor of financial SME support was related to international credit lines. At least, international financial sources from International financial institutions, governmental and non - governmental sources, as a sort of financial aid, were realized, as well.

As result of improved overall business climate and supportive measures for SME development number of SME and small shops increased during the last decade. Total number of economic agents reached 303.5 thousand in 2008, as the last year before Global economic crisis, due to constant increase in number of SME[2]. SME sector became increasingly important for overall economic growth and development. The SME share in total turnover was 66.6%, 59.1% in total added value of non – financial sector and 58.7% in total profit realized [4].

Total number of SME was increasing, but the structure was not improved so much. Micro enterprises are still dominant with share of 95.7% in total number of companies. At the same time they are very concentrated by industry and by region. SME are concentrated mostly in two industries: trade and processing industry. Regionally they are concentrated in two regions mostly: Belgrade city and South Backa region.

SME were very important in opening new working places. In the period 2004-2008 number of working places increased 24.9% (or 187.5 thousand), which offset number of employees who left big companies in restructuring process.

SME were very active in investment. Their share in total investment was 48.1% and the share in non – financial sector even more 58.7%. The share of its investment in GDP increased from 29% in 2006 to 40% in 2007. According to investment structure almost ½ investments is investing in equipment, but investments in construction was high 43%.

SME sector is more competitive than average due to less than average cost of employees and cost of wages per hour. It is interesting to note that after deterioration in the period 2004-2006 the proportion cost of salaries to value added was improved in the period 2007-2008 and now is on average for non – financial sector.

The comparative analysis of Serbian SME sector VS. EU pointed interesting results. Serbian SMEs are on EU average according to number of companies and employment and its share of turnover in total GDP. However, Serbian SMEs are well bellow EU average according to turnover per employee, added value per employee and profit per employee. Similar position is regarding investments. Investment per employee in Serbian SME sector was 4.100€, while in EU was 7.400€ and investments per company 12.200€ in Serbia and 31.700€ in EU [4].

If we envisage achievements in SME development in Serbia more precisely, dynamically and compared to other transitory economies than clear conclusions arose [5]. Firstly, Serbia made big step forward during past ten years, as in meantime SME became important economic agent with high share in GDP formation and total employment, as well. Secondly, it is still well behind other transitory economies, especially matured transitory economies, as they have started market reforms from 5-10 years before Serbia.

3. Global Economic Crisis and its consequences to Serbian SME

Global economic crisis started as crash of US real estate market in mid 2007 and became worldwide during 2008. Serbian economy suffered as highly dependent on foreign demand, mainly from EU countries, and from foreign direct investments(FDI amount dropped from 2-3 billion € to less than 1 billion € per year). The first sign of global financial crisis appeared in May 2007, when all stock exchanges in the region witnessed sharp drop in prices of securities.

Even, before Global economic crisis negatively influenced Serbian economy, it faced limit for further growth. Growth model, which can be labeled as pure neo - liberal one, was non - sustainable in medium – term, as growth was based mainly on increase in public and personal consumption. High share of public consumption in GDP is signal of non restructured public services, from pension to governmental. Above all public companies did not start restructuring process. As a consequence fiscal policy was expansive(In the transitory period 2001-2008 the share of public consumption in GDP was 45-50% and increase in indirect tax duties was 9.8% p.a.) and as counterpart monetary policy was too restrictive in order to safe macroeconomic stability(Inflation was put down considerably and controlled better than before, but it is still higher than in other countries within the region and especially in comparison to EU countries 6.6-40.7% p.a. in the period 2001-2009 – see table 1). Inevitably GDP growth was suboptimal (lower than possible). So, one can conclude that world wide economic crisis was not caused, but sharpened problems of Serbian economy, only.

Government and National bank of Serbia – recognized first signs of the crisis in the last quart of 2008: foreign direct investment inflow has shrunk and outflow of capital has started, saving deposits (FX mainly in the structure) within banks decreased considerably, credit conditions worsened(Banks have started to calculate country risk with 1.5-2% above regular interest rate), companies more difficult collected claims, especially from government and public companies and foreign demand weakened. It seemed that both Government and NBS were surprised, were late and weak in reaction and underestimated consequences.

National Bank of Serbia reacted quicker by introduction of measures with aim to improve bank liquidity. Serbian banks were in better shape than majority of banks among transitory economies, among others due to higher legal requirement for capital adequacy (12% like in Croatia and unlike others with 8% requirement) and capital adequacy was 28% on average[1].

Government reacted lately, at the beginning of 2009, introduced weak encouraging measures. Firstly, in order to safe domestic savings, amount guarantied (insured) by the state was increased from 3 thousand up to 50 thousand €. Secondly, tax duties on saving deposits from capital gain were annulled and tax duties related to securities transfers. Thirdly, in order to curb recession Government supplied support for credit lines (subsidized interest) for: 1) Companies in liquidity problems (0.8 billion €); 2) Companies investing (0.17 billion €) and 3) Citizens (0.2 billion €)[2]

Governmental and NBS measures were mainly in right direction, but late and weak. It was clear that negative influence of Global economic crisis was stronger than expected. As inevitably, an overcome of the crisis was seen with help of IMF, only. The stand by arrangement with IMF lasting until April 2011 was based on projection of decrease in GDP (-2%), with help of 4 billion USD, emphasizing need for public services reform and decrease in public consumption, continuation of structural reforms and macro economic stability.

First signs of (modest) recovery were related to recovery of foreign economic activity and increasing foreign demand. Industrial production in 2010 was higher 3% in comparison to year before. Retail trade was increasing from July 2010. GDP increased 1.5% in 2010 and for 2011 a growth of 3% is expected[4]. Due to Dinar depreciation lasting more than one year export volume increased more than import (21% and 7% respectively). At the end of 2010 and beginning of 2011 the main economic problem is related to high inflation rate, caused by increase in agricultural prices and Dinar depreciation. Year ended with inflation rate of 10.3%[4].

In unfavorable circumstances development of SME and entrepreneurship slow down considerably. There were a lot of unfavorable factors, but the most influential seem to be: 1) Less chances for entrepreneurs then before, as it is usually case during the downturn of economic cycle; 2) More fears for those who started business or want to develop it, because of weak and decreasing domestic and foreign demand; 3) Less credit from bank sources and under more difficult conditions; 4) Decreasing demand on domestic and external market, from both companies and citizens; 5) Increasing competition from big companies and other small companies, as all economic agents try to survive and 6) Lower liquidity and more difficult collecting claims.

Table 3 Number of newly established and closed companies and shops

	Number of companies		Number of shops		Net effect	
	Established	Closed	Established	Closed	Companies	Shops
2006.	11.536	1.528	45.693	27.010	7,5	1,7
2007.	11.902	2.027	47.951	31.619	5,9	1,5
2008.	11.248	3.068	43.375	34.572	3,7	1,3
2009.	10.014	3.597	39.365	36.441	2,8	1,1
2010.	9.391	9.340	35.036	37.168	1,0	0,9

Source: Republican Business Registry, processing Republican Development Bureau

Development of Serbian SME slowed down considerably after the period 2004-08 in which the sector became important factor of the economy in market reform and revitalization [6]. From table above it is clear tendency of slow down in number of established new companies and shops, on the one hand, and increasing number of closed companies and shops, on the other, with zero net effect for companies and negative net effect for the first time in 2010 for small shops. From 2008, as consequence of economic crisis and worsening business conditions, number of newly established companies and shops per year is decreasing, and at the same time number of closed companies and shops is increasing. During whole 2009 10.014 new companies were established and 39.3655 shops (for 11% and 9.2% less then year before) and at the same time 3.597 companies and 36.445 shops were closed (for 17.2% and 5.4% more then year earlier).

During 2010 net effect in so - called business demography was worsening further. This means that tendency of decreasing number of new established firms, on the one hand, and number of closed, on the other hand, got momentum (speed up). As result during the whole year 9.391 companies were established (6.2% less the year before) and 9.340 were closed (even 159.7% more then year before). At the same time 35.036 shops were established (11% less then year earlier) and 37.168 were closed (2% more the year earlier). Net effect for companies (number of established to number of closed) was worsening from year to year and in 2010 was 1:1 (1:2.8 in 2009). Net effect for shops was even worse 1:0.9, which means that for the first time in Serbia there were more closed than established shops.

It was already noted that SME and entrepreneurship development is concentrated by industry and by region, as well. Unfortunately, during transition period regional discrepancies in Serbia were widened. It means that entrepreneurs within developed regions have more potential chances for establishment and development of self sustained firms. The most developed region is metropolitan area of Belgrade city (12.963 or 41.2% of all newly established firms in Serbia in 2010) and South Backa region (4.567 or 14.5% of total new firms). On the other pole in Pcinja (South Serbia) region only 353 were founded or 1.1% of total.

4. Innovative support – first steps

There are clear signs of economic recovery, although modest, in increasing industrial production, trade and GDP increase. SME are very important for further and secure recovery. Until now measures of quantitative support for SME and entrepreneurial development prevailed and their aim to establish critical number of new entities was achieved. Considering that Serbian SME are well bellow EU average, especially measuring certain indices per employee it is right moment to change attitude. In order to increase their efficiency policy support has to change into more qualitative sort. The aim is to transform SME into more competitive on international market, to increase export volume more than import and finally, to create surplus in trade balance.

The first priority of policy support to SME and entrepreneurship development in the future – next phase – is competitiveness strengthening. It should be realized through: 1) *Economic structure development in line with EU and compatible to EU structure*, which means increasing activities with value added above average; 2) *Improvement in competitive abilities of companies*, by closing discrepancy to EU average in gross value added per employee; 3) *More balanced regional development*.

Measures would be introduced for improvement in companies' competitive abilities, in order to operate more successful on the global market, and for technological improvement of products and services. Among others, it is important to strengthen and develop linkages between, on one side, educational and research institutions and companies, on the other side. Programs for improvement competitiveness are especially important and would be oriented to: 1) *Support investing in research and development and innovation*; 2) *Support companies internationalization*; 3) *Introduce strategy for productivity increase in companies*; 4) *Support cooperation and strengthen linkages between companies and developing clusters*.

Serbia was for the first time included into European Innovation Scoreboard in 2009[7]. It is important step for investigation of innovative potential for national economy and SME particularly. The analysis of innovative performances is very important as a starting point for further investigation and more relevant for decision making process about policy and measures for innovative activities support.

Data pointed that Serbia is well bellow EU27 average. If EU 27 innovative index is 47.8 then Serbian Index is 22.7 only. To summarize, it is labeled as catch up country. First dimension enablers: Serbian research system has modest potential comparing to EU average and neighboring countries (Slovenia and Croatia). Human source is also limiting factor (with 19.2% highly educated and 85% with

secondary school in total young population). Second dimension – firm activities: Serbia is investing 0.5% GDP (public and private sources) in research (EU 2%). On the company level 28% of all Serbian SME and shops can be labeled as innovative [8]. There are 3.5% innovative SME with linkages and cooperation in research in total number of SME. Third dimension – outputs: The share of SME introducing processing/product innovations is 18.3% and 18.1% organizational/marketing innovations in total. Comparing to EU and matured transitory economies Serbia is less efficient in utilization of innovations. The share of employment in knowledge based activities is 3.9% of total. The share of medium and high tech product export is 27% in total and knowledge service export 34% in total. The share of sales of new to market and new to firm innovation is 10% in total turnover and lastly, the share of revenues from licenses and patents from abroad is 0.1% in GDP.

Serbia is realizing „Strategy for development of competitive and innovative small and medium scale companies 2008-2013“ from 2008. According to the Report on introduction European Charter for Western Balkan in 2008 Serbian system for encouraging innovation with SME sector is marked with 2.5[9]. Project of technical support for development of entrepreneurship and innovation is joint project of EU and Serbian Government. One of the main achievements of the Project is direct technical support for 150 SME aiming to introduce system for innovation management, which is basis for innovative product and process development and easier access of SME to foreign market. Subproject Support SME competitiveness threw innovation is realized threw several activities: 1) Interactive workshops in innovation management (covered 157 SME); 2) Intensive technical support to companies (covered 20 SME); 3) Training in innovation and 4) Innovation clinics. Serbian achievement in cluster and network development can be estimated as encouraging and according to the Report is marked with 4. Namely, 20 clusters were registered with governmental support for 14 of them.

The second priority is support to dynamic and fast growing companies, especially the most dynamic, so - called gazelles. A number of investigation proved that net increase in employment is result of development of dynamic companies [10]. Those companies are not concentrated in certain industry, but rather are dispersed within whole economy. They are research and development oriented, innovative and younger then average company. Those companies became also subject of interest and economic policy of EU and OECD. While big enterprises dominate, due to sources they are controlling, entrepreneurship, research and development and new working places are development priorities in which small and new firms play important role.

The analysis of Serbian gazelles in the period 2003-2007[11] covered 532 dynamic companies, of which 53 the most dynamic. The main characteristic of those companies, which employed more than 43 thousand workers, is vitality, as they survived and developed in spite of transition problems and increasing foreign competition. The share of dynamic companies in total number of companies in Serbia was 0.6%. Number of employees within those enterprises was dabbled from 2003 to 2007 (more than 22 thousand new working places). Rate of growth of their turnover in real terms was above average (117% in comparison to 54% respectively). So, they increase their share in total turnover from 3.2% to 4.5% at the same time. All business indices during the period were more than dabbled, while income increased more than three times.

Implementation of Serbian Strategy for development of competitive and innovative small and medium scale companies 2008-2013 should concentrate measures and activities to those specific companies with potential for fast growth and export expansion. Priorities for dynamic companies and gazelles support are: 1) *Legal framework reform*, with an aim to harmonize laws in line with EU, to minimize administrative procedures and requirements; 2) *Innovation support*, with an aim to define system of stimulative measures for research and development and innovative activities and their implementation within companies; 3) *Functional education*, with goal to increase overall level of knowledge of managers and employees improving bought formal and especially informal education system; 4) *Financing improvement*, with aim to disperse institutional framework for micro financing, investment funds and venture capital funds; 5) *Closing institutional infrastructure*, in order to develop further institutional network covering whole territory; 6) *Opening to World market*, with goal to improve competitive strength of dynamic companies and gazelles on the global market.

5. Conclusion

During late transition Serbia succeed to improve business climate and introduce great deal of measures aimed to support SME and entrepreneurship development. They became important economic agent and their share in GDP, employment and trade became significant. During economic crisis Serbian SME suffered like others, in spite of increasing financial help. For the first time after

decade number of new established firms slowed down considerably and, even, more shops were closed than founded and net effect for companies is near to zero in 2010. For overall economic recovery entrepreneurs and SME become very important factor. Considering their low efficiency and competitiveness abroad it is time to change SME development supportive policy into policy with aim to encourage innovative and fast growing SME, instead of aim to increase number of them only, which was important until now. Serbia made big step forward in SME development, but is still below other transitory economies, especially matured one. It recently started implementation of measures for development of competitive and innovative SME. Those pioneering efforts are in right direction, but it needs time, experts and sources to catch up other transitory economies.

Polycentric development in Latvia within the context of the Cohesion policy

*Inese Haite*¹

¹Doctoral study program "Economics", University of Daugavpils, Daugavpils, Latvia, inese.haite@rezekne.lv; inesehaite@hotmail.com

In the European Union there are several challenges in the field of territorial development - demographic changes, climate changes, city mobility, degraded territories, social inequality, and global competitiveness. The development policy for 2007-2013 in the European Union has been reasoned with the rules of sustainable development. Currently there are active discussions upon the direction how to develop the area of the European Union within the context of territorial cohesion until 2030. Latvia is also taking part in this process and works out the necessary central policy. The united central policy is based on several significant suggestions from all involved parties, which will define the development of all territory in the European Union and Latvia in the future. In order to develop cities the support of concrete financing is given. At the same time the development of other territories in the country (such as rural areas, seashore, and borderland) must be provided accordingly to the national regional development strategy. Latvia actively supports the idea of providing the support of the Cohesion policy for implementation of local development strategies and initiatives, as well as solves the issues of economic development. A new stage in the Latvian territorial development planning has started and it is closely connected to the policy formation on this particular issue.

Keywords:

Cohesion policy, regional economy, polycentrism.

1. Introduction

Topicality of research. In order to understand the processes within which the cohesion policy is implemented and evaluate the development tendencies of economic centers (towns) in Latvia in the context of sustainable polycentric planning a research shall be conducted on the political regulations of the European Union and Latvia. The aim of the article is to investigate the direction of Latvia in the context of the EU territorial cohesion. The tasks of the article are to get introduced with the characteristics of the Cohesion policy in the European Union, tendencies of urban development in Europe, perspective of urban development in Latvia in the context of polycentric development. The following research methods have been applied: monographic, comparative, logically constructive and scientific synthesis. The research has been supported by the European Social Fund within the project „Support for the Implementation of Doctoral Studies at University of Daugavpils” (Project No. 2009/0140/1DP/1.1.2.1.2/09/IPIA/VIAA/015).

2. Characteristics of the Cohesion policy in the European Union

The notion “Cohesion policy” states political regulations for solidarity on the European level expressed in projects, which throughout Europe are financed by two structural funds, e.g., European Regional Development Fund (ERDF) and European Social Fund (ESF), as well as Cohesion Fund (CF). The principle of economic and social cohesion included by the Member States in the Single European Act

(1986), Article 130a envisages “to reduce discrepancies between regions and underdeveloped regions” [1]. In 1999 there was adopted the European Spatial Development Perspective (ESDP), which is considered to be a significant document to implement the Cohesion policy in the European Union (EU). This document envisages standpoints for promotion of spatial development [2]. In May, 2007 there was adopted the EU Spatial Development Agenda, which envisages standpoints for promoting spatial development [3]. EU has put forward the following aims of the Cohesion policy for the planning period of 2007-2013:

- **Convergence.** This aim supports conditions and factors facilitating growth, which ensure real convergence in less developed Member States and regions. Within this aim there are supported regions, where gross domestic product (GDP) per capita is less than 75 % from the average indicator of the Community. Funding of ERDF, ESF, Cohesion Fund;
- **Competitiveness of regions and employment.** The aim is to strengthen the competitiveness and attraction of regions, which is implemented out of the convergence regions. Funding of ERDF, ESF;
- **Territorial cooperation in Europe.** Within this aim local and regional initiatives strengthen cross-border cooperation, interregional cooperation and exchange of experience. Funding of ERDF [4].

The Cohesion policy is the most financially intensive policy and in the planning period of 2007-2013 it comprises 35.7 % from the total EU budget. In order to implement the aims of the Cohesion policy mentioned above the EU budget has allocated 346.5 billion EUR, which are divided in the following way:

Figure 1 Financial resources available for implementation of the aims of the Cohesion policy in the planning period 2007-2013. Allocation in percentage, billion EUR. Compiled by the author [4]

The Lisbon Treaty, which came into force on December 1, 2009, supplemented the economic and social cohesion by the territorial cohesion policy and introduced its official notion:

“In order to promote overall harmonious development the European Union develops and implements activities strengthening economic, social and territorial cohesion. The Union strives to reduce development discrepancies among regions and handicap of the least developed regions. Among the regions concerned, particular attention shall be paid to rural areas, areas affected by industrial transition, and regions which suffer from severe and permanent natural or demographic handicaps such as the northernmost regions with very low population density and island, cross-border and mountain regions” [5].

According to the Lisbon Treaty the Cohesion policy shall be implemented in the way to facilitate more balanced and sustainable development taking into consideration peculiarities of various territories as geographical and geopolitical challenges. In October, 2008 the EC published the Green Paper “Territorial Cohesion: Turning Territorial Diversity into Strength”, thus launching discussions of the Member States in this field [6]. In the course of discussions there were provided opinions and resolutions from various representatives of the Member States – regional and research institutions, associations, economic and social partners, European Parliament, as well as individuals. It must be noted that discussions did not lead to any agreement on a single definition of territorial cohesion; however, they agreed on the principles characterizing territorial cohesion. The aim of territorial cohesion is to promote harmonious and sustainable development of all territories basing on their characteristics and resources. Territorial cohesion includes five basic elements:

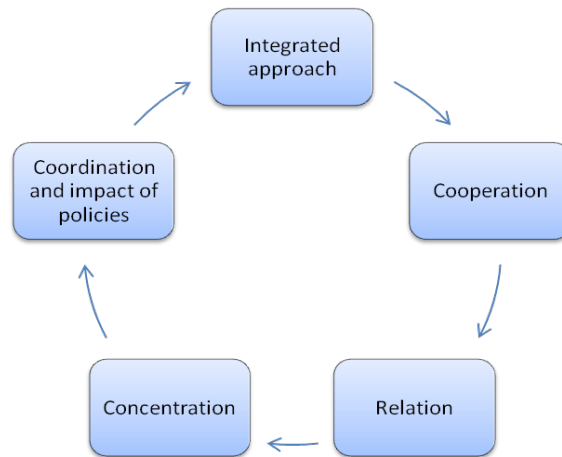

Figure 2 Basic elements of territorial cohesion. Compiled by the author [6]

In June, 2010 there was adopted the EU strategy “Europe 2020” approving the significance of the territorial cohesion:

.....It is also essential that the benefits of economic growth spread to all parts of the Union, including its outermost regions, thus strengthening territorial cohesion. [7].

In the end of 2010 the EC published its Fifth Report on Economic, Social and Territorial Cohesion “Investing in the Future of Europe” including the standpoints within the Cohesion policy to promote territorial cohesion:

Cohesion Policy is the EU’s main instrument for pursuing harmonious development across the Union.The Lisbon Treaty has added territorial cohesion to the goals of economic and social Cohesion. As a result, it is necessary to address this objective in the new programmes, with particular emphasis on the role of cities, functional geographies, areas facing specific geographical or demographic problems and macro-regional strategies [8].

It is envisaged that in May, 2011 there will be adopted the reviewed EU Spatial Development Agenda including the new challenges in the spatial development. In June, 2011 there will be submitted proposals to the EC regarding the prospective EU multiannual budget after 2013, there will be determined the amount of funding to implement the Territorial cohesion policy in the future.

3. Urban development in Europe

On the European Union level territorial development has various challenges – demographic changes, climate changes, urban mobility, degraded territories, social inequality, global competitiveness. Cities play a vital role for the development of European regions. Currently, over 70% of Europeans live in urban areas. Most of the EU’s population just over 60% live in medium sized cities with more than 50 000 inhabitants. There are around 6 000 towns or cities with over 5 000 people and almost 1 000 cities with over 50 000 people in the EU, in which economic, social and cultural activity is concentrated. However, only 7 % of the EU-27 population live in metropolises of over five million [9]. European cities are the key to reaching the Lisbon goals, since they act as the motors for regional growth, innovation and employment creation [10].

The urban development policy for 2007-2013 on the EU scale is based on the provisions of sustainable development attributing polycentric direction. Currently, active discussions take place how to develop the EU territories in the context of territorial cohesion. In the solution of territorial issues within the framework of the Cohesion policy (CP) special attention shall be paid to urban development as cities can have a significant contribution to reach the aims of the EU 2020 strategy. The issues on environmental degradation and social exclusion have become topical. In this process it is essential to ensure involvement of local municipalities, and promote relation between urban and rural territories. It is envisaged that in the EU funds programming documents for the forthcoming planning period urban support measures shall be provided.

The Fifth Report on Economic, Social and Territorial Cohesion “Investing in the Future of Europe” emphasizes the role of cities and city environment in the development of territories, and determines perspectives for further development of cities:

Accordingly, an ambitious urban agenda should be developed where financial resources are identified more clearly to address urban issues and urban authorities would play a stronger role in designing and implementing urban development strategies. Urban action, the related resources and the cities concerned should be clearly identified in the programming documents [8].

In June, 2010 the EU Regional Committee in its meeting provided a statement considering that when making strategic choices for the forthcoming programming period (2014-2020) the EU should recognise the strategic importance of urban regeneration and ensure that the urban dimension is given more priority in all its policies, with a view to making cities laboratories again, this time with a much fuller agenda, to help the EU out of the economic and financial crisis [11]. Solution of the existing challenges in the EU cities and implementation of the “EU 2020” strategy, thus facilitating development of more reasonable, sustainable and socially inclusive cities, has become of the primary aims. In order to have complete understanding the integrated approach to cities, it is necessary to explore and work out a minimum set of common indicators, including indicators of cities sustainability.

4. Urban development in Latvia in the context of polycentrism

Evaluating the current situation it can be noted that Latvia is a monocentric state having a dominant role of the center – Riga – in the total economic development. The capital of Latvia, Riga (and its surrounding territory) has 1.095 million or 48.73 % inhabitants of Latvia [12]. In other four regions of Latvia there are 1.15 million inhabitants; the potential of the network of 25 quite evenly located towns is not sufficiently used. Regional development is unbalanced, thus, it is necessary to implement a purposeful policy to facilitate polycentric development. Regional discrepancies are characterized by the differences of GDP:

Figure 3 Differences of GDP in the statistical regions of Latvia in 2008, proportion in %. Compiled by the author [13]

In the planning period of 2007-2013 Latvia receives funding within the framework of the EU convergence and territorial cooperation. The main aim of Latvia in 2007-2013 is promoting harmonious economic growth and approaching the average EU level of welfare. The strategic aims of Latvia are as follows:

- to develop and use human resources effectively;
- to promote competitiveness and orientation towards knowledge-based economy;
- to improve public services and infrastructure as a precondition for balanced state and territorial development [14].

According to the EU Council resolution on the EU Multiannual Financial Framework 2007-2013, Latvia has received 4.53 billion EUR (EUR 4'530'447'634) to implement the aims of the cohesion policy by ES funding (ERDF, ESF and CF) having the following allocation:

Table 1 Allocation of funding by funds and national co-funding in Latvia in 2007-2013, EUR [15]

	Funding of the European Community	Co-funding of Latvia	Total funding (European Community + Latvia)	% from SF and CF
ERDF	2 440 017 364	662 793 319	3 102 810 683	53.86%
ESF	550 653 717	97 174 186	647 827 903	12.15%
CF	1 539 776 553	381 540 358	1 921 316 911	33.99%
TOTAL	4 530 447 634	1 141 507 863	5 671 955 497	100.00

As one of the support instruments to promote polycentric development in the programming period 2007-2013 in Latvia there is introduced ERDF city environment priority "Polycentric development". Within the framework of this program the planned support activities are directed towards strengthening of cities' potential as a driving force of regions as well as forming functional relations with adjacent territories according to the integrated approach to urban development. The EU financial support is allocated to all large cities of Latvia, including to the capital city – Riga. The aim of the activity "Sustainable development of Riga City" program is to ensure revitalization of degraded territories of Riga City (functional activating) according to the integrated municipal development program, thus facilitating formation of the preconditions for socio-economic growth in the capital city of Latvia. In order to implement this aim there is allocated funding 11.72 million EUR, including ERDF – 9.99 million EUR [16]. Within the framework of the activity "Promotion of national and regional development centers growth for balanced state development" ERDF funding is allocated to 16 national and cities of regional and national importance in Latvia. The total funding is 297.69 million EUR, including ERDF – 253.03 million EUR [17].

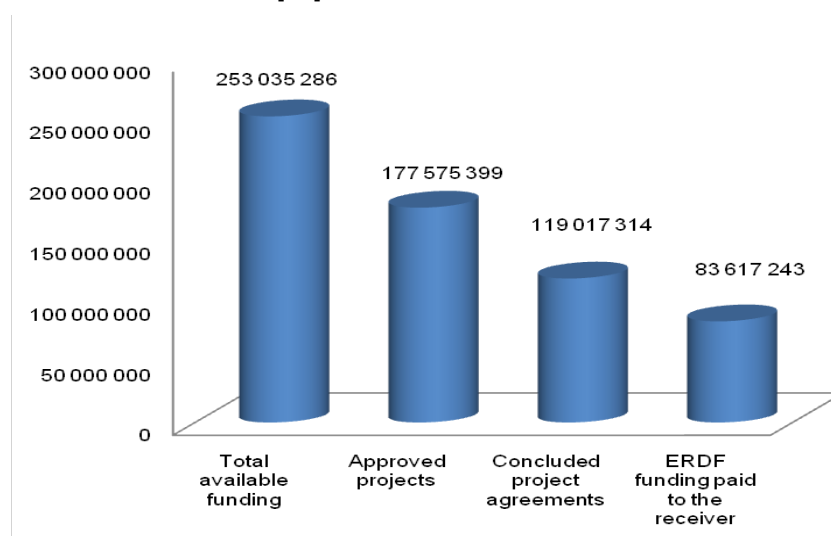

Figure 4 ERDF funding acquisition progress within the activity "Polycentric development" (EUR, 08.12.2010.) [18]

It must be noted that not only the programs mentioned above provide an irreplaceable contribution to facilitation of the polycentric development in Latvia, but also other EU co-financed programs for promotion of the capacity of human resources, stimulation of employment, strengthening of medicine, development of business, improvement of environment, enrichment of cultural environment, increasing efficiency of energy and support NGO.

Latvia is involved in a discussion on the EU territorial cohesion development and works out the necessary standpoints. The common stance is based on several essential proposals, which in the future will determine the territorial development in the EU and Latvia as well. In January, 2011 LR Cabinet of Ministers has adopted a document "National position of Latvia "On Territorial Cohesion """, which states what territorial cohesion principles shall be observed in the development and implementation of the EU policies in the future:

- Subsidiarity – greater trust of the state to the local municipality supporting the local development strategy and implementation of initiatives as well as greater responsibility of the local municipality providing that the available support is used in a more strategic and economical way.
- Coordination of policies – interaction of several branches/ fields and coordinated development in the respective territory.
- Territorial cooperation – more effective use of resources to reach common aims; supplementation of investments and positive impact in development in a larger territory [19].

The government of Latvia has expressed its opinion that the implementation of territorial cohesion shall be ensured on the national level letting the EU Member States and their regions determine and implement their regional development strategies suitable for the peculiarities and needs of specific EU Member State territories. Latvia does not support proposals to change the conditions for allocation of the EU funding in the forthcoming planning period by creating new EU scale support measures for specific territorial groups (for example, cities, remote territories, etc.) because in such case the diversity of European territories and different territorial development levels would not be respected. There are concerns that the territories of Latvia will not qualify for such support measures and will not have an opportunity to attract the EU funding – the territories of Latvia are not qualified as remote on the EU scale, the towns and cities in Latvia are smaller than the European ones.

Latvia joins the EC standpoint that cities shall contribute to reaching the aims of the US 2020 strategy in compliance with the national strategies. In the future the Cohesion policy shall respect the diversity of cities and different challenges they face. Within the framework of the city environment dimension not only problems of large European metropolises (social exclusion, environmental degradation) shall be solved as the EC offers it. In Latvia it is essential to strengthen cities as driving forces of the economic growth in regions primarily solving the issues related to workplaces and availability of services, including for the inhabitants of the surrounding rural territories. Latvia wants to continue the support measures for city environment indicated in the planning documents, at the same time support shall be also envisaged for the growth of other state territories (for example, rural, coastal, border areas) in compliance with the national regional development strategy. Latvia actively supports the idea to provide support within the Cohesion policy for the implementation of the local development strategy and initiatives; a relevant condition for further development is solving environmental and social issues as well as economic development issues. The territorial development of Latvia has reached a new stage closely related to the formation of the EU policy in this area.

5. Conclusions

- In the understanding of the European Union the notion “Cohesion policy” refers to political regulations to reduce discrepancies between regions and eliminate handicap of underdeveloped territories.
- Since 1986 the EU has consolidated its legislation envisaging standpoints to promote territorial development. These standpoints determine the aims of the Cohesion policy and provide funding to reach them.
- In 2010 the EC accepted several significant program documents determining the development of the EU in the period of time till 2020. According to the defined development tendencies the amount of funding to support territorial cohesion after 2013 will be marked out.
- In 2007-2013 urban development on the EU scale is implemented in compliance with the conditions of sustainable development applying polycentric orientation. This tendency is also preserved in the conception of the strategy “Europe 2020” emphasizing the significance of cities in the aspect of territorial cohesion.
- Polycentric development actions are included into the EU program documents which are binding to Latvia as well since its accession to the European Union. Latvia is a monocentric settlement with a dominant center Riga having a large proportion in the common economic system. At the same time Latvia has an extensive and quite evenly located network of cities and towns which potential is not sufficiently used. Regional development is unbalanced and local advantages are not used.
- Program documents indicate that polycentric development is put forward as a priority in Latvia because it creates preconditions for balanced state development by facilitating strengthening the potential of cities and towns as driving forces of regional development and forming a network of towns and cities. In order to promote polycentric development in the programming period of 2007-

2013 Latvia has introduced the priority of ERDF city environment “Polycentric development”. Sufficient funding is allocated to the development of city environment.

- In 2010 Latvia was involved in the discussion on the development of the EU territorial cohesion and formulated its national position determining the principles to be implemented in the future, principles of allocating the EU funding, as well as manifesting support to strengthen cities in compliance with the national regional development strategies.

Techniques design modern elevator construction

Beqir Hamidi¹

¹Faculty of Mechanical Engineering, University of Pristina, Kosovo
beqirhamidi@hotmail.com

The paper discusses the issues of design and construction of modern elevator construction. The situation at the local market construction is much disarranged. There are no serious elevator manufacturers, the production is performed in small and scattered plants and it only partly meets local market requirements, while the export orientation is not even envisaged in the near future.

The paper presents guidelines for designer work in the field of elevator and offers some original solutions in the field of automated calculation of modern elevator installation equipment, kinematics analysis of car door mechanism and car frame construction. The aim of the research was initiate local production of modern elevator installations

Keywords

Elevator, design, mechanism, construction, modern, kinematics.

1. Introduction

The elevator car is moved by a system of cables and pulleys, which link the car to a counterweight, the power usually being generated by electricity (earlier lifting systems had used a variety of methods, such as animal, steam, and water power). The invention of the elevator fostered the development of the skyscraper in modern cities. Following the invention of a safety device by Otis in 1852, the first (steam-powered) passenger elevator was introduced in New York City in 1857. Later improvements have included increased speeds, noise reduction, safety features (such as lighting and alarm systems), the automatic operation of groups of elevators, and two-deck cars (serving two levels simultaneously). Portions of the summary below have been contributed by Wikipedia. An elevator is a transport device used to move goods or people vertically. Elevators began as simple rope or chain hoists. An elevator is essentially a platform that is either pulled or pushed up by a mechanical means. A modern day elevator consists of a cab (also called a "cage" or "car") mounted on a platform within an enclosed space called a shaft, or in Commonwealth English called a "hoist way". In the past elevator drive mechanisms were powered by steam and water hydraulic pistons. In a "traction" elevator, cars are pulled up by means of rolling steel ropes over a deeply grooved pulley, commonly called a sheave in the industry. The friction between the ropes and the pulley furnishes the traction which gives this type of elevator its name. Hydraulic elevators use the principal of hydraulics to pressurize an above ground or in-ground piston to raise and lower the car. Hydraulic elevators are usually slower than traction elevators.

In 1853, Elisa Otis introduced the safety elevator, which prevented the fall of the cab if the cable broke. It consists of knurled roller(s) that lock the elevator to its guides should the elevator descend at an excessive speed, which is monitored by a governor device.

On March 23, 1857 the first Otis elevator was installed at 488 Broadway in New York City. The first elevator shaft preceded the first elevator by four years. An elevator shaft was included in the design for Cooper Union, because Cooper was utterly confident a safe passenger elevator would soon be invented; Later Otis designed a special elevator for the school.

Today the Otis Elevator Company, now a subsidiary of United Technologies Corporation, is the world's largest manufacturer of vertical transport systems, followed by Schindler, Thyssen-Krupp and Cone, in order. The first electric elevator was built by Werner von Siemens in 1880.

The development of elevators was led by the need for movement of large amounts of raw materials including coal and lumber from hillsides. In October 11, 1887 Alexander Miles, an African American

inventor, patented a method which permitted elevator doors to open and close safely. In 1929, Clarence Conrad Crispin, with Inclinator Company of America, created the first residential elevator.

2. Modern elevator construction

Today, elevators are built under strict supervision of the Building Codes. Elevators are generally sold in prepackaged components which are inherently non-proprietary. In the case of renovations, the use of non-proprietary controls has become a large part of that business because it allows the owner to offer the maintenance contract to multiple bidders rather than accept a single manufacturer for the life of the elevator which can be more than 30 years. Non-proprietary systems generally have a higher up front cost, but may be offset by allowing the owner to control the long term costs over the life of the elevator. In some locations, the shaft and parts of the cab are made of transparent material for specialized "Scenic elevators." This allows riders to see outside the cab as they travel on the elevator. Today, all new elevators are computer-controlled and microprocessor based. This allows the elevator system to place cabs where they are most needed in the interest of smooth running, with behavior based on analysis of building use called "Traffic Studies." Traffic Studies are done by professional elevator consultants [2] who use specialized tools to determine the optimum size, speed and number of elevators for a building based on its peak use periods. Methods of access control include card readers, keys, and access codes entered into the control panel of the elevator. Elevators are usually installed in a building during construction.

3. Types of passenger elevators

Passenger elevators may be specialized for the service they perform, including: Hospital emergency (Code blue), front and rear entrances, double ducker, and other uses. The concern for entrapping passengers requires all elevators to have communication connection to an outside 24 hour emergency service, automatic recall capability in a fire emergency, and special access for fire fighters' use in a fire. Numerous building codes require signs near the elevator to state "USE STAIRS IN CASE OF FIRE" [1].

3.1 Residential elevators

This is a small enough for one person while some are large enough for more than a dozen. Wheelchair, or platform lifts, a specialized type of elevator designed to move a wheelchair 6 ft (2 m) or less, often can accommodate just one person in a wheelchair at a time with a maximum load of 750 lb (340 kg).

3.2 Freight elevator

This is an elevator designed to carry goods, rather than passengers. Freight elevators or service elevators (goods or service lifts) may be exempt from some of the requirements for fire service. Freight elevators are generally required to display a written notice in the car that the use by passengers is prohibited, though certain freight elevators allow dual use through the use of an inconspicuous riser. Freight elevators are typically larger and capable of carrying heavier loads than a passenger elevator, generally from 2,300 to 4,500 kg. Although hydraulic freight elevators exist, electric elevators are more energy efficient for the work of freight lifting.

3.3 Vehicle elevators

Are a car lift is installed where ramps are considered space-in conservative for smaller buildings (usually in apartment buildings where frequent access is not an issue). In spite of the sheer size of the car platform and it's perceived "passenger capacity", there are huge passenger and freight lifts that can accommodate more than the rated capacity of the car lift.

3.4 Aircraft elevators

This is on aircraft carriers; elevators carry airplanes and helicopters from the flight deck to the hangar deck and vice versa for operations or for repairs. These elevators are designed for much greater capacity than any other elevator ever built.

4. Analysis of kinematics parameters of door opening and closing mechanism

The importance of the analysis of mechanisms for automatic opening/closing of double car door lies in the possibility of consideration of changes of the expanding valises [3], such as displacement, speed and acceleration of the slide the movement of one door wing. The said analysis is indispensable for the reliability of operation of the mechanism, as well as of the possibility of achieving more favorable values by some modification of the configuration. Also, it is very important to define the value of inertia force acting on the slide, and through the slide on door wings. The value of the said inertia force is limited by national regions.

The researches [1, 4] analyzed the mechanisms made by local elevator manufacturers (L). Characteristic of mechanisms is that they are electro-mechanical mechanisms. Electric motor and mechanical part is system of pulley transmission and leverage. The mechanism practiced by (t) is shown in Figure 1 and its simplified kinematics diagram and the basis of which corresponding parameters were defined are shown in Figure 2.

Figure 1 Door opening mechanism

Figure 2 Kinematics diagram of mechanism

5. Standards of passenger elevators

The mechanical, electrical and operational design of elevators are dictated according to various standards (aqua elevator codes), which may typically be international, national, state, regional or city based. Where once many standards were prescriptive, specifying exact criteria which must be complied with, there has been a shift towards more performance-based standards where the onus falls on the designer to ensure that the elevator meets or exceeds the standard.

Some of the national elevator standards include:

Australia - AS1735 Canada - CAN/CSA B44 Europe - EN 81 series (EN 81-1, EN 81-2, EN 81-28, EN 81-70, EN 12015, EN 12016, EN 13015, etc.) USA - ASME A17

Because an elevator is part of a building, it must also comply with standards relating to earthquake resilience, fire standards, electrical wiring rules and so forth.

US and Canadian elevator standard specifics:

Passenger elevators are required to conform to the American Society of Mechanical Engineer's Standard A17.1 Safety Code for Elevators and Escalators in most US and Canadian jurisdictions (In Canada the document is the CAN/CSA B44 Safety Standard which was harmonized with the US version in the 2000 edition.) In addition passenger elevators may be required to conform to the requirements of A17.3 for existing elevators where referenced by the local jurisdiction. Passenger elevators must also conform too many ancillary building codes including the Local or State building code, National Fire Protection Association standards for Electrical, Fire Sprinklers and Fire Alarms, Plumbing codes, and HVAC codes. Residential elevators are required to conform to ASME A17.1.

5.1 Design of passenger elevators and car frame supporting structures

The calculus ores of the car frame supporting store applied by local lift manufacturers are riot in compliance with the 'valid calculations of steel supporting structures. Approximations of the actual behavior or of the lift car fr-arrxe structures were unacceptably, which resulted in very heavy supporting structures of the lift car arid of the car frame. In this design segment large improvements are back necessary arid feasible. During the research [1, 2] the methodology of calculation of supporting structures of lift cars and car frames was established, based on finite elements method and computer aided. It enables modeling arid calculation of complex structures arid problems [4]. The proposed manner of calculation provides for determinists of a realistic picture of stresses, determination of actual structure behavior, and reliable prognosis of the structure behavior during exploitations etc. The car supporting structure is modeled by beam-type arid plate- type finite elements.

5.2 Automation of passenger elevators and strength

On the basis of theoretical postulations for the calculation of lifts and lift installation equipment, a software package was made during the research [2] with the principal intention of automation of the calculation and establishment of the data base on the corresponding lift elements and equipment.

Calculation of the lift drive comprises calculation and selection of the following components: rope, traction and idle sheaves, electric motor, worm transmission, coupling, brake, as well as calculation of the traction. Calculation of the lift stiffness comprises calculation of the traction sheave shaft in two versions, calculation of the idle sheave axle and calculation of the car guide.

6. Conclusions

The paper presents research which should be carried out in the process of designing elevator installations. Elevator designers and constructors must have the specified knowledge, which must be continuously enhanced. To obtain a good quality product elevator sophisticated methods and techniques mentioned in this paper must be incorporated in the design and construction processes. On the basis of kinematics analysis of parameters of the mechanism for automatic elevator car door opening closing values of inertial forces acting upon elevator door wings can be accurately determined. At the same time these are the forces by which the car doors act upon potential obstacle, and the maximum values for these forces are limited by national regulations. In that way, by an inverse procedure, geometry and dimensions of elevator door opening mechanism elements can be defined. The proposed methodology of calculation of supporting structures of the elevator car and car frame provides for significant savings in material and energy, obtained on the account of reduced weights of the said structures.

The software package for the calculation of the elevator drive and strength presented in this paper provides for a considerable saving in time during the design process, and also creates well arranged data bases on all elements of elevator installations and their suppliers, which can be infinitely expanded and supplemented.

Regional Development under Consideration of Companies' Location Planning Decisions

Melanie Hiller¹, Christopher Stehr²

christopher.stehr@ggs.de

Companies' decision for a location is one of the most long-term and cost-intensive investments. Companies have to consider many quantitative and qualitative indicators as well as chances and risks in the future assuring a sustainable successful business environment. Approved locations, such as existing cluster structures, attract further companies in a particularly way. Aspects like structural criteria, their innovation-friendly environment and interesting tax policies,[1] decide not just about long-term investments but also about the future chances of whole districts. Furthermore, global risks such as demographic development, energy policy and climate change (e.g. EU: Region 2020) complicate the future chances in some areas in the world. These processes establish also metropolises and global cities as well as region as new actors in an active role. Existing measuring instruments can describe and compare homogeneous areas such as global cities. They often don't consider the above mentioned future risks and finally fail in considering the heterogeneity of regions with rural parts.

Keywords

location planning decisions, location comparison, regional development, regional development indicators, case study

1. Introduction

The following article will describe the change in location planning decisions that brings regions in direct competition to metropolises and global cities. On the theoretical side, it will introduce how the change in global competition for locations takes place and which new criteria have to be considered. Along a case study that took place in a region in southern Germany, it will describe how a sustainable profile sharpening can be prepared.

2. Changing Location Planning Decisions

Location planning can have its source in different scenarios, such as a new start-up company, outsourcing of a line of production as well as relocation processes.[2] [3] In any case, this is still one of the most important decisions because a reverse of location planning decisions belongs to the most cost intensive entrepreneurial decisions.

2.1 Changes in Location Planning Decisions

Entrepreneurial location planning process is changing. So far, it took place in three steps. First step is the decision for an economy itself, the international location choice.[4] This level follows factors of market, transport costs or production costs itself and dictates still determining factors such as economic laws, legal security and non-tariff barriers.[5] The second level of location planning contains the interregional decision that determines a geographical and economical region for production or distribution decisions.[6] In the last step the decision for an estate itself is made based on internal

entrepreneurial requirements.[3] According to the companies needs, an individual comparison between several possible locations is mostly made by a value benefit analysis or profitability analysis.[7] These instruments include hard and soft factors concerning all parts of entrepreneurship such as transport connection, labour market, lease costs, near business market or contractors.

Figure 1 Former Location Decision Model
Source: own figure, cf. Schneider 2006

With continuously decreasing costs for transportation and communication – caused by effects of globalization – as well as declining non-tariff and tariff trade barriers (e.g. in economic unions such as EU, NAFTA or Mercosur), the entrepreneurial location planning becomes more precisely and furthermore more flexible concerning time, place and space.[8] Decision parameters, such as closeness to customers, raw material deposit become less important. The entrepreneurial location planning process has nowadays to include these continuously changing patterns: structural criteria, innovation-friendly environment, future development, future demographic development and risk management of the region.

2.2 New Actors in Location Planning Decisions

Leaving national level for location planning decisions, new actors in international competition appear. Already in literature discussed actors are the so called global cities. Saskia Sassen established the term and defines them as new places of concentration.[9] This includes agglomeration of production and management control as well as production factors such as knowledge and high potential resources. Siebel states that global cities reach a certain dimension with at least 6 Mio. citizens .[10] The global city furthermore contains social aspects such as education, health care, cultural offers as well as research centres with international awareness level.[11] Scharenberg subsumes this and declares the global city as the trial to locate the global economic system at a concrete place.[12]

In contrast to a global city a metropolis contains important economical headquarters but must not be a worldwide center of decision and trade market. It is not yet still clarified what is still a metropolis. Heineberg defines a metropolis as a political, economic, social and cultural centre with more than 1 mio. citizens and more than 2.000 citizens per km² with a mono-central structure.[13] Esser and Schamp define metropolises as a smaller level of global economic integration under the level of global cities.[14] Regions finally provide an even smaller value. They are not just a geographical, but also administrative and functional, even social construct with an economical structure with one or several centres and can also feature rural parts.[15] So, in difference to a metropolis regions can have polycentric structures and rural areas.

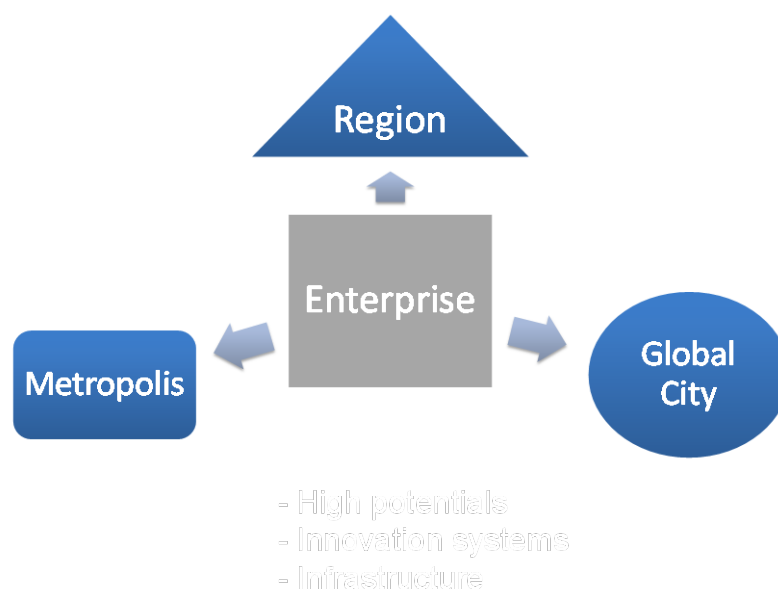

Figure 2 New Location Decision Model (Source: own figure)

Accordingly, especially regions and metropolises face a difficult role in modern times. They crush harder in the international competition since the international location decision loses importance. Now, they have to appear as new actors in the global competition, although they cannot compete directly against more visible players. This sets them in duty to design and influence factors enhancing their attractiveness. The smaller the player is, the more it has to sharpen its profile and adapt its actions to its possibilities. Especially for smaller players this offers new perspectives, but also new risks at the same time such as being “taken over” by larger structural unities.

2.3 New Criteria Set for Comparing Locations

This new set of actors in location planning decisions produces an extremely heterogeneous initial position for an analysis because both, urbanized and rural areas have to be considered the same way as well as several factors of infrastructural expansion stage, power concentration, international impact, awareness level but also furthermore in cultural visibility, innovation intensity and last but not least life quality factors for citizens. Yet, the existing measurement tools to compare global cities or metropolitan areas are not able to adapt to the special need of regions. As well, there exists a lack in regarding future orientated indicators like climate change demographic vulnerability, climatic change and energy supply as mentioned in the EU study Regions 2020.[16]

Furthermore, there is the question if citizens' perspective influences several economic indicators as well. In order to solve and combine this challenge, an enlarged indicator system concerning the special situation of regions as well as larger units is necessary. It should not only compare players but also give the opportunity to name chances and risks as well as recommendations for a sustainable development.

