

SCORING SYSTEMS IN NEONATAL MEDICINE AND DETECTION OF RISKS

Prof d-r Elizabeta Zisovska

University Clinic for Gynecology and Obstetrics

Department of Neonatology

Skopje

- ▶ Early identification of newborn danger signs by caregivers with prompt and appropriate referral, serves as backbone of the programs aiming at reduction in neonatal mortality.
- ▶ Neonates are more prone to show subtle signs of illness and these can only be identified by the immediate care givers who have adequate knowledge on features to look for.
- ▶ Restlessness or difficulty feeding are sometimes the only signs present and illness may advance quickly.
- ▶ Different tools to facilitate identification of these health problems and reduce neonatal mortality have been introduced into health programs in many countries

Medical scores, criteria and classification systems support clinical decision-making and management. They enable the clinician to predict the outcome, stratify risk, assess conditions and diagnose diseases accurately. The desirable properties of neonatal scores have been described as including:

- ▶ ease of use;
- ▶ applicability early in the course of hospitalisation;
- ▶ ability to reproducibly predict mortality, specific morbidities, or cost for various categories of neonates;
- ▶ usefulness for all groups of neonates to be described.

▶ However, these properties are difficult, perhaps impossible, to achieve completely. Although it may be possible to derive a risk adjustment score in a particular study, investigators will often require a readymade score. They may lack the data, resources, time, funding, or expertise required to develop their own, and a previously validated score also has the advantage that it is more likely to be accepted by others.