3. Case Study – Analysing and Comparing Regions

3.1 Study Design

A research project at the University of Ulm developed a triangulated scientific measuring for the region Donau-Iller in Southern Germany which frames ~1 Mio. citizens and a group of 52 regional political decision makers. Donau-Iller is a small region in Southern Germany, located between the attractive metropolises Munich and Stuttgart. With the city of Ulm it shows one regional centre, as well as several district centres like Memmingen, Biberach, Neu-Ulm and Günzburg. Especially the outside sections are rural areas with a lack of economic and infrastructural development and a low density of population. Beside future risks, the research design considers quantitative and qualitative indicators in

the topics economics, demographic development, infrastructure, research and development, education systems, healthcare as well as leisure offers. Already existing studies, local statistics and an online survey with local companies (n=273, in 2009) were combined to current state description. The data was also forecasted. Both, actual state and forecast were set into benchmark to the surrounding metropolis and highly developed regions in Germany and worldwide. Based on a gap analysis and a SWOT analysis, experts from all topics (3 focus groups, 35 expert interviews) and political decision makers evaluated this current status and the best practise proposals for further political decisions. This ensured that perspectives of several stakeholders are included. The triangulated method is capable to compare heterogeneous regions with other actors and gives an information basis to deduce recommendations. It is capable to describe regional competitiveness factors in a more detailed way. It was finally possible to consider specific structural conditions of regions such as a high concentration of world market leaders as well as existing cluster structures.

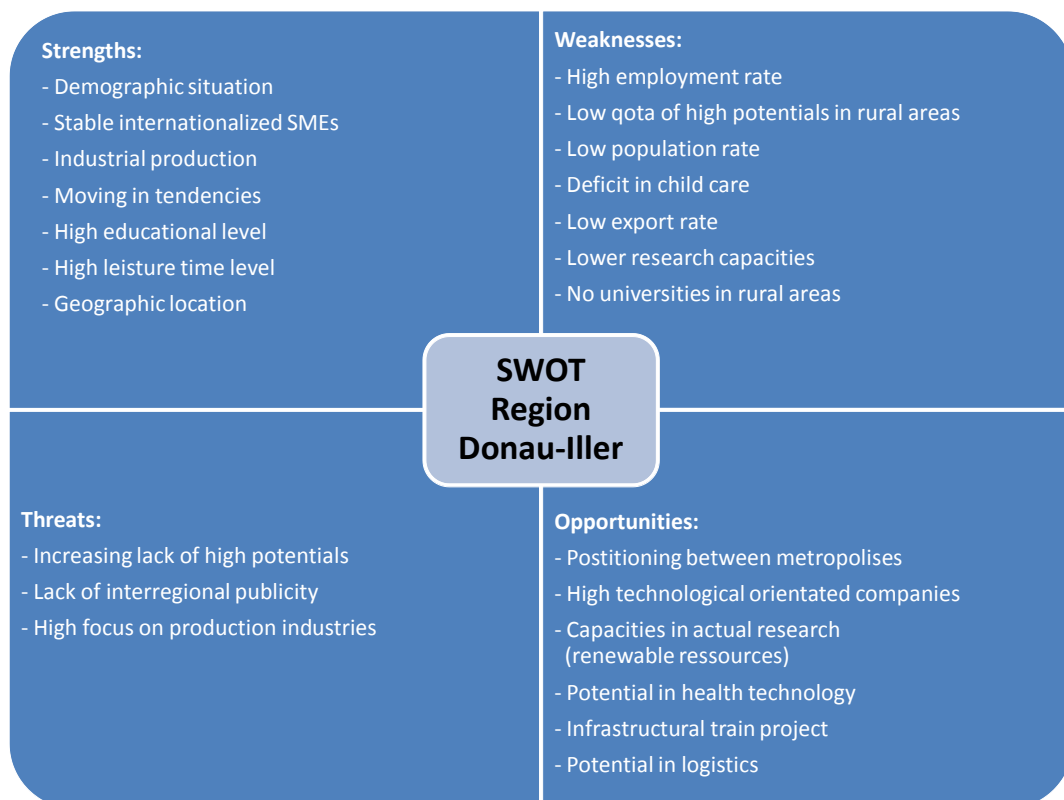

3.2 Quantitative and Qualitative Indicators for Regional Development

It showed up, that the different perspectives of stake holders in the regional context as well as many indicators itself are linked to each other. So, existing indicators have been completed with factors concerning entrepreneurial and civil need. Finally, the developed survey structure includes seven perspectives with up to 35 indicators each. Table 1 shows an excerpt of this indicator design.[17] Structural analysis of the interrelation of indicators leads to some very important functional connections that has to be regarded in coherence. Positive aspects for companies are e.g. a good educated employment market with a sufficient offer of high potentials. Therefore, a certain level of life quality for inhabitants is also important to attract and keep high potentials in this living area. This includes not only infrastructure such as retail industry but also matters of educational and health system as well as cultural and leisure time facilities.

For an innovative climate, cluster structures as well as research networks and existing branch structures are necessary. These pull new companies into a region and help existing branches staying competitive. On the other hand, a lack of infrastructure such as high speed internet connection, abroad highway access as well as missing railway connections and no fast access to international airports can reduce location's attractiveness. An insufficient education system can prevent high potentials from moving in, as well as a lack of leisure time activities. These factors work as barriers and prevent taking easily part in worldwide business processes.

Table 1 Study fields and indicator examples (Source: compiled by authors)

Topic	Main Indicators (excerpt)	Quantitative Dimensions (excerpt)	Qualitative Dimensions (excerpt)
Economy	employment market	e.g. unemployment rate	e.g. education and expert level of vacant positions
	class of business portfolio	e.g. increasing branches	e.g. trends in future branches, analysis of cluster structures
	commuting tendencies	e.g. in- and out-commuting tendencies	e.g. analysis of living and workspace, infrastructural needs
	direct investments	e.g. number and height of investments	e.g. analysis of location planning decisions
Research	patents	e.g. numbers and topics	e.g. research fields
	research clusters	e.g. members, participants and quota of branch	e.g. descriptive research analysis of special research fields and excellence clusters
Education system	high potentials	e.g. numbers of specialists	e.g. professional level
	university students	e.g. numbers of study courses	e.g. analysis of needs coverage
	advanced trainings	e.g. numbers and topics of advanced trainings	e.g. further needs and analysis of provider structures
Health system	hospital medicine	e.g. number of beds, doctors, nurses, patients	e.g. analysis of cases, technical possibilities
	resident doctors	e.g. distance to general practitioner and specialists	e.g. development of health system, situation of country doctors
	nursing	e.g. numbers and location of residential and mobile nursing services	e.g. future needs and changes in therapy

and the summing up SWOT analysis, a theory driven 18 steps action plan for local policy level regarding a sustainable Regional Development was designed.

5. Conclusion

As recommended, the research project and case study showed that the entrepreneurial decision making process concerning locations has deeply changed. Political decision makers should recommend these structural criteria (e.g. regional risk management or innovation friendly environment) as more and more important. These qualitative indicators have to be considered within future political decision making processes. But even if this comes to reality, it might lead to a contradiction between future needs of a region and the personal future of actual politicians. The global competition of regions leads to a more deepened challenge of how to be attractive for further and future foreign direct investments. Competitiveness factors have to be differentiated and to be precisely approved by each of the regional actors. The challenge for all participants of location decisions is that the qualitative indicators become more reasonable on the one hand but on the other hand they are more difficult to be measured. The selective qualitative and quantitative criteria have to be constantly monitored in order to adapt strategic adjustments to inner or external changes.

Administrative procedures in public administration as an obstacle to the operating of SMEs: comparison of EU and selected SEE countries

Barbara Bradač Hojnik¹, Miroslav Rebernik²

¹*Faculty of Economics and Business, University of Maribor, Maribor, Slovenia, barbara.bradac@uni-mb.si*

²*Faculty of Economics and Business, University of Maribor, Maribor, Slovenia, rebernik@uni-mb.si*

Companies act in an environment that is more or less favourable to them. The environment is significantly limited by the institutional framework that establishes the rules of the game and is controlled by public administration, which may be more or less effective, and more or less responsive to the needs of companies. However, companies differ not only by size and industry, but also regarding steps in their life cycle, their international focus, entrepreneur's ambition, etc. Since the essence of entrepreneurship is in obtaining and marshalling resources to exploit business opportunity, unimpeded access to resources is of crucial importance to entrepreneurial activity. However, it is not just about getting financial resources, but also about all other factors of entrepreneurial ecosystem - from hiring and firing people to obtain various licenses, state regulatory statistical and tax reporting, tax burdens and different procedures that must be carried out by entrepreneurs so that their core business, namely the production of goods and services, can take place smoothly.

In the empirical part of the paper, we analyse selected indicators for responsiveness of public administration in selected SEE countries (Slovenia, Croatia, Bosnia and Herzegovina, Serbia, Montenegro and FYR Macedonia) compared to the average European Union (EU). Using the EU's measurements and assessments of different areas of the business environment we analysed same topics as analysed in Small Business Act and Report of European SMEs. The data were obtained directly from the database WB Doing Business Book. Indicators are divided into three periods of the company lifecycle: (1) starting a business, (2) business operation, and (3) closing a business.

Keywords

Administrative procedures, public administration responsiveness, SEE countries, SMEs, entrepreneurship

1. Introduction

Institutional environment determines the conditions in which companies must operate from their establishment until their closing. In this paper, we discuss selected aspects of this environment determined by public-administrative procedures faced by entrepreneurs throughout the company's lifecycle. Modern and responsive public administration has positively impacted the exploration of business opportunities, acting as a supportive environment. In contrast, obsolete and unresponsive public administration further complicates entrepreneurs' life and negatively impacts new business creations as well as companies' successful operation. In general, economic policy makers have two main ways of promoting entrepreneurship [1]. First, their actions may be in the direction of low regulation, or second in the direction of high support. The low regulation can direct economic policies

in two areas. The first one is to enable starting the businesses in the most simple, inexpensive and fast way. The second area is to minimize the number and scope of regulations for companies that already operate. Entrepreneurship policy with the high level of support is actually on the shoulders of taxpayers, covering the provision of many support services. These support services may be different advice, information provision, education, financial incentives, subsidies and similar. The less regulation direction is characteristic for USA, while the supportive policy is more typical for European countries.

The paper provides the overview of the institutional framework for entrepreneurship and presents the results of the empirical analysis of indicators to measure administrative processes and public administration responsiveness in selected SEE countries and EU average. The paper will conclude with some insights that should be considered at the further development of public administration.

2. Institutional framework and entrepreneurship

Entrepreneurship is a scarce resource. Therefore it is of particular importance how it is utilized. Generally, the entrepreneurship as a characteristic of the human spirit is not in certain countries or regions greater, but it is about the "channel of entrepreneurial spirit" [2], where some countries are more successful than others. Major role is played by the institutional system and the rules of the economic system. It is always possible for economic policy to support the creation and operation of companies, but it has to take into account that the effectiveness of support depends on the companies' life-cycle. It must be understood that companies have different needs and are differently affected by external factors, depending on the stage of their life-cycle. The establishment and operation of a company needs particular capital, therefore there have to be considered the influence of income limit [3], because it can have a negative impact. Additionally, transaction costs (e.g. costs of searching and acquiring information, costs of negotiation and decision making, costs of motivation and execution of agreements, costs of control and performance evaluation, and compliance costs of business activities) can be very important factor for operating of companies.

The policy affects the level of business in a society in two ways [4]. The first one is in shaping the quality and quantity of inputs for the entrepreneurial process, and the second one is in shaping the institutional framework that provides the "rules of the game". However, the key question is always, to whom different incentives are aimed at. It is important not only to influence the amount of companies, but primarily their quality. Influence on the institutional framework takes place over the entire set of laws, rules of a competitive market, government intervention, the legal system, tax rules and others. Those are the factors, which [5, 6] direct individuals to decide to engage in (or discourage) the different types of entrepreneurship: a productive, unproductive or destructive. Creative people will get involved in productive entrepreneurship in countries which ensure property rights, fair and balanced legal system [4], and appropriate implementation of contracts. By contrast, in countries with incomplete and inadequate institutions more individuals will engage in unproductive or destructive entrepreneurship. The more the institutional structure is unregulated and the public administration is slow and unresponsive, the greater are chances that companies are directed towards maintaining the status quo instead of innovation, growth, and internationalization.

However, unresponsive public administration brings an additional risk. Entrepreneurial process is largely based on the principle of "attempt - error" [7, 8, 4], it is nevertheless a constant recombination of resources. Therefore, resources have to be free for entrepreneurial activity and should not be burdened with numerous administrative obstacles and processes, which have negative impact on entrepreneurs' core mission, namely the manufacturing and providing products and services that customers are willing to purchase. Therefore, the effectiveness of the entrepreneurial process depends not only on successful products and services, but also on how quickly it is possible to identify failures and to eliminate inefficient combination of resources and based on this enable their more successful combination. The more the economic system is bureaucratic and politicized, the less effective it is. In the strong economy there will always be a huge dynamic of new companies and their failures.

A national policy influence the development of the economy by three aspects [9]: first, by the legislation system which establishes a regulatory mechanism; second, by the development process at national level through various short and long term economic policy measures; and third, by encouraging entrepreneurship in the public sector. However, companies have their life-cycle from inception to closure. Therefore, they need support from public administration to lessen administrative obstacle to encourage entrepreneurship. In continuation is provided empirical analysis of selected indicators of administrative procedures in public administration.

3. Empirical analysis of administrative procedures in public administration

According to the goals of the European Union to become the most competitive economy, the European Commission implemented several initiatives to fulfil that aim. Measurement and evaluation of initiatives' effects are mostly made on the annual level by different systems of indicators. The area of establishment and operation of companies that refer to administrative procedures in public administration are estimated by several indicators, using database of *World Bank Doing Business*. To measure and evaluate impeding administrative procedures in public administration faced by companies in different stages of their life-cycle we used the database *Doing Business 2011* [10] for selected SEE countries (Slovenia, Croatia, Bosnia and Herzegovina, Serbia, Montenegro and FYR Macedonia). The life-cycle of companies was divided in three steps, namely (1) starting a company, (2) operating of a company, and (3) closing a company. In this paper we analyse the first two steps of life-cycle.

Table 1 Overview of indicators, measuring administrative procedures in public administration of companies

Starting a company	Operating of a company		
	Trading across borders	Registering property	Enforcing contracts
<ul style="list-style-type: none"> • Procedures • Time • Cost • Minimum capital 	<ul style="list-style-type: none"> • Documents to export • Time to export • Documents to import • Time to import 	<ul style="list-style-type: none"> • Procedures • Time • Cost 	<ul style="list-style-type: none"> • Procedures • Time • Cost

3.1 Analysis of administrative procedures in public administration at starting a company

Starting a company and its operation requires the entrepreneur's constant dealing with public-administrative procedures and costs. Already the establishment of a company is associated with them and continues throughout its life-cycle. Administrative procedures at starting a company are measured by number of procedures, time, costs and minimum capital required. Definitions of these indicators are as follows [11]:

- *Number of procedures, needed to establish a company* is defined as any interaction of the company founders with external parties (for example, government agencies, lawyers, auditors or notaries). Interactions between company founders or company officers and employees are not counted as procedures. Procedures that must be completed in the same building but in different offices are counted as separate procedures. If founders have to visit the same office several times for different sequential procedures, each is counted separately.
- *Time* is measured in calendar days. The measure captures the median duration that incorporation lawyers indicate is necessary to complete a procedure with minimum follow-up with government agencies and no extra payments. It is assumed that the minimum time required for each procedure is 1 day. Although procedures may take place simultaneously, they cannot start on the same day (that is, simultaneous procedures start on consecutive days). A procedure is considered completed once the company has received the final document.
- *Cost* is measured as a percentage of the economy's income per capita. It includes all official fees and fees for legal or professional services if such services are required by law. Fees for purchasing and legalizing company books are included if these transactions are required by law. The company law, the commercial code and specific regulations and fee schedules are used as sources for calculating costs.
- The *paid-in minimum capital requirement* reflects the amount that the entrepreneur needs to deposit in a bank or with a notary before registration and up to 3 months following incorporation and is recorded as a percentage of the economy's income per capita. The amount is typically specified in the commercial code or the company law.

The Table 2 represents the results of above mentioned indicators by selected SEE countries and EU average for year 2011.

Table 2 Administrative demands in public administration at starting a company by country [10]

Country	Procedures (number)	Time (days)	Cost (% of income per capita)	Min, capital (% of income per capita)
Bosnia and Herzegovina	12	55	17,7	30,5
Croatia	6	7	8,6	13,7
Macedonia FYR	3	3	2,5	0
Montenegro	7	10	1,9	0
Serbia	7	13	7,9	6
Slovenia	2	6	0	45
EU average	6	15	6	18

Among investigated countries, the most procedures to establish a company are required in Bosnia and Herzegovina (BIH) and the least in Slovenia and FYR Macedonia, which are also under the EU average. However, the time, needed to establish a business is also the highest in BIH while are all other countries under the EU average. Costs of starting a company are also the highest in BIH, while in Slovenia there are no additional costs of establishing a company. The last indicator is the required minimum capital which is the highest in Slovenia, while in FYR Macedonia and Montenegro it is not needed. In previous years almost all countries (except BIH) opened one-stop shop systems and eliminated several procedures for establishing companies. Additionally, Serbia is among countries that made the most to ease the process of establishing a company in last years. Consequently, number of registered companies significantly increased. It shows that each of indicators is an important part of number of establishing companies in an economy. However, starting a company is unique event while operating of a company takes over time and is from this point of view more important.

3.2 Analysis of administrative procedures in public administration at operating of companies

In the second phase of life-cycle (operating) companies are confronted with even more administrative procedures and expenses than in the first phase. In following chapters are analysed three groups of indicators, measuring administrative procedures, namely (1) trading across borders, (2) registering property, and (3) enforcing contracts.

3.2.1 Analysis of administrative procedures at international trading

International cooperation is important prerequisite for companies' growth especially in smaller economies. It depends on national conditions enabling trading across borders. Barriers to international trading regarding administrative procedures can be measured by several indicators, among which we selected the following four [12]:

- *Documents for export or import:* All documents required per shipment to export and import the goods are recorded. It is assumed that the contract has already been agreed upon and signed by both parties. Documents required for clearance by government ministries, customs authorities, port and container terminal authorities, health and technical control agencies and banks are taken into account.
- *Time to export or import:* The time for exporting and importing is recorded in calendar days. The time calculation for a procedure starts from the moment it is initiated and runs until it is completed. If a procedure can be accelerated for an additional cost and is available to all trading companies, the fastest legal procedure is chosen.

Table 3 represents the results of above mentioned indicators by selected SEE countries and EU average.

Table 3 Administrative demands in public administration at starting a company by country [10]

Country	Documents to export (number)	Time to export (days)	Documents to import (number)	Time to import (days)
Bosnia and Herzegovina	5	16	16	7
Croatia	7	20	8	16
Macedonia FYR	6	12	6	11
Montenegro	6	14	6	14
Serbia	6	12	6	14
Slovenia	6	19	8	17
EU average	5	12	5	12

The results show that in each country, including EU average, there is needed more or equal number of documents to import than to export. However, it cannot be stated for time to import and export. In general, time to import and export is higher in Croatia and Slovenia than in other countries. The time to import is very high in Bosnia and Herzegovina although they made a reform already in 2008 to simplify the international trade. Additionally, Montenegro and FYR Macedonia successfully implemented measures to simplify procedures and shorten time, while other countries have not implemented special successful measures in this area.

3.2.2 Analysis of administrative procedures at registering property

Registering property includes all steps, time and cost involved in registering property. It is measured by three indicators [13]:

- *A procedure* is defined as any interaction of the buyer or the seller, their agents (if an agent is legally or in practice required) or the property with external parties, including government agencies, inspectors, notaries and lawyers. Interactions between company officers and employees are not considered. All procedures that are legally or in practice required for registering property are recorded, even if they may be avoided in exceptional cases. It is assumed that the buyer follows the fastest legal option available and used by the majority of property owners.
- *Time* is recorded in calendar days. The measure captures the median duration that property lawyers, notaries or registry officials indicate is necessary to complete a procedure. It is assumed that the minimum time required for each procedure is 1 day.
- *Cost* is recorded as a percentage of the property value, assumed to be equivalent to 50 times income per capita. Only official costs required by law are recorded, including fees, transfer taxes, stamp duties and any other payment to the property registry, notaries, public agencies or lawyers.

Table 4 provides results of administrative procedures and costs associated with registering property in selected SEE countries and EU average.

Table 4 Administrative procedures and costs at registering property by country [10]

Country	Procedures (number)	Time (days)	Cost (% of property value)
Bosnia and Herzegovina	7	33	5,3
Croatia	5	104	5
Macedonia FYR	5	58	3,2
Montenegro	7	71	3,3
Serbia	6	91	2,7
Slovenia	6	113	2,1
EU average	5	35	5

The results show that costs and number of procedures is in all countries comparable, while there are major differences in time, which is an important issue in registering property. The worst situation is in Slovenia (113 days) and in Croatia (104 days). However, all other countries except BIH (33 days) are over the EU average (35 days). Although all countries implemented measures to shorten and reduce administrative procedures on this issue, including implementation of electronic systems, it is still not optimal and needs further improvements, especially of reducing time.

3.2.3 Analysis of administrative procedures to enforce contracts

Administrative procedures and costs indicators of enforcing contracts measure the efficiency of the judicial system in resolving a commercial dispute. Administrative procedures in enforcing contracts are measured by following indicators, which definitions are [14]:

- *A procedure* is defined as any interaction, required by law or commonly used in practice, between the parties or between them and the judge or court officer. This includes steps to file and serve the case, steps for trial and judgment and steps necessary to enforce the judgment.
- *Time* is recorded in calendar days, counted from the moment the plaintiff decides to file the lawsuit in court until payment. This includes both the days when actions take place and the waiting periods between. The average duration of different stages of dispute resolution is recorded: the completion of service of process (time to file and serve the case), the issuance of judgment (time for the trial and obtaining the judgment) and the moment of payment (time for enforcement of judgment).
- *Cost* is recorded as a percentage of the claim, assumed to be equivalent to 200% of income per capita. No bribes are recorded. Three types of costs are recorded: court costs, enforcement costs and average attorney fees.

Results of above mentioned indicators for selected SEE countries and EU average are provided in Table 5.

Table 5 Administrative procedures and costs at enforcing contracts by country [10]

Country	Procedures (number)	Time (days)	Cost (% of claim)
Bosnia and Herzegovina	37	595	40,4
Croatia	38	561	13,8
Macedonia FYR	37	370	33,1
Montenegro	49	545	25,7
Serbia	36	635	28,9
Slovenia	32	1290	12,7
EU average	32	549	21

Similarly to the issue “registering property” also the enforcing contract issue differ in time while in number of procedures and costs all countries are comparable. However, at regarding only a time the most effective is FYR Macedonia (370 days) what is also below EU average (549 days). All other countries are above EU average, leading by Slovenia where there are needed 1290 days to enforcing a contract. Additionally, only FYR Macedonia is recorded as a country which implemented some measures to improve this area of public administration in last three years, among which was also a good practice “sustained multitasking” [15]. This area of companies’ operation is important because it can have a major impact on entrepreneurship dynamic, because unsolved commercial disputes can prevent further successful operation of a company.

4. Conclusions

The paper provides an insight into the administrative procedures in public administration for companies during their life-cycle. Provided results of empirical analysis among selected SEE countries compared to EU average.

First were analysed administrative demands at establishing a company. Almost all countries implemented majority of initiatives and conditions for establishing a company were mainly improved.

However, establishing a company is an one-time act. Much more important are administrative procedures and costs for operating companies because they affect business on a daily basis. Nevertheless, study of administrative procedures and costs shows, that analysed countries did not make as much efforts in improving conditions for operating companies as for starting a company. First analysed domain was international trading where almost all countries could improve conditions to lessen the number of procedures and to shorten the time to import or export goods. Fostering international operations of companies positively impacts their growth therefore in the future all countries should implement additional measures to improve conditions for international trade. At other two domains, registering property and enforcing contracts, the main challenge to improve is the time. Almost all countries should shorten the time, needed to register property and to enforce a contract, while other two indicators, namely procedures and costs are less critical issues. It can be concluded that analysed countries still have to improve conditions regarding administrative procedures and lessen costs. However, national economies have to find appropriate level of administrative procedures and costs to foster entrepreneurial activity and at the same time to retain suitable minimum level of administrative procedures to ensure institutional protection and overview.

Business process modelling represents trend in modern business, as it helps to overcome complexity, misunderstandings in conducted activities and communication at all levels. Certain systems have been implemented in Serbia that allow centralized storage of scientific biography of researchers or their papers, however they do not support automated scoring of results nor they deal with the evaluation of research results. The problems were multiplied with emergence of new researchers and with constant flow of new research.

With the goal of improving the existing systems and the introduction of automation in certain steps of scoring and evaluation of research results, we analyzed every aspect of the process and the current situation in Serbia which lead us to the “AS-IS” model. Modelling of “AS-IS” model represents the first step of business process analysis. This model helped us to identify key business processes, and to identify places where improvements and certain automation must be made.

In order to initiate the process of improvement, we developed several alternative “TO-BE” models. Each model illustrates different viewpoints on improvements of the process of evaluation of scientific research results.

Presented paper describes each model with its merits and shortcomings identified through the thorough analysis. The aim of this paper is to perceive all proposals to determine whether one of the suggested alternatives is the best solution. If not, to extract all good recommendation and to consolidate them into a new TO-BE model. The emphasis is put on the proposed improvements and automation of certain steps of evaluation process of scientific research results in the Republic of Serbia.

Keywords:

Education, Process modelling, Scientific research result, Scientific worker

1. Introduction

Business process modeling (BPM) is the best way to understand and analyze processes since they can encounter many difficulties. Modeling helps to combat complexity, lack of understanding and communication problems, both between people and systems. BPM tools provide visibility into the exact functioning of internal processes and services so they can be standardized, understood and better managed. The purpose of BPM is to develop applications that solve business problems. The first step in the creation of a BPM-based application is the development of business process models. These models will be used to illustrate how the work is performed today, what opportunities for improvement exist, and how the work should be improved and automated.

The modeling of a business process starts when a process analyst captures (models) the "AS-IS" process which reflects the current way of doing business. After the business process diagram is complete, it will be used to analyze that process, and make improvements. "Once it is established how the business is currently done, business analyst should strive to find other opportunities of carrying out the business processes and then to compare them. This intermediate stage is characterized by development of potential diagram called COULD process diagrams. Finally, the selection of a new process is done through analysis of proposed COULD diagrams, moving towards the final TO BE process diagram. Of course, it is much harder to carry out an analysis of the current process because it does not have to be logical or make sense, than to create a new process that will be mostly logical." Therefore, the goal is to develop several alternatives of the future business process model, and then to analyze them with the aspiration to determine an optimum TO BE process model that will facilitate company with more efficient way of doing business and will include some automation steps.

Although education is not a business process in the classical sense, in modern terms it is organized in the form of a process. In that process, education and research are intrinsically attached to and dependent one on another. In order to estimate the contribution of scientific research to the improvement of education process, it is necessary to evaluate the results of scientific research and bind them to the authors, i.e. researchers and scientists. By doing this, the contribution of scientific research results of individual authors to the development of certain scientific and research fields can be estimated, and thus their contribution to improvement of the education process as a whole. Evaluation of scientific and research results is especially challenging, because it depends on the type of the result and the specific scientific area of the result.

Regarding the evaluation of scientific and research results in Serbia some problems must be emphasized, such as disagreements regarding the criteria of evaluation; evaluation process is not fully standardized at the state level and it is not a regular and compulsory activity, it is only performed when the need arises; lack of unified database of evaluated results and their authors that would enable easy access to data on existing scientific and research results and their values to all interested parties.

Need for improvement of the process of evaluating scientific and research results was the motivation for this research. First undertaken step was development of an AS-IS model of the process that will help to fully understand and define the current state of the process. The basis for improvement and partial automation of the evaluation process, and therefore the fertile ground for improvement of the education process as a whole, is presented in [2] where authors revealed in detail AS-IS model of the process with all its shortcomings and initial ideas for improvements. This paper will reflect the most important issues of each proposed alternative of scientific and research results evaluation process.

2. Overview of problem domain and current work

The idea of unique bibliographical database exists for several years, but the implementation was not conducted as expected. There was a few separate opinions on how the implementation of this database should be conducted, which further brought up several systems depicting each of the opinions. These systems gave a fertile ground for future development of the unified database. Furthermore, it was noticed that fulfilment of this idea would be increased through the conjoin between the existing systems. A few systems that could represent the initiation of this idea are Kobson, DOI, Scriptor, Svibo, SCIndex.

Kobson, as a portal, is used for online search of articles from a wide range of journals. The access for searching is unlimited, once you have been registered (by identifying the user over the academic network identification or simply by filling the registration form as academic stuff) as a Kobson user. It gives a browsing options over a wide range of the world's most prestigious databases, such as EBSCO, Springer, IEEE, etc. Furthermore, it gives an opportunity for visitors to check the domestic journal archive and access a full text articles. The advantage of the Kobson lies in the possibility to access a wide range of articles, but, on the other hand, it doesn't have an integral database for all those articles that are published in domestic journals.

Digital Object Identifier (DOI) represents alpha-numeric array which uniquely identifies doi pointed digital copy placed at the server. The main task of this service, which is under a jurisdiction of National library of Serbia, is to assign DOI numbers to the articles which are published in domestic journals. This service provides a complete review of articles published in domestic journals and instant access to the full paper of listed references if the user is subscribed to the journal where the referenced article is published. DOI provides the information about the paper used in references, but it cannot give an information about scientific worker to whom reference belongs.

Programming language Svedi is built for gathering and revising article's citation informations. Svedi does the revision of article's references through the strict comparison of references provided in the article and the original one. This helps maintaining and upgrading the national citation index. Another tool which parses bibliographic information is a Scriptor tool. It prepares bibliographic information to prevent wrong transfer of data to the citation database.

SCIndex, Serbian national citation index, was designed as a mean of evaluating scientific work and communication through provision of reliable information about scientific work. SCI index perfectly measures citation index of each article, but it doesn't have a citation list for every author.

While observing current situation in Serbia, it can be noticed that certain functionalities of developed systems can be used in order to carry out the idea of unique bibliographical database development. Besides the existing functionalities, bibliographic and scienometric analysis are extremely important. As stated in reference [2] "often criticized certain deficiencies of the most prominent international citation databases (SCI and SSCI) can be overcome by expressing individual author's citation and on the basis of coauthors' contributions, i.e. in fractional form as recommended in scientometric literature." To sum up, the purpose of this integral bibliographic database would be to give a complete inspection in scientific accomplishments of all scientists.

After detail analysis, it can be concluded that in order to overcome listed deficiencies and promote the process of scientific and research results evaluation, it is necessary to automate the process of evaluation of scientific and research results as much as possible. The first step would be design and implementation of unique national bibliographic database, which would give the scientists an opportunity to register and enter all of their scientific research results, which would further facilitate the scientific worker's personal and research accomplishments data record (KNR) generation and maintenance. In addition, the database should own information of all known journals, publications and projects, providing a possibility to enter new ones, too. In order to keep accurate journal classification according to M categorization, the Ministry of Science should appoint a Committee, which would be responsible for monitoring of journal categorization, as much as reviewing of existing types of scientific research results categorization. Furthermore, the Committee would associate paper categories with a value points, ensuring the valuation of scientific research result is done automatically according to the verified and applied categorization. The database administrator, elected by the Committee, would do the maintenance of the database according to the given instructions.

3. Model description

The process modeling implies that the functions of the overall system should be divided into abstract parts in order to reflect basic functions that should be met. Later on, the abstracted parts are drilled down and divided into smaller parts known as tasks. Each of the tasks should have input and a valuable output, so the process could be called successful. The actors would ensure that the tasks, as part of a process, are appropriately done.

3.1 The first alternative

At the beginning of modeling the process of evaluation of scientific and research results, it is assumed that it should deal with the majority of the drawbacks described above. In order to accomplish the appointed requirements, the following basic sub-processes were identified: sub-process of *Entering the scientific work data into the database*, which will be conducted with the permission of Committee and executed by the database administrator; the sub-process of *Insertion of scientific worker's research result into the database*, whose activities would be conducted by a scientific worker and the sub-process of *Verification of scientific research results* conducted by the verification body. The Ministry of Science and Technological Development of Republic of Serbia will appoint a database administrator, verification body and Committee responsible for running predefined tasks.

The first sub-process concerns database development, which represents the creation of categories and clusters of scientific research results. That way, the database would have the scientific work, and therefore scientific research result unequivocally sorted. Furthermore, when the categories and clusters inside those categories are made, it is only necessary to enter information about certain scientific work (journal/conference/project). In some cases (after the database has been created), it is only necessary to update the information about existing scientific work, like changing the area where it is assigned or adding the citation data if it is journal information. When all the necessary information is updated/inserted, the scientific research can be indexed and assigned appropriate points. The next sub-process is the recording of the scientific research result of a particular scientific worker. This part

of the process represents a standalone sub-process which can be run independently of the database recording flow. Therefore, this sub-process would start when a scientific worker has a scientific research result to record. In order to succeed in this task, the scientific worker has to be a registered user of the portal which provides the service for collecting and evaluating scientific work. If the user doesn't have an account, he/she is offered to create one, using the registration sub-process. This sub-process considers entering/changing the personal data about the scientific worker and the selection of scientific area, in which the user is conducting scientific research. That way, by selecting the scientific area, the user would be evaluated and assigned points only for those scientific research results that are of importance to him/her, while the other scientific research results will represent only the references.

After the registration process, the user needs to login and enter another sub-process which will lead the user to enter the information about scientific research result. First of all, a person, sub-process participant, is being offered a list of all available scientific works, which are entered earlier (during the database creation and maintenance). The participant might notice that the particular scientific conference/journal/project is not in the list. In that case the participant can, with an appropriate proof of scientific journal/conference/project presence, send a request to the database administrator so the missing scientific work can be added. The administrator will check the existence of required scientific work, consult the Committee and add it to the list with appropriate categorization; otherwise, the request will be rejected. The evidence of scientific work existence should be the document that uniquely proves its existence. For instance, the proof of journal existence would be its front page and ISBN. If the person finds the wanted scientific journal/conference/project in the list, by simply selecting it, the scientific work is assigned a category and cluster of the selected item. Furthermore, the particular scientific work is automatically evidenced in KNR of the logged-in user as a scientific research result. All scientific work that is entered by the logged-in user is marked as non-usable until it is verified by the verification body. This controlling mechanism is made in order to prevent misuse of scientific references. It is planned that the verification is done periodically - once per month.

The last, but not the least important sub-process is part of the scientific research result verification sub-process, and is under jurisdiction of the verification body. While, the sub-process of verification is conducted, the scientific worker is required to wait for a period of time, until his/her scientific research results are being verified. This sub-process includes the task of technical correction check and can have two scenarios. The first one would be when the technical data is fine, in which case the scientific research result would be entered into the database along with the assigned points, predefined for it. The second one would be if the scientific research result is not being entered as a part of an appropriate scientific journal/conference/project, the verification body would find the appropriate scientific work, do the technical data correction and assign it to the appropriate journal/conference/project. Finally, the scientific research result will be entered in the unique database of scientific works, the points will be assigned to the scientific worker and the mark of unsafe reference will be removed.

This model deals with drawbacks of the existing systems - automation enrolment and design of a unique database, but still it doesn't cover some of the possible reasonable solutions. The possibility of reviewing the verified scientific research result by a scientific worker could be one of them. That way the process could deal with the situation of disagreement of scientific workers and verification body; providing the participant (scientific worker) an opportunity to submit a complaint about inappropriate classification.

3.2 The second alternative

In second proposed TO-BE model, following sub-processes were identified: Analysis of journals, Journal categorization, Insertion of new scientific and research results into database, Consideration of complaints/requests, Verification of scientific and research results, and Notification about the changes. Activities of the first sub-process – *Analysis of the journals* are conducted by the verification Committee and research institutions. Verification Committee examines to which degree journal, that is not registered in the database, satisfies predefined criteria that must be fulfilled for the journal to be indexed and inserted in the bibliographic database. If all necessary criteria are met, verification body performs its categorization, otherwise the institution is informed about the criteria that must be met for journal to be listed in bibliographic database.

Activities of the sub-process of *Categorization of journals* are conducted by the verification Committee and database administrator. When a need for categorization of journals occurs administrator delivers citation information to verification Committee for consideration. On these bases verification Committee can define M coefficient, scientific fields journal belongs to, and associate it with an adequate value

points. Such information is forwarded to administrator for database update. Described activities are repeated in case someone has objection regarding categorization or if journal is not registered in the database.

Activities of the sub-process *Insertion of new scientific and research results into database* are conducted by scientific workers and verification body. Scientific worker must be registered on a system to be able to add his/her work to the database. Therefore, the first activity is status check. If a new user should appear he/she must create account. After login activity, a user can access journals only from his/her scientific and research field, since that is the only relevant field for assessing the work. The following activity is status check of scientific and research work, which means the separation of the unpublished (e.g. participation in projects) and published scientific work, because there is a distinction in their evaluation. Unpublished scientific work is directly inserted into the database. Otherwise, the user is obliged to select from available journals in the database the one where the work is published. At this point two problems can occur: the journal is not registered in the database, and wrong journal categorization. Both problems should trigger automatic notification of the verification Committee for inclusion of the journal in the database or its' update. If problems should not occur, an automatic categorization of work is performed.

Activities of the sub-process *Consideration of complaints/requests* are conducted by verification Committee and scientific worker. When scientific worker faces with above mentioned problems, complaint (about an inadequate categorization) or request (for journal to be listed in database) is sent to verification Committee. Therefore, the first activity of this sub-process is consideration of complaints or requests. If stated arguments are acceptable journal status must be established: is it a new or already registered journal? In case of a new journal a journal analysis must be performed, while registered journal has to be re-categorized. In case complaints/requests are refused, automatic notification is sent to the scientific worker when the user must reenter scientific work and adapt the existing categorization.

Activities of the sub-process *Verification of scientific and research results* are conducted by verification Committee and database administrator. After scientific worker inserts new scientific and research results into the database, information about this activity is sent to verification body. Verification Committee is obliged to check technical correctness of each inserted paper, before its final insertion into KNR table of the database. If the paper is technically correct it is automatically inserted into KNR table, otherwise verification Committee updates it and sends notification to the user about changes.

Activities of the sub-process *Notification about the changes* are conducted by verification Committee and scientific worker. When verification Committee makes certain adjustments to paper inserted into database, regarding categorization or technical issues, a notification about changes must be sent to the owner of the paper. Scientific worker can object to these adjustments, when verification Committee analyzes it. If there is an agreement, scientific worker sends confirmation to verification Committee so the paper can be inserted into KNR table.

3.3 The third alternative

The third proposed TO-BE model is based on two major assumptions. The first is the existence of one unique bibliographic database of scientific and research results and scientific workers i.e. the authors, with built-in mechanisms for automated categorization and for automated assignment of value points to the scientific and research results that are being entered. The model does not deal with the process of creation or with regular updates of the database – those tasks are performed outside of this model. The second assumption is the existence of Committees for verification of scientific and research results for every research field, appointed by the Ministry of Science and Technological Development, responsible for confirmation of existence and for verification of categorization and evaluation of entered scientific and research results, as well as for cooperation with the DB administrator in the process of DB update by entering new types of scientific and research results and changes in the categorization and evaluation criteria.

Owner of the process is the person in the Ministry of Science appointed to monitor the evaluation of scientific and research results in Serbia. The process is initiated when an author wants to enter a new result into the database. First step of the process is a sub-process *Logging to the DB*, one of two sub-processes incorporated into the process. In this sub-process the authors who already have an account at the DB just sign in to the DB. New authors must first create an account by entering the general information about themselves (name, title and position, name of the institution, ...), then they must choose the research field in which he/she was elected (which affects the classification and evaluation of the authors' scientific and research results) and define a unique user name and password. When

the new account is created, it is stored to the DB and the new author can then sign in to the DB, and with that ends this sub-process.

The next step is the second sub-process *Entry of the scientific and research results into the DB*. The author selects, from the list offered in the DB, the publication in which the result has been published, or a conference at which it has been presented, or the type of the result, or the project that he has participated in and is related to the result. If there is a problem, such as the required publication/conference/ type of the result/project is not in the list, or if it is not properly categorized or evaluated, a complaint is sent to the Committee for verification for the given research field, stating the problem that occurred at the entry. If the Committee accepts the complaint, in cooperation with the DB administrator they enter the correction into the DB. In this activity Committee uses the *Regulation of the evaluation of scientific and research results* and additional documents for the evaluation of scientific research, issued by the Ministry of Science, related to the correction of evaluation criteria based on scientific and research results citation. If the complaint is not accepted, a notification of rejection is sent to the author. In both cases the sub-process continues by returning to the first activity of the sub-process i.e. the selection of the publication, type of the result or the project. If there is no problem with the first activity, the result is automatically entered into a temporary table in the DB and with this ends the sub-process. The output of the sub-process is the temporary entry of the result into the DB.

Further activities are to determine whether the entered result is participation in the project or some other type of result. When it is participation in the project, the activity of categorization is skipped, whereas for any other type of result next activity is the automatic categorization. Based on the selected publication/conference/type of the result and on the categorization rules (the Regulation of the evaluation of scientific and research results) already entered into the DB, mechanisms for automated categorization automatically assigns the appropriate category to the result. After this follows the verification of the entry of the result into the DB: Committee for verification of scientific and research results for the given research field verifies that, in the activity of entering, the result has been connected with the appropriate publication/conference/type of the result/project and that the other entered information is correct, for which the author must provide evidence of the existence of the result. If the entry is correct, next activity is the automatic evaluation, and if the entry is not valid, the Committee re-connects incorrectly entered result with the publication/conference/type of the result/project and re-categorizes it. Any other error is also corrected and the correction is entered into the DB. If there is an error in the categorization of publication/conference/type of the result caused by the DB administrator (whether the entered categorization is not good or it has not been updated), the Committee sends to the administrator a requests to correct the categorization entered in the DB. The output of this activity is the corrected temporary entry of the result. Then the Committee notifies the author of the corrections made to the entry of the result, to which the author may object to. If the author objects to these changes, he/she sends the objection to the Committee and the process continues with the return to the activity of verification. If there are no objections, the process continues with the activity of the automated evaluation, as it does in the case when the entry is correct.

In the activity of the automatic evaluation of the result the mechanism automatically assigns the value to the result in the form of points, awarded based on the categorization and on evaluation rules that have already been entered into the DB. The output of this activity is the evaluated result, which is then finally entered into the DB. Based upon the entered results, a KNR of the author i.e. scientific worker can be generated, and that is the final activity and output of the entire TO-BE model of the Process of evaluation of scientific research results in Serbia.

4. Conclusion

The business process modeling is an ever evolving discipline. One of the definitions of process modeling points out that none of the business process is perfect and therefore, needs constant improvement in order to satisfy its main postulate – ever evolving structure. Considering all of the above statements, it is realized that, in order to accomplish the requirements that are given, it is necessary to be ready for the constant auditing and modification of all of the alternatives.

After detailed analysis of three solutions of TO-BE models given in this paper, it is discovered that there are certain deficiencies in each of them. On the other hand, every model has revealed advantages that could, with minor modifications, be considered as perfect solutions to these particular requirements. Furthermore, some of the advantages revealed in one of the alternatives have been identified as deficiencies in other alternative(s). The conclusion is that the perfect solution for modeling process of evaluation of scientific research results in Serbia would be joining together the advantages of all of the given alternatives and creating a new TO-BE model.

Open innovation is a relatively newly emerged idea. So far, this idea is used in developed countries and focusing on high income customers. In contrast, around two-thirds of the world populations live in developing countries and their income is very low but the cumulative market of this low income stratum is about \$5 trillion. The aim of this paper is to explore the potential of open innovation idea at the bottom of the pyramid. Economies of developing countries are growing rapidly and people living there are becoming more inclined to use high technology in their everyday life. Moreover, they have increasing access to information and communication technologies. No one can be considered as isolated. Everyone is a part of global village. But we need to tap the low income stratum for sustainable development.

Keywords

Bottom of the Pyramid, Developing countries, Open innovation

1. Introduction

World's market can be divided into three major strata: high income, middle income and low income. More than four billion people live in the low income stratum and Prahalad [1] called this stratum as the bottom of the pyramid (BoP). The aim of this paper is to demonstrate the importance and benefits of open innovation for the bottom of the pyramid. In general, multinational companies make initiatives to innovate products, services, and processes focusing high income customers and these customers are largely located in developed countries. High income customers are small in number and market of high income customers is considered as exceedingly competitive comparing middle class and low income markets.

Schumpeter claimed innovation as a sole domain of the entrepreneurs [2]. In productivity innovation, it is necessary to consider external valuable work and talent [3] and firms are increasingly using open source models to collect external ideas for innovation [4] [5], for instance, by means of websites on which customers, suppliers and other external parties can submit ideas for innovations. Open innovation is a new paradigm which considers that both external and internal ideas are necessary for a company to grow. A firm can combine internal and external values for innovation. According to Chesbrough [4], some ideas can go into market through external channels, while others can come from outside in. He also posits that not all talents work for a single company. So it is important to generate ideas from external talents too.

Open innovation is relatively a very recently emerged idea. For many valuable reasons, this idea is getting momentum. However, utilization of this idea is mostly used in developed countries or focusing high income customers. So far, there is almost no use of open innovation for the bottom of the pyramid. To the best of my knowledge, no literature is available on open innovation for the bottom of the pyramid. Thus, this paper is an endeavour to shade light on open innovation for the bottom of the pyramid.

2. Open Innovation for the Bottom of the Pyramid

Open innovation idea is providing an interesting approach to govern the global R&D needs [6]. The increasing development of technologies, scientific initiatives, global market are offering new phenomenon of collaboration [7]. Multinationals are facing the need to adapt their products and services to the large untapped customers at the bottom of pyramid and extensive local knowledge is

necessary to meet that demand [6]. How innovation ideas disseminate is changing all over the world [8]. Developing countries are growingly formulating policies to support innovation [9] and many talents are dormant there too [10].

The share of research and development (R&D) of developing countries is growing rapidly. As shown in the table 1. World's R&D share had increased from around 10% in 1990 to 21% in 2000. In 2007, the developing countries had captured about one-fourth of total world's R&D share. Similarly, in developing countries, the R&D expense in percentage of GDP is also growing. Even though, the R&D share in developing countries is increasing, utilizing open innovation idea has not been considered adequately for innovation.

Table 1 World's R&D Share of Developing Countries

Developing Countries	End of 1960s	1990	2000	2007
Share in Global R&D in Percentage	2.0	10.2	21.0	24.0
R&D as percent of GDP	NA	0.7	0.9	2.3
Coverage	Excluding centrally planned economies	Including centrally planned economies and newly industrialized countries (NIC)		

Source: [11], [12]

Despite the importance of the open innovation in low income stratum, there are no remarkable initiatives to use it. However, a classic example of open innovation is the innovation of BOGO solar light which is increasingly becoming popular in developing countries where more than 2 billion people live without access to dependable electricity and forced to use traditional lighting like kerosene lamp, candles, flashlights etc. [13]. To develop BOGO targeting developing countries, Mark Bent, CEO (Sunlight Solar) had to get help from InnoCentive, the premier open innovation platform of the world. The challenge of BOGO light posted in Innocentive platform and solved to serve the customers in the developing countries. It had brought successful innovation and BOGO is increasingly using it in developing countries where there is no adequate electricity (for more information see www.bogolight.com). A water purifying bottle that uses ultraviolet light to sterilize drinking water is developed through open innovation platform and it will help people of developing countries who have no access to pure drinking water [14]. Even though, open innovation is considered as a glaring importance, it is still not used for the bottom of the pyramid. Thus, real product, price, value etc. remained unexplored as companies are developing product in developed country without involving properly the target users. Customers remained unaware of product as they rarely informed of any product during development process. Additionally, through participating in open innovation process, potential customers become aware of a product and also tell others about the product. Consequently, it results product marketing without expenses. More involvement of customers with product development brings more persuade to use the products. So, establishing open innovation platform for the bottom of the pyramid may help to capitalize from huge number of customers' voices.

3. Interactions with Customers for Innovation

There is an increasing number of researches on how interaction in virtual communities trigger creative activities with cost minimization [15];[16];[17]. Still, innovating with customers' involvement is a relatively recently emerged phenomenon in the academic discipline [18]; [19]; [20]; [5]; [21]. Rapid technological change and squeezing of product lifecycles, made innovation and technology as key sources of competitive advantage [10]. Although there are enormous innovations but relatively few business models capture value from an innovation [4]. Frigo and Ramaswamy [22] believe that risk of innovation stems from inability to change or to create offering or to meet customers' needs better compare to competitors. Additionally, complex challenge involved with open innovation is how to assess cost/benefit impact of factors like projected value, timescales, risk, licensing costs, opportunity cost, and technology integration [23]. Questions for these innovations concerns the cost of individual contributors of submitted ideas as well as means of measuring innovation value and how to integrate all the parties for an idea generation aiming to get better ROI (cost/benefit) are unanswered in open innovation literature. Identifying, assessing, refining and developing an idea into a business concept are crucial and management weakness is more at the initial stage of an innovation process. According to Bessant and Tidd [24], it requires managing creativity to transforms idea into innovation. Despite these glitches, interacting communication is becoming omnipresent [8] and companies are vying to capitalize from it. Though the virtual communities have got immense proliferation, the success factors are limitedly known [25]. Deregulation and emergence of new technologies are enabling companies to move towards increased globalization. Yet, open innovation for the bottom of the pyramid is not considered much by the researchers whereas it is extremely important.

4. Shifting of Innovation towards the Bottom of the Pyramid

Share of developing countries in research and development (R&D) is growing more than ever before. In contrary, open innovation idea is getting popular at a very slower pace. Recent research revealed that individual creativity often matters far less for innovation than connection and networks [26]. Good ideas may reveal from farthest places of an organization [27]. Value is constantly shifting and making difficult to predict due to naturally emergent interactions among consumers and producers [28]. The easy access to internet tools and services for information sharing, interaction and communication have brought sweeping change of the end-users' roles from passive consumers to active co-creators [29]. Creating an experience environment, where customers engage in active dialogue and co-create their personal experiences consequence might be same but customers may construct very different experiences [30].

Table 2 Income Group and Population in the World

Income Group	Income per annum	Population in Million
High Income	More than \$ 15 000	800
Middle Class	From \$ 1500 to 15 000	1 500
Low Income	Less than \$ 1500	4 000

Source: [31]

Larger number of people lives at the bottom of the pyramid. As depicted in the table 2, around four billion people live at the lowest stratum and their income per annum is less than \$ 1500. These 4 billion people need products that are different and customized for them. Products which are produced targeting to high income cannot satisfy with slight modifications. Rather, we need unique products for these people who are living in the low income stratum.