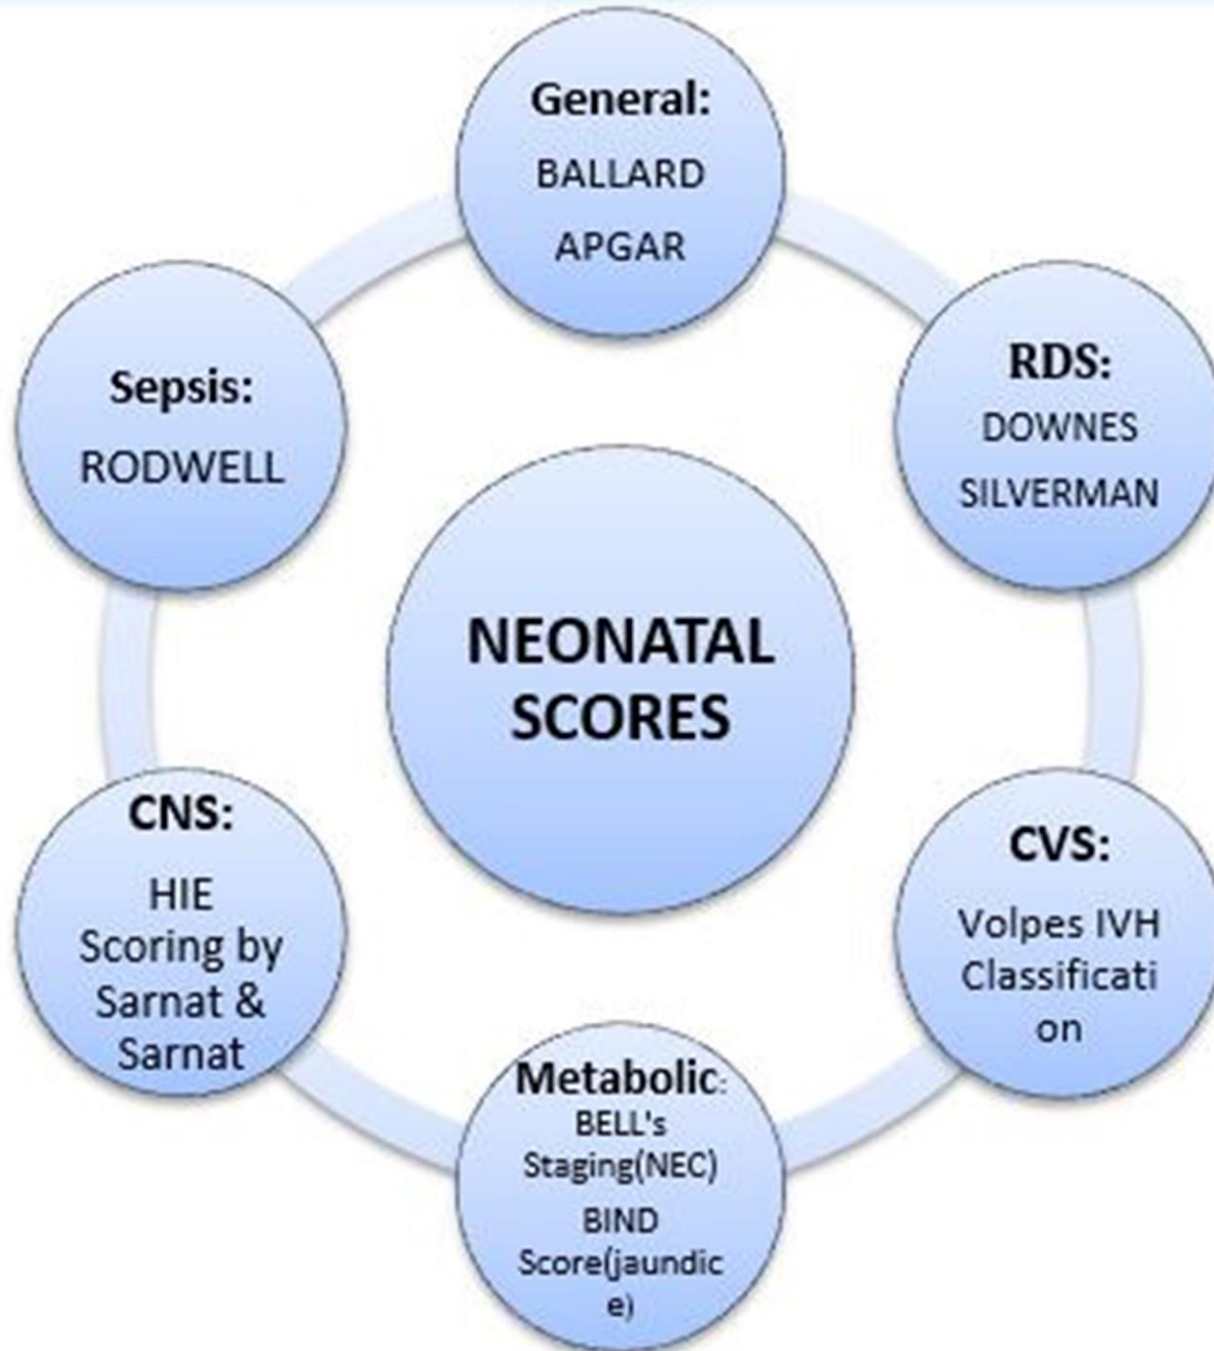

▶ There are various scores derived for neonates in the medical literature, and the choice of which variables are to be included in the score and their relative weights is obviously vital. It also needs to be remembered that no score can completely quantify the complex factors that make up an individual infant's morbidity.

- ▶ Usually, scores are created in one of two ways.
- ▶ Medical scores are derived by an expert panel using clinical knowledge to select the variables to be included in the score and their relative weights.
- ▶ Alternatively, collected data are used in statistical models to produce *statistical* scores by identifying which variables have strong association with the outcome of interest and their relative weights.
- ▶ There is evidence that, in the long run, statistical scores outperform medical scores and today most scores are statistical as there are often relevant data available. However, clinical knowledge may contribute to the choice of variables included in a final model.
- ▶ Although presently there are multiple scores designed for neonates' sickness assessment, none of the score is ideal. Each score has its own advantages and disadvantages along with their merits and demerits.