Limited theoretical attention is given in studies of firms' evolution towards innovation product development [17];[5] despite firms' collaboration with outsiders generates higher percentage of sales from their new products [32]; [33]. Literally, no attention is given in the context of developing countries.

5. The Digital Divide and Open Innovation

The digital divide is the term used to understand the differential access to ICTs based on gender, race, income and location etc. [33];[34]. It has an important relation with open innovation. Narrowing the digital divide gives more opportunity to avail ICTs and it ultimately results more scope for open innovation at bottom of the pyramid. Although, despite devotion of tremendous resources to bridge the gap of digital divides, the result is inconclusive [36]. It is widely recognized that the access to information and communication technologies (ICTs) may result high living standard and improved social welfare [35]). Obviously, the internet penetration is very low in developing countries like India (7%), Sri Lanka (8.3 %), Pakistan (10.4 %), and Bangladesh (0.4%). Even then, there is a huge pool of enthusiast contributors from the bottom of the pyramid to participate in open innovation platforms; little consideration is taken to engage them. Participation of the people who are living at the bottom of the pyramid may bring innovative products for low income people that may be open a new additional market for the multinationals. The regulators need to focus on making networks widely accessible especially targeting the bottom of the pyramid [37].

6. The Digital Divide and Open Innovation

The infrastructure favourable for open innovation is developing rapidly in developing countries. Mobile phone business is largely in developing countries because of high population density and its usefulness. Astoundingly, in India, the figure of subscribers is around 700 Million by July, 2010 and it is one of the most profitable businesses in India. Moreover, number of mobile phone subscribers is 100 million in Pakistan, 15 million in Sri Lanka and 70 million in Bangladesh. These figures tell the importance of mobile phone in developing countries. However, telecommunication field comprised of mobile phone, internet, broadband, digital subscribers links, wireless, VOIP etc. are flourishing tremendously and reducing the challenges for open innovation remarkably at the bottom of the pyramid.

Growing internet especially wireless advantages with mobiles and laptops are changing the scenario of the world swiftly. Moreover, demand of desktop computers in offices and homes are influencing work environment to shift towards utilizing ICT services. Amenities of social networking platforms like Facebook, Twitter, and Skype etc. are attracting people and users' numbers are growing unimaginably. More importantly, governments of developing countries are becoming friendly in helping to innovation activities specially that have potential to improve peoples' living standards. Advanced communication technology is increasingly giving opportunity to people to communicate everyday with modern knowledge. Thus, environment for open innovation is becoming more favourable continuously. Media, in most developing countries, are experiencing freedom and enriching communication and knowledge arena. Local institutes are partnering with advanced universities of the world; western educated people are coming back to home as reverse brain drain [10]. MNCs are using local talents and places to capture customers more profitability. Non government organizations (NGOs) are playing key roles for the development of the society in developing countries. Much of the foreign aids are reaching to poor people through NGOs and these NGOs are helping to provide better products and services to the low-income people.

No business models come without challenges. Open innovation in developing countries is not a different. Companies in developing economies have shortage of advantages which are available in developed countries but it does not rule out the prospective of open innovation locating in developed counties absolutely. Even though, innovation management in the developing countries is assumed to be problematic characterized by poor business model, political instability and these problems tends to restrict the development of innovation environment.

7. The Digital Divide and Open

Open innovation idea is becoming an integral part of research and development in every multinationals. The focus remains mostly towards the high income customers and in developed countries. The influence of technology is increasing in developing countries through penetration of mobile phone, accessibility to internet and customer awareness. Customers are more careful and sensitive than ever before. There is a huge market at the bottom of the pyramid with low purchasing power. Products that can satisfy the need for the bottom of the pyramid have profitable business and sustainable development.

The Role of Supply Chain Management in Fostering Regional Development Throughout Southeastern Europe

Eleftherios Iakovou¹, Dimitrios Vlachos¹, Naoum Tsolakis¹

¹Department of Mechanical Engineering, Aristotle University, Thessaloniki, Greece, eiakovou@auth.gr, vlachos1@auth.gr, ntsolaki@auth.gr

During the last decade, the European Union (EU) has undertaken many initiatives in order to foster economic development and to further support cross-border trading cooperation throughout Southeastern Europe (SEE). Despite its key strategic geographical location, that includes potential vital trading routes between Northwestern European and Asian markets, the region has failed thus far to tie itself effectively to global supply chain networks. Corporations operating throughout SEE report several impediments concerning free-trade facilitation, including a strict regulatory environment, ineffective policies, limited coordination, weak strategic planning, poor logistical infrastructure and financial support, inefficient customs and trade regulations, and corruption. On this basis, best practices, including innovations in Logistics and Supply Chain Management, could mitigate obstacles and risks, enhance competitiveness and improve the performance of ventures operating in the area. Leveraging disruptive reforms can assist enterprises operating in the region to develop appropriate trade competences, to secure sustainable development and to be better positioned in the global business landscape. Under this context, and motivated by the desire to support regional development, the purpose of this paper is twofold: (i) to identify and classify the bottlenecks regarding free-trade facilitation, logistics and supply chain management practices in the region, and (ii) to propose a rather generic strategic methodological framework that could assist governmental authorities, regulators and managers to design and adopt effective policies towards logistics and supply chain management.

Keywords

Free-trade facilitation, Policies, Southeastern Europe, Strategic framework, Supply chain management

1. Introduction

During the last decade, a significant number of initiatives has been introduced in order to promote free trade facilitation in Southeastern Europe (SEE). To that effect, a Memorandum of Understanding (MoU) towards the establishment of a Free Trade Zone was signed in 2001 among seven SEE countries: Albania, Bosnia and Herzegovina, Bulgaria, Croatia, FYR Macedonia, Romania and FR Yugoslavia [1, 2]. In the following years, a network of subsequent intra-SEE Free Trade Agreements (FTAs) was developed to improve the trade related regulatory environment, while several organizations were instituted towards this goal (e.g. the SEETO, an organization dedicated to the development of the multimodal network Southeastern Europe Core Regional Transport Network) [2, 3].

However, the vision of achieving trade integration and liberalisation in SEE, and creating a wider trade partnership in the crossroads between Southwestern Europe and Asia has not yet been fulfilled. Today, this necessity is more pronounced than ever as the SEE region strives to respond to the global economic crisis [4]. Several factors and issues constitute bottlenecks towards the development of global supply chain businesses and trade openness in the region, while additionally preventing domestic enterprises from realizing substantial growth [5, 6]. The portfolio of suggested policies aims

towards the direction of comprehensive and efficient supply chain management that at a second stage will assure the economic viability of domestic enterprises [6].

In this manuscript we aim to investigate the role of supply chain management in the SEE region and to review the relevant growth opportunities in order to foster regional development. The objectives of this research are: (i) to identify the bottlenecks regarding trade liberalization, logistics and supply chain management practices in the region, and (ii) to propose a rather generic strategic methodological framework that could assist governmental authorities, regulators and managers to design and adopt best policies towards logistics and supply chain management. The rest of the paper is organized as follows. In Section 2, we present a brief review of the major challenges regarding Trade Development Strategy in the region. In Section 3, we proceed to policy recommendations that could foster Free Trade in SEE. We sum up in the last Section with conclusions.

2. Trade Development Challenges

The various facets of trade liberalization are affected by a wide array of diverse and versatile factors that can be partitioned in two classes (see Figure 1). The first class captures quantitative and more formal issues such as trade regulations and physical network infrastructure; they are hereby termed as “hard” factors. The second class includes a set of intangible factors which are qualitative and rather informal in nature such as inertia, perception, prejudices and experience. The factors that are classified into this latter category are termed as “soft” factors in this paper. It is now evident that these factors, which capture the culture and tradition, the intuition, the uncertainty and the subjectivity of stakeholders can have a detrimental effect during the decision-making process and they are therefore worthy of additional investigation.

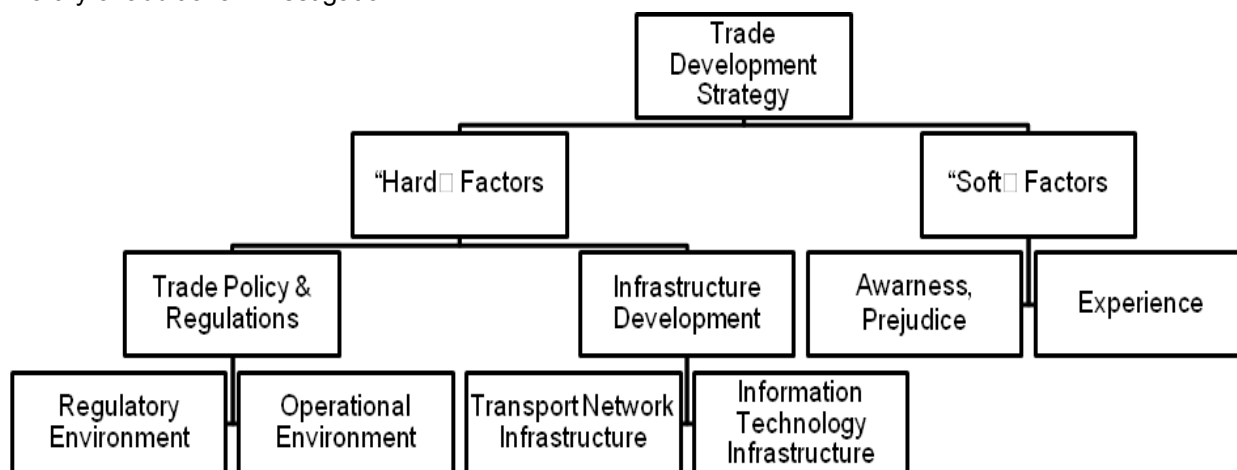

Figure 1 Main components of the required trade development strategy in SEE countries

A careful scrutiny of the national “Logistics Performance Index” (LPI) can yield a first, generic view about the problematic areas concerning supply chain operations in SEE. The LPI is a comprehensive quantitative index developed by the World Bank which quantifies the performance of national logistics systems for more than 150 countries [7, 8]. One of its goals is to assist countries to identify the challenges and opportunities they face regarding the efficiency and responsiveness of their national logistics system [7, 8]. It is interesting to observe the dynamic evolution of the LPI for the SEE countries between 2007 and 2010. The data in Table 1 demonstrate that the overall logistics performance of the countries of the region has declined dramatically from 2007 to 2010.

Table 1 Comparison of the LPI index, 2007 and 2010 [7, 8].

Country	Rank 2010	LPI 2010	Rank 2007	LPI 2007	Customs 2010	Infrastructure 2010	Timeliness 2010
Albania	119	2.46	139	2.08	2.07	2.14	3.01
Bosnia and Herzegovina	87	2.66	88	2.46	2.33	2.22	3.18
Bulgaria	63	2.83	55	2.87	2.50	2.30	3.18
Croatia	74	2.77	63	2.71	2.62	2.36	3.22

Country	Rank 2010	LPI 2010	Rank 2007	LPI 2007	Customs 2010	Infrastructure 2010	Timeliness 2010
Greece	54	2.96	29	3.36	2.48	2.94	3.49
Macedonia, FYR	73	2.77	90	2.43	2.55	2.55	3.10
Montenegro ¹	121	2.43	115	2.28	2.17	2.45	2.65
Romania	59	2.84	51	2.91	2.36	2.25	3.45
Serbia ¹	83	2.69	115	2.28	2.19	2.30	2.80
Turkey	39	3.22	34	3.15	2.82	3.08	3.94
SEE Average		2.76		2.69	2.41	2.46	3.20

¹Serbia and Montenegro was a unified country that was separated in 2006.

A national logistics and supply chain strategy needs to be comprehensive tackling holistically the modules of Figure 1. Below, we provide a comprehensive analysis of the main trade development challenges in the SEE region.

2.1 Trade Policy & Regulations

Trade liberalization is a diverse and challenging subject for both businesses and governments. It involves a broad range of diverse issues (e.g. political, administrative, financial etc.), all of which must be taken into consideration when a country aims to develop a national trade strategy.

To begin with, the greatest threat in developing a harmonized trade strategy in the region is the existence of large deviations among the individual SEE countries. Mainly, the independent character of national consultation institutions, trade regimes and border agencies imposes unnecessary burdens for trade and logistics in SEE [9]. More explicitly, innumerable trade regulations and complicated trade procedures are ensued by added transport and trade costs for local producers, consumers and traders in the region. In addition to the lack of conformity, there has been also observed a lack of public-private consultation on trade issues. This results in a chasm between the interest of business and the other societal stakeholders affecting negatively FDI flows [9]. Furthermore, only few years ago certain SEE countries have adopted the institutional and legislative implementations of world approved trade provisions (e.g. Bosnia and Herzegovina, Montenegro and Serbia approved the provisions of the WTO only in 2006). Additionally, the relation with the European Union is hindered due to the unilaterally implementation of the EU Stabilisation and Association Process (e.g. Serbia). Implementation of EU-harmonized technical standards has become increasingly important in the region, especially for Bulgaria, Croatia, and Romania after their EU accession. The 2004 Regular Report of the EU concludes that the alignment with the EU *acquis* (i.e. "the accumulated legislation, legal acts, and court decisions which constitute the body of European Union law") in these countries is incomplete [10]. Furthermore, the deficiency of a harmonized certification system between the SEE and the EU stems from the lack of the will to establish a common institutional setting in the region. This is more evident in the sanitary and phytosanitary area (i.e. perishable goods and drugs) that comprise the major exports of the region. The lack of streamlined legislative frameworks towards health and safety inspections hampers the trade capacity of local businesses, repels foreign investments and diminishes the entrepreneurial potential in the region.

In addition, SEE countries have not developed yet an evaluation system that could provide valuable feedback while quantifying the outcomes of the applied trade policy at a given period of time [3, 11]. Governments and trade committees have been proven unable to co-ordinate and proceed to streamlined actions due to limited technical know-how. The situation has been exacerbated by the instability of the political situation in the region [9]. In brief, it is well documented that reforms of customs and border-crossing rules are limited by a range of impediments including limited coordination and cooperation, customs corruption, ineffective border clearance, old customs and border facilities, misinterpretations of the legal regulations, obsolete technology in customs, lack of trained cross-border officials and the overall complexity of procedures. It is important to point out that the nature and the extent of the problems that each SEE country faces is different [12].

2.2 Infrastructure Development

Inadequate infrastructure is a constant, prominent obstacle as documented annually by the Southeastern Europe Core Regional Transport Network Development Plan [3]. In addition to the limited number of official border-crossing points, there are many unofficial border crossings with no rules governing trade transactions, a plethora of phenomena of corruption and with no consequent economic benefits for the countries [9]. Thereof, the infrastructure can be regarded from two perspectives: *multimodal (road, rail, sea, river, air) physical network infrastructure* and *information technology (IT) infrastructure*.

Despite the efforts and the huge investments regarding the development of the *physical infrastructure network*, there are major challenges. Through the years, a lack of any systemic maintenance resulted in the declining of the road condition without realizing its full potential. According to data available, there are still 1.122km of bottleneck length in SEE [3]. The condition of the *core rail network* is even worse than that of the road network, considering that maintenance and investment are below requirements [3]. The major bottleneck criterion that hinders rail freight is the limited capacity of the rail network, which is below the standards set by the UIC CODE 406 (i.e. capacity is evaluated by means of capacity utilisation) [3]. The situation is better when it comes to *seaport infrastructure*. Today, excluding Greece and Turkey, there are only ten seaports in the rest of the SEE with overall modest condition, capacity and turnover. Modernization is exerted by the necessity to correspond to the significant incoming Asian trade flows. Asia has emerged as the major supplier of freight for Europe and transport routes pass through the Mediterranean. Rijeka, only in 2009, received 11.24 million tons of freight [3]. Furthermore, all *airports*, except Pristina and Sarajevo, recorded a major decrease in passenger traffic in 2009 because of the economic crisis. As for the cargo transport, airports in the region do not utilize appropriate capacities and terminals, and thus the freight transport is limited only to the airports of Zagreb and Belgrade [3].

Lastly, it is imperative to distinguish between IT infrastructure at the enterprise and at the e-customs level. SMEs that are operating in the region, which comprise the backbone of the regional national economies, clearly recognize the true potential of policy reforms regarding the IT sector [1]. At a greater extent, they can provide valuable insights about the relevant weaknesses and pave the path to policy-makers to proceed to appropriate reforms to enhance competitiveness in the region [1]. The most significant IT problem is the lack of integration between the *information systems* utilized by companies, suppliers and customers that hinders entrepreneurial activity in the region, undermines growth and diminishes innovation indexes [1]. Additionally, a shortage of highly qualified and skilled personnel to operate such systems is observed, resulting in inadequate vendor support and in hidden costs. The same problems appear to the *e-customs* systems thus resulting in time delays, increased variability and costs, and overall low efficiency at border clearance. A significant shortcoming at the *e-customs* domain is the lack of a 'Single Window' environment in SEE. Single Window refers to an integrated information and communication technology system where traders submit only once information regarding their trade practices. The information is then directed automatically to governmental controlling authorities reducing significantly non-tariff barriers and enabling trade facilitation for the benefit of the trade community [13]. Today, only Albania and FYR Macedonia have made some progress towards this direction [14].

Nevertheless, the most important factors in the assessment procedure of the trade liberalization that seem to be the greatest threat in the overall trade reform effort is the lack of political will, absence of common policies and the resistance of the officials towards change which is diffused at all aspects of the Southeastern European countries [6].

3. Recommendations

It is widely admitted that to promote trade liberalization and better cross-border management in SEE, generic recommendations do not appear to be effective [15]. The core of the problems has to be identified at a national level [16]. It is important to further scrutinize specific problematic areas and propose localized recommendations according to the requirements of each individual SEE country (see Figure 2). Given the emerging window of opportunity to establish a new, complete, and sustainable Free Trade Zone in SEE, it is crucial to adopt disruptive innovations for the design and the implementation of a liberal trade regime in order to create distinct competitive advantages compared to other alternative supply chain routes in the global scheme [17, 18]. However, before investing substantially, it is recommended to evaluate the behaviour of the envisioned, integrated supply chains

in SEE through simulations in order to capture the impact of any unpredicted variability [19, 20]. Below, we provide specific recommendations regarding the “hard” and “soft” factors.

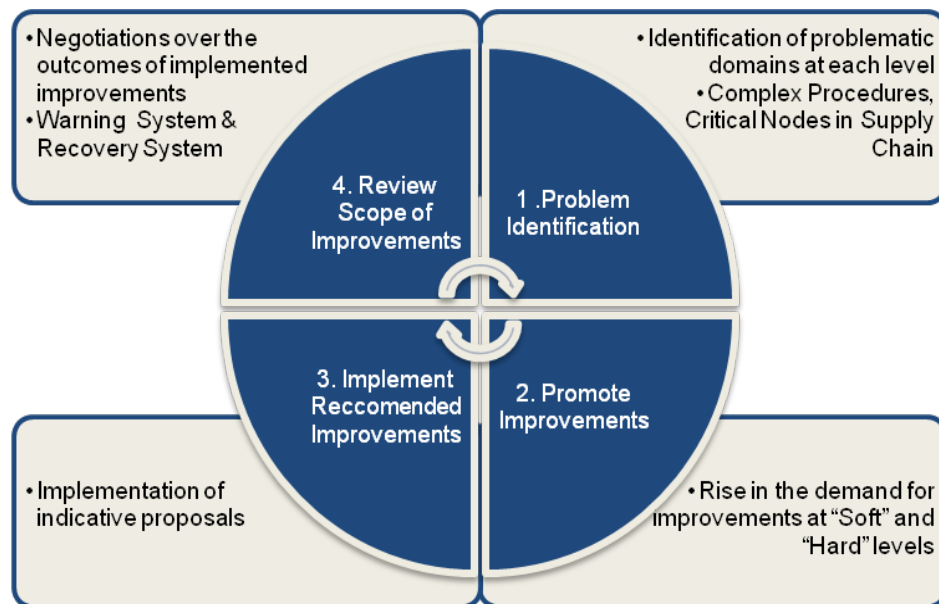

Figure 2 Steps of the Trade Development Strategy that need to be utilized by each SEE country

3.1 Regulatory Environment

The strategic recommendations provided below revolve around the four main modules of harmonisation, standardisation, simplification and modernisation.

“Soft” Term Interventions:

- Develop an environment of close intra-regional cooperation, mutual understanding and genuine dialogue between all the stakeholders in the region, create a common vision and work towards that goal.
- Develop local knowledge capacity and human capabilities. To this direction, the enhancement of the institutional role of the Chambers and the promotion of joint training programs of trade officials must not be neglected. The academia can have a detrimental role in this effort.

“Hard” Term Interventions:

- Establish a common regulatory framework, technical standards (e.g. labelling) and licensing concerning the goods and services traded among the SEE countries [6]. This will lead traders to avoid the duplication of controls and compliance procedures. Considering also the European vision of many SEE countries, it is crucial to align SEE trade regulations with the ones of the EU in order to realize greater trade potential. At a second stage, this harmonization with international laws and standards must lead to the standardization of the necessary trade documents and data sets that will result in increased accuracy and competitiveness, fewer errors, less confusion and reduced costs.
- Apply transparent and operable rules and procedures to avoid phenomena of misinterpreting policies and regulations, and their subsequent costs. It has been observed that non-transparent procedures result in high levels of corruption among the border agencies. Another side-effect of clear regulations will be the enhancement of the national markets. It is perceived that trade is the “fist in the world innovation” that increases the pool of technology and services for the local innovation process [5].
- Establish a regional, independent, common market inspection body that will certify the domestic manufacturers about the compliance of their manufactured or traded products and services. The latter will be extremely useful for the inspections, especially for perishable items such as foods and drugs. The standardization of the import/export requirements and procedures will, at a second stage, be open to every exporter/importer in the region and there will be eliminated any problems regarding the import/export regulations and trade agreements which are altered frequently and are

difficult for organizations to follow. The proposed system resembles the FAST program between Canadian and USA borders which has already demonstrated positive results for major trade firms [21].

- Minimize trade costs and homogenise tax regulations to enhance the trade perspective of companies.
- Develop national logistics action plans and set up national logistics observatories that, in cooperation with EU authorities, will periodically assess the national logistics performance of each SEE country and will monitor the impact of trade actions and reforms.

Finally, Grainger provides a comprehensive, descriptive model concerning the reform procedures in the wider regulatory environment and he proposes a set of eighteen reform actions that should be adopted by governments and business stakeholders [22]. To be effective, however, the proposed actions need to be combined with disruptive, innovative approaches in an organic manner and must be evolved and evaluated at each phase of the implementation process [23]. Applying reforms in the supply chain sector will also enhance domestic entrepreneurship and will impel the interest of foreign direct investments (FDIs). Literature confirms that trade openness is positively related with FDI and that it assists firms in increasing their market share [24, 25]. The main reasons include the diffusion of technology and knowledge base that can foster innovation, entrepreneurial activities and competitiveness of local companies.

3.2 Infrastructure Development

At the intermodal infrastructure network, initiatives should be considered in order to:

- Develop inter-modality connections and capacities with the aim to improve efficiency and security.
- Integrate the road, rail, air, river and sea networks with the multimodal nodes (cities of Thessaloniki, Burgas, Varna, Constanza) to realize the potential of new, emerging markets [26]. It is worth to point out the role and the harnessing potential of the pan-European transport Corridors IV, V and X. In addition, the perspective of the Danube River cannot be neglected.
- Apply "smart", innovative solutions in the physical network design so as to minimize travel distances, travel time unpredictability and increase security.
- Create direct routes between the regional economic centres to support bilateral and regional trade as long as investments [6].
- Establish halfway terminals and warehouse facilities to increase the storage capacity that will service the growing needs of demanding supply chain operations.

Moreover, at the IT sector leapfrog advances should be adopted to enable trade liberalisation and facilitation so as to establish a true, operational, and integrated e-customs system [27]. The careful actions towards this goal aim to:

- Provide economic incentives in order to assist domestic enterprises in the adoption and implementation of sophisticated information technology systems [1]. Except for that, local governments should promote the relative legislative measures to enable the free flow of information.
- Develop national strategic reference frameworks to financially support the companies operating in the region so as to adopt high-tech systems and foster their trade efficiency and capacity.
- Educate the borders' administrative staff about the new IT systems and the vision and the long-term goals of the Free Trade Zone initiative.
- Invite experienced instructors and experts from the European Commission, and build upon existing paradigms so as to enable knowledge transfer regarding practical issues that may inhibit the normal process of the Free Trade Zone implementation. The bottom line of the efforts should be to build upon the increased regional cooperation both at a national and at an enterprise level.
- Capitalize on the experience of existing electronic customs projects (e.g. the Electronic Customs Decision of EU, the FAST program), and request the appropriate assistance and knowledge transfer.
- Apply a common regulatory framework to achieve the implementation of a centralized clearance concept [28]. This will pave the path to establish a Single Window environment in the region in order to ensure efficient trading and governmental controls of trade flows. This will result in more transparent trade operations, improved governance, better efficiency, increased effectiveness and

fewer opportunities for corruption. Nevertheless, a major prerequisite for the implementation of a Single Window initiative in the region is the simplification of documentation and regulations.

4. Conclusions

The problems associated with trade performance in Southeastern Europe demand immediately comprehensive remedial policies. Reforms are imperative at both “hard” and “soft” levels so as to harmonize operations and accomplish similar trade development degree at each individual SEE country. The latter will help the integration with the global value chains and will open new market opportunities. Towards this direction, the fast development of supply chain management strategy cannot be achieved in a haphazard way with huge investments with vague outcomes. Careful scrutiny and due diligence are required to achieve the same level of development at each SEE country in order to attract FDIs that will transform the region in a major trade node between Western Europe and Asian markets [1, 21].

Reforms should be made firstly at the regulatory environment with the main aim the implementation of common policy frameworks at each SEE country. Except for the alignment with global trade standards and procedures, trade liberalizations and the successive foreign direct investments will enhance the diffusion of innovation and foster the competitiveness of SMEs. In addition, expanding the capacity of physical network infrastructure is vital. The utilization of intelligent information systems will enable Single Window operations with the corresponding advantages for the governments, trading parties and consumers.

²*Faculty of Business and Economy, South-East European University, Tetovo, Macedonia, g.rexhepi@seeu.edu.mk*

Recently the role of intellectual is becoming very important inside small and medium enterprises; the main reason is because of their influence in formulation and implementation of strategies in these enterprises. This research will try to examine the links between intellectual capital of entrepreneurs, strategies and entrepreneurship they use to discover business opportunities. This research will try to find the link according to the already made research around the world and also there will be an empirical research that will be made in a forty five enterprises in different cities in Republic of Macedonia. The aim of the research is to emphasize the role of intellectual capital in formulation and implementation of strategies through theoretical and practical research that will explain in a better way the link or the relationship between intellectual capital, strategy and entrepreneurship. This will help entrepreneur to better understand and use intellectual capital in strategy formulation of enterprises by investing in intellectual capital in order to formulate and better implement the strategies in enterprises. Through better use and investing in intellectual capital entrepreneurs and their workers will be able to discover opportunities for new business and enhance their competitive advantage in a market.

Keywords

Entrepreneurship, Opportunity Discovery, Intellectual Capital, Strategy formulation, Strategy implementation

1. Introduction

Globalization and increase in competition has led to the era where the knowledge along with tangible assets has been used as production factor in which the knowledge is the building block of intellectual capital.[1,p29-42].

Businesses who have understood the importance of learning have shifted their strategic efforts from managing financial assets - often confidential - to managing intangible asset of intellectual capital. [2,p202-214]. Intellectual capital, in an increased uncertainty, information needs and managing with change has been seen as vital instrument [3, p151-171];[4,p159-176]; [23,p142-160]; Indeed, today, competitive advantage, material and financial resources of enterprises, rather depend on how they conduct their intellectual capital [7,p267-284]. The future of a business move is to create values of working people, business strategy, structure, systems and processes, established by the enterprise and customer community are only possible with effective management of intellectual capital [5,p366-374]. Future of big businesses very much depend on CEOs (chief executive) as well as the DR capacity for managing intellectual capital effectively and appropriate selection of Chief Knowledge Officer-company information manager. However, the intellectual capital of enterprises is to analyze, measure, develop, use, and studies relating to the effective management of and increased research [8,p489-509]. In this study, primarily we analyse management of intellectual capital components and general information is given, followed by large-scale industrial enterprises in Macedonia who use intellectual capital management practices aiming to determine the results of the research carried out within the framework of evaluation.

2. Definition and components of intellectual capital

Sustainable competitive advantage and intellectual capital plays an important role in creating a superior financial performance that is accepted in all circles and research [9, p1161-1181]; [11.p348-360] J.K. Galbraith in 1969 used the concept of intellectual capital, in the present-day organizational sense which later T. Stewart (1991) defined as "operation that provides a competitive advantage in the market, the sum of all things known to employees as described. Stewart (1997)[12] published his book in the intellectual capital "Welfare use of intellectual material to create wealth, knowledge, information, intellectual property, and a combination of experience". Brooking [16], defined intellectual capital, "to sustain the business activities of all intangible assets" known as the first professional manager of intellectual capital [13, p366-373] and [14, p439-448] have used intellectual capital as "value of information can be converted to".

According to the traditional accounting sense, intellectual capital and goodwill (goodwill) corresponds to the concept of representing the difference between book value of the enterprise market with recognized market value [18];[10,p63-76] , intellectual capital, talent and commitment of employees to identify the product, owned the business and assets of the organization see it as a meta-capability. Intellectual capital is defined as to create value for the future, gained through experience and learning can be used to achieve the strategic objectives of all kinds of intangible assets (Intangible assets),[24, p 1114-1128].The intellectual capital, products and services throughout the enterprise market thinks of as a physical output. All of these definitions can be defined as taking into account the intellectual capital, which directly affect the success of current and future business that provides competitive advantage, create added value, knowledge of the essence, to the whole business of intangible assets owned by organization.[6]. As you can see the intellectual capital, the hidden assets of a company's balance sheet is a collection of unseen and the most important source of competition; [23,p142-160];[15,p51-59]. On the other hand, the classification of intellectual capital components in an effort to use different names with which the authors are committing the same subject [18];[16];[10,p63-76]. In this study, within the framework of the review of the literature, the intellectual capital generally recognized that the components will be discussed under three main headings:

- Human Capital: Employees have the knowledge, skills, abilities and the sum of experiences. For example, the Employee education level, satisfaction, attitudes, values, organizational commitment, motivation, intelligence, creativity, teamwork, problem solving and communication skills, self-confidence, desire to share knowledge, entrepreneurship and leadership skills, innovation and so on. [21,p 251-268].
- Structural (organizational) Capital: Business and truly enterprise owned by the business and employees work in providing products and services are produced and distributed a set of assets [19, p77-78]. The organization's strategy, culture, mission, management philosophy, processes, information technology / systems, patents, copyrights, trademark / secrets, logos, databases, R & D, innovation, such as[27,p27-41].
- Relational (stakeholder based) Capital: business, create added value for all parties (customers, partners, investors, suppliers, distributors, and government) and covers the relationships. For example, customer relations, customer loyalty / satisfaction, business recognized, distribution channels, brand equity, alliances [22, p10-19]), licensing agreements and so on.

The components of this dynamic, complex, fuzzy and original feature and with each other in mutual relationship, as they are reviewed and managed in a comprehensive study.

3. Intellectual capital management

Information, documents and audio format or as a message described. The difference of information from the data, relationships, is organized for the purpose. Information, in a manner that creates business value that can be organized, into group, modelling and passed over data is defined as the action. Knowledge management and intellectual capital management concepts are closely related to each other [29, p93-110].

Knowledge management of the business in the hands of information and raw data transformed into human capital and relational capital comprises activities. However, intellectual capital management information management of the more far-reaching [13, p366-373].

Intellectual capital management, organizational value for the discovery of the creative elements and from increasing the market value into a conversion, to measure the value of intellectual capital management of the development process [21, p61-77]; [10, p72-73].

Intellectual capital management business is an important managerial responsibility and intellectual capital, performance can be measured. For this, a systematic approach to be developed. In this regard, various models have been developed [28, p160-173]. Some of them, Skandia's manual, Dow Chemical's value platform, intangible assets monitor, balanced scorecard, intellectual capital index [26, p413-426], American Education and Development Association Stylesheets [25, p414-432]. These models are examined, some elements of each model are highlighted, and they focus on. Most two models mentioned in the management of intellectual capital are examined briefly below [20, p206-240].

4. Role of intellectual capital in strategy

Many researchers have tried to understand why some enterprises are profitable. Porter [30] considered that industry profitability arise from the interaction of five competitive forces that he proposes and that profitability of the industry depends on impact of these five forces. But why do companies within the same industry differ in the profit earned? This question influenced many researchers to try to answer this question. Some studies suggest that profitability between companies inside the same industry vary three to five times more than profitability between different industries [31]. Excellent response to this issue we can find in the research made by Teece, who considers that the answer to this very complex question lies in the following three aspects [31 p5-7]:

- **The paradigm of a competitive force** – according to this aspect the main credit in enterprise profitability comes from intellectual capital. This capital has a tremendous impact when enterprises think on organizations strategy. This is especially evident in organizations that rely on intellectual capital such as universities, hospitals and so on. The main reason why some companies are more profitable than others is that they prevent other companies from coping of their strategies that result from using of intellectual capital.
- **The paradigm of resource-based approach** - the profitability of an enterprise comes from their resources portfolio (known as strategic assets). The term resource refers to the untouchable i.e. intellectual capital and touchable resources. Untouchable resources incorporate knowledge, competence, intellectual agility, the ability to establish links and attitude of employees. Very important characteristic of the untouchables resources compared with touchable resources is that they are not owned by the company but by the very individuals who possess these values.
- **Evolutionary paradigm** - is based on the Charles Darwin theory, according to whom strategies through time emerge and only those organisms (strategies) that exist in their environment will reproduce and multiply. This approach is explained in evolution of strategies.

If we analyzing these proposed aspects it can be noted that the first two aspects actually point to the importance of intellectual capital. The importance of individual skills is reflected in their power that these resources possess and which is related in a increasing of the companies' value. In order to use this value or its materialization it is required an appropriate strategy that will transform individual capabilities in to value. This is the very goal of competitive strategy which tries through creating of additional value to achieve competitive advantage.

According to Goèran Roos [31, p1] formulation of the strategy is an activity which stems from the creativity of the human brain and there is no written formula that will give the correct answer. This definition refers to individual skills (intellectual capital) that a person or persons have when they decide on choosing the right strategies. This line of thinking in which we accept creativity or that that strategy depends on personal abilities it is related with entrepreneurs or entrepreneurship.

When we are talking about intellectual capital primarily we think about its impact on formulating and improving of strategies. As a very important factor that affects intellectual capital is knowledge, i.e. knowledge based approach. Knowledge based approach conceptualize company as an independent regulatory system that optimize the interactions of individuals and groups in creating and implementing knowledge in formulating the strategies of the companies [32, p179]. The importance of knowledge for enterprises was launched in early 1990 with the appearance of many studies that focused on the knowledge which contribute to the emergence of a new approach based on knowledge. This approach includes analysis of resources, capabilities of the company and organizational knowledge [33, p133]. Authors David M. Brock and Eyal Yaniv, believed that knowledge is an important resource for the organization, but they also emphasized that enterprises know very little how this knowledge can be used by businesses in achieving competitive advantage, mainly for its movement through the organizational hierarchy. This knowledge can come from the experience and knowledge that their employees have (internally) or by consumers, competition, or literature (external). It happened with the

company Sharp, when they used their knowledge for production of flat-display which allowed them to be leaders in market worth seven billion dollars [34].

When we talk about the role of knowledge in strategies we mean for the knowledge that both enterprise managers and employees have. Employees knowledge very usually can be a limited factor in formulating the enterprise strategies, this for a reason that some employees may not understand them. This is one of the biggest problems that manager's face, and that is the risk that employees won't understand the enterprise strategies. Studies have shown that from the total number of employees in enterprises only 5% to 8% of them understand enterprise strategy [35, p2]. Most of the knowledge remains tactical which means it is harder for others to access or to imitate. Knowledge operates in a very mysterious way, for example knowledge used in Toyota when they produce cars refers to a very strong social and specialized organizational relationship that evolved through decades [32, p179].

Experience is a crucial component of knowledge. Experience refers to the individual or collective past that is being built through the process of repetition, trial and error, feelings, observation, analysis, implementation of practices, etc.[36, p403]. Experience is associated with so-called replication strategy used in hotels, fast foods, home visits etc. These are some classical examples of the transfer of knowledge and the possibility of accumulating knowledge [37]. Knowledge and experience of people can be key factors that influence the success of the strategy. Possession of a unique competent people in enterprises as a top surgeon in the hospital or outstanding professor/researcher for the university does not mean automatically possession of competitive advantage. These people very easily can leave the enterprise or retire and that's why enterprise should take their knowledge and experience and allocate through organization in order to achieve sustainable competitive advantage [38].

The achievement of many goals of the enterprises depends primarily on their employee's i.e. human resources available to the enterprises. Human resources are very important strategic resource for the enterprises. Companies should compete in attracting and retaining best employees in their ranks. These employees in continuance can be excellent basis for achieving competitive advantage over the competition. Although the use of different techniques and technologies can contribute in achieving

a significant competitive advantage, however from employees depends the ability of utilization in achieving competitive advantage. Sometimes the impact of one employee can be so large that in case of his dismissal he can take with himself many consumers. This is why enterprise need to have continuous training and rewarding of enterprise employees. The main task of enterprises would be to use the maximum from their employees [39].

Many theoretical and practical studies have found that people are very valuable and important resource for success of a business and that they can be an important source of competitive advantage for enterprises [40, p1901]. This and other authors actually found that companies that apply the human resource management practices are internally more consistent and more compatible with the enterprise strategy and show far better results than other enterprise who do not pay attention to this aspect. Research in this area suggests to a new area called the Strategic Management of Human Resources (SMCHR). Strategic Management of Human Resources indicates use and connecting human resources management with enterprise strategy, business strategy and strategies at all levels of the enterprise and use of their potential in achieving the objectives of these strategies. Strategic Human resource management should not be understood only as a use of management of human resources in achieving the strategies. The Strategic Human resource management includes knowledge, skills and attitudes in organization and that some individuals are better than others in managing [41p.192].

Human resources are mostly highlighted as unique, valuable, difficult to imitate and difficult to substitute which is great base for achieving sustainable competitive advantage. They can serve as a core competence. Companies' core competence of a company depends on several factors such as [42, p172]:

Knowledge - information on market intelligence on competition, technological expertise and understanding of political and economic surrounding.

Abilities - refers to the potential of enterprises to perform an activity or task.

Attitudes - refers to positions within the organization. Athlete without winning mentality cannot win. The position of the company may be oriented towards innovation, being aggressive or competitive oriented improving the quality and so on. A recent survey found that many managers believe that human resources are critical to the future success of their business, but also they believe that management of these resources or any poorly or not there [43, p172].

5. Conclusion

Except theoretical research that has been made as part of this researches a practical research have been made in 45 enterprises in Republic of Macedonia. The data from this research have been proceeded using SPSS and STATA as statistical software programs in order to get to needed information.

- Empirical research has confirmed the overwhelming influence of experience and knowledge in enterprise strategies and that there is a connection between strategy and knowledge. Using cross tabulation results showed that there is a connection between level of education and the choice of the original strategy. Thus managers who have completed university, masters and doctoral studies used primarily original strategies or strategies that are very different from competitors, as opposed to managers with lower levels of education. Also the results showed that there is a connection between having a formal strategy and level of education of managers. In 100% of the companies whose managers have completed master's and doctoral studies have noted the use of formal written strategy, as opposed to those companies whose managers have completed secondary education, where only 10% of them use formal written strategy. That it makes successful managers who have completed secondary and primary education is the great experience that these managers have in the business where they are as well as their experience in management positions. Thus only 4% of all managers have explored less than 2 years experience of managerial position, and this 4% were all managers who have higher levels of education. The analysis showed also that managers who have greater experience in management positions believe that the experience has more influence in formulating the strategy in relation to those managers who have less experience.
- The ability for strategic thinking of managers who carry strategic decisions is very important. So for all managers in the analyzed companies it has been noted relatively good capability for strategic thinking that is associated with the possibility of starting a new business that is observed in 75% of cases, 58% were able to revive a business from the crisis and 56% of these managers were at lower management levels. Almost all managers noted that they were in at least two of the above three situations. Given that most of the analyzed companies have been successful in recent years than it we can conclude the impact of managers' ability for strategic thinking on the success of the enterprise.
- The ability of employees to carry out the strategy and the enterprise ability to harness the intellectual capital using empirical research it can be concluded that they have great influence in formulating the strategy of companies. Thus only 6.5% of managers considered that the education of their employees have little influence in formulating their strategies and that only 2% of managers considered that the quality of intellectual capital that they have don't have influence in the formulation of strategy. In relation to the level of education of top managers it may be noted that only 2% of them have completed doctoral studies, 7% are with completed masters' studies, 50% have completed university study, and 11% have completed higher school while the rest have completed secondary and primary education.
- During this research we found that unlike the relatively low level of education of managers, most of them have great experience in the business in which they are located. Similar is the situation regarding the experience of managerial position where 60% of these managers have more than 9 years of experience, and that only 4% have one to two years experience in managerial positions. Thus analysis also showed that managers who have greater experience in management positions believe that the experience has more influence in formulating the strategy in relation to those managers who have less experience.

Competitiveness of Serbian Economy in the Region and it's Prosperity

Silvana Ilic¹, Milorad Sakan²

¹ Faculty of Management -Zajecar, Megatrend University - Belgrade, Serbia, silvanailic@fmz.edu.rs

² Manager, PTM SABAC, Serbia, milorad.sakan@gmail.com

Up to date experiences have shown that, subsequent to the democratic changes, the Serbian economy has survived the increase in social gross products within the period 2006 - 2007. It is clear that this is a consequence of the period of the highest inflow of foreign investments in Serbia. Taking into consideration that, the world economic crises has reached the largest multinational companies, it has reflected to the domestic economy. The extent of foreign investment has been decreased which lead to the decline of basic macro economical indicators in our country, as well as to the decline in economic growth. The future of Serbian economy and a revival of the economic activity may stimulate direct foreign investments through miscellaneous forms and modes of cooperation.

Serbia is a country which has a very favourable geographic position, skilled and relatively cheap work force and is rich in natural resources. Its future economic development will be based on agribusiness and metal-processing industries. Nowadays healthy food is the world's imperative and this should be the main economic activity of our country in the future.

Keywords

agribusiness, investments, economy, resources

1. Introduction

The previous year 2009, in economic terms, was the most challenging period for the Republic of Serbia, ever since the democratic changes which occurred in 2000. The global crisis has negatively reflected itself to the Serbian economy, among all other economies of the countries in the region, practically all the European economies and a vast majority of the economies worldwide.

The economic growth ceased in 2008 and economic entities operated with the loss of 37 billion RSD. During 2009, the economic crisis initiated a significant decrease of business activities for more than 16%, to the lower demand on the market, reduction of industrial production, lowered income of foreign investments and a deceleration of loan activities. Besides, an illiquidity increase and a previous massive indebtedness of the economy together with more severe conditions for subsequent debts amplified the sensitivity of our economy to all of arising challenges which originate from the surrounding.

Even though, in the course of the year 2010, the slump in economic activity has been stopped and a growing trend of industrial production and economic export has been maintained, generally speaking, a noteworthy recovery is not yet perceptible. Furthermore, risks of the further weakening of the national currency, a decline of demand, illiquidity growth and expensive financing sources are still present, together with a risk of business operation ambience which generates high costs. Likewise, unemployment risks and growth of social tensions are still present as a consequence of existence of a vast number of illiquid and insolvent companies. The economy is facing an enormous count of menaces. It is obvious that there is no significant recovery of economy without the increase of production and export, while, on the other hand, without the eventual recovery of the economy and its structural adjustment, there will be no way out of the crisis. The ongoing year is extremely challenging for the Serbian economy and generation of a favorable investment ambience is of an essential

relevance for engaging direct foreign investments which represent a main generator of stability and economy growth.

2. Current state of affairs in Serbia

The global recession has amplified, in the course of 2009, the macro economical vulnerability of all transition economies which were faced to the negative growth rate. Serbia, as a transitional country, has faced the consequences of the global recession, yet, compared to other surrounding countries, it had a milder decline of social gross products in 2009 mainly due to the package of incentive economic regulations. The economic activity in 2009 has been drastically decreased due to the abundant decrease of domestic and export demands, decline of loan activities and companies' liquidity.

Social gross products records the decline of -3% and the highest negative effects of the crisis reflected on the industry (decline of -12,1%), especially the processing industry (decline of -15,8%), where the growth was entirely nullified within the period of 2001-2008, thereafter, the trade (decline of -12,3%), and civil engineering (decline of -25,1%)[1]. The largest proportion of the social gross decline is possessed by the sectors of traffic and merchandise storage and the sector of real estates, leases and business activities. The physical scope of the industrial production in 2009 records a descent of 12,1% in comparison to the previous year.

The decrease in production has been affected by the immense decline of a loan activity and aggregate demand, increase of economy liquidity and additional burden of debtors with the depreciation of RSD. The decline of domestic demand as a consequence of a decrease of individual consumption and a decline of manufacturing activity has lead to a decrease of foreign trade activity, primarily import which has affected the decrease of Serbian deficit in 2009 (1,7 billion euros) for 4,2 billion euros comparing to the year 2008 (5,9 billion euros), which represents the sole positive point. The inflation rate within the year 2009 amounted to 10,4 %, RSD has depreciated in regards to euro for 8,2% .

General decline of economic activity within 2009 has lead to the deceleration of incomes` growth, decline of employment and increase of unemployment. The average net income in Serbia within the course of 2009 amounted to 338 euros, the total number of employees has decreased for 5,5 % compared to the year 2008 and the unemployment rate up surged for 2,6 % compared to the year 2008. In the course of 2009, the wages were realistically lower for 0,1% (while the nominal value records an increase of 8,5%)[2].

The Republic of Serbia has attracted 25% less direct foreign investments in the course of 2009 than during the previous year.

Table 1 Movement GNP i millions USA and GNP per capita in periods of 2001-2009.

Source: Statistical office of the Republic of Serbia, 2010.

Figure 2 Structure of gross value added in 2009

Source: Statistical office of the Republic of Serbia, 2010

The very state of affairs has reflected on companies business performance in Serbia, which were already burdened with old difficulties, such as illiquidity, high indebtedness and accumulated deficit from the previous period, therefore, they had to face themselves with a problem referring financing current business operations, what, under the conditions of decreased inflow of direct foreign investments, has caused the increase of their illiquidity and decrease of extent of their business activity. The companies, along with the decreased range of economic activities, operated in the course 2009 with a deficit which has been doubled in comparison to the previous year and amounted to 95.732 million RSD.

The Government of the Republic of Serbia and miscellaneous competent institutions (The National Bank of Serbia above all) has promptly and rather thoroughly reacted to the outbreak of the crisis.

Priority proceedings were directed to the preservation of macro economical and financial stability. In this sense, the arrangement with MMF must be singled out (the total value of 2,87 billion euros out of which, Serbia has withdrawn 2 loan tranches in the amount of 1,13 billion euros, mainly intended for reinforcement of foreign currency reserves), and the so called Vienna initiative, which has assured the substantial foundation for amortization of the impact on banking and financial system of the country.

The decline of economic activities has reflected itself on the decrease in budget income inflow which has solely deepened the gap between the fiscal incomes and expenditures.

Budget deficit has been partly covered with means obtained on the basis of sources allocation with MMF and partly by emission of treasury notes- state bonds. Likewise, the Government has enforced the Decision that the solution to the problem with the budget deficit ought to be sought among the

expenditures- by means of cost reduction, which made it possible to avoid the VAT rate escalation and, this action should maintain Serbia on the list of potential destinations for foreign investors.

The Government key actions within the year 2009 referred to the so called Stimulation package intended for the economy, in the value of 180 billion RSD, which has been under application since May 2009. Within the aforementioned package, a special position is occupied by liquidity loans, intended for reinforcement of companies, together with the investment loans.

These actions have been primarily directed to overcoming the crisis` consequences and, it is apparent they gave a positive result in mitigation of the consequences since the beginning of recovery of the economy become evident as the year 2009 expired.

Gradual growth of the economy activity which commenced at the end of 2009, has continued within the year 2010. Macro economical data for the first half of the year 2010 draw attention to a gradual recovery of the economic activity which has mainly been based on the external demand recovery, the positive trend of growing export has been recorded within the first half of 2010.[3] Serbian export amounted to 4 billion euros, which shows the increase of 19,6% compared to the same period of 2009. World trade deficit was 9,7% less than during the same period of the previous year, since the import value was 5,1% less and it amounted to 7 billion euros.

However, export increase in the first half of the year 2010, unfortunately, was not the anticipated consequence of the production increase due to the industry`s slow recovery from 12,1% descent from the previous year which was finally brought to a closure in September 2009, but it is in stagnation ever since. Analysts of economy movements point out that the immense import growth for the first six months of this year was realized on the account of an increase in placement of black and colored metallurgy and, agricultural products, as well. Since the products in question make a significant portion of Serbian export structure, the tendency of a positive increase of export may continue within the forthcoming period, imposes itself. Likewise, the following fact ought to be kept in mind: the descent of RSD value compared to euro has significantly stimulated the export and helped it grow with greater velocity than the import.

Therefore, it is clear that the end of the crisis is not yet in sight and that the year ahead of us will, by no means, be easy, despite the encouraging forecast of positive economy growth in 2010.

3. Movement of direct foreign investments worldwide and Serbia

The economic crisis has reflected on the decrease of direct foreign investments worldwide and in Serbia as well. Net inflow of direct foreign investments in Serbia during 2009 was 1,8 billion dollars (1,4 billion euros) which is, compared to the year 2008, 853 million dollars (452 billion euros) less.

Table 2 FDI, net in millions EUR

Year	2001	2002	2003	2004	2005	2006	2007	2008	2009
Value	184	500	1194	774	1250	3323	1821	1824	1372

Source: National Bank of Serbia

The total net direct foreign investments in Serbia, in the course of the period 2001-2009 amounted to 15,6 billion dollars (12,3 billion euros) whereas, the highest income of 43 billion dollars (3,3 billion euros) was realized in 2006. Within the aforementioned year, Serbia achieved the highest rate of direct foreign investments from 2000 onwards, which draws attention to the enormous significance of direct foreign investments for the economic activity of the country. The most important investors in Serbia in the course of 2009 were as follows: [1]

- Russian Federation; due to the purchase of the majority of shares of Serbian Oil Industry (535 million dollars)
- Austria (322 million dollars)
- The Netherlands (242 million dollars)
- Italy (239 million dollars)

The first quarter of 2009, 46,8% of the total annual inflow of direct foreign investments was realized and, the greatest part refers to the privatization of the Serbian Oil Industry. In the course of the second and third quarter, the continuous slump of direct foreign investments occurred. The greatest part of foreign net investments was directed to the processing industry (532,9 billion euros), real estate operations (239,8 million euros), sale (222,2 million euros), traffic (118,5 million euros). The remaining

part of the investments amounted to 2,9 million euros, whereas the significant part of assets inflow stood for the means of MMF based on the Stand by Agreement.

Alongside with the global recession, foreign investors' interests for investing in Serbia economy decreased. Supporting the previous facts goes the data on unsuccessful Government's attempt to privatize some of the largest companies in the country: RTB Bor, JAT airways, JAT technique.

Investments participation in BDP in the course of 2009 amounted to 18,2% (in 2008 - 23%) which was insufficient for the noteworthy growth of industrial production and competitiveness increase. Available domestic means cannot cover domestic investment needs, due to which, the direct foreign investments are crucial economy development.

Direct foreign investments have an immense significance for economic growth and expansion of developing and countries in transition. Recent experiences indicate that foreign investments played an important role in structural changes of production, export and business method in the user –countries of these sources. Serbia, as a country under transition, defines foreign investments as a noteworthy source of economic development, modernization, production employment and income escalation. The ingress of foreign investments would result in up-to-date knowledge, experiences and technology.

Likewise, direct foreign investments possess a vast political and economic importance since they signalize that the country in question offers miscellaneous performances and economic future and that the investment can turn out to be profitable. In the course of previous years, Serbia showed an immense progress referring political and economic reforms. Substantial law reforms which are under process have for their aim to harmonize our legal system with the legal heritage of the European Union and, they have been frequently complimented by the leading international institutions.

Although, Serbia has vastly evolved referring management of structural reforms, the world economic crisis in 2009 has set back the dynamics of reforms' conductions and additionally deteriorates the low level of the economic competitiveness. The World Bank Business Report 2010 (Doing Business 2010) points out that Serbia occupy 88. position on the list of 183 countries referring business conditions. The report indicates that the structural reforms under process, directed at the economic growth by means of investment surroundings' improvement were not powerful enough within the course of 2009 as to absorb negative consequences of the world crisis transitional process, therefore, a noteworthy improvement of business surroundings never occurred. A comparative analysis of the dynamics and tempo of business surrounding improvement to the neighboring countries points out a slowdown of economical reforms in Serbia. Serbia has achieved the most important improvement of ranking in the field of companies' foundation where the escalation for 35 positions was perceived.

Within the field of loans obtaining, Serbia is best ranked and occupies the fourth position, which presents the improvement for 8 positions. From the standpoint of political and economic investing risks, the loan risks of the country is BB-, which indicates the unfavorable investment surrounding.

Serbia pays a special attention to incitement of investing in the development of the private sector. Law regulations stimulate private investments and guarantee the transparency protection, non-discrimination and ownership rights protection International companies in Serbia are guaranteed the same legal treatment like domestic companies. Likewise, they are allowed to invest in whichever industry they choose, moreover, to freely transfer all financial and other actives, including profits and dividends. The factor which significantly contributes to the more favorable investment climate is a stimulating tax surrounding. The company income tax rate amounts to 10% and it is among the lowest in the region. The foreign trade regime is stimulating the export increase. Potential investors were sent a positive signal by signing the CEFTA agreement signed by the Republic of Serbia on December 19, 2006, and the EFTA agreement signed on December 17, 2009. Direct foreign investments are generators of production and export increase and, they spur the competitiveness of export-oriented company by means of knowledge and technology transfer.

4. Conclusion

It is evident that the crisis has not yet elapsed and that the year 2010 will, by no means, be easy, The existent economy structure, low investments consumption, current level of technological development and knowledge, adverse financing sources, and substandard overall business performances of the economy result in minimal potential for economy development. The crisis can be overcome by means of defining a new offensive and sustainable strategy of economical growth. Long term stability can be enabled solely by means of considerably larger and continuous inflow of foreign currency originating from export which implies the necessity for modification of economic structure towards the export-oriented. Also, a special attention ought to be paid to the incitement of foreign investments, since, only the investments rise and a continuous inflow of investment capital can lead to the positive change in

economic structure and construction of competitive economy, which exports goods and services of a high additional value. It leads to economical stability. That represents the challenge ahead of the forthcoming decade of Serbian development.

The Most Common Obstacles in Granting Patents for Macedonian Inventors in International Applications

Bogoljub Ilievski¹, Gjorgji Filipov²

¹*Intellectual Property Agency BERIN LTD Skopje, b.ilievski@berin.com.mk*

²*Intellectual Property Agency BERIN LTD Skopje, filipov@berin.com.mk*

The paper gives a brief introduction to the definition of patent and necessary features of invention (invention) that should be possessed in order to be protected by patent. The benefits inventors and holders of the right (the owners) to acquire the international filing of patent applications pursuant to the Treaty on Cooperation in the field of patents (RST) and the procedure of the European Patent Convention, EPC are listed. The essence of the paper addresses the question emerges as the biggest obstacle observed in international examination reports from international examiners in respect of patent applications submitted by the Macedonian inventors and that is lack of novelty and inventive step. The knowledge is gained from the experience of agency "BERIN" and based on the Representation of over thirty patent application from Macedonian inventors before the World Intellectual Property Organization (Geneva) and the European Patent Organisation (Munich). The notable obstacles in international reports on patentability of inventions are: the industrial applicability is present, but not a novelty, especially the innovative step, which indicates a weak knowledge of the inventors in Macedonia with the modern trends of research techniques and lack of available patent information. This paper also gives suggestions and guidance for inventors to remove deficiencies and highlights the methods for recognition of innovative steps in their inventions.

1. What is a patent?

"Patent represents one of the industrial property rights which protects the invention"[1]. "Invention is the solution of technical problem relating to a product, method or composition of matter itself, which is the result of a particular procedure,"[2] This is the general legal definition defining invention in almost all national Laws on Industrial Property. There is a so called, engineering definition of a patent, which unites the definition of invention and it reads as follows:

"Patent represents an exclusive right that is assigned to the patent holder who created the invention which provides a new way to do something or a way that offers new so far unknown solution of a technical problem."

Concerning the exclusive rights, they relate to rights to:

- use the protected invention in the manufacture,
- releasing in market of the products produced in accordance with the invention, and
- prohibits third parties to use the protected invention in the manufacture and market without permission.

Taking into account the above mentioned rights and interests, therefore the interest of a new technical solution to obtain a patent and to gain the possibility of unlimited exploitation of the invention within 20 years, as well as the fact that this exclusive right guarantees "monopoly" on the market, it could be concluded that the owner of the right posses huge advantage over the competition. However, the Macedonian inventors prefer to transfer their patent rights to other for adequate cash compensation. In an internal questionnaire by the Agency for Intellectual Property BERIN, about 30 Macedonian inventors, holders of the patent, were asked about their future plans concerning acquired patent rights. Only 90% of them responded that they will sell the patent right for the invention in order to gain financial benefit[3]. Only 10% were willing to invest in their own business and to exploit the invention

on the market. It is obvious that the entrepreneurial spirit is the weak side of the inventors from the Republic of Macedonia, although they have in their hands a powerful tool for personal and economic development.

2. Patentability requirements (The three patent commandments)

Once it became clear what patent is and what rights arise, further we are referring to the features that should have the invention to gain the patent right. Figure 1 shows a common rough structure of the procedure for patent granting.

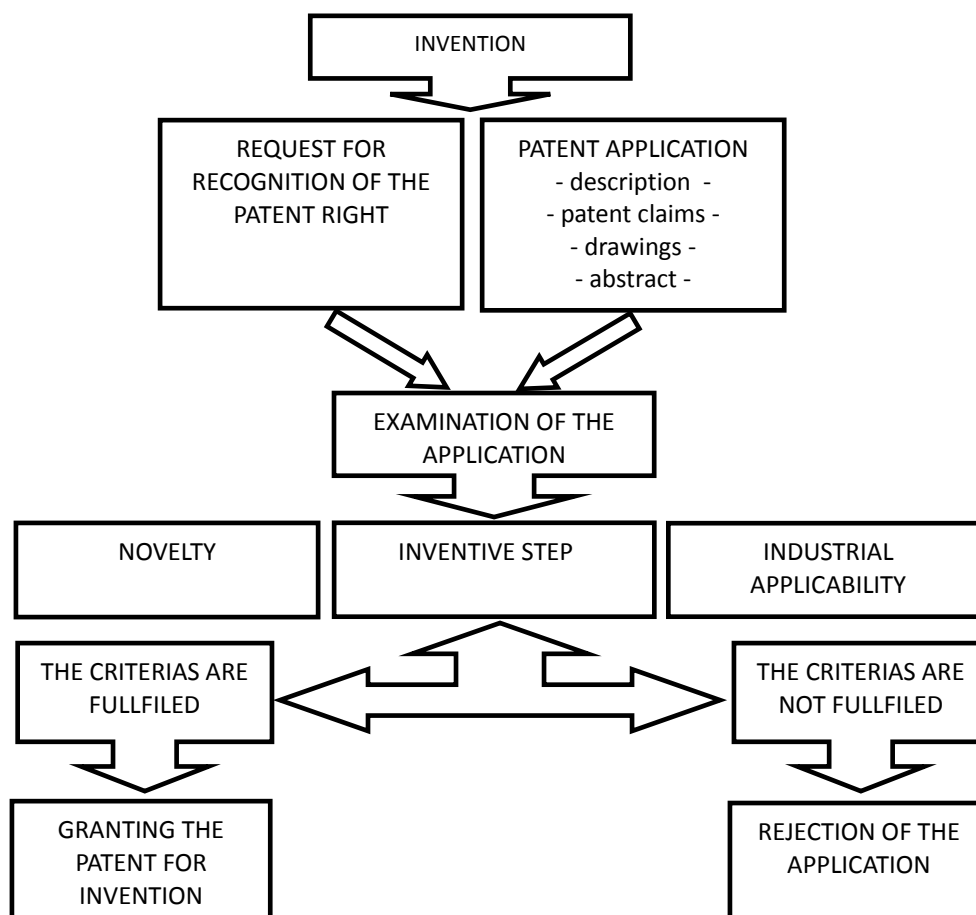

Figure1 Common rough structure of the procedure for patent granting

- It is clear from the figure 1 that besides completing the request for recognition of the patent right before the State Office of Industrial Property, it is also necessary to file patent application that contains:
 - Description of the invention that should be clear and precise for the skilled examiner to determine the applicability of the invention,
 - One or more patent claims, defining the scope of protection, the claims be clear and fully contained in the description of the invention,
 - Summary of the essence of the invention (abstract), and
 - Drawings.
- Further, the request is being considered as the patent application is being examined. Generally, the patent will be granted if the examiners (employees in the Office of Industrial Property), that are skilled persons in a particular area of technology for which the invention relates, determined that the invention meets the three patentability requirements:
 - Novelty,
 - Inventive step,
 - Industrial applicability.

The NOVELTY means that the claimed invention is new. But what does in reality mean that something is new? In everyday life the concept of novelty is taken for granted. " New clothes, new house, new love, and everyone thinks it is relatively easy to decide by himself "what is, and, what is not new". But, can be so easy determine whether the claimed invention meets the first patentability requirement? Within the The State Office of Industrial Property (SIPO) considering the Law on Industrial Property, examiners will evaluate and accept the invention as new if it is not disclosed in the prior state of the art.

The state of the art means everything that is available in the front of the world public by describing the invention of the written or oral route, using or in any other manner before the date of filing of the patent application in a way that skilled in the relevant field allows to apply. On that basis, the local examiners from the Macedonian Institute should decide whether an invention is new. Typically, they will search the contents of national patent applications with the exception of the abandoned, foreign patent applications (European and international) that are valid or for which protection is validated in the country.

The invention meets the requirement for INVENTIVE STEP if for an expert in the field, the subject of the invention is not obvious from the state of the art. This is a general definition, that will be further explained in details.

INDUSTRIAL APPLICABILITY is the third patentability requirement, which is considered to be fulfilled when the invention is produced or used in any branch of industry. Somewhere, this requirement is considered only as an additional, and it rarely happens not to be fulfilled. It is also the simplest way to determine since it is the most tangible category, and least suspicious to be understood from the examiner. Inventions are material creations that have adequate technical construction or composition, and anyway the idea of creating the invention is to be used in the industry and as such must be produced there.

It is important to note that the Macedonian examiners from the SIPO shall examine only the first and third patentability requirements and if they are met the patent right will be granted but with a limited duration of 10 years. Certainly there is option for prolonged duration of patent right for an additional 10 years, but if on the prescribed time the applicant submits a positive report from the total (substantive examination) of the patent application prepared by the authorized institutions for international examination.

3. International protection of the inventions

Macedonian inventors and applicants of the patent applications can (and most often) confer their patent rights in the Republic of Macedonia. The available statistics show that, within the last 7 years, a total number of 423 patent applications were filed before the State Office of Industrial Property by the domestic applicants (inventors). In the same period, the total number of patent applications filed by foreign applicants was 2751. Hence, the share of number of patent applications filed by domestic inventors in the total number of patent applications filed in Macedonia is only 8.6% (Figure 2) [4].

Figure 2. Share of patent applications filed by domestic and foreign applicants before SOIP in the period 2002 - 2009

- Benefits of the patent right can also be conferred in foreign countries, wherein patent applications can be filed before the Patent Offices in each country separately or before patent offices of the regional patent organizations. It should be noted that there is no world institution or body that examines patent applications or can grant patents solutions for the right of a patent that will be valid in all countries in the world. Although, this is something that every applicant (inventor) wishes, in economic terms, the reduction of the costs, at this moment that remains only a “sweaty dream”. Therefore, until realization of this dream, the only remaining option for the domestic applicants is international protection, according to: National laws and procedures, wherein the obtained patent rights are valid only in territory of the state where the patent application is filed,
- European patent procedure before the European Patent Organisation (EPO) [5] located in Munich
- Patent Cooperation Treaty (PCT). The procedure is being carrying out before the World International Property Organization (WIPO) based in Geneva. Macedonia is a full member of PCT Union since 10.08.1995. From that date, the domestic inventors could file their international applications through the National IPPO or directly in the Secretariat of this organization.

The first option for obtaining the patent right is mandatory filing of patent application in each country separately, wherein significant costs appear, which increase with each submitted application. The protection of inventions before EPO is a possible option for domestic applicants, but considering the high initial costs for filing the European application, unfortunately, till now, there is no single patent application filed before European Patent Organization by Macedonian private or legal person.

It seems that the filing of patent application under PCT is most popular option for Macedonian inventors. The benefit of the international application is one that provides a unified procedure of filing an international application for protection of invention in any Member State of WIPO (up to now a total of 142 countries). Since acquiring independence of the country, the total number of 60 PCT applications was filed in WIPO by domestic applicants.

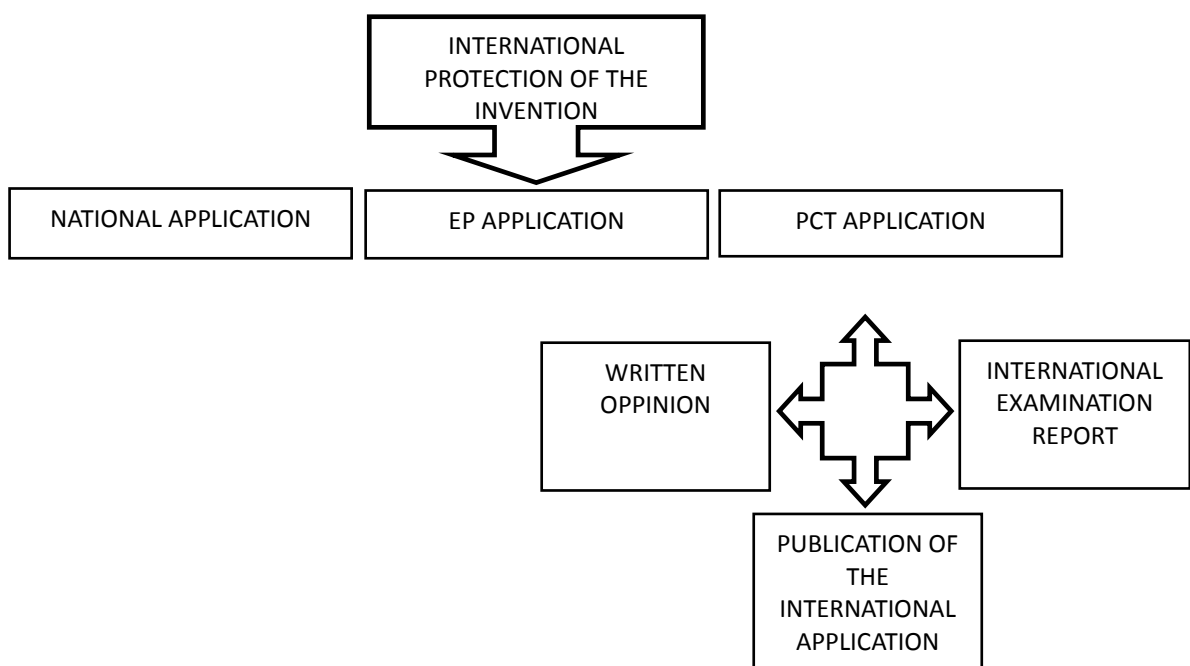

Figure 3 Essential phase of International Protection of Invention

4. PCT procedure

The procedure for filing a patent application under the PCT can be seen in the Figure 3 and it consists two phases:

- International Phase, and
- National Phase.

The International phase begins with the filing of an international patent application directly to WIPO or

SOIP which has the role of receiving office for these applications. Later, in a time period of 9 months after filing the international application the applicant receives the „search report“ performed by an International Searching Authority (ISA), accompanied by a written opinion regarding the three patentability criteria of the invention, being the subject of the application. 18 months after the filing date or the priority date, the international application is published in the gazetta of the International Bureau together with the already performed International Search Report. Since the invention is now disclosed it becomes part of an international patent data base and thus part of the state of the art.

International phase ends 31 months after filing the international patent application as the "National / Regional" phase beginning. This phase is actually a continuation of the international phase, as now the patent application enters in national and regional phase with filing of request in each contracting state. Once again, the PCT application itself does not mean requesting a grant of patent right, and it will not become such unless it enters national or regional stage.

The following are the benefits that can be acquired for domestic applicants (inventors), for the patent right under this procedure:

- Postponing of national or regional phase for a period of 31 months from the priority, that saves considerable amount of money for respective official fees and translation costs for entering in national phase in each country.
- The "Search report" from the "International examination", the applicant will acquire information concerning the current state of the art and information about any similar inventions patented in the contracting states. Based on this relevant information, the applicant can decide whether it would be worthwhile to seek national protection of the invention in the national stage, and if required, in which countries, which will save on unnecessary costs in those countries where the report showed the existence of similar inventions.
- Many national patent authorities will rely on the international search report instead of starting from scratch to search the prior art themselves, and the applicant may be able to save in search fees as procedure for the recognition of the right to patent these countries is very simplified. As previously noted, International patent application under the PCT procedure is the most popular and most useful way for international protection of invention among Macedonian applicants (inventors). The essence of this paper is to present the biggest obstacles, which are outlined in reports from international research in relation to applications submitted by the Macedonian inventors. Such obstacles certainly limit further protection of the invention, and bring disappointment among inventors.

5. Weaknesses in the Search reports from the International Examinations present in the patent applications from the Macedonian applicants (inventors)

International search reports and the "written opinion" concerning three patentability criterias are performed by the European search authorities based in the EPO branch Office in The Hague. Although the application is submitted in Geneva, further it is distributed in The Hague where the search shall be made and the report and opinion shall be formed. These results, are sent to the applicant.

The „search report“ from the „international examination“ is usually written in two to four pages. The report lists the classification of the subjected invention as well as the class for which the search is performed. The most important part of the report are the cited documents that are considered relevant to the subjected invention. The relevance of the cited document is marked with a category. There are 9 categories beginning with the lowest "A" – referring to documents where the general state of the art is not relevant to the invention up to the highest "&" - that shows invention from the same patent family (same invention but from other inventor).

Table 1 provides a detailed view of the number of appearances in the categories of relevance in 44 international search reports of patent applications filed by the Macedonian applicants (inventors). Only three categories are considered relevant

- Category "A" - referring to the documents, wherein the general state of the art is not relevant to the subjected invention,
- Category "X" - referring to the documents of particular documents which indicate that subjected invention can not be regarded as new and does not involve inventive step,
- Category "Y" - referring to the documents of particular relevance that indicate that subjected invention can not be regarded as new and does not involve inventive step, according to the cited

documents, and the opinion of the skilled person for a given technical problem is that the solution from the invention is already known. The remaining categories were not anticipated since their appearance was "one" or "zero".

Table 1 Number of the appearances in the categories of relevance in international search reports of patent applications filed by the Macedonian applicants (inventors)

Categories	A	X	Y
Number of appereances	68	92	26

It is evident from the Table 1, that category "A" which is considered as positive, indicating that the invention has novelty and inventive step, appears only in 68 cases.

Category "X", which is considered negative and indicates that there is no novelty or inventive step occurs 92 times while the most negative and non desirable category "Y" indicated that there is no novelty, inventive step or even technical problem which resolves domain is already disclosed appears even 26 times.

Figure 4. Total ratio between apperaences of positive and negative categories in the „search reports“ from the „international examinations relating the Macedonian inventors

Percentage ratio between positive and negative categories in international reports is 1:2,2. Respectively, one appeared to be positive category is being followed by more than two negative categories. Overall, in examined 44 patent applications only 34% of them or 12 could be considered to have meet the patentability criterias and as such are eligible to be granted the patent, while in the 76% or in 32 international patent applications the „search report“ is **negative** and does not meet the patentability criteria so consequently the patent would not be granted for the invention.

As a conclusion, the fact that the invention subjected to the examination is determined not to be new can be established by its negative categorization in the “International Search Report”. In a word, negative categories in the „search report“ lead to a negative written opinion concerning the first patentability criteria.

The same goes for the inventive step. It was pointed out that the invention would have inventive step if it is not part from the state of the art. The examiner who gives this opinion, at first identifies the most relevant state of the art from the „search report“. If the report is negative, ie prevailing categories X and Y, then definitely what follows is a negative opinion concerning inventive step.

6. Conclusion

Given the fact that nothing is perfect, we believe that there is no ideal “International search report”, wherein the invention for which protection is sought will be entirely new and absolutely unknown to the state of the art. There is always a probability that an inventor, for example, in Japan or in Chile, came to the same or similar idea with those one of the Macedonian inventor, as well as the innovation resulted from this invention (patented or published much earlier) or being worked on or thinking about it simultaneously, is already being processed and implemented in the praxes. There are examples in

the world technical history when two scientists came to the same discovery, scientific formula or method at the same time, though never meet or know each another. The point is that, the possibility that sometimes the idea of making a discovery which is equivalent to that of the Macedonian inventor as the invention was patented long ago, should never be neglected..

To summarize, the above negative results regarding novelty and inventive step in patent applications by Macedonian inventors (applicants) are considered to be due to:

- insufficient research of available patent information, and, or
- lack of awareness and poor knowledge of domestic patent applications of applicants with the modern trends of technique.

The following are the recommendations for getting an international report with a better quality, that will lead to a positive opinion on these two criteria:

1. Immediately, after the birth of the idea and before the start of realization to create an invention, it is necessary to search available patent information, which will gain insight into the state of the art in the field of the invention. There are numerous sources that offer online information for searching existing patents and patent applications. Or, by simple entry of a term characteristic for the invention, the internet browser will certainly list the relevant information that will provide to the inventor insight into the state of the art.
2. It is always better and most recommended to consult patent agents who are skilled experts in this area and can instruct and advise inventors about the state of the art of patents in the particular area of interest. The experience of the agent will provide more skilled preparation of patent documentation and representation before national and international institutions.
3. Change the attitude that "nobody else but me is able to create an invention same as mine". Changing this attitude will save money and hassle before being aware that sometimes the idea as a basis for creating the invention is not new. Following this recommendations the applicants (inventors) will have enough relevant information for the guidelines of creation their invention and for making a quality patent application, which will lead to a positive report from the International examination, and also simplifying the procedure for grant of patent in the countries of interest.

The purpose of this paper is to investigate whether and in which ways South East European (SEE) small to medium-sized enterprises (SME's) are benefiting from the enterprise resource planning (ERP) implementation. The study is based on a survey research and aims to help SME's in this region to take appropriate decisions about ERP implementation. The research is exploratory in its nature. Namely, a survey methodology is used which is cross-checked with personal interviews conducted with the main personnel in the SME's and the ERP vendors. A structured questionnaire was developed to collect the data. The survey of 63 SME's in SEE reveals that most of them have implemented ERP to integrate the existing information system and found ERP implementation beneficial in inventory reduction, customer service improvement and improved communication. Also top management support and user involvement, as well as participation, are found to be the major contributors for the ERP success. A research limitation of this study is that of the scope since it could not get more responses for the period planned, the results are quite encouraging with very good response rate from the SME's, even though the industry-institute is not so strong in collaboration and information sharing for research developments. Other SMEs that are planning to implement ERP in the near future will highly benefit from the performance appraisal of ERP in SEE - SME'S.

1. Introduction

In the opening up of the economy business era, liberalization, privatization and deregulation have thrown many challenges to SME's in the fast developing economies like SEE region. Compressed product development life cycles, cut throat global competition, rapid change of customers preferences and volatile financial markets have increased the pressure on SME's to figure out effective and competitive advantages to survive and succeed. ERP is often considered as one of alternative solutions for their survival [4].

Until the beginning of – 1990s, SME's in SEE region had operated under much-protected economic regime characterized by limited competition and highly regulated business environment. This business environment had resulted in limited focus regarding the process efficiencies, centralized control structure, highly formalized business settings and lack of professional business practices. However, following the economic liberalization and opening the economy to foreign multi-national companies, SEE SME's have adopted modern business practices and strategies, which can provide a turnaround edge to competition.

ERP system integrates many functional spheres in an organization; it acts as a link through the entire supply chain, aimed at adapting best industry practices in order to provide the right product at the right

place at the right time at the lowest cost. ERP in this case has the ability, once implemented, to integrate all major activities across the organizational departments using an integrated software solution. In fact this can greatly assist the enterprise to carry out its operations in more effective and efficient manner and allow the workforce to interact and collaborate in an environment where information is enabled.

Using ERP, manufacturing firms are linking up with their suppliers and customers located anywhere in the world. Employees are sharing information with each other on time. ERP can accelerate responses to customers' orders and queries, reduced inventory, shorten production cycle time, improvement quality, enforced efficiency of delivery of products and services and strengthen inner coordination [9]. However, after emphasizing on the large-scale firms, the ERP suppliers are now aiming on SME's. Recently many international firms have restricted their operations to partnering only those mid-sized enterprises that are using compatible ERP system. Thus, it becomes important for many mid-sized enterprises to adjust their business models and adopt ERP software that is compatible with the large companies with which they deal. Though ERP is needed in all firms, its implementation is not successful all the time. There are many failure companies that have the resources needed to perform a careful planning and implementation. A mischief that has gained acceptance recently is that ERP's are meant for large organizations. This statement is partially true. The ERP's marketed are expensive and smaller firms cannot afford those [10]. Taking into account the uncertainties in the business environment, most ERP vendors are moving their attention towards SME's by offering cheaper and straightforward solutions that requests this market segment such as ERP system which compact package, flexible pricing policy, new methodologies for implementation and specialized functionalities. The successful evaluation and implementation of ERP in SME's is an important study to know the present status of ERP implementation in SME's and how they are performing. An extended body of literature exists on the ERP selection, its implementation and critical success factors (CSF's) mostly dealing with large-scale companies. As ERP implementation started in 90's, most studies on ERP are found after 90's in the developed European countries and US industries. In contrast very little effort has been made in the fast-developing countries in SEE region. The critical analysis of which will become a guideline for the SME's to extract more benefits from their ERP system and other SME's those who plan to implement ERP in the future. Authors in this study have evaluated and presented the appraisal of SME's who have implemented ERP based on the survey conducted and in-depth interviews with ERP vendors as well as key personnel in the user enterprises.

2. Review of Literature

Nowadays many companies have embraced new tools for planning and resource management software systems in order to integrate their processes enhance data integrity to manage better resources. These package systems are broadly classified as ERP systems [1], [3].

Before emergence of the ERP, industries have enjoyed benefits of material resource planning (MRP) in inventory turnover, delivery performance and other benefits, but there are mixed reports when it comes to ERP implementation. Hence, 80 percent of the large industries that implemented ERP, around one-third of such systems failed [2]. In addition a 65 percent of executives strongly believe that ERP systems could be harmful, this perception being buttressed by specific instances of how pitiable implemented ERP systems have contributed to the bankruptcy of many firms [5]. On the other hand there is evidence that indicating the various tangible and intangible benefits of ERP's.

Indeed ERP systems reduce costs by improving efficiency through computerization and augment decision making by offering on time information to the whole enterprise. The result of implementing ERP does not, however always prove successful. In spite numerous problems, small-and-medium sized firms are now also starting to embrace ERP but because of the complexity of system implementation, the efforts may be expensive. Thus, top managers are likely to require an appraisal of the success of the resulting system [7].

Different results lead researchers to evaluate the appraisal of ERP implementation. There are many methodologies developed by the researchers. Some researchers have identified that the balanced scorecard approach may be an appropriate technique for evaluating the performance of ERP system [6], [10]. In addition, Teltumbade [8] noted that appraisal methodologies relying on financial cost benefits utterly fail to apply. There must be a mechanism in order to determine whether ERP is needed and once implemented, whether it is successful [12]. Basically user satisfaction is one principal mechanism for determining system success. Besides, productivity measurement of information technology (IT) investment is very difficult since it incorporates various factors [9].

According to Singh et al. [11], SME's are facing many pressures and constraints due to globalization of markets to sustain their competitiveness. Very few SME's carried out performance appraisal though it is vital and very few recent studies have focused on ERP also. Ngai et al [13] in their study investigated the CSFs in the implementation of ERP across ten different countries/regions. In their 18 CSFs "top management support" and "training and education" were the most frequently cited critical factors to successful implementation of ERP system. Another study conducted by Malhotra and Temponi [14] identified that the best practices of the critical decisions while implementing ERP as project team structure including implementation strategy and database conversion strategy. Nevertheless, comparison of local or global suppliers is critical as well. The more localized ERP system developed by local suppliers is more sensitive to the link between attitude in the direction of change and perceived usefulness. Another issue that must be stated is the organization's preparedness and the emergence of implementation problems.

The empirical analysis on the appraisal of the ERP is rarely found in the literature. Therefore authors in this work aimed to put the empirical results of the survey of SEE region.

3. Motivation, research objectives and methodology

In a wide spectrum SME's play an important role in both developed and developing countries. SME's in SEE are no exception because they occupy prominent position planned development economy. Over the years, most ERP suppliers have modified their products so they can suit SME's working environment and affordable prices for them. Authors have attempted to conduct a survey-based research to get insights of performance appraisal of ERP implemented SME's, a progress driver of SEE economy.

The research objectives are:

- to investigate the extent to which SME's are familiar with the ERP concept;
- to analyze the penetration of the ERP in SME's;
- to explore the implementation of the ERP implemented SME's;
- to appraise the performance of ERP implemented SME's ; and
- to investigate the enablers and inhibitors for the success and failures of ERP implementation.

As the research is exploratory in nature, a survey methodology was used and emphasize of the study was cross-sectional with personal interviews of the key persons in SME's. The main issue was to interact with the ERP implemented SME's and to collect the quantitative and qualitative data through structured questionnaire. Out of 170 ERP implemented SME's; the questionnaire was sent to 135 firms. Therefore, only 63 SME's responded with complete filled in the questionnaire, this is shown on the table below.

Table 1 SEE countries - research participants

Country	Frequencies	Percent
Albania	12	18.8
Bulgaria	10	15.6
Greece	11	20.3
Montenegro	8	17.2
Serbia	9	14.1
Total	63	100

4. Results and discussion

According to the findings ERP penetration is very less in SME's and is increasing with very slow pace. Some of the issues regarding ERP implementation in SME's for the SEE region are given below.

4.1 Information of ERP system

The responses concerning the “information about ERP system” revealed that ERP is evolved from basic idea of MRP and manufacturing resource planning. Since most of the firms are not using the production planning, maintenance and most quality management modules that are critical functions in manufacturing. The main purpose that ERP became popular is that of the common modules in the industrial sector that include inventory management, procurement and financial management modules. The ERP implementation in SME’s in SEE region are 90 percent late. Therefore, the respondents have not filled the cost of the ERP which they have implemented. Following up with the respondents, it was found out that either firms want to keep it secret or are unaware about the cost. The cost dealings are done mostly with the top management. Nonetheless, in most firms a team of four-five personnel was formed before implementing the ERP taking two-three key employees, one from each department and IT manager as a team leader.

4.2 Motivation to implement ERP system

These days there are different advanced manufacturing technologies adopted by different enterprises so they can improve the productivity of their organizations. ERP implementation is one of the tools, but the reasons to implement it are different in all companies. The information collated in this study show that 60 percent of the enterprises have implemented ERP “to integrate the existing information system”. In contrast, the reason was the opposite from the employees who wanted to continue with existing system. The second priority was given for replacing “weak existing information system” that gained 40 percent from the responses. In general assumption of the SME’s that ERP is not for them and it is affordable only to the big enterprises, consequently some sort of information systems which were developed by local firms were bought by them. Hence, either MS access format or excel format was their back end. The third priority “replacement of legacy system” scored 34 percent, where as “complementing legacy system” comes as the final priority with 72 percent of the responses.

4.3 ERP benefits

To appraise the performance of the SME’s after implementing; its benefits must be measured. As mentioned earlier that one third of the ERP implementation failed in large firms or expected goals are not achieved. The objective of this part of the survey was to find out whether SME’s are benefited by the ERP implementation and in what aspect benefits are more compared to others. The respondents were asked to indicate their responses on 11 different tangible benefits and 8 intangible benefits. These benefits are present to act as catalysts of ERP success. The summery and analysis of the responses are given below.

Table 2 ERP tangible benefits

Nr.	Tangible benefits	Most beneficial		More beneficial		Beneficial		No benefit	
		F	%	F	%	F	%	F	%
1	Reduced planning cycle time	41	64.1	19	29.7	3	4.7	0	0
2	Reduced manufacturing cycle time	3	4.7	11	17.2	40	62.5	9	14.1
3	Improved customer service	39	60.9	18	28.1	6	9.4	0	0
4	Decreased lead time	42	65.6	16	25.0	5	7.8	0	0
5	Reduced cost	17	26.6	38	59.4	8	12.5	0	0
6	Reduced inventory	46	71.9	11	17.2	6	9.4	0	0
7	Reduced error in ordering	20	31.3	39	60.9	4	6.3	0	0
8	Increased throughput	36	56.3	24	37.5	3	4.7	0	0
9	Increase in sales volume	7	10.9	17	26.6	33	51.6	6	9.4

Nr.	Tangible benefits	Most beneficial		More beneficial		Beneficial		No benefit	
		F	%	F	%	F	%	F	%
10	Improved competitive position	35	54.7	24	37.5	3	4.7	1	1.6
11	Improved communication	39	60.9	21	32.8	3	4.7	0	0

It is clear from the table 2 that “reduced inventory“ is found out to be as most beneficial factor of the ERP with 46 enterprises responding as most beneficial. The “decreased lead time”, reduced planning cycle”, “improved customer service “and “improved communication” are the next priority with the most firms. The “increased throughput”, “improved competitive position” and “reduced error in ordering” are considered also the areas where firms found benefit to certain extent.

The respondents were also asked to quantify the benefits from comparing the performance with the previous record, but such contemporary records could not be available with them. Nevertheless, this issue was discussed in group meeting with key employees as well as with the ERP vendor’s representatives. The reduction in cost can be combined effect of reducing the manpower cost, decreased lead time, reduction in inventory and so forth. Basically man power is not reduced but keeping the same manpower, the turnover of the firm is increased which results in saving the manpower cost. By computing the proportional increase in manpower cost with the increase in turnover, one can find out the reduction in cost due to ERP. On the other hand, except the tangible benefits there are many intangible benefits as well, that can be seen in table 3.

Table 3 ERP intangible benefits

Nr.	Intangible benefits	Most beneficial		More beneficial		Beneficial		No benefit	
		F	%	F	%	F	%	F	%
1	Better coordination in between managers	35	52.2	26	38.8	1	1.5	0	0
2	Improved forecasting	24	35.8	36	53.7	3	4.5	0	0
3	Reduced inventory delay	45	67.2	15	22.4	2	3.0	1	1.5
4	Improved decision making	49	73.1	10	14.9	4	6.0	0	0
5	Streamline the business processes	44	65.7	16	23.9	3	4.5	0	0
6	Improved competitive position	58	86.6	3	4.5	0	0	2	3.0
7	Improved communication	54	77.6	9	13.4	1	1.5	1	1.5

It can be seen from the table 3 that “improved competitive position” is the most rated intangible benefit and this is due to the advantage that mostly tasks are fulfilled more accurately from the system. Also “improved communication” gained solid rating from the responded because it is easier when integrated communication is applied. To wrap up, those inhibitors that gained low scores are the main facilitators for failure of the ERP system.

3.4 Return on Investment

In the context of possibility to provide for and achieve a meaningful return on investment (ROI) for ERP projects, various aspects measured are summarized in this paragraph. About 40 percent of firms fairly agreed that there were more intangible benefits from ERP; while, very few firm (5 percent) fairly agreed that there were more “tangible benefits” from ERP. However, on the issue “ERP ROI can be computed” and “ERP ROI cannot be computed”, there were more contradictions regarding the respondent’s view. This particular point was always raised with the respondents while interviewing. Some firms respondent that ROI can be computed but is hard to quantify its benefits. Besides few respondents said that ROI cannot be computed as intangible benefits are more as compared to tangible benefits and thus ROI will be less in spite the fact of the utility of ERP beyond doubt.

4. Conclusions

The findings show that after completing the ERP implementation in most large firms, suppliers aim to penetrate now the SME's. In our sample data enterprises have local/global ERP. The study also revealed that SEE- SME's are using ERP to integrate several of data everywhere into single software. Almost all firms have reported that they are benefited by the ERP implementation in reducing inventory, decreased lead time, and reduced planning cycle time and improved communication and customer service. Yet, authors feel that SME's are not extracting benefits from ERP to a fullest extent. In addition, there are more intangible benefits of ERP and therefore implementation should not be related with ROI.

The major contributors of ERP success are: top management support, user involvement and participation along with the understanding the ERP concept. In the present time of globalization, it is clear that the survival of the SME's will be determined and must be addressed extensively. Accessing the right information at the right time is the main objective to manufacturers/suppliers so they can operate with lowers cost, with less delivery time, minimum defects by using less resource. The issue of ERP is the need of the moment and thus the need of ERP in SME's is beyond doubt. The fear of SME's about its failure histories is high but this should be tackled intelligently.

This paper aspires to contribute to the dialogue on the modes of cooperation and success factors of the knowledge exchange between research and entrepreneurial communities at local level. We present the results of a survey aiming at the identification of successful knowledge exchange practices between academia and enterprises in the wider Thessaloniki area. The results of the survey, combined with the examination of the context within those cases take place; aim to identify relevant best innovation policy practices at local and regional level. The survey constitutes a core activity of the INNOPOLIS project, an Interreg 4C project focusing on the investigation of existing knowledge endowments in university-city regions, the advancement of innovation, and by implication economic development.

Keywords

Knowledge exchange, knowledge transfer, innovation policy, entrepreneurship, intellectual property

1. Introduction

Universities are an important source of new knowledge creation and dissemination, which is a fundamental element for the promotion of regional development. The transfer of technologies from universities to enterprises is considered to boost competitiveness, stimulate economic growth and increase prosperity [1]. Whereas the benefits of knowledge exchange between universities and enterprises have been documented in various cases, there is still a long way to go considering the identification of the best-suited policy framework for the enhancement of this process, on national and regional levels.

In recent years, a number of contributions have been developed considering the models that describe the process of university to industry knowledge transfer [2], as well as the relative importance of the different channels for its diffusion [3], [4]. In the literature, the transfer of technology has been met as a linear sequence of steps [5], but also, in the framework of informal interpersonal networks and established relationships that promote knowledge sharing and learning [6].

Regarding the potential paths through which knowledge is being transferred; these include publications, network formation, recruiting cooperation in R&D, joint ventures, contract-based research, and consulting. Next to these, people's mobility by visiting conferences and workshops is considered to create social networks and generate knowledge spillovers. A lot of attention has also been drawn in the intellectual property rights (IPR), in the form of patenting, co-patenting, licenses,

and academic R&D valorization. The proliferation of patent-related empirical studies cannot be attributed to its importance as a knowledge transfer mechanism, since it has been proved to represent only a fragment of the total effort [7], but mainly to methodological convenience due to the availability of quantitative data [8]. Finally, a popular mechanism for the introduction of a new technology into the market, especially in industries like biotechnology or ICT, is through the formation of spin-offs. The relative importance of the above mentioned knowledge diffusion channels have been assessed in many empirical studies with, sometimes, contrasting results.

Having identified the possible ways of knowledge transmission, a number of policies have been developed with the aim to stimulate interaction between academia and enterprises and to foster knowledge exchange partnerships. Policies studied include the setting of institutional frameworks favoring technology cooperation and the formation of intermediating organizations, i.e. organizations which seek commercial applications for university research, the development of business incubators as managing facilities in support of new technology-based business [9], the development of technology platforms and virtual innovation environments [10], the establishment of international networks etc. So far, many of these policies have failed to provide a sustainable model for the regional fueling of university produced knowledge and to address the observed inability of European regions to transform top-level scientific research into commercial products, a problem expressed by the Community as 'the European paradox' [11], [12].

Still, knowledge exchange between academia and industry is a highly complex and risky process that often fails due to a number of factors. These factors can be addressed to the particular properties of the knowledge exchanged (tacit-explicit, interdisciplinary, basic-applied) [4] or to the specific context in which the knowledge is developed and transferred, such as the institutional structures (legal framework) or the individual (culture, habits) and organizational (norms, regimes) characteristics of the stakeholders involved [13]. The latter also include firm characteristics that influence its ability to learn and utilize externally generated knowledge, such as the level of 'connectedness', or the firm's 'absorptive capacity' [7], [14]. Finally, it should be added that empirical evidence shows large differences in the way knowledge is being exchanged in different countries, universities [15], sectors [16], and types of industrial knowledge bases (analytical, synthetic, symbolic), a fact that requisites the disposal of a wider set of policy measures that should be taken according to the circumstances.

The complex, interactive and mutually benefiting activity in which new knowledge is being transferred to and utilized by enterprises can be seen as the central function of a 'university-based innovation ecosystem' [17], comprised by a number of components which interact with each other and work cooperatively in a specific/local environment. Apart from the main players at the two ends of this process (universities and enterprises), in this web of interactions are also included technology transfer and liaison offices, financial organizations or even governmental institutions. In this context, it is crucial to identify a set of national or regional good practice policies for the enhancement of knowledge exchange and network creation that would match the regional structural conditions and fit to the specific properties of different ecosystems.

2. The INNOPOLIS project

The survey presented in this paper constitutes a core activity of the INNOPOLIS project (funded by the INTERREG IVC Programme of the European Commission). The main idea of the INNOPOLIS project is to realise the potential impact of the mobilisation and valorisation of the existing knowledge endowments in university-city regions towards the advancement of innovation, and by implication economic performance. More specifically, the project aims to enhance the process of knowledge exchange between universities and enterprises with the support of local/regional authorities, with the aim of facilitating knowledge co-creation & innovativeness. The main methodology of the project consists in the identification of regional and national best policy practices that foster knowledge exchange as well as the creation of networks and learning tools that support best policy transfer. INNOPOLIS focuses on localities of high academic concentration (at least three multi-departmental universities and 60,000 students) which are labeled as "university city regions". The metropolitan area of Thessaloniki is a "university city region" identified in Greece [1], which hosts 3 public Universities, one of the biggest public research institutes and a number of public and private academic and research organizations, concentrating more than 100,000 students in total. A mapping of the knowledge exchange between these institutions and companies in the area has been attempted though the examination of 35 best practices of knowledge exchange between academic institutions and enterprises.

3. Methodology

The best practices survey was conducted by interviewing thirty five researchers and company representatives that have been engaged in knowledge exchange activities during the past three years. The survey focuses on identifying the details of existing knowledge transfer collaborations between academic institutions and companies. The participating researchers and company representatives have already been active in knowledge exchange at least once. In this sense, this was not a statistical survey of how much knowledge exchange is taking place between academia and industry in the region, but rather provided an in depth understanding of what the two sides of the exchange are expecting, how they interact and what is the added value they gain from the exchange.

Table 1 depicts the type of companies that participated in the best practices survey. It should be noted that the majority of the surveyed companies belong to the ICT sector, which can be explained by the fact that ICT companies are knowledge intensive companies coupled by the fact that Thessaloniki has a very dynamic ICT sector and also is the home of important ICT academic units. The existence of incubators among the companies was a predictable finding since Thessaloniki has the highest incubator concentration in Greece. Finally the participation of associations of companies underlines the crucial intermediary/facilitator role in KE practices that these organizations play, especially regarding the initialization and the sustainability of the practice.

Table 1 Type of companies participating in the survey.

Sector	Number of companies
ICT	20
Consulting	2
Manufacturing	4
Energy	3
Retail	1
High tech incubators	2
Other services	1
Associations	2

The participating Higher Education and Research organisations are shown in Table 2. As expected the biggest University of Thessaloniki (Aristotle University) holds the bigger share, followed by CERTH which is one of the major public research centres in Greece. It is worth noting that a number of companies have knowledge exchange relations with academic institutions outside of the wider Thessaloniki and Central Macedonia area.

Table 2 Academic institutions participating in the survey.

Name	Location	Number of cases
Aristotle University	Thessaloniki	18
CERTH	Thessaloniki	5
CITY College	Thessaloniki	3
TEI of Thessaloniki	Thessaloniki	2
University of Macedonia	Thessaloniki	1
SEERC	Thessaloniki	1
University of Patras	Patras	1
University of Thessaly	Volos	1
TEI of West Macedonia	Kozani	1
Mediterranean Agronomic Institute	Chania	1
Perrotis College	Thessaloniki	1

Thirty five pairs of interviews (one at the company, one at the academic institution) were held based on a pre-defined open questionnaire which was structured around the following issues:

- Description of the knowledge exchange practice
- Characteristics of the organisations involved in the knowledge exchange

- Type of knowledge transferred / exchanged
- Formal aspects of knowledge exchange
- Benefits of the knowledge transfer / exchange
- Risks along the knowledge exchange
- Key success/failure factors & policy for the knowledge exchange

4. Discussion of results

4.1 Key motivators

The factors cited by the two parts of the KE practice as motives that encourage the engagement in such activity, vary depending on whether the viewpoint is academic or business. Table 3 presents a collection of the most important of them.

Table 3 Key motivators of knowledge exchange.

Academia	Companies
Establishment of a market	Financial benefits
Exploitation of research results	Benefits of working with experts
Ability to use in practice and improve knowledge that has been designed in the institute's labs.	Identification of entrepreneurial opportunities
Contribution to the society	Development new products and improvement of existing products
Ensuring practical experience for their students	Easier goal achievement through the use of academic knowledge
More and better academic publications	Use of universities' infrastructures
Gain specific expertise from companies	Acquire knowledge and know how in a specific field that will open new markets
Publicity and dissemination of research results	Explore the possibility of fruitful co-operation with academic teams
Practice new research on fields of interest	Development of human capital

4.2 Type of knowledge transferred / exchanged and IPR issues

The majority of the cases (52%) involved transfer of knowledge from academia to the companies. Still a significant percentage (34%) involved reciprocal knowledge exchange and a smaller one (14%) transfer of knowledge from companies to academia. In the cases where knowledge was transferred from academia to companies, this involved highly technical and scientific knowledge in various fields (i.e. atmospheric physics, image processing, 3d modeling, genetic analysis, photo-electro-chemistry) while in the cases where the company disseminated the knowledge towards the university, the knowledge transferred was market oriented knowledge and included i.e. market intelligence, production technology, costing techniques, marketing, branding and product management. The majority of the knowledge created in academia has been "produced" through the core activities of universities/ research centers such as research and teaching activities. In many cases, those activities were part of projects funded by EU or regional/national programmes and initiatives. However knowledge transferred from companies to universities was mainly acquired through market perception, product development and marketing.

Focusing on the recipients of knowledge, it is interesting to note that about 50% of the cases indicated the existence of previous related knowledge in the organisation, approximately 30% answered that there was limited previous knowledge and not sufficient for their operational needs, and 20% claimed that they didn't have any relevant knowledge prior to the KE practice.

Around 40% of the KE cases involved the transfer of intellectual property (IP) and in most cases an intellectual property agreement was in place. It has been noticed that in some practices that involved IP, there was no agreement signed and on the other hand, in cases where there was no issues of transferring intellectual property, an IP agreement was signed. This can be explained by the level of

confidence build between the two parties as well the general mentality and procedures of the organizations involved.

4.3 Benefits and risks of the knowledge transfer / exchange

The main benefits of the KE practices are differ significantly for academia and companies and can be divided in 4 categories: Financial, Knowledge, Image and Networking. The following tables describe the main benefits for the two types of organisations involved:

Table 4 Main benefits for academia

Financial	Knowledge/ know how
<ul style="list-style-type: none"> • Increased income • Easier access to research funds • Creation of extra professional opportunity to researchers • Financial support for travel / conferences / staff mobility 	<ul style="list-style-type: none"> • Testing and improving research results • Getting precious feedback from the market • Increase of theoretical and practical knowledge • Training material and workshops designed and implemented based on the results of a KE practice. • Re-usage of knowledge gained in other fields and areas • Involvement of students in the KE practice procedures • Gaining experience on how to bring purely scientific knowledge closer to the market
Image / prestige	Networking
<ul style="list-style-type: none"> • Academic publications • Publicity, fame and market appreciation • Recognition of the role of the university towards the society • Professional recognition for the university's labs and teams 	<ul style="list-style-type: none"> • Development of new contacts • Gain complementary knowledge regarding the market, entrepreneurship etc • The participation of an organisation in a project, often brings the participation of the same organisation in new projects

Table 5 Main benefits for companies

Financial	Knowledge/ know how
<ul style="list-style-type: none"> • Creation of new product/service • Gaining a competitive advantage • Expansion to new markets, which were not accessible without the implementation of the KE practice 	<ul style="list-style-type: none"> • Gain of know-how • Reuse of knowledge gained • Experience gained by the co-operation with high skilled scientists • Participation in R&D proposals
Image / prestige	Networking
<ul style="list-style-type: none"> • Improvement of corporate image and prestige • Publicity • Creating value that can be transformed into a business opportunity 	<ul style="list-style-type: none"> • New contacts • Enhancement of the relation with the University for further co-operation. • Networking for further participation in new projects

Knowledge exchange practises involves also risks that the participants were ready to point out. The major risk that both universities and companies have taken in consideration is the possibility of wasting time and effort with no tangible results. This risk is considered the most important inhibitor for sustaining knowledge exchanges between universities and companies. For that reason, most of the KE practices take place in the framework of EU and other funding programmes that provide for the reduction of the financial risk. Other risks that were common to both academics and companies include the risk of not reaching the desired results, the potential problems due to potential copyright infringements and the possibility of losing the goodwill between the parties. On the other hand academics pointed out the risk of potential disorientation towards entrepreneurial oriented activities while companies were afraid that failure to deliver might affect their image.

4.4 Key success and failure factors

Key success factors for a successful KE practice can be identified for the organisations and the people involved. At the level of organisations, the quality of the counterpart organisation plays a significant role. Flexibility, readiness to deal with bureaucratic procedures, clear setting of objectives and roles, having realistic expectations and identifying early the expected benefits for both sides are also important. Finally, existence of previous related know-how, frequent and smooth cooperation and respect towards agreed procedures are also considered as valuable assets in KE cooperation.

At the level of individuals, it is important to establish good communication at a personal level, to assign experienced staff and to make available open-minded, professionally skilled people. The most important success factor though is trust and this has to be build on a personal level.

Other key success factors include higher management commitment, the necessary time frame given to the KE practice, the careful selection of partners and the geographical proximity.

On the other hand, factors contributing to the KE failure are the state bureaucracy, involvement of third parties, unwillingness to cooperate, lack of time, last minute changes to KE practice objectives and the excessive focus on maximizing short term financial gains.

According to academic institutions, the most important barriers for cooperation are the high cost of the cooperation, the lack of trust between potential partners and the lack of appropriate partners for conducting a KE practice. Other barriers reported are the shortage of time, difficulties in communication, bureaucratic obstacles, the lack of devotion of partners to the KE, lack of geographical proximity with large companies and lack of cooperative mentality within their own organisation.

According to the companies the major barriers for the conduction of KE practices are the high cost involved and the lack of knowledge of market needs by the universities. The latter is explained as a possible reluctance on behalf of the academic community to get involved professionally with the private sector. Other barriers include the absence of a mechanism that will bring researchers and industry closer together, the knowledge gap (or complete ignorance) on the part of the private sector about the research activities and results produced by the universities within the region and the lack of incentives for universities to liaise with the industry.

5. Conclusions

Knowledge exchange between academic institutions and enterprises is a complex activity that involves high risk and is build upon trust. The survey confirms the existence of a variety of paths towards knowledge exchange that may or may not involve IP agreements and the importance of informal networks and good interpersonal relations. It also underlines the need for more focused policies that will take into account the large differences in the way knowledge is being exchanged based on country, sector and cultural specifics, minimize the inherent risk involved and focus on creating sustainable human networks.

The survey demonstrates that successful experiences tend to be repeated and become sustainable after a number of repetitions. The benefits as well as the direction of the knowledge transfer are often reciprocal, with the academic institutions benefiting from market knowledge and entrepreneurial approach of the companies, as much as the latter benefit from the new research results and knowledge stemming from the earlier. From the point of view of the participants to the KE exercise, it is important to proceed having recognised the risks involved and be clear about the expectations of both sides. It is also important, for anyone involved, to recognize from the beginning the fact that this is a long process that might not yield immediate tangible results but it is one that when pursued consistently brings benefits in the long run.

Based on the results of this survey, the key elements of a successful “university-based innovation ecosystem” as defined in [17] would be:

- Building of mixed teams that will allow for a continuous flow of ideas and knowledge between the researchers and the enterprises based on trust.
- Designing and implementing strategies and policies that will encourage exchange and minimize risks.
- Involve liaison/ intermediary mechanisms that will recognize the expected benefits, reduce bureaucracy and allow the involved parties to engage with flexibility.

- Taking advantage of EU and other funding mechanisms, viewing them not as short-term financial incentives for both sides but as tools to build sustainable relations that will yield major reciprocal benefits in the long term.
- Defining clear and flexible strategies on IPR exchange that will protect knowledge but also make it available for mutual benefit.

Planning and mainly spatial planning has relation about the spatial dimension of development. It concerns not only the architecture work, but mainly where people live and work, like the location of social and economic activity. Also, the way in which resources that we possess in limited supply, how much are exploited so as to achieve socio-economic objectives. The SDI-EDU project aims to transfer former experience from EU research projects dealing with education in Spatial Data Infrastructure (SDI) spatial planning as Humboldt and Naturnet Redime towards planners in European Regions and municipalities. The project will use innovating educational methods that can combine methods of distance learning vocational training, e-learning and knowledge sharing that will allow transferring the experience and teaching how to deal with SDI spatial planning for real users. The project will also transfer newest research results from Humboldt Project and it will transfer it into research courses. The SDI-EDU project aims to support training focused on spatial planers. The SDI will be extended in the frame of the implementation phase of the INSPIRE Directive (General framework for a SD) for the purposes of European Community environmental policies and policies or activities which may have an impact on the environment). It will run until 2019. For two years, SDI-EDU will support training of responsible people to set up and use some of these services according to the specific problems of the EU regions in local and regional level. Thus, the project will let the regions participate actively in the implementation of the INSPIRE Directive and enter into the modernity permanently. The acquisition of these best practices is irreversible and will create a new demand of new services. The SDI-EDU project aims to participate in the creation of interregional education portal which will be a crucial element of the implementation of European INSPIRE Directive. The European regions, provinces and municipalities will use the results of SDI-EDU to promote their cultural and socio-economic heritage and will find the SDI useful to the regular management joining their territories to the others from Europe with the ambition to exchange the knowledge between all the regional identities. In conclusion, the SDI-EDU project will be presented before explaining the different education and training tools with their roles. The last part analyses the added value of this project for target groups in the regional spatial planning.

Keywords

Urban planning, Spatial Data Infrastructure, INSPIRE directive, cooperation, education, training.

1. Introduction

The geographical information takes an important place in studies and projects in relation with the regional and urban planning. It represents 80% of the general information and they are inevitable for making studies of spatial planning. It is particularly demonstrated at the European level for the

INSPIRE directive application. This Directive aims to build a geospatial database having a relation with the environment themes in the 27 countries of the European Union.

The content of the INSPIRE Directive is complex and that explains the needs of facilitations to help clearly the planners. It is important to support planners and people in relation with the geographical data. They must understand how to apply correctly this directive for the planning projects.

The SDI-EDU is a Regional and Urban Planning project and it was accepted by European Commission within the Framework of the Leonardo Da Vinci – Multilateral Projects/ Transfer of Innovations Program.

The project aims to improve the quality of the European Vocational Education and Training system by adapting and integrating innovative content of results from previous Leonardo da Vinci or other innovative projects into public/or private vocational training systems and companies.

This project has been programmed for 24 months with a beginning on October 2009. It regroups 10 partners in 6 countries of the European Union. The University of West-Bohemia is the project coordinator.

This project permits the former transfer experience from E.U research projects dealing with the education in SDI and Spatial Planning towards planners in European Regions and municipalities. It will use innovative educational methods of distance vocational training, e-learning and knowledge sharing. They will be available by the public services and companies for the national frameworks.

The project objectives are presented successfully and firstly about the former transfer experience from European projects.

It presents the SDI-EDU project in a second part as an innovative project using educational technologies. Finally a last part presents knowledge transfer experience from SDI-EDU to the final users which have a role in the national spatial planning.

2. The SDI-EDU project aims to transfer former experience from EU research projects dealing with the education in Spatial Data Infrastructure (SDI) spatial planning

2.1 State-of-Art

A first step is to build a state-of-art in relation with the theme of Spatial Data Infrastructure, Regional Planning and INSPIRE Directive. It is an important phase before the building of the future SDI-SDU computer system. The SDI-EDU project is based on implanted methods from the Humboldt and Naturnet Redime Projects. This application demands cooperation with companies but not only.

This State-of-Art concerns the following aims:

- Cooperation with others projects at the construction level.
- Analysis of active examples on the territories for the application of methods and tools of SDI construction based on the INSPIRE Directive.
- Analysis of ready tools and data sources available to be used during the training for the SDI construction.
- Preparation of materials from previous experiences with tools and data to contribute at the SDI-EDU project.

2.2 Requirements guide of the training environment

It is necessary to have a Guide for the collection of user requirements. In fact, it is not possible to imagine what the requirements for each final user are. So, it is important to create a questionnaire diffused in different organisms having a relation with each project partner.

This questionnaire shows the principles themes of the possible training:

- Political consequences of INSPIRE on both local and regional level (in relation with the spatial planning)
- Inspire requirements on the local and regional level from the technological point of view
- The examples of solutions for SDI building
- INSPIRE, spatial data and spatial planning

- INSPIRE networking architecture
- Intellectual property rights and Spatial Data Infrastructures
- Monitoring Obligation
 - + Practical examples (*how to*)

This guide is available in multiple languages. It shows a respect towards each partner for a better comprehension and efficient results. The results are in the following scheme:

Table 1 Scheme about the results of the questionnaire in relation with the needs of training for the final users (120 respondents).

From this scheme 1, the spatial planners seem to be interested by the following themes:

- Political consequences of INSPIRE at the local and regional level (in relation with the spatial planning)
- Inspire requirements on local and regional level from the technological point of view
- INSPIRE and metadata
- The examples of solutions for SDI building

The state-of-art and guide is a first step for the final users in order to aim the objectives.

3. USE OF INNOVATIVE METHODS FOR TRAINING

3.1 Tools used for training sessions

The used tools for the training sessions are principally issued from computer technologies and they allow the former transfer knowledge. Uniform Resource Management (URM) and WIKI are two of them. The users have an access to the tools that they are a part of a Spatial Data Infrastructure. The

tools are a theme for the training system. The used material for the training is linked to the SDI and its name is Computer Assisted Educational Processes (CAEP).

3.2 Uniform Resource Management (URM)

The SDI-EDU project permits the capabilities transfer by a portal hosted based on services using the Web Semantic methods (<http://portal.sdi-edu.zcu.cz>). This portal uses the GIS, e-learning platform, CAD (computer aided design) and the virtual reality. All the necessary material for the training sessions is published on the project website.

3.3 Computer Assisted Educational Processes (CAEP)

The tools permit to help users for an education by innovating technologies like an e-learning platform. For example, the Biz-biz tool has been developed by one partner of the SDI-EDU project.

This tool is one open web browser based on tools for the e-conference, cooperation, the training and it supports presentation (slide shows), website browsing, pre-recorded video display, chat and online discussion with a web camera. The on-line video, website and presentation are dynamic with the explanations of the users. They are downloaded for a future training. The training contents have been created with the help of metadata and they are implanted in the metadata catalogue for a greater access to the information and data. The Biz-biz tool has been developed by the Mathematics and Computer Institute (IMCS) of Riga. It is available on this website: <http://bizbiz.ccss.cz>

4. REGIONAL AND URBAN PLANNING WITH HELP OF THE SPATIAL DATA INFRASTRUCTURE FOR THE FINAL USERS

4.1 Training completed from real users and specialists.

The training sessions are 17 lessons with common themes: the INSPIRE directive, spatial planning and Spatial Data Infrastructures:

- SDI – importance, awareness and its role in spatial planning
- INSPIRE directive and mechanisms for its application
- Transfer of the INSPIRE directive in the national law
- Application of the INSPIRE directive and innovation in the European project.
- Consequences of the INSPIRE directive in the national context
- Application of INSPIRE in the national environment
- Laws, rules, practises, methodological institutes and cooperation
- Metadata, catalogs for/in spatial planning
- Spatial data – Approach of the INSPIRE directive in spatial planning
- Use of software in spatial planning
- What is necessary to make with the spatial data; having a relation in spatial planning and have compliant with the INSPIRE directive?
- How can we find, appreciate, choose and use heterogenic spatial data and metadata?
- How to create a new spatial metadata in order to be compliant with the INSPIRE directive?
- How to manage and to improve the existing metadata in order to be compliant with the INSPIRE directive?
- How to create new spatial data in order to be compliant with the directive INSPIRE?
- What is seems harmonization of geodata?
- Important and special cases in countries

4.2 Cooperation with others projects

The SDI-EDU project is setting up by a cooperation with other research European projects that use geomatics technologies. This is the case for the HUMBOLODT and the PLAN4ALL projects.

4.2.1 PLAN4ALL project

The SDI-EDU project can re-use contents and materials from the PLAN4ALL project (source: <http://www.plan4all.eu/>).

The spatial data was used in this project and has been referenced in the themes of the Annex II and III of the INSPIRE directive. Aims of the PLAN4ALL project:

- Promotion of the Plan4all project and the INSPIRE directive in countries, regions and communities ;
- Creation of one profile metadata for the spatial data in relation with the spatial planning ;
- Creation of a standard of the data in relation with the spatial planning.
- Creation of one network architecture for the exchange and the centralization of spatial data and spatial services in spatial planning ;
- Certification of a metadata profile, data modelization and network architecture on local and regional level ;
- Installation of a European Portal for the spatial data in planning ;
- Data and metadata production in local and regional level.

These results can be inserted directly in the training sessions of the SDI-EDU project. They are in relation with the subjects of metadata; INSPIRE directive and use of spatial data in spatial planning.

4.2.2 HUMBOLDT project

The Humboldt project has like a mission the creation of a European SDI (ESDI) with an implantation of spatial data disposed by a lot of European organizations. It aims to improve the number of users of this ESDI.

(Sources: <http://www.esdi-humboldt.eu/home.html>). The main objective of this project is to contribute for an harmonization of the spatial data.

4.2.3 Nature Net Redime project

The main aim of the NaturNet-Redime project is to support a sustainable development of the knowledge in relation with the permanent evolution and to provide the training. They concern the social, economic and environmental capacities for the strategic application of the sustainable development in the European Union.

(Sources: <http://www.naturnet.org/>)

One of the axes for the realization of this project is concerning knowledge and training by the use of tools like the GIS and virtual image tools.

5. CONCLUSION

The SDI-EDU project concerns an innovating opportunity from previous research European projects. They are linked to the use of geospatial data and tools that permit a great use of them.

It illustrates a path of the future INSPIRE directive application in different European projects. The comprehension of setting up this directive for the spatial planning work is complex. It is a reason that explains why the SDI-EDU project aims to promote the indispensable tools to the users and to local organizations, so as to overcome the technical and theoretical difficulties.

The ten partners concentrate their knowledge and capabilities to provide to the final users the tools and materials. They permit them to gain more knowledge for a best understanding of the European directive. This is a crucial step for his application in all European scales.

By an external cooperation with different European research projects, this project has an important source of material about the new technologies of information and communication. It refers the development of innovative tools based on GIS, computer design and in virtual reality for a better comprehension from the final users of this directive.

In conclusion, it is important to refer the results of this project because they will be transmitted to the final user (that is in relation with the spatial planning affairs) in order to assure the correct application of the INSPIRE directive with a final aim of a better equality between the territories.

With the right idea to leadership of a regional cluster of suppliers

Aleksander Janeš¹

¹ Faculty of Management, University of Primorska, Koper, Slovenia,
aleksander.janes@fm-kp.si

Technological and green entrepreneurship are today's driving factors for many Small and Medium Enterprises (SME's). In our paper we present the Ydria Motors d.o.o. company case study which produces semi products for household appliances. The company is a part of ebmpapst international Group and focuses on new products due to environmental standards and logistic services. In the Slovenian regional area the company is important member and cofounder of supply cluster. Now cluster consists of 27 companies from different parts of Slovenia, which are divided into three groups: material suppliers, service providers and suppliers of tools and equipment. Most of the cluster members are smaller companies. Much attention is devoted to education and mutual knowledge.

Knowledge and development will provide needed supplier base cluster, which together with Ydria Motors Company will become an important factor in the supply chain, especially for the companies of household appliances in the EU and beyond.

Within our survey we stressed the influence of implemented management standards on the products, people and society. The survey question is: Which performance indicators (PI) should be measured to fully fulfill the strategy and what are their causal relations? Preliminary results are indicating the benefits and opportunities for improvements on the field.

Keywords

Causal relations, Granger test, management standard, stationarity, technological entrepreneurship

1. Introduction

Ydria Motors d.o.o. (YM) company produces small electrical motors and fans and is one of the leading players in the industry of motors for home appliances in Europe and in the world in terms of quality, quantity and flexibility.

The company was first located in the vicinity of the 500 years old town Idrija known as one of the largest mercury mine in the world and famous for the Idrija lace. It developed from the former plant of Iskra from Železniki, which later became Iskra Rotomatika, then Rotomatika, part of which finally became Ydria Motors. Due to problems with space, the company decided in 2002 to find a more suitable location and moved to Podskrajnik, the Municipality of Cerknica.

The company is wholly owned by the company ebm-papst from Landshut, Germany with a wide spread sales network all over the world. YM exports as much as 95% of its production and only 5% is sold on the Slovenian market. In 2006 it established a new international logistics centre which is in charge of accepting materials and dispatching equipment from the parent company in Landshut and Mulfingen and distributing products directly to end buyers. It is also a system supplier of electrical motors and fans for key large customers – producers of top-class home appliances e.g. AEG, Electrolux, Bosch-Siemens and Miele.

The company manufactures more than one thousand different end products, differing in terms of appearance and integration options (drying and washing machines, refrigerators, fan and microwave ovens, independent fans).

The company follows the principle of contributing to the social responsibility with care for people, society and environment in which it operates. Therefore, sponsorships and donations are an essential

part of YM operations. Above all, company support activities that are in any way connected with our employees and investments in the area where the employees come from. YM also support sustainable impacts on the environment and the society and the activities based on voluntary work. Thus the company fulfils part of its social responsibility, its values and care for the future [1]. The company, according to its development, is facing questions about its future organic growth. Thus, the company faced the challenge of setting PIs', which are the central theme of our research.

Analysis of researches, documents and records and processes KPI's values indicates the latter's significant influence on the company's strategy fulfilment. Analysis of many qualitative and quantitative researches about KPI implementation performed all over the world indicates the general favourable influence of KPI's on the strategy fulfilment of organizations [3], [4], [5], [6] [7], [8]. Namely, a recent trend in companies' performance valuation is the increasing emphasis on the intangible, qualitative and non-financial perspectives [19].

2. Literature review

Balanced Scorecard (BSC) or key performance indicators (KPI) origins date back to the time when the management of organizations generally rely on short-term perspective and taking into account historical data, which represented mainly financial indicators [2], [3].

Gradually, the need arises to take into account perspectives such as customer satisfaction, the internal process perspective and the perspective of learning and growth. In nineties of the last century, the consideration of various perspectives of business operations and associated financial and non-financial indicators has become an important topic of practitioners, experts and researchers.

On the basis of cause - effect relations between these four perspectives can be completed long-term strategic goals of the organization. This can be achieved by the degradation of vision and strategic objectives of the organization on a set of causally related performance indicators (PI), which represent financial perspective, customers and internal processes and learning and growth perspective. Suchlike set of indicators should be cascaded across all levels of management so as to promote understanding of the objectives of the organization from the perspective of managers and all employees [4], [3], [5], [6].

As a rule, are determined PIs' from past experience, and by regularly reviewing. Where appropriate, expands range of PI is confirmed, and some of them are also being phased out.

It is necessary to clarify why we measure, what and how often we measure, before we decide how to measure [17]. Managers should be first asked questions about what they want to achieve, what their objectives are and how they describe them. Therefore, we begin to set up the system of performance indicators by consensus of managers regarding the description of their goals in four aspects. This will facilitate the determination of measurement as well as changing the PI themselves and the sources of data [7], [8], [5].

Historically, the processes in the organizations were investigated mainly qualitative, verbal and linguistic. Previous research in the field of business processes have been predominantly performed with the data within a short time period.

Meanwhile, the longitudinal and dynamic researches for developing theories in this area are very rare. An example for updating the research methodology could be the theoretical physicists (e.g. Einstein), who think in the context of mathematical equations. Thus, the mathematical tools are appropriate to increase the exactness of the conceptual and empirical research. Completion of qualitative research business processes with statistical tools hold great potential in this area. Namely inclusion of the process approach and methodology of longitudinal treatment of business processes makes very important addition to the conceptual thinking of researchers [9], [10], [11].

Given the framework of the strategy map, which consists of four perspectives, and within them a large number of related strategic objectives, it is considered that business processes added value is increased by indirect and mixed in mutual relations. Added value in business processes is manifested in the form of chains of cause - effect relations from nonfinancial and quantifiable PI in the learning and growth perspective, all to the results in customers' perspective [12] and financial perspective [13].

Since we do not know exact lawfulness between the observed variables, or PI, which were taken into account, in addition to the available literature, researches and documents and records we especially took into consideration information's contained in the time series of observed variables (PI).

Already through the observation of linear regression between pairs of variables or PI we can presume causality, which is then confirmed by Granger causality test [14]. It should be noted that from the literature review so far we did not found any similar case study.

3. Methodology

Purpose of our research is to explore and clarify the cause - effect relations between PI. This will give us a basis for understanding these relations and understanding about the relations between business strategy and operations at all levels. In this quantitative research the influence of the measured process PIs' on the company's strategy fulfilment is discussed. As a research method was chosen case study [15] of the YM Company which is based on the following criteria:

- Environmental management system ISO 14001 certificate is received in 2000,
- Quality management system ISO 9001 certificate is received in 2003, and
- Family-friendly company certificate is received in 2010.

Documents and records were studied closely and included analysis of public available data from company's documents and records and web sites. Observations were performed during research which is still being continued in its preliminary phase. Data for the model testing, application and analyses were gathered in August and September 2010.

The main research question is: Which performance indicators should be measured to fully fulfil the strategy and what are their causal relations?

4. Empirical findings and discussion

Due to limited space, we present only some of the findings of calculating a linear relationship to the selected PIs'. To calculate the model parameters were collected PIs' of the company. All variables represent PIs' that are monitored by the company annual reports which are submitted to the company owner, ebmpapst Landshut. The PI used are: production volume of the three selected products, sales quantities of the three selected products, total production, total sales, number of production workers and the number of supervisory workers. Performance indicators used were ten in total.

We analyzed linear relationship between pairs of PI during the period from January 2004 to July 2010. The analysis was carried out in the manner that:

- the relations between the indicators are linear,
- we considered scatter diagrams and,
- linear regression was calculated between pairs of selected PI.

In general, the degree of linear relationship and the variance between the performance indicators is medium to high (e.g. from $EM25S = 0.8886 \times EM25 + 139087$ and $R^2 = 0.3141$ to $EM21S = 1.0136 \times EM21 + 1677.3$ and $R^2 = 0.9527$), as a result of numerous factors.

One of the most important is the quality and consistency of the data used since the time series are based on monthly data. In addition, production has been subject to instability, such as the impact of the global crisis in the period from 2007 to 2009, from which the company bear the consequences even today. All these factors affect the quality of the identified linear relationship between PI. For this purpose, we continued analysis of the empirical testing of the causal relations between PI.

4.1 Stationary test

We first performed a stationarity test (see Table 1). Stationarity means that the time series has its mean and variance constant during the observation period and the value of covariance between two time periods depends only on the lag between the two periods [16]. Stationarity was tested to confirm that there is no spurious regression between the PI.

Table 1 Stationarity test.

PI	T1	T2	T3
EM21	0.223554	-3.499143	-2.504887*
EM25	1.062103	-2.387780*	-0.702753*
EM30	-1.423983*	-1.987317*	-2.313793*
EM21S	0.342541	-3.100907*	-1.696859*
EM25S	0.766911	-2.768304*	-2.751491*
EM30S	0.561337	-2.356120*	-1.251995*
TOTALPP	0.736998	-1.905930*	-1.426430*
TOTALSP	0.810399	-1.650425*	-1.595853*
PRODW	0.418330	-2.019898*	-1.548013*
SUPRVW	1.078856	-1.701756*	-2.274803*

Note: values marked with an asterisk * means stationary time series; T1 stationarity test - None, T2 stationarity test - Trend and Intercept; T3 stationarity test - Intercept. Selected critical value of t statistics is at 10% level.

EM21, EM25 and EM30 are numbers of produced pieces; EM21S, EM25S and EM30S are numbers of sold pieces; TOTALPP is total number of produces pieces; TOTSLSP in total number of sold pieces; PRODW is number of production workers; SUPRVW is number of supervisory workers.

Based on the stationarity test (see Table 1) we formed twelve causal relations. These relations were defined on the basis of the relations between business processes: e.g. (1) Production of product EM21 may be related to quantity of sales of this product EM21S, (4) Production of product EM21 may be related to the total products quantity produced TOTALPP, (6) the quantity of product EM21S sold may be related to the total quantity of products TOTALSP sold, (9) the number of production workers PRODW may be related with the total quantity of produced products TOTALPP, etc (for more see Table 2).

4.1 Causal relations between performance indicators

Selected relations were tested with Granger causality test in the statistical software Eviews 7.1. Each test was performed by taking into account the different periods between successive values of PIs'. Thus, we considered the period from 1 month in the first test to one additional month for the next test, all the way to 24th months in the last test (i.e. 1 month, 2 months, 3 months, etc., up to 24 or 25 months). In Table 2 are the causality test results for the period between the selected indicators, which include 1, 2, 4, 6, 10, 11 and 12 months.

Our results show that between the production of EM30 and sale of EM30S there is a statistically significant causal relationship where EM30 is the cause and EM30S the effect. Under certain conditions, as a statistically significant are causal relations between the rest of the PI: e.g. TOTALPP and EM21, EM25 and TOTALPP, TOTALSP and EM25S, etc. Very interesting is also a causal relation between the number of production workers PRODW and the total quantity of manufactured products TOTALPP, and the total quantity of products sold TOTALSP and the number of supervisory workers SUPRVW. Other examples of where it was possible to identify statistically significant causal consequent relations can be seen in Table 2.

Table 2 Causal relations.

	Causality / lags	1	2	4	6	10	11	12
1	EM21S → EM21	0.7847	0.8635	0.8237	0.6640	0.7281	0.6404	0.6343

6	EM21S → TOTALSP	0.4949	0.6679	0.8037	0.8399	0.8219	0.6301	0.4070
7	TOTALSP → EM25S	0.0002*	0.0046*	0.0112*	0.0133*	0.0071*	0.0055*	0.1223
7	EM25S → TOTALSP	0.0029*	0.0235*	0.3211	0.1124	0.0823*	0.0685*	0.2924
8	TOTALSP → TOTALPP	0.5284	0.2765	0.2664	0.7528	0.2953	0.0666*	0.2908
8	TOTALPP → TOTALSP	0.8138	0.2709	0.0276*	0.1056	0.0605*	0.0153*	0.4670
9	TOTALPP → PRODW	0.2030	0.1904	0.1334	0.1344	0.0239*	0.0438*	0.0404*
9	PRODW → TOTALPP	2.E-06*	8.E-07*	7.E-05*	3.E-05*	0.0012*	0.0077*	0.0607*
10	TOTALSP → PRODW	0.2739	0.2689	0.1925	0.1927	0.0582*	0.0322*	0.0589*
10	PRODW → TOTALSP	2.E-07*	3.E-06*	8.E-05*	5.E-05*	0.0020*	0.0056*	0.0733*
11	TOTALPP → SUPRVW	0.2533	0.2529	0.1568	0.1011	0.1162	0.0634*	0.0180*
11	SUPRVW → TOTALPP	0.0023*	0.0418*	0.4030	0.6281	0.2116	0.3334	0.2674
12	TOTALSP → SUPRVW	0.3461	0.1151	0.1909	0.1053	0.0878*	0.0627*	0.0164*
12	SUPRVW → TOTALSP	0.0002*	0.0189*	0.3836	0.5569	0.5843	0.7191	0.2662

Note: values marked with an asterisk * means a causal relation between PI provided by the Granger test. The necessary conditions for causality, is that the cause happens before the effect and contains unique information about the latter [18].

In the case of production of EM21 and EM25 products, it was not possible to identify causality with their respective quantities sold EM25S and EM21S. This fact can be seen as recognition by the Granger test that it is the same entity, i.e. produced quantity of product EM21 and quantity of sold product EM21S and in the same manner EM25 and EM25S. Which opens up further research sub-questions in the context of causality and what relations we should add into the consideration in the further analysis? Based on preliminary results we will further develop our case study research methodology with its qualitative dimension.

5. Conclusions

From this preliminary test of causation, we come to important conclusions. The first is that the PIs' are systematically monitored and that the resulting data are consistent and suitable for further study. The second observation relates to the period from 2004 to 2010 which covers the information about causality contained in the time series in the long term and is crucial for determination of causality [14]. In addition, in the data is captured the impact of global crisis on the company. The third finding relates to the fact that the company has opportunities for improvement in the field of relations between the PIs. Which consequently enables support to the company's management in taking a leading role in cluster of supply companies. A recent trend in companies' performance valuation is the increasing emphasis on the intangible, qualitative and non-financial perspectives [19]. As we can conclude from analysis of many qualitative and quantitative researches about KPI implementation performed all over the world, which indicates the general favourable influence of KPI's on the strategy fulfilment of organizations [3], [4], [5], [6] [7], [8].

The National Policy Mixes of the Republic of Macedonia toward European Research Area

Saso Josimovski¹, Kalina Trenevaska Blagoeva², Mijalce Santa³

¹²³*Faculty of Economics, Ss. Cyril and Methodius University, Skopje, Macedonia, sasojos@eccf.ukim.edu.mk*

The competitiveness of small countries economies mainly comes from their ability to develop and internationalise their R&D and innovative systems and to create knowledge that can be transferred in successful products. The national policy mixes have the crucial role in achieving these objectives.

Research, education and innovation are three central and strongly interdependent drivers of the knowledge-based society. In the last few years, the need to better coordinate activities within the knowledge triangle (education – research – innovation) both at national and at international level has been spelled out repeatedly in several policy documents in the Republic of Macedonia, but the implementation has remained slow. A wide range of initiatives are taking place within individual parts of this triangle without systematic consideration of interactions between the three parts, which leads to non consistent policies. To make the triangle fully functional a smooth flow of information and knowledge has to be guaranteed thus leading to complementary activities and policies.

The main objective of the paper is to present and to assess the national policy mixes of the Republic of Macedonia in the perspective of the Lisbon goals and the Europe 2020 strategy. The assessment will focus on the national R&D and innovation targets, the national policies and investments into R&D and the articulation between research, education and innovation. The methodology that will be used is primary based on the framework recommended by EC, and is adopted by all countries monitored through the ERAWATCH initiative in order to ensure the comparability between countries.

Policy Mix, R&D, Innovation, European Research Area, Republic of Macedonia

1. Introduction

The importance of determining optimal policies towards R&D and innovation is immense, given the worldwide interest in their fostering [1]. The importance of R&D and innovation as main factors of sustainable growth in highly industrialised economies is undisputable, especially on the background of the structural shift from resource-based economies to modern knowledge-based economies [2]. Advanced economies see innovations that fuel IT and “New Economy” as a major goal to partake in the processes associated with the current wave of innovations, and therefore their interest in R&D policy is immediate and pragmatic [3].

EU Member States are aware that enhancing their economic performance and responding to societal needs will require R&D policy to be placed in a broader context and to be developed in coherence with other policy fields. The most apparent approach is the link with the innovation policy, but other policy domains are also taken into consideration by national policy makers, such as industrial policy, education policy or fiscal policy [4].

Since the Republic of Macedonia became a candidate country in 2005, European Research Area (ERA) and ERA-related policies have been integrated into the main national research programmes. In order to support the integration of the Western Balkan countries, a consortium representing organisations from 14 European countries including all Western Balkan countries was formed in 2004 and launched the Southeast European ERA-NET (SEE-ERA.NET). The importance of the R&D policies for Macedonia should not be neglected, especially when the outcome of the R&D can improve

the competitiveness of the country. However, R&D policies are, by their very nature, medium to long term, implying that a proper assessment can be made only over such an extended time horizon. Therefore, it is important to assess whether appropriate policies are supported towards reaching those objectives (even if, of course, to assess their effectiveness more time is needed).

The objective of this paper is to present a summary of relevant information on R&D policies in Macedonia and in second part to make evaluation of the R&D policies through the lenses of strategic ERA objectives.

Furthermore, in this paper the strengths and weaknesses of the Macedonian research and innovation systems will be evaluated from different perspectives: the integration of Macedonian researchers into European labour market of researchers; participation of Macedonian researchers in the European research infrastructures; strengthening the research organisations; identification and supporting of the Macedonian national R&D and innovation challenges.

2. Main features of Macedonian R&D and innovation system

The Republic of Macedonia was granted a candidate country status for EU membership in 2005 (total population of the country is 0.41% of EU population and 0.6% of the EU total surface area). Those shares do not correspond to the overall level of economic development having in mind that in 2008, Macedonian GDP represented only 0.054% of EU GDP, the GDP per capita was only 13% of the EU-27 average. Country's total spending in R&D or GERD was €15.08m (only 0.006% of EU 27 GERD or as a percentage of GDP, GERD was 0.225% which was significantly lower than the EU 27 average of 1.85%)[5,6]. The Republic of Macedonia for example lags significantly behind not only to Slovenia (1.45%), Czech Republic (1.54%), Estonia (1.14%) and Hungary (0.97%) as recently accepted members, but also when compared to candidate countries, Croatia (0.81%) and Turkey (0.72%). [5,6]. One can distinguish three levels of the R&D and innovation system of the Republic of Macedonia: policy, operational and performing. The main ministries involved in R&D and innovation policies, the Ministry of Education and Science (MES) and the Ministry of Economy (ME) are responsible for the operational level. The main work for developing and administering Macedonia's science and innovation system is performed in the MES to the phase of the prototyping of the products and services. This is fully focused on both research policy and all levels of education. Other ministries with a focus on their specific sector-oriented responsibilities are also active in the field of research and innovation policies such as the Ministry of Information Society, the Ministry of Agriculture, Forestry and Water Management, the Ministry of Health, the Ministry of Environmental Protection and the Department for European Integration.

On the real performance level main subjects are faculties and public research institutes, as units of the five state universities, with the biggest university, "Ss. Cyril and Methodius" in Skopje, comprising 56% of the total research and teaching personnel in the country or 71% of the total research and teaching personnel in the state university sector for 2008 [6]. According to the methodology for providing R&D figures, public research institutes are considered as part of the government sector. The Macedonian Academy of Science and Arts (MASA) is the second biggest player in the sector considered as a part of the government sector. Consequently, the government sector is the largest R&D performer in the country with 40% of the total GERD, while the higher education (HE) sector is the second largest R&D performer with 31.1% of total R&D expenditures (in 2008) [6]. The private universities that employ 20% of the total research and teaching personnel are small research performers with marginal participation in the R&D activities as they mainly perform educational activities.

Important R&D performers are R&D units in the industry sector and the different forms of science-industry cooperation like technology parks, business start up centres and incubators, as they perform 28.9% of the total R&D and participate with 37.4% in total R&D funds [6]. The main actors in the business sector are big companies. Intramural business expenditures represent 77% of the total funds provided by the business sector [6]. We should stress out that the growth of business expenditures is the main positive structural change in the national R&D system. For example, in 2003 the Republic experienced the lowest level of business expenditures as a percentage of GDP, only 0.003% [6]. The main reasons for the lack of business sector R&D finances were the prolonged privatisation processes and the economic problems that the country has been facing since its independence in 1991. However, from 2003, intramural business expenditures have been increasing, achieving 0.065% of GDP in 2008, whereas the total business expenditures rose to 0.084% [6]. Still, undoubtedly significant increase of business R&D expenditures was not accompanied with a permanent increase of GERD. Quite the opposite, the absolute minimum for GERD was achieved in 2007 (0.175% of GDP)

[6]. In 2008, GERD was increased to 0.225% of GDP, because of increase in both private and public funds [6]. For 2009, it is known that the economic crisis significantly decreased public funding (GBOARD was €4.26m when compared to €6.92m in 2008) [7]. The conclusion is that in Macedonian relative R&D expenditures are much lower than the EU 27 averages in total R&D expenditure (1.85% of GDP) and business R&D expenditures (1.21% of GDP) [5,6]. Therefore, the Republic of Macedonia urgently strives for major increase of both public and private investments in R&D in order to narrow the gap between the country and EU 27.

3. Recent R&D policy changes in the Republic of Macedonia

The legal framework for scientific research and technological development in the Republic of Macedonia is made of five laws: Law on Scientific and Research Activities, Law on Encouragement and Support of Technological Development, Law on the Macedonian Academy of Sciences and Arts, Law on Higher Education and Law on Industrial Property. The country still doesn't have a separate national R&D and innovation law. Therefore, the main policy development directions for the R&D sector are part of the general programmes of the Government of the Republic of Macedonia and in the policy documents for HE. In the Programmes, the government has defined a long term strategy for promotion of knowledge, in order to stimulate young people to get to a HE diploma. In these programmes, the government promotes science as an important factor for economic development. It needs to be noted that the economic decline because of the crisis has influenced the implementation dynamics of some R&D policies. On the other hand, the Ministry for Education and Science has been engaged in a more proactive approach toward science, R&D and education through new measures, like equipping laboratories for scientific research.

Recent policy changes with the highest impact expected are the changes in the Law on Higher Education adopted in August 2010, and the programmes that directly target the goals, measures and priorities of the Industrial policy of the Republic of Macedonia for the period 2009-2020. By the new rules on HE, the public universities must allocate 40% from students' tuition fee to R&D activities. It is unpredictable to estimate the direct financial effects these measures will have on the R&D budget, but it is obvious that with €47.4m in 2010, the self-financing budget segment available for the HE sector is higher than public GUF as self-financing represents 55% from the total budget for the HE sector [8]. Regarding the involvement of the business sector in R&D the MES increased the government participation for R&D projects proposed by the business community through programme for technological development (from 30% to 50%).

In 2010 the Decree on Norms and Standards for Establishing Higher Education Institutions and Performing Higher Education Activities was adopted that defines the criteria required for recognition of a HE institution and the performance of scientific research. One of the mandatory requirements is the involvement in the educational process of professionals with experience from the business community. The Industrial policy for the Republic of Macedonia 2009-2020 involves programmes oriented towards support of R&D and innovation in different industrial sectors. The programmes of the industrial policy 2009-2020 that have direct impact are those for support of the textile industry, development of Clusters' Associations, development of entrepreneurship, competitiveness and innovation of SMEs. For successful implementation of specific programmes, the Government will have to double the annual budget costs for competitiveness of the industry, by increasing the designated budget from 0.43% of the national budget in 2008 to 0.85% in the years to come [9].

In the last two decades, it was hard to recognise a specific fiscal policy that supported the R&D sector in the country. Fiscal policy instrument that indirectly supports R&D investments is a zero corporate tax on all profits that are re-invested into company development. This policy does not differentiate between R&D and other investments, but it encourages all profit-oriented companies, including private universities, to reinvest the profit for their development. A clear step is made towards direct fiscal policies by exempting VAT for purchases made with funds from EU projects.

In this direction as a part of the Programme of the Government of the Republic of Macedonia 2008-2012, the government developed a "Higher Education for All" policy with the long term strategy goal to have 25% of the population with HE. To achieve this goal and enable a larger group of students to enrol at universities, in 2008 the government opened a new university in Shtip and dispersed studies of faculties located in other cities with low tuition fee. Furthermore, in 2009 the government opened the University for Information Science and Technology in Ohrid with the intent of becoming the leading ICT university in the region. Although not clearly covered with a specific measure, the government has stated that it will stimulate the return of Macedonian professors from abroad to teach in their home country.

Another set of measures refers to providing scholarships and other funds for students. The complete costs are covered for students that will enrol into PhD or master studies at one of the top 100 world universities or top 20 European universities from the Shanghai Jiao Tong University ranking. In a similar competitive selection process the MES is awarding scholarships for under-graduate, post-graduate and doctoral studies at local universities.

To get more researchers exchange Republic of Macedonia is part of the Euraxess Jobs Portal (formerly known as Mobility Portal) and Euraxess Service Euraxess Service Network (formerly known as the ERA-MORE network). The participation of Macedonian researchers in EU programmes is strongly encouraged and is considered as one of the most important potential for human resource development. Research mobility is mainly achieved through bilateral agreements between universities and through EU programmes, such as Erasmus Mundus, Marie Curie, CEEPUS, NUFFIC, DAAD, etc. Furthermore, the signed Memorandum for Cooperation between the main universities and chambers is expected to strengthen their cooperation on R&D projects. Furthermore, in 2010 the government made a decision for a compulsory 30 days internship in a company or government institution for all students, which is in line with the objectives of the National Strategy for the Development of Education in the Republic 2005 – 2015. We don't think that this plan is feasible having in mind the scope of economic activity in the country and the capacity of firms that are prepared to accept internships.

A few policy developments were initiated by the State Office for Industrial Property in 2009 which improve the protection of intellectual property and promote innovation markets and regulations. A new Law on Industrial Property entered into force in 2009. The new solutions in this law refer to further harmonisation of legislation with international agreements of the World Intellectual Property Organization (WIPO), particularly the Patent Law Treaty and the Trademark Law Treaty. Hence, the procedure for implementation of industrial property protection is simplified and benefits are introduced for the users. At the end of 2009 the Parliament of the Republic of Macedonia passed the Law on Ratification of the Patent Law Agreement, adopted by the World Intellectual Property Organization. The aim of the agreement is to harmonise, simplify and improve the formal procedure of submission of national and international patent applications. In 2009, the Government of the Republic of Macedonia passed the Strategy for Intellectual Property of the Republic of Macedonia 2009-2012 and Action Plan of the activities for operational implementation of the Strategy.

According to the new Law on Public Procurement, 70% of the public procurements have to be done electronically or through e-auctions in 2011 which will additionally encourage the public and private entities to implement the electronic public procurement system.

Starting from 2005, ERA and ERA-related policies have been integrated into the main national research and innovation policies and programmes. Some of the EU targets and priorities are set as national goals, and some are adopted according to the capacity of the national research and innovation system. What is common for all national targets is that their realization relies on cooperation and openness of the national research programmes in the ERA framework. The dedication of the country towards ERA is also manifested through delegated country representatives in European Strategy Forum on Research Infrastructures (ESFRI) and the following European research bodies: European Research Area Committee, the European Strategy Forum on Research Infrastructures and the Steering Group on Human Resources and Mobility.

4. The instruments and targets of the national policy mix

From 2008, the Government has communicated a high degree of commitment for strengthening R&D and innovation.

The main directions of the current research policy were introduced with the Programme of the Government of the Republic 2006-2010. The focus is on improving the scientific-research infrastructure, support through fiscal policies, and promotes the internationalisation, knowledge transfer and cooperation with foreign scientific-research institutions. More focused research policy goals are specified with the Law on Scientific and Research Activities and with the Law on Encouragement and Support of Technological Development, both adopted in 2008.

The oldest measure for encouragement of private R&D investments, by co-financing R&D and innovation projects in the business up to 50% of the total value of the project, is strengthened by new measures and instruments based on the Industrial Policy for the period 2009-2020, Programme for Developing Entrepreneurship, Competitiveness and Innovation in SMEs and changes in the Law for Higher Education.

The main instruments of the policy mix, along with their specific goals are the following:

- Co-financing R&D and innovation projects up to 50% of their value stimulates greater R&D investments in R&D performing companies;
- The policy developments in the protection of intellectual properties, along with financial support for patent applications and support by several fiscal measures are expected to have impact on innovation;
- Co-financing of business incubators and clusters and business centres, through the programme of the ME promotes the establishment of new indigenous R&D performing firms;
- Innovation Voucher counselling scheme stimulates firms that do not perform R&D yet;
- Financing international projects attracts R&D performing companies (and universities) from abroad. The establishment of Technological–Industrial Development Zones can attract foreign companies to invest in the country;
- The mandatory involvement of industry professionals in the universities' educational and R&D activities, along with government support for university start-up centres and centres for transfer of technologies are supporting extramural R&D by the business sector in close cooperation with the public sector;
- Institutional funding of scientific public research institutes through block grants and for specific projects, and equipping laboratories for scientific research and applicative activities, increases R&D performance in the public sector.

The objectives in all policy documents and programmes for development of the national R&D system in the period 2002-2010 are focused on increasing R&D investments, adoption of EU goals, and integration of the national R&D system into the European research system. National R&D targets for GERD and BERD (Business expenditure on R&D) were set for the first time in the Programme for Development of Scientific and Research Activities for the period 2006-2010 at 1% of GDP for GERD and 0.36% of GDP for BERD until the end of the period [6]. Still, in 2008, the government proposed a more ambitious national R&D target to increase the R&D funds for 35% per year, which in essence was a target in accordance with well known EU goal of 3% of GDP for R&D. The GERD as a percentage of GDP was increased from 0.175% in 2007 to 0.225% in 2008 [6]. For 2009 there is no official data for this target, but due to the global economic turmoil it is difficult to expect that. In reality, the country is still far away from both targets.

There are numerous barriers that jeopardise the achievement of R&D investment goals. According to the official statistics, only several companies have considerable investments in R&D. Specialised research and technology organisations and agencies with the capacity to enhance the number of innovative business entities, including SMEs are still lacking. Only one company comprises 88% of the reported intramural business R&D expenditures in 2008. Unfortunately, the general impression is that there is low awareness among companies that investments in R&D could be the main driver for improving their competitiveness. Out of 1367 researchers in the country in 2008, only 15 researchers were employed in the business sector and the companies lack employed researchers on a permanent contract [6]. Having in mind that business sector performs 29% of the total R&D in the country, it is obvious that either the quality of statistical data is not very good or additional in depth analysis is required to clarify this issue. Another inconsistency with official business sector R&D data for 2008 is the zero reported funds by business sector from government and from abroad. The business sector received some funds from projects financed by EU, but they are really small compared to the funds received by HE and governmental sector. In EU 27 the biggest share of the funds from abroad are used by the business sector (75% in 2006) [5]. The conclusion is that the Macedonian companies are not competitive enough for international funds, which is another big barrier for fulfilling the R&D investment targets. The links between HE and the business sector are weak. The main reason is lack of finances for R&D and innovation programmes, not only because the GERD as a percentage of GDP is very low, but also because the country has a very low level of GDP per capita. Furthermore, the direct fiscal incentives are missing while the direct foreign investments are very low.

The research infrastructure in the Republic is in an indigent state. Research laboratories are primarily located in MASA and at the public universities and institutes. In the business sector small number of businesses has established research laboratories. This is a result of modest investments in research infrastructure in the past two decades. Even more, most of these investments were result of international projects initially financed through various donor programmes.

Internationalisation of company activities is a key factor for the success of any small economy. According to a survey conducted in 2008 [9], the main market for Macedonian companies is the domestic market (55.2%), followed by neighboring countries (2.2%), EU countries (17.3%) and rest of the world (5.2%). As expected, it is not surprising that only 11.3% of SMEs have introduced new products or processes either in-house or in combination with other firms [10].

The structure of the economy relating to export is not favourable, since Macedonia's share of high tech exports for 2008 was 4.7% of EU average [9]. Foreign Direct Investments (FDIs) as very important driver for the internationalisation of the R&D and innovation system of the small countries, like Macedonia are not even close to satisfactory. Since the country's independence in 1991, the FDI inflow per year has created only a small portion of the Macedonian GDP. FDI inflow has been mainly realised through acquiring existing companies that were positioned as a monopoly on the domestic market. Under these circumstances, the foreign investors have not expressed more than a nominal interest in making additional R&D, innovation and technology transfer investments [11].

5. Assessment of different policies within the knowledge triangle

The general characteristic of the Macedonian research system is its underfunding by both private and public sectors. As a consequence, low quality of the produced knowledge, the presence of brain drain and low demand for knowledge from the private sector, are the biggest challenges for the policy makers. Additionally, according to the SSORM, in 2008 the business sector reported zero funding from the government and from abroad. Although it is obvious that current data is inconsistent with previous reports, both statistics confirm the passive role of the business community within the national R&D and innovation system.

In the period 2008-2010 the Government had set very ambitious R&D goals, but these goals have not been supported by appropriate measures. In other words, due to the unfavourable situation of the R&D system, instead of individual, isolated measures, a set of coordinated measures is needed in order to achieve the objectives. The financial support is lacking. This is obvious with policies that affect all knowledge domains: demand, production and circulation of knowledge. In 2010 some very ambitious measures were promoted like new quality criteria in the HE sector and dedication to stop brain drain process. Unfortunately, they are not supported with clear financial measures. Also, new research laboratories valued 10 times higher than the Government Budget Appropriation for R&D (GBOARD) for 2009 are promoted. However, until these measures are realised, no real effects in national R&D and innovation system could be discussed.

The Macedonian economy is a small open economy where exports and imports account for a considerable part of GDP. In 2010, employment in high-tech manufacturing sectors and knowledge-intensive services as percentages of total workforce were 4% and 4.7% respectively [10]. Similarly, the exports of medium and high-technology products as a share of total exports were only 0.98 in 2008 [10].

In the last decade the number of researchers and R&D employees in the Republic has fallen for 30% on average, with very sharp decrease of 70% in the business sector [6]. The number of researchers (FTE) per 1000 population in the Republic of Macedonia was 0.37 in 2008, whereas the EU 27 average for 2007 was 3.01 [5,6]. From the presented statistics it can be concluded that the overall decrease in the number of researchers for the period between 2000 and 2008 is a trend that has already existed before the latest crisis, primarily because of the under-funded R&D sector.

Since two thirds of researchers are employed in HE and HE in the country is the main supplier of potential researchers, the policies that refer to HE have the biggest influence on the balance of demand and supply. The supply of potential researchers is relatively low when compared to EU 27 averages, with new doctorate graduate per 1000 population aged 25-34 set at 0.4 for the country and 1.6 for EU 27 [5,6]. Furthermore, there is no inflow of researchers from abroad. Conversely, the demand for potential researchers with a PhD in the HE sector has increased, due to the many new HE institutions opened by the Government and the private sector.

Low salaries for researchers, along with the low availability of cutting-age research infrastructures, make the domestic research market unattractive for foreign researchers. On the contrary, foreign research markets are very attractive for domestic researchers because of the working conditions and higher salaries. As an outcome, since its independence the country has experienced brain drain. The government has tried to prevent brain drain and repatriate researchers that leave the country through political measures. However, the main reasons for brain drain still exist.

The quality of the knowledge produced by the HE sector in the country is not on an acceptable level. Not a single Macedonian university is ranked in the first 1000 positions on the world ranking lists with good reputation. Also the mobility of students and professors is very limited, due to the fact that there is almost no possibility to study/teach on English.

According to the National Science Foundation statistics, the total Macedonian scientific and engineering article output growth in the period 1995-2007 is very modest and the maximum of the

country's article output was achieved in 2001, when it was 68. (The output is measured as contained in the journals tracked by the Science Citation Index (SCI) and Social Sciences Citation Index (SSCI) [7]. In the period between 2007 and 2010 Macedonian organisations have shown the biggest interest for the FP7 inter-governmental scheme. They have participated in 271 eligible proposals, with 45 proposals retained for funding with a total amount of €7.47m [7]. With a success rate of 17%, the country has achieved the average rate of South Eastern European countries, which is lower than the EU 27 average success rate of 21% [7].

The Republic of Macedonia has been a member of EUREKA since 2008. In this period the Republic has been involved in seven projects in the fields of Industrial Manufacturing and Materials and Bio Sciences and Technologies. According to the total national value of the projects of €0.98m and number of participants until October 2010 [7], the performance of the Republic of Macedonia in this programme is worse than those of Serbia and Croatia [7].

The bilateral international cooperation is one of the main instruments for international cooperation as evident from the signed agreements for cooperation in the area of education, science and technological development. In the period from 2006 to 2010, the MES realised a total of 99 scientific research projects, and gave 42 scholarships based bilateral agreements with ERA countries [7]. From a total of 99 projects, 67 projects are with EU countries with total value of €0.676m and 32 projects with non-EU countries with total value of €0.351m [7].

The main changes and issues in the research policies are increased governmental participation from 30% to 50% for R&D projects proposed by business community through a Programme for technological development; mandatory spending of HE on R&D from their self-financing budget; and decreased GBOARD in 2009 for 38% when compared to 2008 [8].

The strength of these recent changes is that the business entities now have more stimuli to perform R&D activities. This can subsequently increase the business share in the total R&D funding of the country. Also the HE – industry linkages are encouraged, which are very weak at the moment. The absence of separate research policy, along with a lack of quality R&D data, could create a situation where the policies are not based on well elaborated analysis. Furthermore the small R&D funds in absolute terms (very low GERD as percentage of GDP, along with a very low GDP) are still a strong weakness of R&D in Macedonia.

The biggest number of policy changes is made in HE. The strengths from this can be twofold. First, providing researchers with diploma from foreign prestigious universities, and second the quantity and quality of tertiary and doctoral graduates could be increased. Still, the following weaknesses should be taken in account. Changes in quality criteria can cause decrease on some quantitative figures, which are anyway much lower than EU 27 averages (number of tertiary and doctoral graduates). Regarding the human resources aspects the frequent legislative changes can cause uncertainty among researchers and universities regarding long term human resource policies. The increased number of HE institutions in a very short period could have a negative influence on the quality of the education process. Also, without clear and significant financial incentives for foreign professors and researchers, the very low average salary in the country is a barrier for spreading out the inflow of foreign researchers and professors and probable return home to our scientist now working abroad.

The developments in the policies for Intellectual Property and Public Procurement contribute towards promotion of innovative markets; harmonisation of national legislation with European legislation; and simplification of the procedure for submission of national and international patent application.

The recent policy changes address the following ERA objectives:

- Ensure an adequate supply of human resources for research and an open, attractive and competitive single European labour market for male and female researchers
- Increase public support for research
- Increase European coordination and integration of research funding
- Strengthen research institutions, including notably universities
- Promote structural change and specialisation towards a more knowledge - intensive economy

6. Conclusion

The presented analysis and assessment of the Macedonian knowledge triangle effectiveness is based on related laws, policies and measures as well as on available statistical data and published studies along with our own estimations. The general conclusion is that the Macedonian research and innovation system is still very weak, reflecting in reality the state of the national economy. Fast improvement of the current level is not possible, but with appropriate measures and active policy measures positive changes can be recorded on mid term.

According to the recently adopted main governmental policy documents, R&D, innovation and HE have the highest priority and are regarded as the main drivers for the development of the national economy. However, the main weakness of the adopted policies is the insufficient financial support from the public budget, weak and inactive private sector, unfavourable structure of the national economy and the export and low level of FDI.

The Macedonian research system is underfunded by both private and public sectors and GERD as a percentage of GDP was 0.225%, in 2008, which is one of the lowest figures in Europe [5]. Low demand for knowledge from the private sector, low quality of produced knowledge and the presence of brain drain are challenges for the policy makers in the country. Additionally, the number of researchers is extremely small, particularly in the business sector.

The main R&D performers in the business sector are large companies, while SMEs participation is not significant. The biggest share of these expenditures was directed towards the manufacture of chemicals products and was spent by one company. Firms do not innovate, especially small ones. As expected, the country has not experienced an inflow of new technologies, innovations, new knowledge and increased export through FDIs.

Most of the EU and ERA targets and priorities have either been set as national goals or adopted in accordance with the capacities of the national research and innovation system. Macedonian organizations have been active in FP7, EUREKA, COST and ERA-NETs programmes more than to bilateral projects induced by the government.

There are several opportunities, but also risks that the targets will not be met. The technological obsolescence of the companies creates a potential risk to slowdown the process. New universities, new PhD programmes in accordance with Bologna and financing students are opportunities that could increase the number of quality researchers. However, fast pace and quantity of the produced highly educated workers is not guaranteeing their quality. The mandatory involvement of business placements of students probably is not feasible in the current economy. Previous human resource policies at HE institutions were primarily focused on education and the research criteria will be hard to achieve for a considerable part of the university staff.

Aligning strategy with operational activities is one the top management issues and one of the biggest challenges that organizations are facing. In other words, there is a discrepancy in the decision making on different management levels.

The decisions made at the operational level need to be aligned with the organizations' strategy; but also, the decisions made at the strategic level need to be carried out according the possibilities, capacities etc. on the operational level. So, one of the biggest challenges would be to develop a system that will link and "synchronize" the decisions made at the two different levels using simulation tools.

A hybrid system consisting of system dynamics (SD) components at the higher decision level and discrete event simulation (DES) components at the lower decision level will be developed. The system should enable the decision makers to select the optimal set of control parameters based on the previous estimated behaviour of the system. These control parameters should be used by the SD and DES models to determine the best plan based on the actual behaviour of the system.

As a result, an integrated system of system dynamics and discrete event simulation model focused on a certain problem area will be created, in order to achieve optimal decision making in the field of enterprise restructuring/improvement.

Keywords

Discrete event simulation, integration, simulation, strategy alignment, system dynamics.

1. Introduction

Aligning strategy with operational activities is one the top management issues and one of the biggest challenges that organizations are facing. In other words, there is a discrepancy in the decision making on different management levels [1]. An illustrative example of the interactions that are undertaken can be seen in Figure 1.

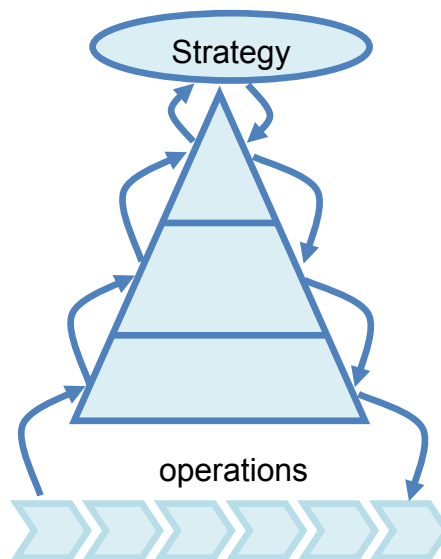

Figure 1 Interactions between different management levels

The decisions made at the operational level need to be aligned with the organizations' strategy; but also, the decisions made at the strategic level need to be carried out according the possibilities, capacities etc. on the operational level. As an example, types of decisions on strategic level would be to increase the quality, decrease the costs, increase productivity etc.; on operational level would be to decrease the additional time in production, the scrap percentage, idle time etc. This means that certain adjustments should be done to the decision supporting tools in order to fulfil previously mentioned efforts. Due to the fact that different management levels are dealing with different levels of structured knowledge, different tools that do not communicate to each other are used. So, one of the biggest challenges would be to develop a system that will "synchronize" the decisions made at the two different levels using simulation tools. This can be arranged through various systems like the SDES described in [1].

The same situation is with the Modelling and Simulation systems as one of the most prominent and perspective decision support tools. Namely, system dynamics modelling is a set of conceptual tools that enable business process designers to build models and develop computer simulations of complex business process behaviours.

Concerning the modelling and simulation of the enterprise performance and behaviour there are two general types of models, system dynamics and discrete event simulation.

System dynamics models provide accurate description of system behaviour along the time dimension [2]. The system dynamics has found most of its use in situations which cannot be represented with mathematical formulation and are of nonlinear type, like the unstructured knowledge within an enterprise. It uses very basic elements, like stock and flows to simulate even the most complex systems. It is a convenient tool to conduct what-if analysis through dynamics points of view and it is the most convenient tool for modelling at the strategic level of the organization.

A business process model is an abstraction of its target business operations in the real world. Intuitively, a business process can be represented by a set of activities with a set of links connecting them. A best representation of the activities in the business processes is through discrete event simulation (DES). The simulation model advances by executing specific procedures at discrete points in time and terminates when all events have passed. DES is a widely used method for studying the design and operations of manufacturing systems [3]. DES allows tracking the status of individual entities and resources through the business process and estimating numerous performance measures associated with those entities. Additionally, with some modifications, DES can even use real-time data from the system (already integrated Enterprise Resource Planning solution, for example [4]). Following all of these, DES are very appropriate for simulation on the operational level of the enterprise.

2. System dynamics as a methodology

System dynamics is a method for studying the dynamics of the real-world systems around us. It has its origins in the control-engineering work of Jay Forrester [5]. He views system dynamics as a conceptual approach to facilitate the understanding of complex problems. Its central concept is that all the objects in a system interact through causal relationships. These relationships come about through feedback loops, where a change in one variable affects other variables over time; these variables, in turn, affect the original variable, and so on. System dynamics asserts that these relationships form a complex underlying structure for any system. This structure may be empirically or theoretically discovered. It is through this discovery that the causal relationships become clear and predictions of the future behaviour of the system become possible. The creation of a complete dynamic model of a system requires the identification of the causal relationships that form the system's feedback loops [5]. Feedback loops can be either negative or positive. Causal loop diagrams are important tools for representing the feedback structure of systems. A causal loop diagram consists of variables connected by arrows denoting the causal influence among the variables. The important feedback loops are also identified and displayed in the diagram.

Traditional mathematical programming approaches to generate strategic plans use production capacity and demand forecasts, for example, with both assumed to be known and fixed for each time period. However, making a prediction of the manufacturing system capacity at the beginning of each period is very difficult. This can result in infeasible plans. SD presents a natural way to model the dynamics associated with the production rates in the system. The interrelationships between the production rates with inventory, labour, and capacity utilizations can be explicitly modelled. The identification of the key factors, their relationships, and the time delays among those relationships can be captured in the causal feedback loops. Simulating such loops can provide insight into important causes and effects, which can lead to a better understanding of the dynamic and evolutionary behaviour of the system as a whole. Hence, SD helps develop a time-based plan suitable to the actual dynamic system. One example of using SD in an enterprise environment can be seen in Figure 2. This is only part of the simulation model and represents the influence of the scrap in the production process. Using the iThink[®] software different options for managing the scrap are presented.

Figure 2 Simulating types of scrap in an enterprise environment [6]

3. Discrete event simulation as a methodology

DES is typically used for performance data collection where important entities such as parts and resources are modelled using state variables that change only at discrete points in time, called event times. The simulation model advances by executing specific procedures at these event times and terminates when all events have passed. DES is a widely used method for studying the design and operations of manufacturing systems. There are two main reasons:

1. DES can describe the most complex manufacturing systems and include stochastic elements, which cannot be described easily by mathematical or analytical models.
2. DES allows one to track the status of individual entities and resources in the facility and estimate numerous performance measures associated with those entities.

These properties are especially important for the detailed operations level. As noted above, DES can model the uncertainty and unforeseen disturbances typical of manufacturing systems. Hence, we believe that DES is the best choice to model accurately the required level of detail to ensure that the developed operations plan is valid. Furthermore, the models can be changed easily and run quickly to reflect changes that occur in the real time. When problems occur, the SD model can be informed immediately, as described below.

One example of DES model can be seen in the following Fig. 3. It is basically a part of a simple model of a glass manufacturing enterprise that is currently developed at the Division of Industrial Engineering and Management at the Faculty of Mechanical Engineering. As it can be seen, this is the last phase of the production, where the glass is packed, the workers are “released” from this item and will continue to work on the next one, where items are then counted and placed in a box of 6 pieces.

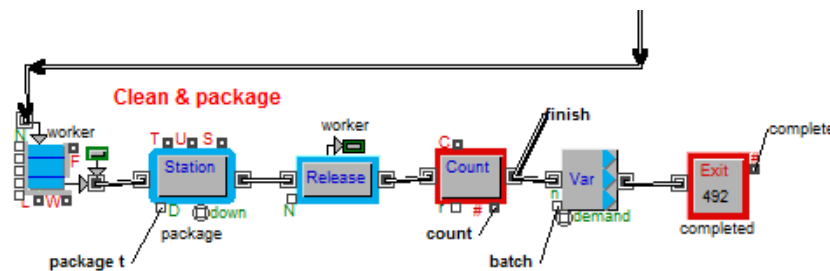

Figure 3 Example of a DES model

4. Discussion

There are numerous attempts to incorporate two different types of simulation. An approach for integrating agent-based simulation models with systems dynamics for the need of the automotive industry can be seen in the work of Kieckhaefer and others, [7]. In the work of Dubiel and Tsimhoni an agent based simulation model was combined with a discrete event simulation model for the needs of a theme park, [8]. There are even examples where the Balanced Score Card has been utilised together with simulation models in order to improve the performance of the emergency department in the hospitals, [9]. Applicability of this kind of simulation models and this kind of supporting tools is not so unfamiliar in the healthcare industry. Two of the many relevant papers describing applications are [10] and [11], each of them describing situations in the emergency departments. These are all examples where one simulation model or one homogenous model can not address the problems of one situation on itself.

So far, at the Division of IEM there were only homogenous models developed, particularly using the DES methodology. Typical example of such developed models is a simulation model for a specific performance measurement methodology [12]. It was developed in the iThink software. The simulation model was mainly utilized in the part of the methodology that deals with the generation of the actions for the improvement of the current situation and evaluation of the effects of their utilization i.e. it was focused on the operational level. In other words, it was used to learn and to model how different

changes in the enterprise environment would affect its performance. Due to the proposed goals of the model, it encompassed only 3 key indicators: Productivity, Quality and Finances.

5. Challenges

An enterprise consists of multiple business processes. Along the way of the business process, many decisions have to be made in order to finalize the process. In everyday practice, a finished process does not mean that every decision that was made was the “best” one or the most optimal in the given situation. Business processes are very dynamic and should not be repeated solely on intuition or historical performance. Wrong decisions at the beginning of the process may lead to catastrophic consequences to the goal of the process and thus on the performance of the business organization.

Every department in the organization is important for the achieving the overall goal of that organization and all departments need to work together and align their efforts for the same highest goal - profit. That same philosophy guided us in the idea of making an integrated simulation model, consisted of DES and SD models. This combined model, according to our previous experience, would be based on some performance indicators that would be simulated and analysed. The processes at the operational level would be simulated using DES. On the upper management level, the results of the operations would be monitored and transformed in the SD environment. This SD model would take in considerations that environmental factors and would try to model them and send the new “situation” to the DES model. The idea is to adjust the operations of the enterprise to the external factors and demands as soon as possible. We believe that implementing separate models for this kind of situation (problem area) would result in getting sub-optimal results, if any at all.

The communication between the models can be achieved to be manual or automatic through the High Level Architecture [13] and [14]. The HLA will be the mediator that will transfer the data between the models. In order to do this, the simulation softwares are required to have really good exporting and importing capabilities. If the exporting data from one software cannot be read by the HLA or the other software, than the integrated simulation model will not function. At this moment, a small research is being conducted about the different simulation software capabilities and what needs to be utilized in order for everything to function as it should be.

In general, the goal is to develop an integrated simulation model for the PMS and that model to be easily modified so that it can tackle different kinds of problems. That was one of the goals of the PMS model itself. Of course, this is more easily said than done. Because of the complexity for modelling every possible key indicator of the PMS, in our previous works we did not use every key indicator, only the ones that are the most affected in the current situation. In this future combined model, the idea is to represent every key indicator of the PMS as a separate module. These modules will be separately saved and will be combined as needed. In this way, there may be models with three-four modules, but there can also be modules with up to 18 different modules.

The idea of using the principle of combined modules came as an option when we discussed where this integrated hybrid model would be applicable. As scientists in the field of Industrial Engineering and Management, the application area is very wide. From production to service based organizations, from medium to large in size and practically every industry area. This universal approach is also very applicable for the PMS itself. The goal is to adjust the model according to the current situation and the demands of the customer. So, for a particular industry, type and size of organization, an appropriate set of modules will be selected, organized and connected with each other in order to meet the goal. It must be noted that this type of modules will be more exploited in the SD simulation; for the DES model and the operations that need to be modelled we think that it is more useful to stay with customizable models and not to use any patterns. They will only set boundaries and you will lose the creativity for modelling the details at that level.

Business and Financial Support to Small and Medium Enterprises in Serbia

*Slobodanka Jovin*¹

¹*Higher School of Professional Business Studies, Novi Sad, Serbia, boba_jovin@yahoo.com*

In developed economies and in economies in the process of transition, small and medium enterprises are considered as a source of local and national economic growth. Economic potential of the SMEs and their importance for an economic development is getting more and more emphasized, but in order to generate it, it is necessary to make stimulating business environment, both institutional and financial one as well as to provide direct measures of support to this sector's development.

Expectations of the SMEs sector are large, but from another side, their business is made harder by a number of obstacles. Thus, it is necessary to provide better business environment which considers an adequate approach to the fresh capital, development of business support that would support interests of the sector and implementing of training programs for entrepreneurs. In the frame of business support, it is very important to underline an importance of availability of advisory services that are closely connected with financial services.

Despite of obvious significance of SMEs in Serbia, their treatment by banks and other institutions is not appropriate, especially in the area of lending. An approach to finance is partly obstructed by the lack of the loan methodology for the SMEs financing and by expensive administrative procedures. The short-term loans are dominated, interest rates are high and procedures of obtaining the loans are long and expensive. Taking into consideration an absence of financial specialization for this area of banking support, the SME financing is considered as a challenge which the banks are to be faced with.

This paper is dedicated to an analysis of the business and financial support to the SMEs development with a special emphasis on Serbia, and to an anticipation of some proposals for the development of an optimal and interactive relationship of these enterprises and environment.

Keywords

Banks, business support, counseling services, financial support, small and medium enterprises

1. Introduction

Small and medium enterprises and entrepreneurs (SMEEs) are considered as a backbone of economic development and the main carriers of employment, creating new working places, generating gross domestic product, export, import and other indicators of the market economy development.

An importance of small business and small enterprises (employing up to 100 persons or significantly less) is not a phenomenon of recent days, but it is undeniable that today "giants" renounce their place to the small enterprises. That is proved by comparative analyses confirming extremely high presence of SME in economies of developed countries. There is a very indicative data stating that small enterprises, of approximately 60 fundamental discoveries in XX century, produced around a half of them; all of them were individual discoveries and innovations done by people bearing all costs of those actions [1]. In certain number of developed countries, small enterprises are involved into the production programs of large enterprises. It is to say that the way of collaboration vary depending on economy system and economic development degree. Thus, the world's experiences show that small enterprises are moving up from the activity where they are competitors to the large ones, precisely on the activity they are complementary.

2. An importance of small enterprises for economic development

Only large enterprise existing is not sufficient or crucial enough for the economic prosperity of one country. Small, medium and large enterprises stand both in competitive and complementary relations. In a modern economy, especially in developed countries it is not simple to define the term of small enterprise, primarily because determining if some enterprise is a craft, small or large enterprise depends on a number of factors that, moreover, differ in countries and sectors. Therefore, there is no unique approach in defining that term, both in West-European countries or in global scale. Theory and practice of many countries in the world define the term of a small enterprise differently and, mostly, very incomplete.

According to the legislation in force, in the Republic of Serbia (primarily, the Law on Accounting and Auditing) all enterprises are classified as small, medium and large ones which depends on the number of employees, budgetary revenues and summary of operating assets and liabilities per annual calculation for the last two years. In that sense, small enterprises are those ones that fulfill at least two of listed criterions:

- according to the number of working hours, number of employees is up to 50 workers,
- annual income is up to 2.500.000 EUR,
- an average validity of business assets is up to 1.000.000 EUR.

This term "small enterprise" itself may be misleading because small enterprises in EU represent 99,8% of all enterprises and 66% of all employees who make 65% of total turnover.

It is relatively easy to establish small enterprises; they link their fate to the marketability of their programs. Since is very hard to survive in competition, near 90% of enterprises stop working relatively quickly, but their capital is not going to be destroyed, it just changes its owners and is engaged for some other programs and similar [1].

Entrepreneurship brings several advantages to some society. It encourages an economic growth, production, produces new technologies, products and services, changes and makes younger the market competition, forms new working places etc.

1. **Economic growth.** One of the reasons which made economists to pay more attention to small new companies is their ability to ensure majority of working places in our economy. According to some researches in the USA, more than four fifths of all new working places have their background in the sector of small economy. More than 30% of these working places are ensured by companies working less than 5 years. However, not all enterprises are of those ones that create working places. This is mainly a few that start and spread out in "youth", going out of the framework of "small" during that process. New companies, and, as well an employment they create, are more and more often found in the sector of services, not in the sector of producing.
2. **Productivity.** One of the reasons for an increased interest for entrepreneurship was more often recognition of its role in increasing of productivity. The main engine of focusing on productivity was an international competition. More productivity is mostly the matter of production techniques improving. Two keys for higher productivity are researching and development on one side and investment in new equipment, on another one.
3. **New technologies, products and services.** One consequence more between entrepreneurship and change is the role that the entrepreneurs have in promoting some innovative technologies, products and services. Many people who have developed those new technologies, products and services, were employed in big corporation that refused to apply those inventions, pushing the inventors to become the entrepreneurs. However, it is unlikely that small enterprises will play a strong role in innovations where we find high capital costs and where are required economies of the scope but it is sure that small enterprises will have a big role in innovations in segmented markets for special products.
4. **New working places.** Those new working places steam from generating new enterprises and their later expansion. Advantages as flexibility of working time, general independency and independency in working, more often have a greater importance than financial compensation. Apart of that, due to small enterprises, the level of competition has been increased and the market of manpower has been made dynamic, especially qualified and manager ones.

Never in history of mankind had been created so many new enterprises like at the end of 80s and 90s of the last century. This process is very characteristic for all parts of the world, starting from more developed west countries to developing and former socialist countries.

3. Analyses of business support to small enterprises in the Republic of Serbia

The experiences of highly developed countries tell us about widely developed networks of institutions for encouraging both establishment and development of small enterprises. Those states, which today have the most developed small economy, simultaneously have the longest tradition, the most jagged system of support and the most outspread network of institutions over which that help is given.

The lack of wider offer of consulting services often is a consequence of the following factors [2]:

- Lack of the number of private consulting companies;
- Poor network of regional agencies for small enterprises development;
- Lack in connection between the system of education and economy;

In developed countries, consulting services have a long tradition. Their appearance is connected to 19th century and services developing through the Chamber of Commerce. Since then, different kinds of institutions which provides this kind of service (public, private, non-governmental etc) are developed on different levels, starting from national to the local ones, with variations in their targets, way of providing services as well their funding.

In the domestic entrepreneurs there is no developed preference for using business advices from specialized institution or companies. In business, mostly they rely on advices of their colleagues and business partners or the accountants. Approximately 74% of surveyed responds are related to those categories of the consultants. National institutions consulting services and chambers have absorbed 9% of the answers and private consulting institutions consulting services have absorbed 4%. Business advices of the accountants are likely used by micro enterprises and shops, as well as the entrepreneurs from the area or retail, catering, software producing while the managers of production, graphic and transportation companies are more relied to the colleagues from the same business. The following figure represents the kind of business support that the entrepreneurs in the Republic of Serbia mostly use [3]:

Figure 1 Business consultants

In the Republic of Serbia, in the previous period, the entrepreneurs have been left to their own capabilities and financial assets. They have been faced with an unfavourable environment in which they've performed their business without consulting, financial, organizational or any other kind of support in the process of their establishment and further development.

The circumstances in which operates today's domestic entrepreneurship are the following [4]:

- narrowed market,
- lack of information on business and development circumstances,
- high price of capital,
- financial indiscipline,
- insufficiently stimulating tax policy,
- shortcomings of technical and technological knowledge,

- expectation of big and quick profit.

According to the researching done by Republic Agency for Development of SME and Entrepreneurship, in collaboration with the Republic Institute for Statistic during 2009., there was a conclusion that improving and success of business depend on external influences; the biggest of them is an influence of the state (through the larger scope of support or decreasing of limiting) and support of local environment. There is 62% of all answers related to these aspects, and greater support of business banks, as a condition of business improving, is related to 18% of answers. The benefit of better business relations to the partners takes the pre-last place on the scale of conditions for improving business, and the last one belongs to improving of management functions in the enterprise (6%). Above stated conclusions are shown by the following graph [3]:

Figure 2 The conditions of business improving

Realization of strategic providing of support to SME and entrepreneurship development suggests:

- An adequate business ambient and suitable legal regulative;
- Non-financial institutions which will provide the best business services created according to the market demands i.e. adjusted to demands of existing and potential small enterprises and entrepreneurs;
- Financial institutions which will provide establishing of new small enterprises and growth of activity of existing small enterprises;
- Educational systems that will provide an advance knowledge acquiring and an entrepreneurial culture accepting;
- Special programs that will increase the resource usage effective level and provide making new profit prices [5].

In the Republic of Serbia, an institutional infrastructure, made by Government, Ministry of Economy and Privatization, Republic Agency for SME an Entrepreneurship development, a number of local agencies, National Employment Service, National Bank of Serbia, financial institutions, Universities, associations of the entrepreneurs and other.

For a success of institutional infrastructure and their benefit to creating surrounding for small enterprises, it is very important that those institutions act in entrepreneurial manner, to be innovative and flexible.

In the Republic of Serbia, at the general level, a big obstacle is an ignorance in the area of possibilities and effects of business support utilizing. A national network for small enterprises development support is made of relatively new institutions still developing their programs and methodology of work with the entrepreneurs. Except of the national network supporting the small enterprises development, on the area of the entrepreneurial training, consulting and informing, there is a market to be developed in the framework of private sector. Since this market is still being in the stage of development, a competition still hasn't separated any organization with proved quality of services and there are no determined standards of valuation for programs and contractors in private sector. In the area of business consulting, we can notice a rapid growth of a number of private advisors, auditors, associations, entrepreneurial centers where, in quality estimation, all small enterprises are left to themselves.

The most important categories of advisory services in Serbia are an approach and management with finance, support in business plan development, marketing services (researching of the market, contacts in selling and distribution), entrepreneurial training, training in management etc.

4. Financial support to the small enterprises in the Republic of Serbia- achievements and limitations

A lack of financial assets is very often stated as the one of the biggest obstacles while establishing and spreading private enterprises in the countries of transition. In literature on entrepreneurship, very often is possible to read that money is not the main factor for entrepreneurial investment success achievement. According to the statement of the theoreticians, the most important is an idea. If there is a good idea, the way for ensuring financial assets will always be found. However, capital is a big problem for the entrepreneurs in Middle and East Europe and very often it represents a serious obstacle on their way towards an achievement of success [6].

In Serbia, the entrepreneurs provide an initial capital most often from their own sources. Personal savings is represented in 46% of cases while only 13% is relied on banking sources. Development Fund and National Employment Service were supported only by 4% but one should bear in mind that a significant number of enterprises was established before activating the program of state support for beginners in business.

This graph shows SME funding sources in Serbia, according to researching of Republic Agency for Development of SME and Entrepreneurship [3]:

Figure 3 Sources of the business beginning funding in %

In the past and in recent time, banks have had aversion towards supporting small enterprises. Some of most common reasons are [7]:

- Unfavourable bank strategy of lending that do not meet requirements of small enterprises;
- High risk connected with lending to small enterprises;
- Lack of collateral;
- High operative costs;
- Poor education, management and entrepreneurial skills;
- Inadequacy of investment project submitted to the bank;
- Unreliable financial reports that makes credit analyses hard and unreliable;

The biggest problem for a big number of SME in the Republic of Serbia and in developed countries is the approach to financial sources. Although total value of granted credits in those enterprises is increasing all the time, an individual small enterprise has some difficulties in providing loans needed for business. Namely, bankers associate a lack of credibility to small companies, so entrepreneurs and enterprises have a lot of problems while convincing banks that their suggestions are qualitative. While considering applications for granting loans, very often entrepreneurial qualities are not appreciated enough or aren't taken into consideration. The factor, considered as even more serious obstacle in obtaining loans for small enterprises, is related to procedural issues. Of course that every entrepreneur would gladly accept decreasing of interest rates, but long and, often, unclear procedures while submitting an application for taking loan, is considered as something that the entrepreneurs

would like to change as well. The loan granted to late is considered, in its core, as the loan that is refused.

An access to finance is partially hindered by the lack of credit methodology for small enterprises funding and by expensive administrative procedure. This is the main reason why banking systems usually avoid providing their services to micro and small enterprises although the small enterprise can be capable to pay real interest rates and be very profitable for financial institution, under condition of having constant and reliable access to different credit products.

The biggest problems in banking and financial sectors are connected to dealings with small enterprises; they influence a possibility of estimation of the creditworthiness and are listed as following [8]:

- Lack of experience, especially in estimation and monitoring of the small enterprises and entrepreneurs business, which creates a consequence in considering funding of those enterprises as too risky;
- Lack of registration on the entrepreneurs and small enterprises business in previous period of time, in correlation with the fact that an environment is being changed very quickly, makes an inherent risk of projects to be more higher than in comparable west economy;
- Lack of diversified financial institutions that are common in developed countries, such as for example "venture capital" institutions. A reason for that is not just in environment but also in the lack of suitable legal procedure and experiences, as well as of resources;
- Lending to small enterprises is very risky because of high level of uncertainty that small enterprises are faced with (non-existing of qualified non-financial services that would decrease an influence of the non-financial risk of those factors- quality analyzing of the market, competition, managing weak points, weaknesses of products and services organization and distribution, etc);
- Small enterprises often are not able to ensure any pledge and or security instruments required from credit institutions;

It is true that a number of small enterprises don't fulfil a minimum of criterions settled by banks. Many banks agree in one: There are a lot of credit applications, but there are very few good projects and qualified clients as well.

More than 70% applications are refused due to the following:

- Business plans are not real;
- Non-existence of an adequate security;
- State of incomes doesn't show real state;
- Enterprises are overloaded by debts

Despite of limitation listed, business policies of banks and other financial institutions pay more and more attention to interests of small enterprises.

It is approved also by the fact that a significant number of banks have organized special parts, specialized for dealings with small enterprises while, in the purpose of providing all required financial assets for this sector, Guarantee Fund's activities as well as donor support through credit lines, have been intensified. Also, an advisory support and trainings of bank staff for an estimation of the entrepreneurs application, will have a positive implications to an affirmation of small enterprises sectors as an important targeted group of banking institutions.

5. Conclusions

Small enterprises in developed countries deal in different business environment and have a significant assistance and support by the government, which certainly contributes to economic development of the state in general.

In the Republic of Serbia the entrepreneurs were, in previous part left to their own skills an personal financial assets. They were faced with an unfavourable ambient where they were performing their business with no advisory, financial, organizational or any other kind of help in the process of their establishment and latter development.

Unequal position of small enterprises on the market imposes a special need for taking some additional affirmative measurements by the state and regional i.e. local authorities, pointed to this sector development. Basic incentives can be noticed throughout simulative tax policy, state assets, increasing of risk capital and as the most important, changes of business policy of banks related to small enterprises financing.

Support to small enterprises in the area of financing, is a very important part of an encouraging policy of small enterprises in all states where this part of economy is considered as very significant. Realization of that support in large scope depends on following question: how big part of policy in the area of entrepreneurship financing is adjusted to entrepreneurship in reality? Except of above stated, difficult approach of small enterprises to financial services can be avoided by combination of supportive measurements and scheme of financial support. Supportive measurements, such as advisory services, trainings etc., should have the target in increasing awareness of small enterprises on existing financial services and better understanding of banking procedures.

Reengineering of Industrial Manufacturing – Imperative of Development and Competitive Capability

Milan Jurkovic^{1,2}, Vlatko Dolecek¹, Isak Karabegovic^{1,2}, Zoran Jurkovic³

¹Society for Robotics of Bosnia and Herzegovina, mi.jurkovic@gmail.com, vldolecek@gmail.com

²Faculty of Technical Engineering, University of Bihać, Bosnia and Herzegovina, isak1910@hotmail.com

³Faculty of Engineering, University of Rijeka, Croatia, zoran.jurkovic@riteh.hr

Reengineering of production is a process of continuous innovation and advancement of existing products, technologies, production processes and systems, and the survival of numerous manufacturing and business systems depend on the efficiency of their application. Reengineering radically changes a traditional solutions instead the slow implementing of a production-organization changes reengineering demands the fast and radical changes with the aim of achieving a competitive advantage. Reengineering of manufacturing systems is the procedure of the continuous and radical redesigning and/or redefining of manufacturing. The general trend of development a manufacturing in technologically developed countries are increasingly based on reengineering and modernization which means the implementation of new technologies, a flexible automation and organization and computer integrated manufacturing with basic aim in order to produce in terms of quality, cheaply and faster. The restructuring has to be done in the area of the business system, which means in the area of technology, organizational structure, process and information. Restructuring programs include not only changes the orientation of the titular private ownership. It is necessary production and business restructuring that provides returning of lost markets, higher level of producing capacity utilization and other resources as well as competition. The practice till today has shown the gap between expectations and the way of real execution. In the paper are spoken about reengineering and new manufacturing philosophy, phases in the development of the modern industrial production, simulation, quality system at reengineering and the algorithm reengineering of manufacturing processes.

Keywords

Industrial manufacturing, New philosophy, Quality system, Reengineering, Simulation

1. Introduction

Industrial manufacturing is realized with a continuous and intensive changes that is consisted in the adaptation of new technological and manufacturing circumstances, the market demand, competitiveness and changing of a production structure.

Reengineering of industrial manufacturing is a process of continuous innovation and advancement of existing products, technologies, production processes and systems, and the survival of numerous manufacturing and business systems depend on the efficiency of their application. The need for the reengineering is greater at the companies of transition countries which kept a planned economy for the most part and where the radical changes in the all elements of company, the logistical support and particularly at system of quality are needed.

Because of that reengineering is the basic concept of the transition of company without reference to their quantity and profitability. The usefulness of reengineering can be observed in terms: the maximal simplification of working processes, reduce the amount of work, the improvement of business results, the implementation of new techniques and technologies, the advancement of product quality and market recognized manufacturing.

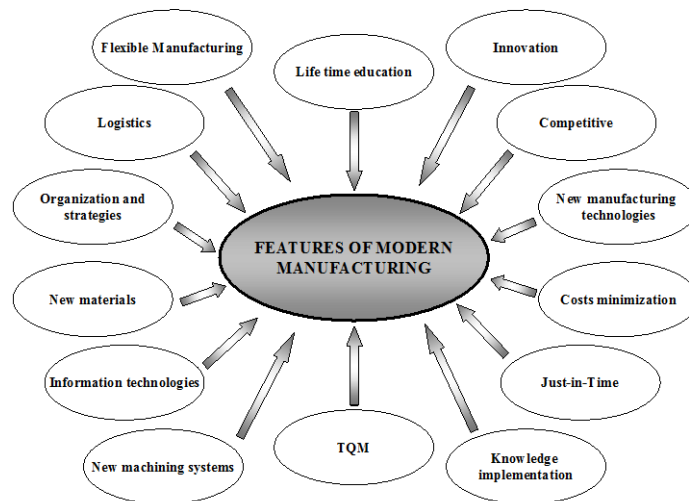

Figure 1 Features of modern industrial manufacturing

In the paper is performed industrial manufacturing and new manufacturing philosophy, reengineering of industrial manufacturing, simulations in the reengineering and some effects of reengineering [1-15]. The basic feature of modern industrial manufacturing is great number of variables influential parameters (Figure 1.), which have influence in the improvement of business results and to achieve a competitive advantage.

2. Industrial Manufacturing: New Manufacturing Philosophy and Reengineering

General trend as regards the growth of industrial production in technological developed countries is more and more based on reengineering and modernization, application of new technologies, flexible automation and organization of production and computer-integrated manufacturing, with basic objective which is to achieve a higher-quality, cheaper and faster production.

New manufacturing philosophy is: introducing a new manufacturing and information technologies, new materials, expert systems, integrated and flexible manufacturing, improvement of product quality, minimization of manufacturing expenses, increasing of productivity and the high level of implemental knowledge.

Therefore, a new manufacturing philosophy is founded on knowledge, a new manufacturing and information technologies and manufacturing Just-in Time (Figure 2.). In industrial manufacturing is definitely need to implementation of new manufacturing philosophy, that is principle of modern manufacturing.

The main basis in the development the modern industrial production are: new manufacturing technologies and technics, information technologies (CAD/CAPP/CAM-CAQ), rapid development of products, application of knowledge, innovations, flexibility and modern production systems with the aim to achieve a competitive advantage and the decreasing of production costs.

The basic aim of the reengineering is to reduce the running costs of production per unit product and improvement of quality by the application of new manufacturing philosophy.

A new manufacturing philosophy is founded on knowledge, a new manufacturing and information technologies and manufacturing Just-in Time. The basic aim of the reengineering is to reduce the running costs of production per unit product and improvement of quality by the application of new manufacturing philosophy (Figure 2).

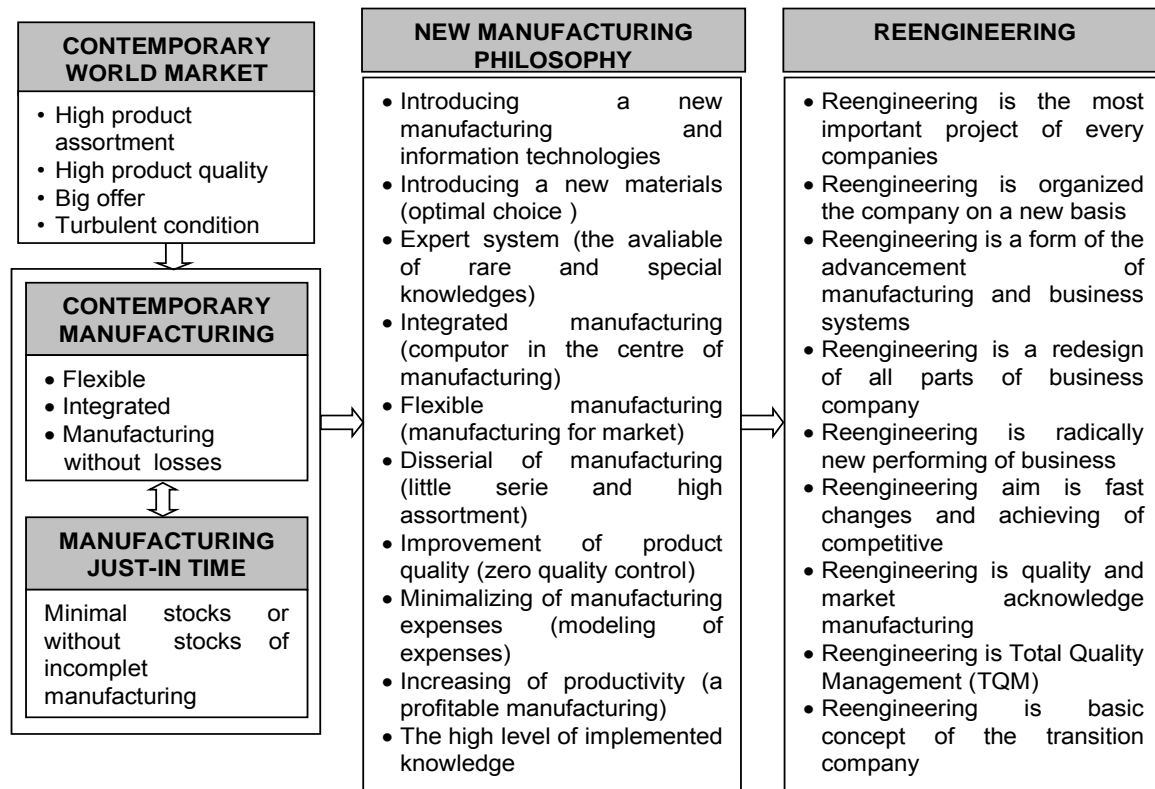

Figure 2 New manufacturing philosophy and reengineering

3. The Main Phases in the Development of the Modern Industrial Production

Reengineering of industrial manufacturing is defined as the organizing of production on a new basis which will be radically redesign a manufacturing processes in order to improve the efficacy of business (quality, expenses, the speed of materials flow, the duration of cycles, the degree of a consumer service,...).

The reengineering of industrial manufacturing means the following steps:

- analysis and evaluation of existing manufacturing state,
- research of markets needs and competitors,
- identification of bottlenecks in manufacturing process,
- definition of problems and target function of reengineering,
- alternative and solution for achieving of target function of reengineering,
- to choose optimal solution for accomplishment of reengineering aim,
- realization of the procedure of reengineering,
- maintenance of manufacturing system in reengineering,
- analysis of reengineering results,

- reengineering successfully accomplishment and
- manufacturing system improved by reengineering.

The main phases in the development of the modern industrial production are (Figure 3):

1. Defining the bases that are indispensable for development of the modern industrial production (real state, product and design, human resource and knowledge, new technologies and technique, information technology, ...).
2. Implementation of new manufacturing philosophy.
3. Realization of the reengineering project of industrial production (Advance of processes).
4. The modern industrial production.
5. Analysis of results (terms, competitive, costs, quality, profitable, Just-in-Time).

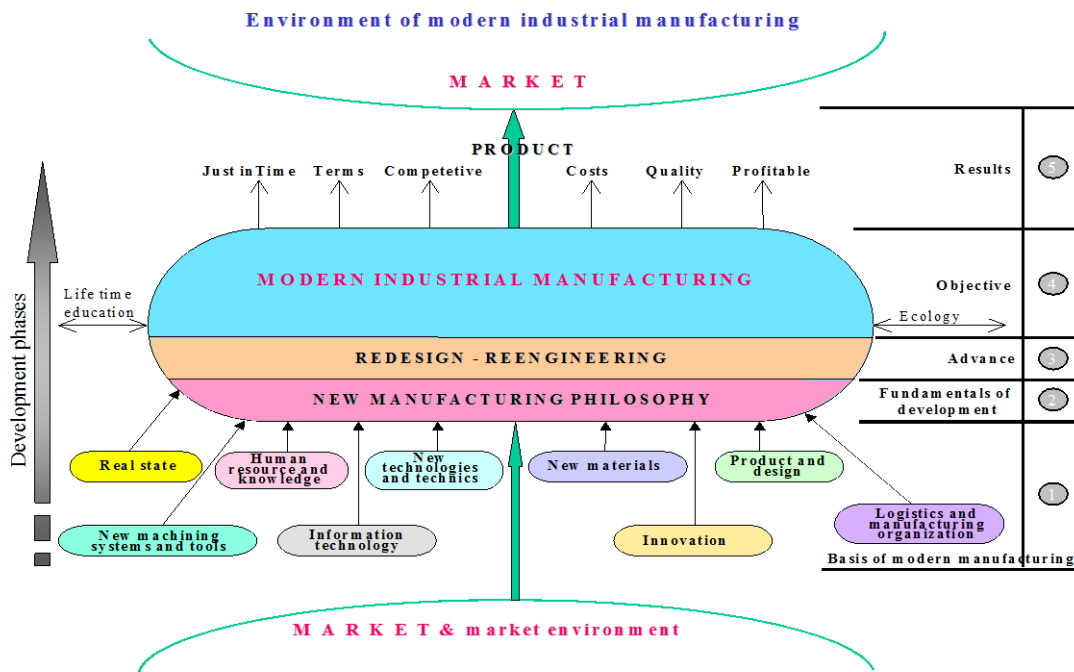

Figure 3 Phases in the development of the modern industrial production

4. Simulations in the Reengineering

Simulation is one of the methods for the verification of model. A simulation in modelling and the analysis of activity at reengineering implementation has a important part because it gives the quantitative evaluation of redesign processes. For the past ten years the simulation is most often applied in manufacturing activities for the purpose of controlling and increasing of the productivity of manufacturing processes.

For the purpose of the faster development of new products, the reducing of manufacturing cycle and the introducing of the new procedure of machining the application of simulation in the reengineering of processes is irreplaceable.

The basic feature of simulation is the possible of repeating and changing of input parameters as well as following of influence of those changes on output results. Hereby, the communication between the user, who change the conditions of performed simulation, and simulation model is enabled.

Some of that reasons for applying a simulation in the reengineering of manufacturing and processes are:

- The possibility of the survey of process dynamics (the length of time, time of resources use, waiting time, ...).
- The including of the influence of random variables on the development of process.
- The prediction of reengineering results at quantitative values.
- The using of simulation software enables visualization and animation of a existing and new processes.
- The simulation of variant solutions, analysis and forecast of process state at designing phase.
- The constant innovating of technologies and products.

Simulation and choice of optimal solution have four steps (Figure 4.).

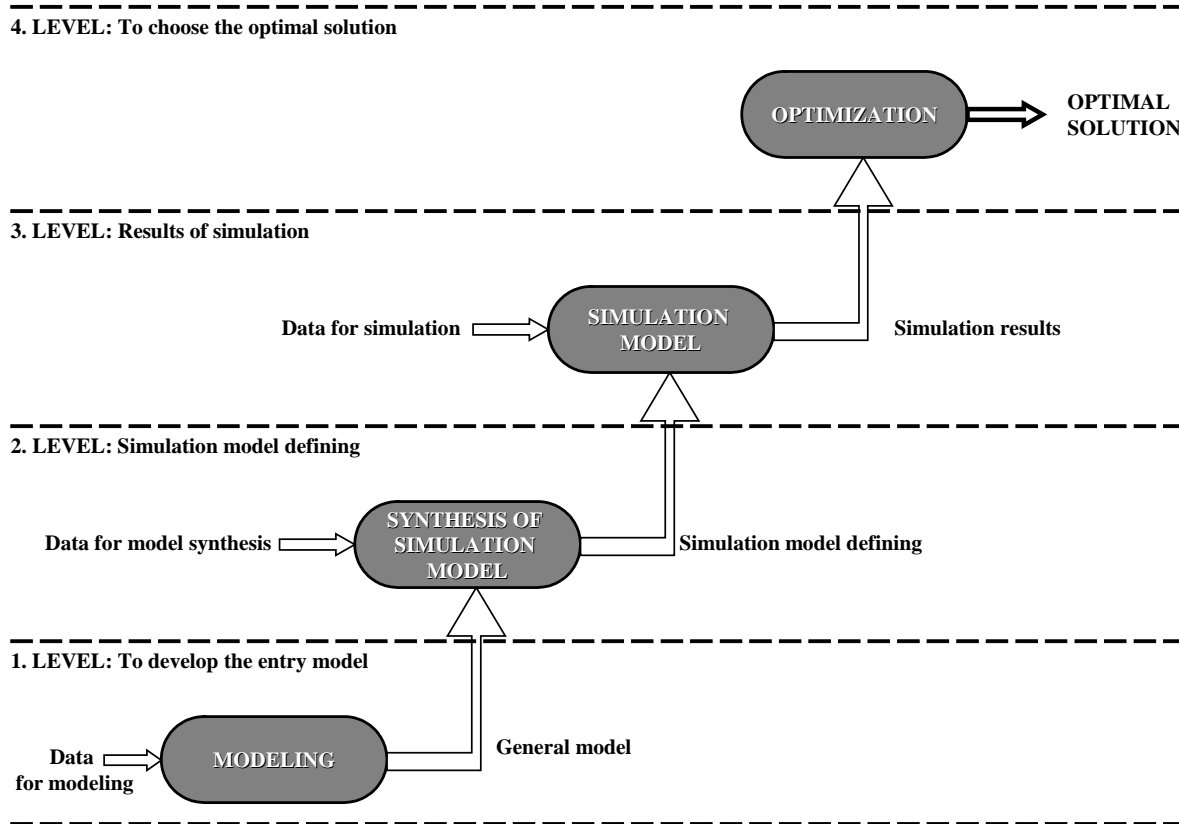

Figure 4 Simulation and optimal solution choice

Tools for modelling and simulation of processes have to fill the following functions:

- the textual and graphic documentation of process (analysis of a existing condition and the development of model),
- the changes in the structure of process (reducing the production time, and reducing the number of needed manufacturing systems...),
- the expressing of the performances measures of systems by quantitative (the process time, the standard of material consumption, the number of needed machines,...) and by qualitative (the priorities of performing a procedure, materials,...),
- communication links,
- the use and the implementation of knowledge.

According to that, the simulation is important for reengineering of manufacturing processes and systems.

5. Reengineering and Quality System

Quality system is the superstructure of reengineering process. At the beginning, it realizes slowly, however, by realizing the determined activity of reengineering the development of quality system is emerged (Figure 5). Thus, by introduction of quality as the system of quality (SQ) or a total quality (TQ) the process of advancement obtained with reengineering keeps the trend of growth. The system of quality enables the achieving of a optimal results of reengineering and the application of standard ISO 9000, ISO 14000 and others needs the application of further reengineering.

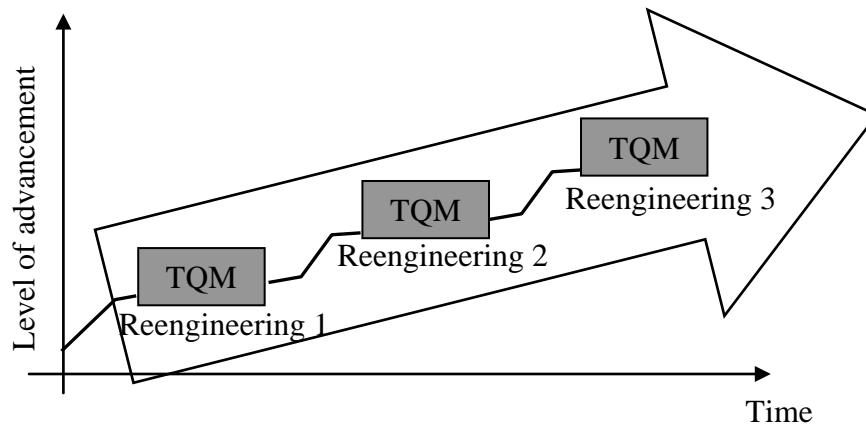

Figure 5 Reengineering and TQM

A total quality assurance and reengineering are not contradictory and complementary than two parts of the same approach and aim.

6. Algorithm of Manufacturing Reengineering and Some Effects of Reengineering

6.1 Algorithm of Manufacturing Reengineering

Technological reengineering is the basic foundation for the successful reengineering of manufacturing and the main element for acquiring a competitive advantage (Figure 6).

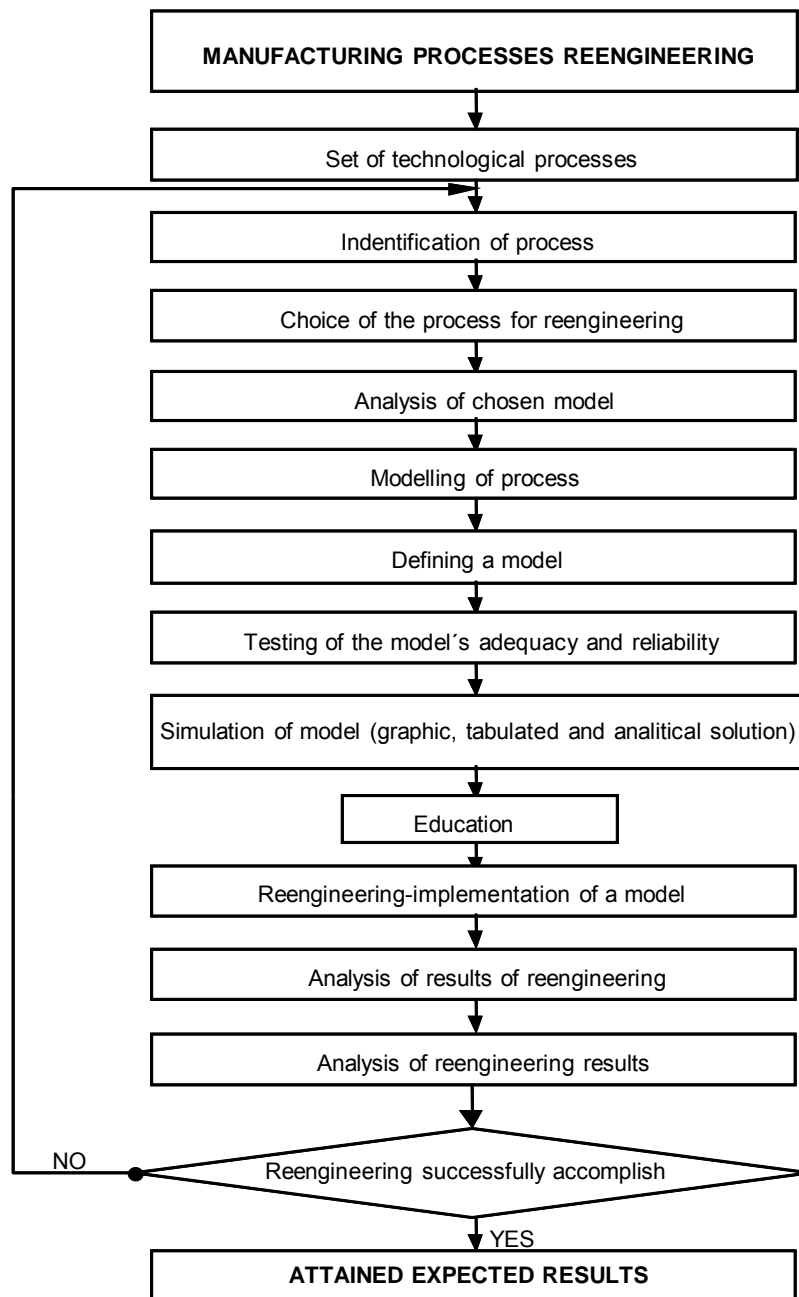

6.2 Some Effects of Reengineering

The efficiency of reengineering can be shown through the following basic characteristics:

- The maximal simplification of working processes that are the reflex of buyer's demands with clear aims.
- The innovating of technology and products.
- Reduce the amount of work and the time cycle of manufacturing.
- The improvement of business results of company.
- The constant advancement of business with the implementation of new techniques and technologies.
- The advancement of quality system of a working process and product quality.
- The market acknowledges manufacturing.
- The radical advancement of a total business system is the foundation of the development strategy of company.
- Implementation of new methods and improving the existing ones as well as improving the machining procedures.

- Reengineering is basic concept of the transition and advancement of company without reference to their quantity and profitability, etc.

Figure 6 Algorithm of manufacturing processes reengineering

7. Conclusions

- Company founds its development strategy, on reengineering as the radical procedure of advancement of a manufacturing and total business system.
- Reengineering of industrial manufacturing is organized the company on the new bases with the aim of achieving a competitive advantage.
- The need for the reengineering is greater at the companies of transition countries which kept a planned economy for the most part and where the radical changes in the all elements of company, the logistical support and particularly at system of quality are needed. Because of that

reengineering is the basic concept of the transition of company without reference to their quantity and profitability.

- The usefulness of reengineering can be observed in terms: the maximal simplification of working processes, reduce the amount of work and the manufacturing cycle, the improvement of business results, the implementation of new techniques and technologies, the advancement of product quality and market acknowledge manufacturing.

For the past ten years the innovation and advanced technologies is most often applied in manufacturing activities for the purpose of optimization, controlling and increasing of the productivity of manufacturing processes. The usefulness of innovation and advanced technologies can be observed in terms: the reduce the amount of work, the improvement of business results, the implementation of new techniques and technologies, the advancement of product quality and market acknowledge manufacturing. The need for the innovations and reengineering is greater at the companies of transition countries which kept a planned economy for the most part and where the radical changes in the all elements of company, the logistical support and particularly at system of quality are needed. Because of that reengineering is the basic concept of the transition of company without reference to their quantity and profit. Industrial manufacturing is realized with a continuous intensive changes that is consisted in the adaptation to new circumstance and of the market claims. Competitiveness and change of a production structure, market orientation, reengineering and revitalization of a business and manufacturing processes and systems are an imperative of company existence.

Industrial production require continuous innovation and advancement of existing products, productions processes and systems, technologies and work quality and the survival of numerous production and business systems depend on the efficiency of their application.

In the paper are performed innovation, advanced technologies for transition countries, information technologies, implementation of knowledge methods (modeling and simulation), advanced technologies and reengineering of production in transition countries.

Keywords

Advanced technologies, Innovation, Modern industrial production, Reengineering, Transition countries

1. Introduction

Innovation manufacturing processes and systems is a process of continuous innovation and advancement of existing products, technologies, processes and systems, and the survival of numerous manufacturing and business systems depend on the efficiency of their application. General trend as regards the growth of production in this technologically developed world is more and more based on human resources, knowledge's, innovations, reengineering and modernization, on application of innovations, new technologies, flexible automation and organization of production and

computer-integrated production, the main aim of which is to achieve a higher-quality, cheaper and faster production.

The development and application of innovations in machining processes are based on application of knowledge, which is condition for transformation of the conventional processes into the modern ones, with what criteria of process optimality in technological, economic and market terms are satisfied. Consequently, and machining technologies, that have been applied for a number of years in definite conventional form can be innovated by applying corresponding innovations without considerable financial investment but by using high knowledge from the area of: simulations, optimisations, computer technique and other close areas [1-15].

The usefulness of innovation, new technologies and reengineering can be analyzed and observed in terms of: enlargement of process productivity, usability of machining system, increasing product quality, reduction of machining time and preparation expenses, respectively.

Modern technology and technological processes reduce the direct consumption of living labor (the work time on the machine and alike), and increased participation of intellectual labor (the time of preparation, design, programming, etc.) Figure 1.

Figure 1 Living labor work and intellectual work (%) included in product price

2. Process Innovations at Reengineering

The system of innovation has an important place in the modern manufacturing engineering because of that management functioning as an innovation is developed to insure a favourable environment for the development of innovative activity [1,2,3]. Because of that:

- Innovative factory is supposed to be in condition to present its new product in short order.
- Innovative factory has to be flexible.
- Ability of innovating is a key for the realization of a competitive advantage on the market.

Process innovation means performing a work activity in a radically new way. Process innovation is generally a discrete initiative and it also implies the use of specific change tools and technology for enterprise engineering and transformation of business processes [1,3], Figure 2.

Figure 2 Industrial innovation field

In Figure 3 are shown the model elements of process innovation [11] (R1: effects of innovation initiatives on process characteristics, R2: change in processes-change in performance of processes).

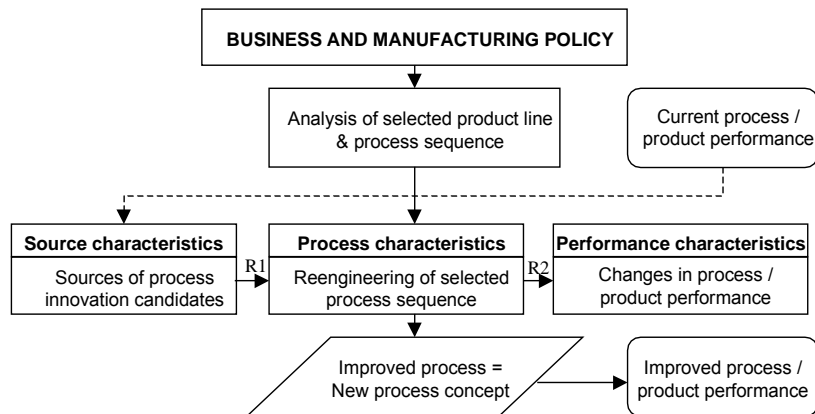

Figure 3 The basic model of process innovation

3. Reengineering and Information Technologies

Reengineering means the implementation of information technologies in the stream of a manufacturing and business processes as [1]:

- the advancement of technological and manufacturing processes,
- the optimization of manufacturing processes and systems,
- the innovations of a manufacturing and non-manufacturing processes,
- the changing of manufacturing structure (redesign and/or redefining).

Information technologies are in the centre of the reengineering of a integral manufacturing and business processes where they serve as tools for making the competitive advantage of company (Figure 4).

By applying informative technologies realize competitive advantages.

Characteristic	Information technology
• The reducing of organizational complexity	improves and facilitates the communication of all organizational entities
• The management of knowledge	facilitates the transfer of knowledge in real time
• The control	enables and improves monitoring and informing on the condition of individual resources, products, materials,...
• The time cycles of working processes	reduces a cycle and enables the application of the simultaneous stream of working processes instead of sequence one
• The information abilities	improves and simplifies the application of complex analytical models and processing of the great numbers of informations needed for a business deciding
• The automatization	the increasing of a product quality, the shortening of technological time, reducing of workers
• The dislocated ness of object	transfer a needed information on to long distance fast and simply
• The integration of a manufacturing and business processes	a integrated factor CIM, CIB
• Inovative activity	facilitatess, accelerates and improves the organization of working operation
• The technological preparation	shortens the time of a technological preparation and increases the number of a process variants needed for the choice of a optimal variant
• Modeling and the simulation of processes	enables the efficacious application of modeling, particulary simulated modeling for the outline of process and the choice of optimal variant
• The analysis of process and system	shortens the time of analysis and enables the exact identifation and analysis of process and system

Figure 4 The increase of productivity by applying information technologies

4. Some Examples Reengineering of Manufacturing Technologies

Reengineering means radically a new way of performing a business which shows following examples. Technology is the basic foundation for the successful reengineering.

4.1 New Machining Technology and Reengineering

In Figure 5 and 6 is shown the considerable reducing of manufacturing expenses at the substitution of conventional technology (warm forging) with a new technology (cold extrusion) at the manufacture of machine elements [1]. Consequently, it is achieved total saving 42,5% per piece and energy saving 92,5%.

Figure 5 Reducing costs per piece by using of new technology

Figure 6 Energy saving by using of new cold extrusion technology

Therefore, in Figure 5 and 6 are presented the effects of reengineering by using of cold extrusion technology.

4.2 High Speed Machining in Reengineering

The high speed machining (HSM) is reflected in: reduced machining time and production costs, decreased non-machining time, improved work surface quality, etc. Figure 7 and Figure 8 show the advantages of high speed cutting (HSC) in die and mold making [1, 11].

Figure 7 Conventional NC and HSC machining

Figure 8 Conventional milling and HSC milling

5. Modeling and Simulation at Reengineering

5.1 Modeling

The basic purpose of modeling is the defining of mathematical and other models (graphic, analytical, software...) that are indispensable for reengineering of processes and systems. Reengineering as the method of improving of process and system sets the procedure of modeling of processes and systems at the first place. Defined model is the foundation of improving of analysis and simulation of process which needs to enable the choice of a optimal solution [1, 2] (Figure 9).

5.2 Simulations

For the past ten years the simulation is most often applied in manufacturing activities for the purpose of controlling and increasing of the productivity of manufacturing processes. With the faster development of new products, the reducing of manufacturing cycle, the introducing of the new procedure of machining as the aim of the application of simulation in the reengineering of processes is irreplaceable. Simulation is one out of the methods for the verification of model. A simulation in modeling and the analysis of activity at implementing a reengineering has a important part because it gives the quantitative evaluation of redesign processes. Some out of reasons for applying a simulation in the reengineering of processes are:

- The possibility of the survey of process dynamics (the length of time, time of resources use, waiting time).
- The inclusion of the influence of random variables on the development of process.
- The making possible of foreseeing of reengineering results at quantitative values.
- The using of simulation software enables visuality and animation of a existing and new processes.

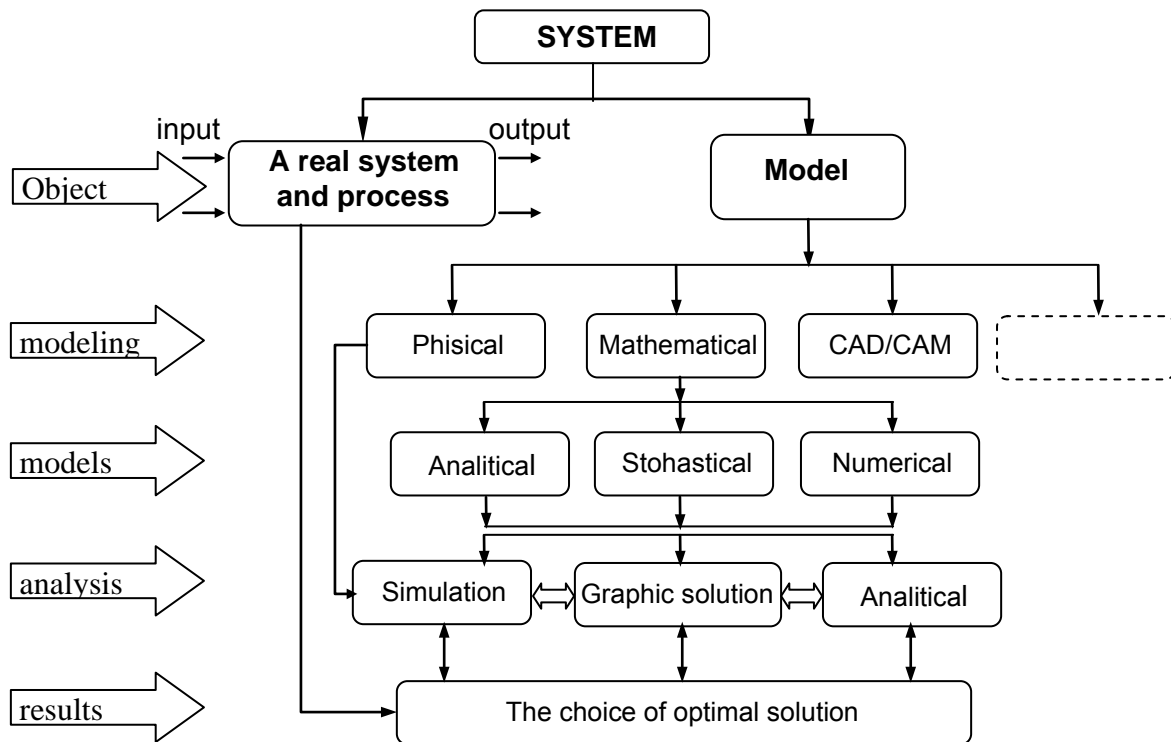

Figure 9 Modeling and the simulation of solution

The basic feature of simulation is the possible of repeating and changing of input parameters, following of influence of that changes on output results. With that, the communication between the user that changes the conditions of performing a simulation and a simulation model is enabled (Figure 10.). Tools for modeling and simulation of processes have to fill the following functions:

- the text and graphic documentation of process (analysis of a existing condition and the manufacture of model),
- the changes in the structure of process (reducing the length of time, and reducing the number of needed manufacturing systems...),
- the expressing the measures of the performances of systems by quantitative (the length of process time, the standard of material consumption, the number of needed machines,...) and by qualitative (the priorities of performing a procedure, material,...)
- communication links,
- the use and the implementation of knowledge. According to that the simulation is important for reengineering of manufacturing process [1].

Figure 10 Modeling and the simulation

6. Conclusions

The need for the innovations and reengineering is greater at the companies of transition countries which kept a planned economy for the most part and where the radical changes in the all elements of company, the logistical support and particularly at system of quality are needed.

Reengineering is the contact form of the advancement of manufacturing and business systems even at technologically developed countries.

A simulation in modeling and the analysis of activity at reengineering implementation has a important part because it gives the quantitative evaluation of redesign processes.

Because of that reengineering is the basic concept of the transition of company without reference to their quantity and profitability.

The producing reengineering is one of the most complex action of radical improving and modernizing of producing in the aim of competitive advantage at the global market.

ICT diffusion and use in student environment in Tetovo

Lazim Kamberi¹, Sadri Alija², Llukan Puka³

¹*Faculty of Math-Natural Sciences, State University of Tetova, Tetova, Macedonia, lazimkamberi@yahoo.co.uk*

²*Faculty of Business and Economics, South East European University, Tetova, Macedonia, s.aliqi@seeu.edu.mk*

³*Faculty of Natural Sciences, University of Tirana, Tirana, Albania, lpuka2001@yahoo.co.uk*

It is considered in general that ICT is a support for a new economical development. But those considerations are mixed with misgivings, because the equipment of the population in ICT equipment is characterized by inequalities. Found in a situation of general economical and political transformation, the country is in front of a development marked mostly by the changes and market in a context of a general transition than the necessity for the population to master those equipments.

The situation was studied in the higher education environment in Tetovo (two universities and a secondary school) for having also a local and regional view on the use of ICT. The paper presents the results of a study which try to measure the level of penetration of ICT technology in this student environment and by them to their families. The survey, done during June-November 2010, shows the environmental situation and tries to compare it with the country situation. It seems that the diffusion of new technologies is characterized some times by inequalities between regions, generations, and technologies.

The principal results concern the equipment and mode of use of the telephone (fix and mobile), the computer and the internet. The situation is considered for two groups: the students from higher education and the students from the secondary education.

Keywords

ICT, e-readiness, regional digital development, economic development

1. Introduction

ICT (Information and Communication Technologies) is part of contemporary human life, is undivided part of his daily activities and synonymous with readiness to deal with the problems of the present and the future. Over the last decade ICT and internet have brought significant changes in economic and social development. However, ICT and the Internet revolution have not been over yet. In recent years internet is much faster, with lower prices compared to fix and mobile phones, and the possibility of fast media, etc. ICT has recently been part of student life and their family, where it becomes a comparison of the use of ICT by students and their families with all families in our country.

The main purpose of this paper is to see how students use information and communication technologies and for what purposes they use them. In order to find out about this state, a questionnaire was designed, which can be seen as part of the following results.

The results were found through a questionnaire carried out within students of SEE University and State University of Tetovo. The questionnaire was based on certain principles: Initially, a correct representation of the environment of university students, secondly the content, in order to better reflect the current situation.

The survey analyzed 1382 students, 47.5% were surveyed in SEE University and and 52.5% in the State University of Tetovo, respecting the proportionality of respondents: data for the number of

students were in instructional secretaries. At university level, the representation was achieved on the basis of faculty and year of study.

The data were collected: for person, equipment with fix phones, equipment with mobile phones, equipment with computer at home, access on internet, etc, for their personal and familiar use, knowing and using the internet, the purpose of use, proposals for development of internet at home, central and local policy evaluation for internet situation and its development. In general this content was discussed in 39 variables (indicators). Here are presented the results for a part of these variables.

One of the most important purposes of our study was data mining of a standard list of indicators as a base on which a situation was evaluated and compared with corresponding indicators of all the country. To these indicators was dedicated with a special attention.

2. RESULTS

2.1 Mobile and Fix Telephony

It is evident from the study that 74.4% of the students have fix phones in their houses, from which 63.4% are prepaid users with a single operator, where 56.6% use the operator T-Home. Mobile phone has a large extent in student environment. Around 96% have a mobile phone, where 21.5% once have changed their first mobile phone, 16.5% twice, 18.9% three times, , 35.5% more than four times and only 7.6% declared that never changed their first mobile phone. Average number of sending SMS per week is 52. According to their mobile phone use 83.65 use to send SMS, , 54.7% to browse in internet, 54.4% to download games, photos(photo),music (ring), 40.2% to read e-mails and 24.8% to watch television(Graph 1).

Graph 1 The Use of Mobile Phone

2.2 Equipment and the Use of Computer and Internet

The results of the study show that 94.8% of the students have computers in their houses, where 60.2% of students have one computer and 34.6% of them declare that have some computers in their houses, 53.2% of them have laptops. 87.4% of them that have computer also have internet in their houses. The indicator is higher than corresponding identifier, already twice higher with me 46.1% [4].

Regarding the possibilities of using computer and internet connection at the university where the study 56.9% reported that yes, of whom claim that computer and internet use every day with 75.4%, 14% once or twice a week, 5.5% more rarely and 5% said they do not know. If we take a look between universities shows that most equipped with computer, laptop, IP are SEEU students. And the Internet connection at home, university and more frequent use of the Internet follows the same lines.

Public places (library, internet cafe, commercial centers) are places where students connect to internet with computers or laptops, with other devices (Wi-Fi or, mobile phone), where declare that last 12

months are connected everyday with 24.0%, 15.3% once or twice a week, 25.4% rarely, 23.7% never and 11.6% declared don't know.

The main use of the Internet in two universities in Tetovo is seeking the information and the materials for their professional activities in the framework of their studies, then its fun, download music, movies and software. Following by watching television, performing administrative activities, creating a website and looking for a job from the internet (Figure 2).

Figure 2 Among the following uses, indicate what you have done in the past 12 months, on a computer or the Internet?

Regarding the communication of students from their homes via the Internet 44.8% reported that call by placing a microphone on their computer or using software such as Skype or Net Meeting and 33.9% call connecting fix phones on a box as (Freebox, 9box, Livebox, Cbox...), also connected with phone jack figure 3.

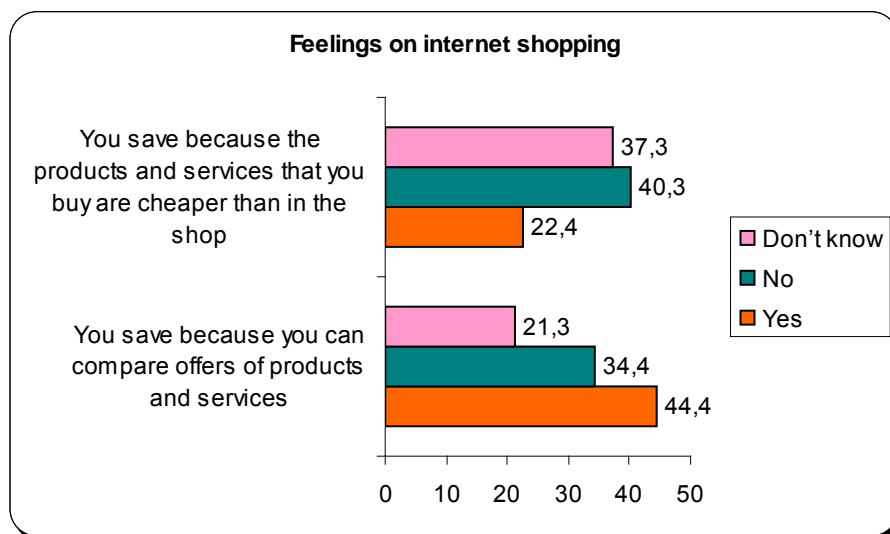

Figure 3 Do you call from home through internet (by way of the Internet) ..?

Related to shopping via the Internet, 21.6% of students say they are shopping using internet (graph 4)., then review and thanks to the Internet they can save while comparing offers and service, with a large percentage stating that they do not know with 37.3% and 21.3% respectively (Graph 5). This comes as a result they do not use this service.

Graph 4 In the past 12 months, have you made any shopping via Internet (books, disks, travel tickets, computer equipment, food, etc.)?

Graph 5 Do you feel that thanks to the Internet ...

When asked whether internet and computer is a threat or an opportunity for artistic creativity, environment and sustainable development and employment they claim that artistic creativity is a chance with 62.2%, 54.4 employment and environment and sustainable development with 43.2% (graph 6).

Graph 6 According to you, computers and Internet are a threat or an opportunity for ...

The Internet is a media that allows better tracking of reality with 30.3%. But to follow the reality is television with 27.3% then the Internet 25% (**Graph 7**).

Graph 7 Among the following media, which is according to you that which lets you do better tracking and understanding of reality?

The element that most curbs Internet usage is the quality of service (speed, cuts, .) which is not satisfactory with 21.3%, personal data are not protected properly with Internet 18.6%, following the subscription price and equipment and with a small percentage is that the Internet is not necessary for daily life.

3. Conclusions

Results show that information and communication technologies are used more in student environments. They are related to personal development, a typical example is mobile phone, computer, and laptop and so on. The introduction of technologies for domestic purposes also has

huge growth compared to previous years. Internet shows that it has become a mass communication tool. This comes from that the universities in Tetovo created conditions of ICT which are of great importance to students. And the connection to the Internet at home and more frequent use of the Internet follows the same lines. This comes as a result of the fact that most students come from families that have a good economic status. The Internet has become part of everyday life of students, where 75.4% use Internet every day: looking for information and materials for their professional activities under study, for communication fun and different information. Moreover, the use of ICT is very important for the students after finishing their studies. Knowledge of ICT can help students in the future to find a job and gives them a competitive advantage compared to others who are not familiar with ICT.

Empowering Youth Entrepreneurship through Online Business

Mira Kartiwi¹, Abu Osman²

^{1,2}Department of Information Systems, Faculty of Information and Communication Technology, International Islamic University Malaysia, mira@iiu.edu.my

The notion of entrepreneurship has grown in importance in the global economy over the last couple of decades. Both the theoretical and practical economic and business development literature acknowledge the key contributions of entrepreneurship and SMEs, to the development both nationally and internationally growth of economy. Among the initiatives taken by governments to promote the entrepreneurship and to boost the number of SMEs establishments is through the introduction of entrepreneurship course into the university curriculum. However, previous research highlights the varying degrees of success of this initiative. One of the issues that lower the effectiveness of the entrepreneurship courses offered by these higher education institutions was the lack of teaching tool that enables to students to learn the know-how of being an entrepreneur. It is the aim of this paper to examine and propose the use of electronic commerce (e-commerce) portal as an entrepreneurship course teaching tools. A survey was carried out to explore the potential benefits of implementing such portal as an educational tool and incubator to enhance the entrepreneurship skills among our youth in higher education institutions.

Keywords

Developing Countries, Electronic Commerce, Entrepreneurship Education

1. Introduction

Much has been said on the importance of youth entrepreneurship. In fact, entrepreneurship has been seen as one of the important pillars on which economic health of societies was built [1, 2]. Particularly for developing countries, young entrepreneurs have been identified as critical resources that need to be tapped to enable them to compete in a globalizing market economy [3, 4].

It is also very clear that increasing number of graduate unemployment is driving government policy to equip student with entrepreneurial skills, knowledge and abilities [5]. Despite the widespread recognition on the importance of the entrepreneurial education in higher education institutions, the entrepreneurial action at graduation remains low [5]. This might be attributable to the nature, focus and process of the education in many tertiary institutions that often too mechanistic and does not promote entrepreneurial activities and behaviours [4].

Therefore, it is the aim of this paper to examine the potential benefit of adopting electronic commerce (e-commerce) portal as an educational tool in tertiary institution.

2. Entrepreneurship Education

Given the importance of entrepreneurship to a nation's economy, governments have taken their step to promote the entrepreneurship and to boost the number of small firm establishments through the introduction of entrepreneurship course into the university curriculum. However, recent study show that the level of entrepreneurial action at graduation are still far below expectation [5]. Earlier research [6] explained that such phenomenon may be due to the fact that formal education in general does not encourage entrepreneurship. Rather it prepares the students for corporate domain, promotes 'job-taker' mentality and suppresses creativity and entrepreneurship [7]. In other words, the focus and

process of the education, particularly in many tertiary institutions, often too mechanistic and does not promote entrepreneurial activities and behaviours [4]. Thus, these educational and training institutions are facing the challenge of how to create an enterprise culture which will further foster the development of small firms.

Given the critical role of tertiary institutions in promoting more entrepreneurial attitudes and behaviours among their students, more and more attentions have been given towards the research within the area of entrepreneurship education. A number of studies had rigorously assessed the success of many university-based entrepreneurship curricula. Among the recommendations made in these studies was the importance of tertiary education to incorporate interactive learning, experience based learning, role models, as well as community and business links [4, 7-9].

3. Teaching Tool: E-commerce Portal

Today, e-commerce is radically changing the dynamics of the business environment and the way in which people and organisations are conducting business with one another. Indeed, Lee et al. [10] suggest that e-commerce has altered the outlook of businesses by focusing more on information which they term as economics of abundance. In addition, e-commerce is known for its capacity to remove barriers to entry and allows competitive local companies to reach more markets in an effective and efficient way [11].

Despite the many anticipated benefits of e-commerce, little or no attempt has been done on utilizing such technology for educational purposes. The author believe that through the use of e-commerce portal, the tertiary institution would be able to create a program that incorporate an interactive learning, experience based learning, role models, as well as community and business links as proposed by earlier research [4, 7-9].

As part of this study, an e-commerce portal – named Geraiserumpun.com – was developed to enable the students to promote their product and run an online business. This portal is aimed to enhance the current entrepreneurship course that mainly focuses on enhancing the skills on writing a business plan.

In addition to the use of this portal as a tool for entrepreneurship teaching and learning, the e-commerce portal will also serve as:

- Forum for students to exchange ideas and information
- An avenue for students to experience managing a real online business
- An avenue for the Government to disseminates any information on assistances and business set up procedures for young entrepreneurs
- Online business incubator

On the implementation of the portal, each student will be given a seller account (see Figure 1) that will allow them to post products or services as they have proposed on the business plan. In the seller's page, the student also would be able to monitor of any order made by customers and the availability of the products being advertised.

Whereas for the instructor of the course, one of important element that could be observed by using such systems is the student's creativity in promoting the product, such as putting the right description, post the right and attractive images of the product, and so on. From the instructor account, the instructor would also be able to monitor and observe students ability and promptness to respond customers' orders and enquiries.

It is also important to be emphasized that the reason of not using the readily available external e-commerce portal – such as *ebay* or other local portals – is due to the restrictions that many these portals have. These restrictions would include the requirement that the student should register using credit card or bank account, and the inability for the instructor to monitor the 'back office' of the students' business. Therefore, in reducing the students' apprehension in revealing their financial information online, this portal will be adopted. Other benefit of using such portal is the ability for the instructor to include the course materials and any other relevant information – such as, government policies and regulations – that would increase the students' awareness in starting up their own business.

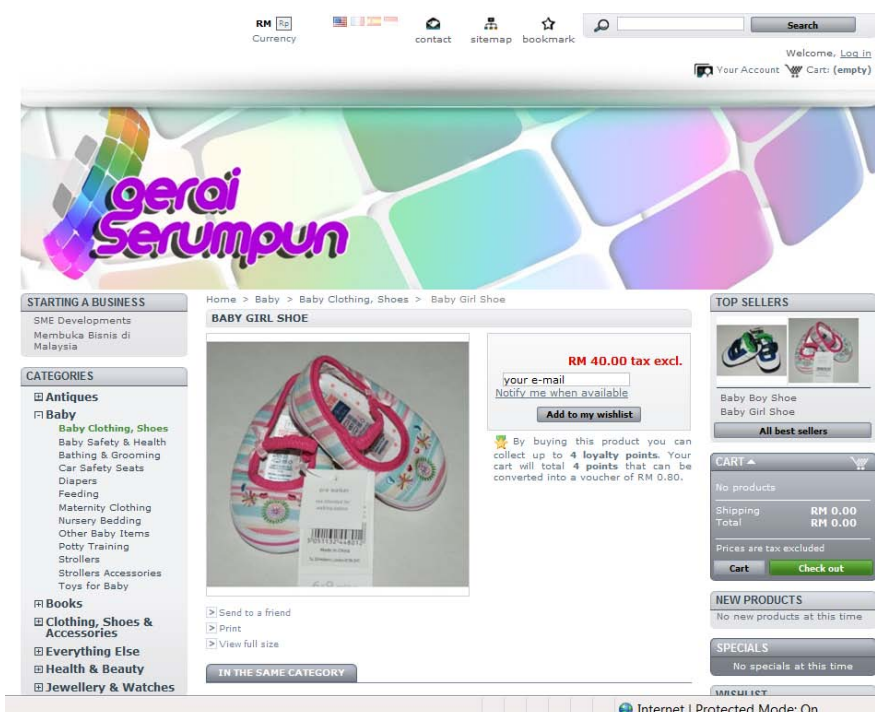

Figure 2 Product Catalogue of Geraiserumpun.com

4. Methodology

The aim of this research is to investigate the potential use of electronic commerce (e-commerce) portal as an entrepreneurship course teaching tools. A survey was carried out to explore the potential benefits of implementing such portal as an educational tool and incubator to enhance the entrepreneurship skills among our youth in higher education institutions.

In order to accomplish the above aims, a purposive sampling was used in this study to obtain useful information from local and international undergraduate and postgraduate students studying in International Islamic University Malaysia. Given the nature of purposive sampling, respondents were chosen from different disciplines according to a pre-set quota. In this pilot study, however, the respondents' discipline will be divided into two categories, namely business and non-business disciplines. Each discipline category will be represented by an equal number of respondents.

Self-administered questionnaires were distributed to targeted students. This method allowed respondents to clarify doubts and ask questions on the spot and thus motivate respondents to

participate in the survey. During this pilot survey was conducted, 110 questionnaires were distributed to graduate and postgraduate students within a period of one week.

5. Results

The aim of this research is to investigate the potential use of electronic commerce (e-commerce) portal as an entrepreneurship course teaching tools. A survey was carried out to explore the potential benefits of implementing such portal as an educational tool and incubator to enhance the entrepreneurship skills among our youth in higher education institutions. Cross tabulation and Pearson Chi-square were used to analyse the data obtained from the questionnaires. Gender, level of education, student's educational discipline background and their intention to start their own business were crossed with the perceived of benefits of using e-commerce portal to enhance their learning experience in entrepreneurship course.

Table 1 Chi-square Analysis of Perceived Benefit of Using E-commerce Portal among Males and Females Students

Gender	n	E-commerce portal will enhance my entrepreneurship course experience		χ^2	p
		Yes	No		
Male	55	39	16	.767	.381
Female	55	43	12		

An examination of Table 1 shows that there is no significant relationship between gender and students' perceived benefits of using the e-commerce portal in their learning experience. This result confirms earlier work by Veciana et.al [12] who found similar finding in their study of university students' attitudes towards entrepreneurship in Puerto Rico.

Table 2 Chi-square Analysis of Perceived Benefit of Using E-commerce Portal among Undergraduate and Postgraduate Students

Degree	n	E-commerce portal will enhance my entrepreneurship course experience		χ^2	p
		Yes	No		
Undergraduate	73	54	49	.038	.520
Postgraduate	37	28	9		

An examination of Table 2 also shows no significant relationship found between students' level of education and their perceived benefits of using the e-commerce portal in their learning experience. Despite an earlier finding of a study conducted by Bates [13] who suggests that people with higher level of education are more likely to have a positive attitude towards entrepreneurship compared to those who do not, clearly it does not demonstrate in the current study.

Table 3 Chi-square Analysis of Perceived Benefit of Using E-commerce Portal among Business and Non-business Disciplines Students

Discipline	n	E-commerce portal will enhance my entrepreneurship course experience		χ^2	p
		Yes	No		
Business	55	36	19	4.791	.029
Non-business	55	46	9		

To investigate whether students from business and non-business discipline differ on their perception towards the benefit of using e-commerce portal in their entrepreneurship course, again, a Chi-square was used. An examination of Table 3 shows the Pearson chi-square result indicates that students from business and non-business discipline background are significantly different on their perception toward the benefits of using the e-commerce portal in their learning experience.

In the current study, the result shows that students from non-business discipline are more likely to perceived the benefits of using e-commerce portal compared to those from business discipline ($\chi^2 = 4.791$, $p < .05$). Such difference is perhaps due to a better knowledge and exposure to greater business context that students from business discipline have, thus inspire them to enhance their entrepreneurship through other means. While for students from non-business discipline, an e-commerce portal could be seen as an easier way to experience a 'real world' of entrepreneurship [4].

Table 4 Chi-square Analysis of Perceived Benefit of Using E-commerce Portal among Students

Plan to open a business in the future	E-commerce portal will enhance my entrepreneurship course experience			χ^2	p
	n	Yes	No		
Yes	81	64	17	5.355	.021
No	22	12	10		

An examination of Table 4 shows the Pearson chi-square result also highlight significant relationship between students' intention to open a business in the future and their perception of benefits of using the e-commerce portal in their learning experience.

As expected, the result shows that students who plan to open a business in the future are more likely to believe that the use of e-commerce portal will enhance their entrepreneurship course experience ($\chi^2 = 5.355$, $p < .05$).

6. Conclusions

This paper mainly highlights two important findings. First, align with the findings of previous studies [4, 5, 7], student's attitudes towards starting their own business significantly impact the entrepreneurial learning experience. This thus lead to the second finding, that is, the enterprise education should be tailored to suit the non-business disciplines where many business/product ideas emerge, but are often ignored because the students are not adequately educated with the knowledge and skills required.

Therefore, it is critical for higher educational institutions to engage experts from multidisciplinary background when designing programmes to suit different student groups. This will then improved students' awareness of the reality of working in their field. Also, perhaps at the same time, the well designed entrepreneurial education programmes will provide the students with awareness, interest and preparation for self-employment as a career alternative.

E-commerce and Female Entrepreneurship Development in Urban and Rural Developing Countries

Mira Kartiwi¹

¹Department of Information Systems, Faculty of Information and Communication Technology, International Islamic University Malaysia, mira@iiu.edu.my

The importance of the small to medium enterprise (SME) sector as the cornerstone of most economies is widely recognised. This is not only borne out by the number of SMEs (almost 90% of the total number of businesses across the world), but also by their significant role in creating employment opportunities. SMEs are considered to be the only realistic employment opportunity for those in lower income brackets, especially women in developing countries. However, studies also show that there are inherent issues impede the growth of female-owned SMEs, particularly those in rural areas in developing countries. Among others are the difficulties in accessing financial assistance to set up a business, the child-rearing obligation which limits women's mobility and access to information of the available market. Electronic commerce (e-commerce), on the other hand, has radically changing the dynamics of the business environment and the way in which people and organizations are conducting business with one another. For SMEs, e-commerce has the potential to become a source of competitive advantage. E-commerce is a cost effective way of accessing customers globally and competing on par with large businesses. Despite the many benefits of e-commerce, little research has been done to investigate the role of e-commerce in mitigating the location and gender specific barriers to SME growth. Therefore, it is the aim of this study to address such gap in the literature, as well as to identify strategy that can be used to stimulate the development of female-owned SMEs in urban and rural developing countries, using Indonesia as case study.

Keywords

Developing Countries, Electronic Commerce, Entrepreneurship, Gender, Rural Development.

1. Introduction

For developing countries, integration into the global economy through economic liberalisation, deregulation, and democratisation is seen as the preeminent way to overcome poverty and inequality [1]. SMEs are considered to be the only realistic employment opportunity for those in lower income brackets, especially women [2, 3] in developing countries. This is especially the case for most of the countries in the Sub-Sahara, South East Asia, and lower income parts of Latin America, where the private economies are almost entirely comprised of SMEs [3].

Electronic commerce (commonly referred to as e-commerce), is where business activities are enhanced and accelerated by the Internet, and is one of the technologies being promoted by Governments to address some of the critical issues affecting SMEs [4]. It provides the opportunity for low-cost entry into the global marketplace [5] where this was once seen as impossible for the SME sector. Among other advantages noted in the literature, are increased access to markets [6], increased partnerships between large/intermediate and small businesses [7], and improved communications with customers and suppliers [8]. Given the benefits of e-commerce discussed above and the strategic roles of SMEs, more and more Governments both in developed and developing countries are now promoting the use of e-commerce in SMEs. However, developing countries are facing different challenges compared to their developed counterparts.

One of the renowned challenges to developing countries is the widening development disparity between urban and rural areas. In their report titled “Reducing disparities: Balanced development of urban and rural areas and regions within the countries of Asia and the Pacific”, the United Nations [9] suggests that rural-urban disparities continue to be much in evidence because development policies are largely determined by urban-based groups, especially those in the main cities. This means that there is little awareness of the actual rural needs or the problems facing rural SMEs, as policies are pre-occupied with urban issues. As a result, many of the policies and development strategies in developing countries seem to be directed to giving more privilege to some groups while the majority of the population feel left out [9]. Therefore, in order to mitigate the urban-rural development disparity and to provide the same opportunities for rural SMEs to grow and succeed, an understanding of the actual needs or the problems of rural areas requires urgent attention. Particularly, promoting e-commerce use to increase female entrepreneurs SMEs’ competitiveness and identifying the urban-rural differences facing SMEs in adopting e-commerce are essential first steps. This is extremely important if Governments believe that e-commerce can foster economic development.

However, no previous research has attempted to examine how e-commerce is being adopted by female-owned SMEs – or issues that inhibit them to adopt – by comparing the situation in urban versus rural areas, particularly in developing countries. Therefore, it is the aim of this study to fill this gap in our knowledge by investigating the differences in e-commerce adoption between urban and rural female-owned SMEs in developing countries, using Indonesia as a case study.

2. E-commerce and SMEs in Indonesia

Small and Medium Enterprises (SMEs) historically have played vital roles in the Indonesian economy. They continue to receive significant attention from both Indonesian policy-makers and researchers. This importance is reflected through the high proportion of SMEs in Indonesia, the level of employment in Indonesian SMEs, and the percentage of GDP attributable to SMEs (see Table 1). A survey conducted by the Indonesian Central Bureau of Statistics [10, 11] shows that the majority of SMEs are located in rural areas and are linked to the local economy. As such, SMEs are becoming important players in the development of regional economies and communities as well as in the elimination of poverty by providing job opportunities, particularly for women and people in lower income brackets.

Table 1 Proportion of Small and Medium Enterprises Contribution to GDP

		2009
		Percent
1	Small Enterprises	43.06
2	Medium Enterprises	13.47
<i>Total SME contribution to GDP</i>		<i>56.53</i>
3	Large Enterprises	43.47
TOTAL		100.00

Source: DEPKOP (2010) Indonesian Statistics of SMEs, <http://www.depkop.go.id>

Furthermore, the growth of SMEs in Indonesia has been dramatic. Currently there are a total of more than 40 million SMEs in Indonesia - in 2009, they accounted for 99.9 percent of the total number of enterprises (see Table 2). Indonesian SMEs has been able to adjust to financial crisis and maintain employment levels while other sectors of the economy have contracted.

Table 2 Number of Small Medium Enterprises in Indonesia

		2009	
		Unit	percent
1	Small Enterprises	52,723,470	99.92
2	Medium Enterprises	41,133	0.07
		52,764,603	99.99
3	Large Enterprises	4,677	0.01
TOTAL		52,769,280	100.00

Source: DEPKOP (2010) Indonesian Statistics of SMEs, <http://www.depkop.go.id>

As can be seen from the data in Tables 1 and Table 2, SMEs play a key role in the economic development of Indonesia and this has led the Indonesian government to give greater attention to the sector as a whole. SMEs are now a focus of employment opportunities, a large contributor to economic and social development through diversification and provide a structure that can promote and sustain long term economic growth [12].

The prospects of e-commerce in Indonesia are bright as there is a rapid increase in the number of Indonesian connected to Internet, which has placed the country in the “Asia Top 10 Internet Countries” [13]. In recognising the prospect of e-commerce and the importance of SME growth to the national economy, the Government has taken several initiatives dedicated to promoting and encouraging SMEs to go online. This is manifested in symposia and forums organised for SMEs [14, 15], online websites, television and radio programs as well as articles in the media [16].

By adopting e-commerce, the Government aims to improve SMEs access to information – such as to find potential buyers; to locate product/service suppliers; and to undertake price/product comparisons. Other expected benefits of e-commerce were improved marketing and improved competitiveness [17]. Although many programs and incentives have been initiated for SMEs, the level of e-commerce adoption among SMEs is still low in Indonesia. Hence, in order to understand the lack of, or slow uptake of e-commerce technologies, one should look into the environment in which they operate. In addition, previous studies [18, 19] also highlight the significant influence of gender on the perceived factors that inhibiting the uptake of e-commerce.

3. Female-owned SMEs in Indonesia

Studies in developed countries show that women are one of the fastest rising populations of entrepreneurs [20]. They make a significant contribution to innovation, job and wealth creation in many economies. However, recent studies also show that the level of women participation in entrepreneurship varies significantly from country to country, and in spite of national variations, women participation rates across countries is measurable at about two-thirds that of men [21, 22].

Despite the rapid growth of women participation in entrepreneurship across the globe, the participation of women in entrepreneurship is still at a very low level. The number of business actors or entrepreneurs in Indonesia is under two percent of the total population, whereas of this, the population of female entrepreneurs is still below 0.1 percent [23]. This low level of women participation in entrepreneurship may be attributable to, among others, the difficulties in accessing financial assistance to set up a business [21, 24]. Other possible caused, particularly in developing countries, is the child-rearing obligation which limits women’s mobility and access to information of the available market [25] and other networks in acquiring resources [26].

4. Methodology

The study presented here is part of ongoing study into IT and e-commerce adoption in small to medium sized enterprises in Indonesia. The larger study was concerned primarily with SMEs located in rural areas, especially since no other research has investigated e-commerce adoption specifically in these areas. As a result, the study was conceived primarily as exploratory in nature.

In conducting the survey, the draft questionnaires (both adopter and non-adopter version) were pre-tested by six SMEs entrepreneurs (with 4 adopters and 2 non-adopters). These entrepreneurs were

the participants that also contributed to the qualitative phase of this study. The pre-testing provided constructive feedback that served to ensure that the questionnaire could be administered in less than half an hour, that items on the questionnaire were easy to read and understand, that the survey was free from ambiguity and bias, and that the terminology was relevant to SMEs entrepreneurs. Modification was made in accordance with their suggestions.

The final version of the questionnaire was then translated into Indonesian language (Bahasa Indonesia) by the researcher, and was then reviewed and edited with the assistance of IT consultants and lecturers in Indonesia. The questionnaire was then translated back to English by a different person so as to ensure that the translated instrument carried the same meaning as the original version.

A total of 330 questionnaires were distributed, and only total of 179 responses was collected, which gave a response rate of 54.24 percent. Of these usable responses, only 36 respondents were female – with 16 e-commerce adopters and 20 non-adopters.

5. Results and Findings

It is the aim of this study to investigate the differences in e-commerce adoption between urban and rural female-owned SMEs in developing countries, using Indonesia as a case study.

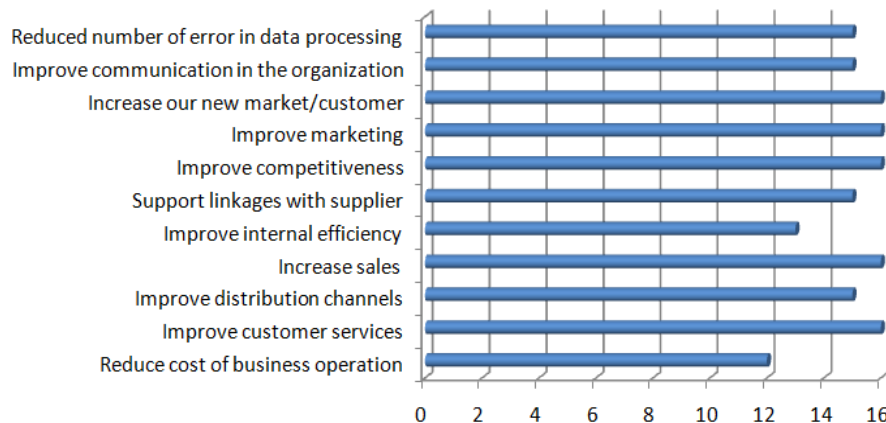

Figure 1 Benefits of E-commerce Experienced by Female-owned SMEs

An examination of Figure1 shows that, among adopter respondents, it is found that most of the benefits of e-commerce suggested by previous studies were also experienced by female entrepreneurs in Indonesia. However, among the identified benefits, only small number of female entrepreneurs agreed that e-commerce had helped them to reduce cost of business operation. In order to better explain the possible cause of such phenomenon, the data was then divided according to their business location to enable the comparison between urban and rural areas.

The comparison of the results from the two locations as indicated in Figure 2 shows that there is similar experience on some of the benefits generated from e-commerce adoption. These are: increased our new market/costumer, improved marketing, improved competitiveness, increased sales, and improved customer service. Interestingly, there are two benefits of e-commerce that was rated differently by women entrepreneurs in urban and rural areas, namely improve internal efficiency (urban = 100%, rural = 66.7%) and reduce cost of business operation (urban= 87.5%, rural = 66.7%).

The smaller number of female entrepreneurs in rural areas experienced the 'improved internal efficiency' benefit of e-commerce compared to those in urban area, may be attributable to the nature of the businesses in this area. Generally businesses in rural area are family businesses and many of the decisions are made personally by the entrepreneur, thus make corporate structure simple and did not require a complicated internal mechanism.

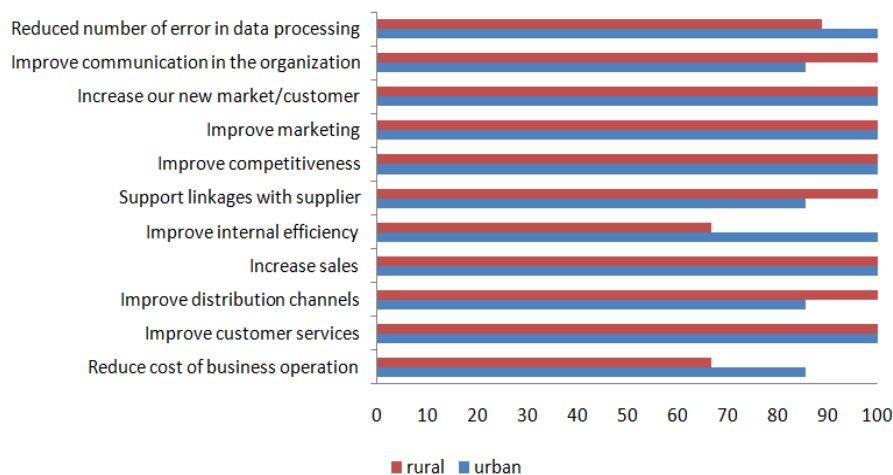

Figure 2 Benefits of E-commerce Experienced by Female-owned SMEs in Urban and Rural Areas

Whereas, the smaller number of female entrepreneurs in rural areas found that e-commerce had helped them to reduce the cost of business operation highlights the development disparity between urban and rural areas in Indonesia. While the urban businesses have the privilege to enjoy a fast connection broadband, many of the rural businesses are connected to the Internet using a dial up connections. This dial up service is often too slow as some area the speed may only be about 20-23 kbps, and yet they still have to pay for an expensive metered call [27, 28].

Figure 3 Barriers to E-commerce Adoption Experienced by Female-owned SMEs

In examining the barriers to e-commerce adoption, Figure 3 shows that, among non-adopter respondents, it is found that most of the inhibiting factors to e-commerce adoption by Indonesian female entrepreneurs were the lack of knowledge and skills on using e-commerce, and difficulty in choosing appropriate e-commerce technology that suitable for them. However, different to expectation, only a very small number of respondents found the inability to perceive the suitability of e-commerce to their product and services as well as other benefits of this technology, to be the inhibiting factors.

Again, the data was then divided according to their business location to enable the comparison between urban and rural areas.

The comparison of the results from the two locations as indicated in Figure 4 shows that there are differences on how barriers were perceived by female entrepreneurs in the two locations. It is found that 92.9% of the e-commerce non-adopters in urban area believe that difficulty in choosing the appropriate e-commerce technology was the most important barriers that led them to forgo the adoption of this technology.

Figure 4 Barriers to E-commerce Adoption Experienced by Female-owned SMEs in Urban and Rural Areas

Whereas in rural area, as expected, the two key inhibiting factors to e-commerce were the lack of knowledge and skill of using e-commerce and the lack of time to adopt. This results echo previous findings of Minniti et.al [26] and Handy et.al [29] who found that rural women tend to have less access to education and other resources compared to those located in urban area.

Clearly, as the results show in this study, there are different challenges faced by female entrepreneurs in urban and rural area. This highlights the need for a different set of strategy to be implemented in these two location categories. Perhaps, to increase the awareness of e-commerce in rural area, the Government could develop a *telecentre* in the same area as where the local kindergarten or primary school is. This, thus, will enable the local rural women to participate in various training activities provided by the Government by not leaving their main duty to take care of their children.

6. Conclusions

This study has shown that e-commerce has successfully level the playing field. With the development of e-commerce, female entrepreneurs will be able to enjoy a convenient access to a greater market improved their business competitiveness. E-commerce has also become an important avenue of the IT-enabled home based working. The e-commerce technology had provided an easier and cost efficient for female entrepreneur, particularly those in urban area, to run a viable business from home. This finding advocates the need to promote the use of e-commerce within women-owned SMEs as suggested by UNCTAD [30]. In the report, UNCTAD [30] considers e-commerce as a “potential gold mine for women in developing countries”, since it opens the opportunities for self-employment for women in the developing world, be they micro-entrepreneurs or women working from home, to earn income and save time and costs while also meeting their family responsibilities. Success stories recorded in that report included the e-marketplace called IndiaShop in India that has eliminated middlemen in the selling of saris and also a nationwide housewives’ network in Peru, Tortasperu, which bakes confectioneries and sells them over the Internet.

The finding of this study also shows that a greater attention is needed to be geared towards increasing the female entrepreneurs’ capabilities particularly in relation to ICT areas by taking considerations of their locations and the responsibilities they have to ensure the work-life balance.

Professional education and entrepreneurship challenge for Albania.

Mimoza Kasimati (Skenderi)¹, Semiha Loca²

¹Faculty of Economy, Tirana University, Albania, moza_kasimati@yahoo.com

²Semiha Loca, University Marin Barleti, Tirane, Albania, semi.loc@gmail.com

During the last 20 years, the close down and privatization in Albanian economy brought about a surplus in the labour offer for some key specialties and professions. The unemployed professionals changed occupation, or emigrated. A shortage of different professionals is feeling in the everyday life. The new developments have also created a remarked need for some new professions, which are performed by unqualified individuals by now. Meanwhile, there is a boom in higher education, not accompanied by the creation of specialists in these professions on demand; many of which can be created by the high school education. The Government of Albania has now understood that there is an imperative need to strengthen the high education that educates professionals. But in spite of the measures taken, there is still not the expected massivity in this kind of education, and potential high quality students prefer the general education, instead. Although there are reports of economic growth, there is not enough growth in the formal side of the labour market that may allow the employment of high school professionals. Those who choose this kind of education have no clear chances of employment, and the majority reorients their career on further education. The only possible way for them to make use of the profession taken by the high education, and for the country to move out of this crossroad, is to engage in private/individual enterprising.

As an economy in transition and inspiring European inclusion, Albania needs to create a sustained basis of growth. Self-employment sustained by the entrepreneurial learning is an important way for economic efficiency as well as an alternative way to joblessness.

Focused on the role of the Albanian professional education in creating the entrepreneur, the authors of this study analysed the Strategy of Education, the curricula and study programs of the professional education and conducted half structured interviews with school directors and curricula authors. The purpose was to understand how individual traits and behaviours, such as creativity, opportunity identification, risk assessment and risk taking, and resource management which make up the entrepreneurial character are included in the curricula. It came out that entrepreneurship is introduced as a key competence within mainstream curriculum. This is made possible by innovative teaching and learning arrangements that are part of the reform in education. Structured interviews with students of the professional schools were conducted, focused on the motives for choosing this education, the perceived possibility offered by the actual study programs.

Keywords

Professional High School Education, Entrepreneurship Education, curricula.

1. The rationale

Until 1990, the words *mass production* and *massivity* were very familiar in Albanian reality. There was mass production in many industries, mass production in agriculture, massivity in education, etc. During the 5-year Plans of the State, the focus on education changed according to the transformations

in the economic sphere. Increased industrial investments modified the state's demand for educated people, orientating their capacities toward non-agricultural means of production. This demand was reflected in the number of vocational schools that sprang up with programs in technical professions that were designed to support industrial technological development. By 1980 the number of schools and teachers had tripled compared with 1960, clearly demonstrating the state's efforts to increase the quality and the quantity of education programs [1]. At the same time, the number of students had doubled, increasing both the average length of study and the percentage of people who completed primary education. The state's vision about secondary education in Albania was ambitious, and included objectives to increase the number of people with vocational training. (Table 1)

Table 1

Years	1950	1960	1970	1980	1990
NUMBER OF SCHOOLS					
Primary	193	557	1374	1559	1726
Secondary,vocational	17	69	131	263	466

Secondary,general	91	502	1157	1732	2318
Tertiary	13	288	926	1103	1806

Source: Albanian statistical yearbook 1989.

Each year the number of students in vocational training was greater than the number enrolled in general secondary education, vocational schools far outnumbered those offering a general education. The vocational schools were diffused throughout the country, which was consistent with the state objective of increasing equity in educational achievement between urban and rural areas. The huge expansion was in response to the economy's need for professional skills in the labour force, mainly in agriculture and industry. On the other hand, general education was not popular and the state was less involved in expanding the number of such schools. They were nevertheless on the increase in the last years of the regime, from 17 institutions in 1980 to 43 in 1989. The number of students in higher education doubled from 1960 to 1980 and reached at 27,000 in 1990. Even so, the state was parsimonious in the recruitment of the students after completion of secondary education and the selection was made by rigorous vetting procedures [2]. About 40 percent of students finishing secondary school entered at the tertiary level in year 1980.

Education was generally of a high quality and based on strict army-like discipline, uniform programs, uniform methods of teaching and studying, uniform dress and uniform models of behaviour. Education on all levels was centrally controlled and highly bureaucratic, and was particularly influenced by the need for an instrument of ideological indoctrination [3]. The system rested on a triple foundation of theoretical learning, productive work and physical as well as military training. Above all, the educational system was meant to prepare young people for the entry into the centrally planned economy.

In this kind of system, the level of education attained by individuals had less to do with overall economic success than it typically does in a market economy. Many well-educated people during the communist period earned only a little more (and sometimes less) than production workers, although they did enjoy better working conditions, an important "non-wage benefit". Centralized planning artificially controlled the demand for education and employment.

To conclude, the communist regime made real efforts to increase of school attendance. At the end of the communist period in 1990, about 45 % of the population between 35 and 45 years had completed secondary education [4].

But there are years now that this *massivity* is no more a matter of fact. Close down, downsize, privatization, are the words in these last 20 years. This of course, was accompanied by a surplus in the labour offer for some key specialities and professions.

After 1990, the Albanian system of vocational education was abandoned in favour of general secondary schools. The ratio of students undergoing vocational training versus the total in secondary education was much lower in 2003-2004 than in 1990 [5], indicating a dramatic change in the educational system. Before 1990, vocational schools provided agricultural and industrial training, and 70% of the students attended those schools. After 1990, the unemployed and unwanted labour power educated in these professions, changed occupation, or emigrated. Most of schools were subsequently closed, and today vocational education does not play an important role in the context of secondary education [1]. The situation has worsened by the failure of vocational training in the regions.

Not only the state withdrew from financing such an expensive network of schools, but young people themselves are showing more interest in general education as a way to build opportunities in various types of postsecondary or higher education.

The specific nature of vocational training is lagging far behind young people's aspirations. The number of vocational schools in 2003-2004 was only 53 (a mere 4 of which were located in rural areas) compared with 454 schools in 1989. Pupils in vocational education represented about 16 percent of children registered in secondary education in 2004 (21,900 students). Vocational schools are a male domain, enhancing their professional orientation toward technical positions.

However, the type of qualifications, as well as the specific knowledge/skills that young people acquire in the educational system, often does not fit the labour market demands. Albania's market reforms did not create efficient links between schools and enterprises. Examples still exist of narrow vocational training for employment in industries for which demand has now collapsed.

The centrally planned economy's historical emphasis on industry and agriculture at the expense of services had major implications for the education system. Every day now, a shortage of different professionals is feeling in the everyday life. The new developments have also created a remarked need for some new professions, which are performed by unqualified individuals by now. Meanwhile, there is an increase in massivity in higher education, not accompanied by the creation of specialists in these professions on demand; many of which can be created by the high school education.

According to OECD evaluation [6] Albania's young people, like those in other transitioning countries, need to prepare for a world where they will have to make intelligent choices, solve un-anticipated problems, and take responsibility for finding their own paths in a rapidly changing economy. None of these skills was highly prized under the old system—centrally planned economies emphasized the learning of carefully selected facts, because they left little room for uncertainty, and they did not encourage independent thought. By contrast, life in a market economy means that most young people will change jobs and occupations several times during their working lives, and to do this they need independent thinking and learning skills[7]. Pupils are probably still over-tested but under-assessed in terms of flexible skills.

The Government of Albania has now understood that there is an imperative need to strengthen the High Education that educates professionals. Vocational Education follows right after the 9-year basic education track and has as its main goal to enable students to develop vocational skills and practical knowledge. This type of education yields craftsmen with the necessary skills for a specific job, but also allows pupils to carry on with higher education.

During the academic year 2009-2010, a new Vocational Education structure (41 vocational schools in total) is introduced. It consists of three levels (2, 3 and 4 years of education). This structure is in conformity to the International Standard Classification of Education (ISCED), with the Albanian Qualification Framework (AQF) and with the European Qualification Framework (EQF). Commencing with the 2009-2010 academic year, vocational schools apply the new Frame Curricula for Level I (covering 22 educational profiles), which is developed by the National Agency of Vocational Education and Training (NAVET). The level II of VET will comprise two or additional profiles, in order to keep up with labour market needs.

But in spite of the measures taken, there is still not the expected massivity in this kind of education, and potential high quality students prefer the general education, instead (Figure 1).

Source: Developed by the authors over the data from the Ministry of Education.

As we see in the red column, the General Education has its high and low developments in these 20 years of decentralised economy, but the Vocational Education enrolment (the turquoise column) is always comparatively low.

Although there are reports of economic growth, there is not enough growth in the formal side of the labour market that may allow the employment of high school professionals. Those who choose this kind of education have no clear chances of employment, and the majority of them reorient their career on further university education. The only possible way for them to make use of the profession taken by the higher education, and for the country to move out of this crossroad, is to engage in private/individual enterprising. In these grounds, many questions arise: How much is the high education, especially the professional direction helping to develop the entrepreneurial capabilities of the students? How many individuals graduated the professional education have opened their own activities? What is the actual entering cost in the actual market for a certain profession? Is there any state policy in favour of this entrepreneurship?

The individual motives and attitudes of the students themselves are the other very interesting side of the token. Are they conscious that many of them will have to cope with the challenge of creating their own employment? How much do they feel supported from the actual study programs to cope with this immediate future challenge? Is there applied any selection policy by the professional schools, based on the knowledge that the entrepreneur has some special personality characteristics? Some of these questions were in the base of our inquiry and what we discovered is broadly explained in the following parts of this paper.

2. Literature review

For the purpose of this study, a literature review was considered, with the main concern on: The role of formal education in developing the entrepreneurs' characteristics; the characteristics of the entrepreneur, and the role of entrepreneurial education in a country's development.

Empirical data shows that the development of enterprise within a country can create wealth for the country by lowering unemployment levels, reducing the dependence on welfare and generate tax revenue for the country [7]. Governments can take direct policies to promote entrepreneurship within their country ranging from financial initiatives to educational training [8]. Carter and Wilton [7] discuss the importance of entrepreneurial education in government policy citing the example that "just making finance available without the training on its proper management is inadequate". It can therefore be seen that there is a growing desire not only for entrepreneurship within a region but also entrepreneurial education.

Entrepreneurial education is continually increasing in developed countries with the level of courses provided at higher educational institutes greater than ever [9]. According to Chell and Allman [10], "over the last two decades there has been an increase in the number of courses and programs aimed at entrepreneurship and enterprise." There has also been an increase of entrepreneurial education in developing nations with focus on using entrepreneurship as a method of economic development in these regions [11]. As Falkäng, Kyro and Ulijn [12], "The past twenty years have witnessed an

enormous growth in the number of entrepreneurship courses at different educational levels" There are many forms of entrepreneurial education ranging from pre-university entrepreneurial education at both a primary and secondary level and also both publically funded and privately funded entrepreneurial programs at both a local and national level [13].

There is an on-going debate as to whether an entrepreneur is born or can be created through entrepreneurial education [14]. Vivarelli and Santarelli [15] state that the entrepreneurial personality can be described as follows: "innovative, flexible, dynamic, risk-taking, creative and growth-oriented". Drucker [16] on the other hand argues that the viewpoint that one is either born with or without an entrepreneurial personality is false. Instead he concludes that all successful entrepreneurs had made a "commitment to the systematic practice of innovation" [16]. The belief that the entrepreneur can be created is furthered with the idea that this systemic approach can be fostered through entrepreneurial education.

Policy makers in Europe have identified education as an instrumental factor in developing entrepreneurship. The European Commission in 2006 published the "Oslo Agenda for Entrepreneurship Education in Europe" to ensure that EU members were focused towards increasing entrepreneurial education. According to the European Commission [17], "Entrepreneurial programs and modules offer students the tools to think creatively, be an effective problem solver, analyse a business idea objectively, and communicate, network, lead, and evaluate any given project." By encouraging entrepreneurship in this manner, there is an underlying assumption that policy makers believe that entrepreneurial skills can be taught.

Government backed entrepreneurial programs are also increasing, which demonstrates that there is a belief at an administrative level that this type of education has positive social and economic results. As Edelman, Manolova and Brush [18] discuss, entrepreneurship is a "major public policy concern because of [its] impact on economic growth, particularly job creation." The society and the business world require and demands entrepreneurial competencies, which place more stress on the individual's attitudes and skills than before [19] and that it is of interest to study how entrepreneurial education affects the attitudes and motivations of those undertaking this types of programs. It is now widely recognized in education that it is important to promote entrepreneurial attitudes and behaviour. Moreover that Europe must stimulate the entrepreneurial mindset and encourage innovative business and new start-ups [20]. Attitude and motivation have an important role as they have been reported as the most critical factors for success in learning [21]. There is also widespread perception that motivation is the most important factor in educational success in general [21].

Entrepreneurial development is a key focus on any government's agenda due to the fact that it has been shown to provide solutions for a country's social and economic problems.

3. The role of the Albanian vocational education in creating the entrepreneur

Education is a long-term investment widely considered as an important basis of growth and competitiveness [22]. This recognition is generating new policy interest in the potential of entrepreneurial learning for improving productivity, innovation and economic growth. There are two broad considerations about the effect of the entrepreneurial education: it contributes to the competitiveness (the efficiency model), and it contributes to socio-economic inclusion (the equity model). Theoretical and empirical support is strong for both models [23] and is included in the EU Lisbon Strategy for Growth and Jobs. Being an economy in transition, and inspiring European inclusion, Albanian economy needs to create a sustained basis of growth. Self-employment sustained by the entrepreneurial learning is an important way for economic efficiency as well as an alternative way to joblessness [24].

3.1 The Curricula

As education is considered important in shaping the entrepreneurial mind, the notion of entrepreneurship is a competence that needs to be included in education. Professional high education was in focus of this study. Authors of this study are conscious about the conceptual problem created by concentration only on the high education, while conscious that the society's efforts in education of the new generation are very complex, not only through school.

Focused on the role of the Albanian professional education in creating the entrepreneur, the authors of this study analysed the curricula and study programs of the professional education. It comes out that

entrepreneurship is introduced as a key competence within mainstream curriculum. This is made possible by innovative teaching and learning arrangements that are part of the reform in education. Authors of the study analysed the curricula trying to understand how individual traits and behaviours, such as creativity, opportunity identification, risk assessment and risk taking, and resource management which make up the entrepreneurial character are included. It comes out that there are no specific subjects addressing these characteristics in the curriculum of the professional schools, although in The National Strategy of Education [25] there are some provisions focussed on teaching and learning arrangements for entrepreneurial learning (although the term “entrepreneurial learning” can be found nowhere in this Strategy). Although the professional education is now constructed in layers (as mentioned above), there are no specifications in the Strategy about these different levels of education. Curriculum adjustments and teacher training is mentioned in the national Strategy together with compulsory or elected subjects, out-of-the school activities, and cooperation between schools and enterprises, without specifications on levels of the professional education. There can not be found indicators on the built up intelligence on entrepreneurial learning, and nowhere is mentioned how the developed information on this will be reported and broadcasted.

Parallel to that, *half structured interviews with 10 school directors and curricula authors were conducted*, focused on the intended possibility of the study programs on educating entrepreneurs. The first thing to be discovered was that the discussion could be conducted only for the vocational schools on economy. The other professional schools like those in arts, electronics, etc had no orientation on entrepreneurial education as there are no subjects to address opportunity identification, risk assessment, risk taking, resource management, marketing, or business plan included in their curricula [26].

3.2 Pupils' selection

Based on the knowledge that the entrepreneur has some special personality characteristics, the authors of this study interviewed the professional school directors about the selection policy applied by the professional schools. The selection criteria more frequently mentioned by the professional school directors were: the *overall grade* of the previous level of education, the grade taken in *Mathematics* subject in previous levels of education and the grade in *Albanian language* subject.

3.3 Professional practice

80% of professional school directors interviewed answer positively-to moderate to the question: Do you believe that professional practice really helps pupils to have a sense of reality?

But in a scale from 1(not at all) to 5(completely), only 2 of 7 professional school directors choose nr 5 to answer the question: How much do you think your school makes pupils ready to have a private activity of their own after graduation? Five of them give answers ranging from level 3 to 5, giving a total of 70% moderately positive to positive answer to this question.

3.4 Pupils perceptions and motives

With the purpose of understanding if there were individual motives for choosing this education, and the perceived possibility offered by the actual study programs, authors prepared standard questionnaires. The underlying research questions were: Are they conscious that many of them will have to cope with the challenge of creating their own employment? How much do they feel supported from the actual study programs to cope with this immediate future challenge?

Considering the conclusions taken by the curricula analysis explained above, the authors were concentrated on the professional high schools offering education on *economy*. 150 questionnaires (see Anex1) were distributed in pupils of 4th and 5th grade in Professional School of Economy in Tirana. 146 of them were filled by 61 male and 85 female pupils, 34 of which were 4th year and 108 in the 5th year of education.

Pupils of the professional schools interviewed do not seem to have much aspiration on entrepreneurship after finishing the studies. Only 8.2% of those interviewed (Tot.146) choose “having my own business” as the possible answer to the question: What do you think you will do after finishing this school? 86.99% of them will follow further education.

Pupils see many factors that keep them away from a possible entrepreneurship, but surprisingly enough, 50% of them believe “lack of capital” is the main reason, followed by the “competition” (15.75%) and “lack of experience” (10.96%). This is almost the same for male and female pupils, with the difference that female pupils are afraid from “lack of experience”, while males are more concerned

about the "high taxes". The reason "lack of capital" tells a lot about the level of information these pupils have, and how helpless they feel although they have subjects that teach them how to make a business plan, etc. Authors have reasons to believe this answer is not only a question of personal perception.

Meanwhile, to the question "Explain in a scale from 1(not at all) to 5(very much)how much this education you are getting helps you have your private activity after finishing this level of schooling", 91.4% answer from a level from 3 to 5, where 54.1% are for a level of 4 and 5.

They mention 18 subjects as a possible answer to the question "What are the subjects that teach you how to open a business of your own?" *Accounting* is the more mentioned subject by 74.66% of the pupils, followed by *Economy of enterprise* (63.7%), *General economy* (27.4%) and *Macro economy* (21.9%).

It is clear that they get a lot of knowledge in the field of economy, but authors are not enthusiastic about the real abilities of these pupils to become entrepreneurs once finished the high school.

4. Main difficulties to perform this study

Authors had planned to include even an evaluation of the actual attitudes of the individuals graduated during last five years, who have their own professional business. Semi-structured questionnaires were constructed to interview individuals fulfilling this criterion. But because some technical problems like: impossibility to identify successful entrepreneurs graduated from the professional high schools and the wide spread of the subjects, this part of research could not be performed. Thus, we are missing important information about the actual value of the professional education on entrepreneurship and self-employment. Authors are also conscious that they are partial by concentrating only on a certain category of education (high professional), while knowing that there is still a strong tendency to pursue the high education way as the safest possible way of life in Albania.

The present paper discusses the concept of entrepreneurship in relation to emerging challenges of global markets and changing enterprise, and the ability of higher education to adjust to these challenges and deliver high quality learning outcomes for both students and SMEs. Immigrant entrepreneurship is emphasized as a tool to provide the necessary knowledge and real life experiences that may promote entrepreneurial learning in cross-cultural environments. It is believed that learning through the experiences of immigrant entrepreneurs can lead to a better understanding of the obstacles, challenges, and facilitating factors for successful entrepreneurship in times of economic hardship and globalization. This knowledge can later be infused into higher education curricula in order to better reflect the needs of students and SMEs in developing international and cross-cultural capability. Although immigrant entrepreneurship has been mostly studied in relation to ethno-cultural characteristics and processes, we offer a new approach that may potentially lead to culturally-sensitive lifelong learning and training programs, and thus increase access to global markets.

Curriculum, Immigrants, International Entrepreneurship, Internationalisation, SMEs

1. Introduction

Immigration is not new to human nature. In fact, it can be surmised that immigration has played a key role to the survival of the human species throughout the centuries. In modern times, immigration can largely be seen as the shifting of people between countries. In most cases, immigrants move from a low-resource country, to a high-resource one, with the prospects of improving their overall quality of life and gain access to more opportunities for development and growth. Nevertheless, the society often views immigrants as low-skilled people intended to be employed in low-level and low-paid jobs [1]. Empirical research, however, points out that immigrants who take on entrepreneurship initiatives in a host country, are likely to outperform locals and lead growth in their area of interest [2-4]. Thus, entrepreneurship seems to play a key role in fulfilling immigrants' dreams for prosperity and improved quality of life, and helping them climb the social status ladder in the host country [5]. Furthermore,

entrepreneurship has the potential to renew existing organizations and increase social capital, develop new business and leverage national economies [6-8].

Embedding entrepreneurial culture within formal education systems is of vital importance as it can lead economic growth and sustainability in the future. Still, transmitting entrepreneurship skills to students or non-student populations (e.g., in SMEs) is not an easy task, and has led scholars to wonder if entrepreneurship can really be taught at all, or whether it reflects personality attribute [9-10]. Following a systematic review of the literature on entrepreneurship teaching in higher education, Pittaway and Cope [11] argued that there are areas for development and gaps in the existing knowledge base, as well as a growing need for cross-fertilization of research themes.

The present paper responds to that need by proposing immigrant entrepreneurship as a potentially new driver in entrepreneurship education. Specifically, it is argued that the knowledge base and teaching of entrepreneurship can be significantly enriched by the careful consideration of immigrant entrepreneurs' experiences in setting up and sustaining their businesses in cross-cultural settings. The development of learning frameworks that can complement and improve the existing knowledge-base and delivery of entrepreneurship education using the knowledge gained from immigrant entrepreneurship experiences that focuses on the lived experiences of immigrant entrepreneurs can provide students with a more realistic view of what it means to be an entrepreneur in a dynamically changing cultural environment, and may potentially highlight the skills needed to achieve this goal more effectively. Furthermore, focusing on the experiences of immigrant entrepreneurs provides a shift in our attention from theoretical perspectives, to more applied and realistic aspects of entrepreneurship that can hardly be conceptualized at a purely theoretical level. Finally, the challenges and prospects experienced by immigrant entrepreneurs can give an insight into the processes that promote (or hinder) entrepreneurship initiatives in the face of an emerging global market.

2. Characteristics of Immigrant Entrepreneurship

Immigrant entrepreneurship has been a topic of special interest, especially in Europe [12]. Several theorists and researchers have argued that immigrant entrepreneurship can have different motives, ranging from labour market disadvantages, to group resources and opportunity structure [13]. In particular, immigrants may start up their own business as a way to overcome discrimination and block mobility in labour markets of the host country, or as means to achieve a higher quality of life [14-15]. Also, immigrant entrepreneurs may initiate small-to-medium enterprises that serve locals (e.g., ethnic restaurants and bars), focus on niche markets [16], or exclusively serve customers of the same ethnic origin and/or immigrant network [17-18]. According to the 'opportunity structure' hypothesis immigrants enter businesses that are of less interest to large-scale markets and require low human capital and financial resources [19-21], and in some cases the traits and attributes of their ethnic origin (e.g., religious beliefs, traditions) may shape their business opportunities and choices [22]. However, there are reported cases where immigrant entrepreneurs have leveraged progress in their field of interest, or successfully led big corporations [23-25]. Overall, it can be surmised that immigrant entrepreneurs have vastly different experiences from local entrepreneurs, both in terms of access to rights and opportunities, and drivers and motives to entrepreneurial culture. The diversity of the immigrant entrepreneur experience has attracted the research interest of anthropologists, sociologists, and even human geographers. We argue that the lived experiences of immigrant entrepreneurs can help researchers and theorists refine old concepts, and accordingly develop new learning frameworks of entrepreneurship that will benefit entrepreneurship teaching in higher education.

3. The Potential to Drive a New Model of Entrepreneurship Research and Teaching

The current approach to entrepreneurship has been largely shaped by concepts that apply to large corporations, and can hardly reflect the dynamics and processes of small enterprises. Furthermore, the business concepts used tend to be culture-specific, and fail to grasp aspects of the globalizing economy. Consequently, the existing theoretical base of entrepreneurship is rather fixed, and relatively inflexible. This may lead to several problems, including a mismatch between theoretical concepts and views and realistic aspects of entrepreneurship, as well as limitations and outdated approaches to entrepreneurship teaching in higher education or in skills-training programs. Focusing on immigrant entrepreneurship can generate the knowledge needed to overcome these limitations,

and provide a more realistic aspect of entrepreneurial culture in an era characterized by global economic challenges and ongoing mobility of people between countries. A few examples can better illustrate this argument.

Firstly, immigrant entrepreneurship is a dynamic process, requiring the acquisition of the necessary skills, overcoming challenges (e.g., discrimination), and identifying potentially successful business opportunities. The arsenal of traits, skills, and behaviours needed to complete this task successfully may vary between ethnic groups of entrepreneurs in a country. Hence it is difficult to distinguish between 'successful' and 'unsuccessful' qualities, unless a tailor-made theoretical model of entrepreneurship is used. Such a model can greatly influence current conceptions and understanding of entrepreneurship, and would only be feasible if we take a closer look at the experiences of immigrant entrepreneurs. This way, the existing evidence and knowledge base of entrepreneurship would significantly widen, and allow for the development of culturally-sensitive models that better describe entrepreneurial cultural in times of global change.

Secondly, whereas large corporations' behaviour does not change very often (as it takes a lot of effort and risk to do this), small businesses must be very flexible and adapt to trends and new paths that might lead to success. It can be argued that the small enterprises of immigrants may represent case studies of business success and development (or failure), and this knowledge is important in at least two respects: a) it may inform governmental policies and plans for immigrant employment opportunities, and b) it may drive lifelong learning and skills acquisition programmes, and thus improve the learning of entrepreneurial skills.

The aforementioned arguments pinpoint that an emerging aspect may be missing from our current understanding and conceptualization of entrepreneurship. Addressing immigrant entrepreneurship also changes the generation and flow of knowledge in rather interesting ways (Figure 1). Instead of using theoretical concepts generated by the academia to inform society and SMEs, it is suggested that academic recognition that the immigrant entrepreneur is expert in their experiences will allow immigrant entrepreneurs to generate knowledge that will inform academia, refining traditional views and terminologies of entrepreneurship, or developing new ones.

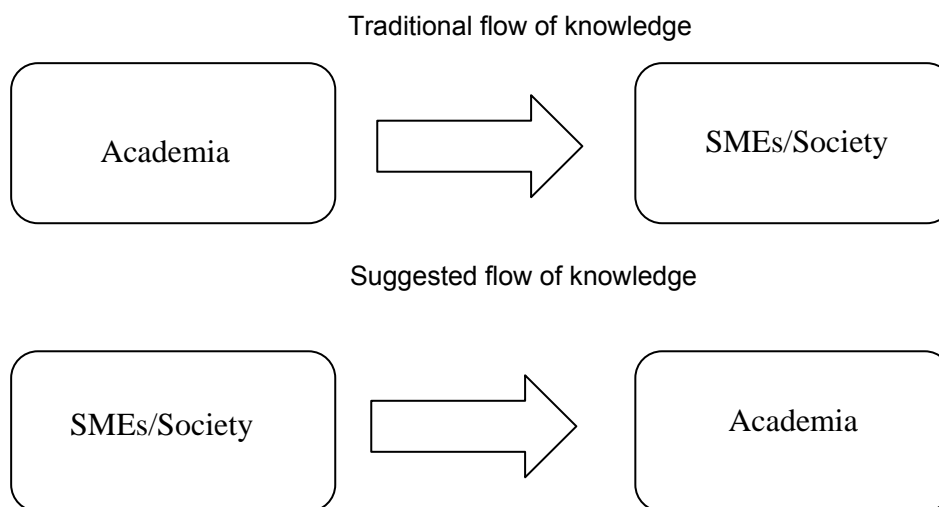

Figure 1 Flow of knowledge between academia and SMEs/Society

4. Bolstering Entrepreneurial Learning

Learning, as a concept, has been defined in numerous ways by many different theorists, researchers and educational practitioners. Although a single definition cannot be given, many common elements can be observed in various definitions. According to Ertmer and Newby [26] learners use past experiences to create new knowledge. In the same direction, Shuell (as interpreted by Schunk [27]) conceives that "Learning is an enduring change in behaviour or in the capacity to behave in a given fashion, which results from practice or other forms of experience". Thus, learning may be conceived as continuous change in the observable behaviour of an individual, which can be acquired by interacting with situations like everyday experiences. However, this continuous change cannot be entirely defined in order to provide a suitable definition for learning and due to this, one can assume that a single

definition for academic learning will be problematic also. According to Laurillard [28] “when asking academics to define learning they come up with ambitious definition. Academics see learning as not simply a product, but as a series of activities, and developing skills and capabilities as much as formal knowledge”. This development of skills and capabilities provides a widely accepted framework for entrepreneurship learning which may be viewed through both concepts: learning and academic learning.

Entrepreneurial learning reflects the process by which entrepreneurs accumulate and use knowledge for future business ventures and entrepreneurial initiatives. Entrepreneurial learning is largely experiential in nature, mainly driven and shaped by past experiences of business failure or success [29-30]. The experiences of entrepreneurs, therefore, play a major role in shaping entrepreneurial knowledge. This knowledge is reflected in the entrepreneur’s abilities to recognize opportunities and cope with the liabilities of newness [31-33]. By this token, the experiences of immigrant entrepreneurs can lead to models of entrepreneurial learning that are more concerned with cross-cultural and human mobility issues, such as the ability to adapt to the host cultural environment, coping with prejudice or discrimination from other ethnic groups or indigenous entrepreneurs or suppliers, and the ability to integrate one’s own cultural views and traditions to the broader social and cultural context of the host country. Basically, the cross-fertilization of the personal skills with the knowledge gained from the experiences faced in the host environment creates a lateral transfer of knowledge that leads to an optimized set of skills/model directed towards a more intuitive character. This model of entrepreneurial learning can create a repository of experiences, which can lead informed decisions of future immigrant entrepreneurs and SMEs vendors.

5. The Internationalization of Curricula in HE and Immigrant Entrepreneurship

Higher education plays a central role in the development and prosperity of local economies, and may offer a competitive advantage to each country in terms of developing and sustaining knowledge economy [34]. A central aspect of competitive higher education is the ability to become internationalized, namely, to widen the participation of students from all over the world [35]. The overall aim of such an approach is to promote equal opportunities for learning, and produce graduates who can work in an increasingly global environment [33-37]. Gaining access and being competitive in a global market, however, requires that graduates are able to adapt to new and unfamiliar cultures, are culturally-sensitive, and can appreciate and cope with the cultural diversity of international businesses and markets [38]. At this point, it is useful to recall that these attributes are also essential and necessary for immigrant entrepreneurs. Besides, university graduates moving between countries with the intent to start up their own ventures or be employed, represent a new wave of immigrant entrepreneurs, albeit with comparably higher academic prospects and skills as compared to low-skilled individuals. Put simply, the necessity to foresee business and employment opportunities in other countries puts pressure on university graduates in terms of increasing their arsenal of attributes needed to successfully adapt to cross-cultural environments. The attributes and skills needed to become competitive in a global market can be effectively delivered through the learning outcomes of carefully designed HE curricula that commit to the new dogma of internationalization. Learning from the experiences of immigrant entrepreneurs can lead the development of such curricula and provide realistic views of what it means to adapt and develop successfully (or unsuccessfully) in a cross-cultural setting.

6. Conclusions

Overall, immigrant entrepreneurship has been traditionally viewed as the business initiative of low-skilled and low-paid immigrants in otherwise economically developed countries. While this topic has attracted the research interest of sociologists and anthropologists, immigrant entrepreneurship might have a lot more to reveal. Firstly, the experiences of immigrant entrepreneurs can benefit existing research and theory in entrepreneurship by allowing for a more realistic view of what it means to start up a new business or foresee self-employment opportunities in a dynamically changing and challenging global market. This approach can change the flow of knowledge from the society and SMEs to the academia, and, hence, strengthen the link between these two entities. Secondly, immigrant entrepreneurship represents a dynamic process of entrepreneurial learning, which can significantly widen the knowledge base of culturally-sensitive entrepreneurial experiences. Finally,

immigrant entrepreneurship can be an important aspect of internationalizing higher education and improving the quality of learning outcomes delivered to students aiming to access global markets with a competitive advantage.

Innovation System in a Producing Company

Andras Kicsi¹

¹*Subotica Tech-College of Applied Sciences, Subotica, Serbia, andras.kicsi@rs.atb-motors.com*

This paper describes a production company manufacturing electric machinery and its system of innovations. Parallel to this the general legalities and rules related to innovations in the production company are outlined. The elements of the production company are described: personnel, means for production, products and organization. The innovations are presented and described in each of these elements. Other possible divisions of innovations are also given and each division is separately analysed. The most significant divisions are the strategic, tactical and operative innovations.

The necessity of determining the goals of innovations is given and arguments are provided for the harmonization of the goals. The available resources for innovations in a company are limited thus these resources should be spent in such a way as to optimize the entire functioning of the company as much as possible. In practice it is rather difficult to achieve the optimum, but there must be an intention for achieving sufficient efficiency. The paper presents the bases for establishing these sufficient efficiencies.

In order to achieve satisfactory efficiency, it is important to control the system of innovations. The control process implies determining the goals, planning, realization and realization follow-up and the statement of the level of achieving the goals and the undertaking of corrective actions in order to improve the achieving of the goals. It is a continuous, dynamic process requiring constant care and supervision.

The analysis of the system of innovations is performed in a given company, it shows their number on a time scale and lists them according to types and conclusions are made about the trend of the required actions to improve the system of innovations, and thus the production company as a whole.

The scope of this paper does not permit the presentation of the overall analysis in all its details, but the author of this paper has tried to make conclusions that could be useful for guidance in case of similar analyses.

Keywords

Innovation system, personnel, production means, products, organisation.

1. Introduction of the production company

This paper studies an analysis system of innovations in company A. The company mainly produces electric motors and other products which use electric motors such as pumps, gear boxes, grass mowers and some other products which can be produced on request, periodically. Reparation of electric motors and other products is performed in the company, too.

The company has a tradition which has lasted for many decades as well as the necessary international quality certificates for selling the products on the markets all over the world.

Business has become heavier in the last few years because of the world economic crisis which makes markets smaller and exposed to the competitors' actions. It is very difficult to win new markets and find new customers. In spite of the economic difficulties, company A achieved some profit in the last years; however it is at a lower level than planned. In the last year the annual income was 45 million EUR and the profit reached 1.5 million EUR. Besides the profit which expresses total business efficiency, attention has been paid to the accomplishment of value added per employee. The value added in the

last year was 18 million EUR, and the number of employees was 750. The value of the fixed assets, small inventory and material stock, semi-finished goods and finished products was 26 million EUR.

Company efficiency is conditioned with permanent innovations in all its fields. To make bigger review of planning, realization and innovation tracking, it has been agreed to define and track innovations according to the company elements. The elements can be defined in different ways, but here the company elements are: personnel, production means, products and organization.

Personnel include all company employees with all their knowledge and skills. Production means in this sense represent all material and financial business basis: fixed assets, small inventory, all material stock, semi-finished goods and finished products and funds. Products represent all types of products and services which are in production, i.e. which are performed in the company, in all versions, together with designing documentation, as well as work on market research and sale and purchase. The organization is represented by complete know-how of the company, organizational structure, method of market and sale research, job planning and control, functioning of complete quality control system as well as all law and organizational regulations which define certain basis for employees' behaviour, certain acts and mutual relations between employees during the functioning process of the company.

2. Types of innovations in the company - Innovation system

Innovations have to be done permanently in the company but the process of innovation itself is developing through innovation of some concrete company element. If the definition of company elements according to item 1 is accepted, then they are innovations concerning personnel, production means, products and organization.

Innovations can be classified according to the other criteria, for example, according to values of effects, course of accomplishment, and subject of realization, importance to company business or degree of long-term effectiveness.

There are significant differences for company business according to the innovation hierarchy. There are innovations most significant to the company, while some of them are less significant and some are peripheral. According to the hierarchy they can be divided into strategic, tactic and operative innovations.

Each innovation has defined aim which has to be achieved by its realization. In essence, the significance of an innovation depends on the importance of the aim which is set. To have harmonized and rational company development, it is important to have harmonized aims. Aims harmonization means that they have to be observed in mutual connection. Defined aims cannot be placed without taking into consideration the other aims which have been already defined and whose preparation of realization or realization is in progress.

If we follow the above mentioned company elements, it means that aims are set on all four elements. It has to be provided that both the aims inside of innovations for defined company elements and between innovations aims of different company elements are harmonized.

The most important innovations are at the highest level of hierarchy and they have strategic aims. It means that there is the aim to introduce new product into production program. In the field of production means, for example, there is introduction of new technologies at new machines. For personnel, it can be the adaptation of personnel structure to the whole strategy of the company, but for organization it can be the construction of optimal organizational structure within the existing conditions.

For the given company A, the most important strategy decision concerning product development is the introduction of small hydroelectric power plant production where market research showed significant interest because of bigger necessity for alternative source of energy. The aims of the other innovations concerning personnel, production resources and organization have to be adapted to this innovation.

For example, five Masters of Electrical Engineering with energetic major have been employed, the production of new tools in amount of EUR 800.000.00 is prepared and new organization unit for small hydroelectric power plant design has been established.

3. Available resources for innovations

Innovations are necessary and they represent condition for company existence in the future but, it is important to have in mind, during their conception and planning, that they cause some expenses and

that available resources are limited and they cannot be predicted and planned without taking into consideration the whole business dealings. For innovations, only those resources which are earned during regular dealings and which are left after settling of all expenses for usual and necessary activities during current functioning of the company can be spent.

In the given company A, even though there is no precise evidence about all innovations during these years, it has been calculated that during the last ten years, between 8% and 10% of the total income was spent on innovations. Earlier this percentage was higher, but the conditions of doing business decreased the possibilities of financing new innovations.

By reconstruction of the data, it has been tried to clear innovation investments of some company elements.

It has been concluded that during the last few years relatively small investments were made for new machines which provide new technologies but significant innovations and relatively significant investments were made for tools as it was important to develop products which need new tools. Since machines and tools belong to the production resources, entirely observed investments have relatively constant ratio about 3 - 4% of accrued total income.

Investments into products as well as into organization become higher. Research of new selling markets has been made, new software's for product calculation and designing have been bought and testing for bringing new materials into production has been done, too. For these purposes, between 2% and 3% of accrued total income in company A, during last ten years, was spent.

For personnel education, an average of 2, 5% of accrued total income was spent, so it was necessary to provide participation of personnel from company A in training for use of new software in product designing and development tracking at important fields (quality control, designing methods, supply rationalization).

Organization has required some changes such as rationalization of jobs structure, so the number of employees was reduced from 1000 to 750 in the last ten years. In that period, three social compensation programs were done, so performed innovations had the average annual costs between 2% and 3% of accrued total income.

4. Company innovations analysis in the last period

By analysing innovations in the last period, the following data have been concluded (in the table numbers of innovations in the years are given):

O.Nr.	Year	Strategic innovations				Tactical innovations				Operative innovations				Total
		Per	PM	Prod	Org	Per	PM	Prod	Org	Per	PM	Prod	Org	
1	2001	2	2	3	1	5	3	7	2	8	5	8	5	51
2	2002	3	3	5	-	7	5	4	3	9	7	13	5	64
3	2003	5	4	5	2	8	10	10	4	12	15	12	7	94
4	2004	4	4	6	4	8	12	11	5	9	13	16	10	102
5	2005	3	5	4	3	5	7	5	7	7	8	14	13	81
6	2006	6	6	6	5	6	9	8	5	10	11	19	12	103
7	2007	4	4	7	5	10	13	10	6	11	12	15	15	112
8	2008	6	3	9	6	6	8	12	8	12	10	16	17	113
9	2009	7	6	6	7	9	10	8	12	13	13	14	14	119
10	2010	6	4	7	6	10	9	9	11	11	13	15	18	119
Total		46	41	58	39	74	86	84	63	102	107	142	116	958

Per – Personnel innovations, PM – Product means innovations, Prod – Product innovations, Org – Organization innovations

Detailed analysis of trends needs long period of time and it cannot be described within the scope of this paper, but generally speaking an increase in the number of total innovations during the years can

be established. This can especially see at organization. While at perssonel, production means and products innovations number of innovations during that period is increased for about 1.5 to 2.5 times, this increasing at organization is four times higher. It is the result of the wish to come closer to the optimal organization which provides the best business effects, as much as possible. Smaller innovations in organization do not cause higher expenses and they can be realized without higher limits, and probably because of it, these possibilities have been used as much as possible.

All realized innovations had influence on development and functioning of the company, and they represent elements of the innovation system. For this system the following characteristics can be established: it is relatively stable in functioning with trends which are the results of market business condition movements and significant decisions by company management. Their analysis gives the possibility for planning and prognosis of the future in this field and indirectly in company functioning. Following the trend of the number of innovations is only one aspect of the analysis, in a deeper analysis it is possible to make a correlation analysis between the number of innovations and the total income trend, values added and profit the realized.

5. Harmonization measuring of the company elements innovations

Harmonization of the company elements innovations is a condition for efficiency of the whole innovations system functioning. The characteristics of the optimal functioning are: complete achievement of the set business aims, stabile market position, provided possibility for further development which is speeded up.

Practice usually retreats from optimality. It is a real aim to achieve satisfied quality of functioning. It is not qualified on strictly defined values but in defined ranges of some characteristic scales, for example, market representativeness of the company, realized income and the most important, realized profit.

These are indirect criteria which are important at the observation level of company functioning in a whole. There can be direct criteria such as number of innovations, or number of innovations per defined company elements, according to realized effects, per terms of planned realization, etc.

To define harmonization degree of the innovations per company elements, a questionnaire filled by company experts can be used. This questionnaire cannot be the integral part of the paper because of the volume, but it is necessary to mention that it has to be very detailed to record condition of some company elements from one side and from the other side to provide comparability of development degree of some elements. With the questionnaire some characteristics can be scored, definition of optimal conditions and deviations from them can be done and in that way conclusion about **harmonization** degree can be made indirectly, i.e. it can be concluded which elements have to be innovated faster and higher to get harmonization degree of high quality.

According to these analyses, action for harmonization degree increase can be defined and certainly it is task definition for development and innovations of some company elements.

With the mentioned way of innovation analysis, it has been concluded in company A that harmonization degree of some company elements promotion is insufficient, that it is necessary to get faster and significant product and organization development with better product characteristics, better marketing appearance and innovation of organization for raw materials supply.

6. Managing with innovation system in the company

To get better functioning, it is necessary to set some aims and define actions for them. But to reach the aim it is necessary to get it and in that direction manage with the innovation system. During this process the necessary actions are predicted and it can be developed in details by planning. The given plan must be realized, so some activities have to be done according to the plan. In the end, development validity of the whole process has to be checked by realization control.

The managing of innovations which are followed according to the elements of the production company and the hierarchy of their importance for the company imposes the need to analyse the matrices of innovations in which the strategic, tactical and operative innovations are represented and within each of them the innovations according to the elements of the company. The analysis of this matrix enables creating the necessary grounds for reaching sufficient efficiency for the functioning of the system of innovations as well as the overall company.

In the company A, the performing of innovation plans is continually tracked and reporting about the degree of realization each month. Conclusions are given in which phase the innovations are and if necessary decisions are made (about necessary corrections or necessary new innovations).

In this given case, in company a, it has been established that the degree of efficiency for standard electric motors has to be increased according to the international standards, and new markets with mild requirements concerning the above mentioned motor characteristic have to be discovered. The measurers can be defined with the other company elements as well as their degree of development and predicted innovations from their areas.

7. Innovations planning

Innovation plans are necessary to achieve development harmonization at some company elements, as well as in the whole company. However, degree of plan development is very different depending on the strategic, tactical or operative aims which can be achieved by innovations. There can be dilemmas about plan details of some innovations. General instructions cannot be given as there are very different innovations with different needs concerning degree of detailed plan development.

The most detailed plans are made for the most important and strategic innovations by top management. The next level is that tactical innovations are coming from strategic ones, i.e. they represent how to provide achievement of strategic aims. For these innovations plans are made more globally, without lot of details. Tactical innovations may have needs to perform operative innovations where the most global plans can be developed, with the most important parameters (what, who and how far concrete innovation has to be realized).

During the innovation planning process there have to be some stages. There has to be planned completeness of development with all necessary innovations. First strategic innovations are planned then according to them tactical ones and according to these operative ones. General plan for innovation needs has to be the base for plan creation of some innovations. The degree of detailed creation of their plans depends on the degree of innovation importance in the whole innovation system.

In company A, there is innovation plan whose aim is to improve characteristics of some products. There is innovation plan for calculation, designing and scheduling of designing-technical documentation, then innovation plan whose aim is to make technological documentation because of production rationalization and price reduction. Besides this plan there is a plan to provide necessary tools, and plan for employees' knowledge innovation which will be included in production preparation and production of the innovated product.

Like a necessary base for the above mentioned activities it is necessary to plan innovation

For finding new markets with new customers, as the existence of investment possibility presents the base for product innovation with such execution which can be sold on the market.

It is important, in innovation plans, to define the necessary activities as well as the terms and responsible persons for them.

8. Realization and control of innovation performance

Innovation plans have to be realized. Special attention has to be paid to the stage of realization, as it is the most important stage of the whole process for innovation conduction. It is not enough to have a high-quality plan if there is an interruption in the process of realization, as the plans do not show their validity. Having this in mind, it is good to know that partial terms in realization have been done by responsible and competent persons. Innovation performance can be related to only with one person, many persons or a team, and there has to be necessary to have synchronized action, collaboration between many departments.