CONTENT OF THE PRESENTATION

- ▶ Assessment before the birth – Obstetrician, antenatal controls
 - ▶ Assessment immediately after the birth
 - ▶ Apgar score
 - ▶ Gestational age
 - ▶ Assessment during the early neonatal period
 - ▶ Danger signs, Silverman score, Sepsis score
 - ▶ HIE: Sarnat&Sarnat, Finner
 - ▶ Prediction of the neonatal outcome
 - ▶ CRIB score, SNAPPE
 - ▶ MAIN score, Perinatal score
 - ▶ Assessment of the neonatal behavior - NBAS
 - ▶ Assessment of the procedural pain
- 

APGAR SCORE

- ▶ a rapid method of assessing the clinical status of the newborn.
- ▶ Limitations of Apgar score: the Apgar score is an expression of the infant's physiologic condition at one point in time, which includes subjective components. There are numerous factors that can influence the Apgar score, including maternal sedation or anesthesia, congenital malformations, gestational age, trauma, and interobserver variability. In addition, the biochemical disturbance must be significant before the score is affected. Elements of the score can be subjective, and partially depend on the physiologic maturity of the infant.
- ▶ There is also an expanded Apgar score which may prove to be useful in the setting of delayed cord clamping, where the time of birth, the time of cord clamping, and the time of initiation of resuscitation all can be recorded in appropriate box

APGAR is an acronym for

- A** Appearance (skin color)
- P** Pulse (pulse rate)
- G** Grimace (reflex irritability)
- A** Activity (muscle tone)
- R** Respiration (breathing)

A PPEARANCE

- Pink all over \equiv 2
- Pink body, blue limbs \equiv 1
- Blue and pale all over \equiv 0

P PULSE

- >100 bpm \equiv 2
- <100 bpm but >60 bpm \equiv 1
- <60 bpm or pulseless \equiv 0

G GRIMACE

- Strong Cry \equiv 2 (or cough/sneeze)
- Weak or irregular cry \equiv 1 (or grimace only)
- No response \equiv 0

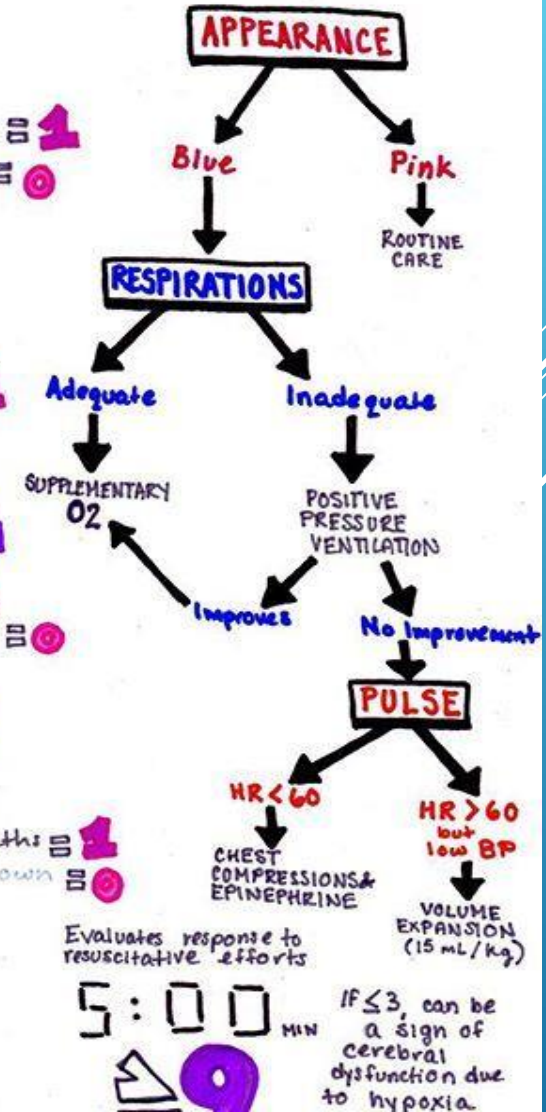

A CTIVITY

- Active Movement \equiv 2
- Some limb flexion \equiv 1
- Flaccid tone, no movement \equiv 0

R RESPIRATIONS

- Deep breaths \equiv 2
- Weak or irregular breaths \equiv 1
- Not breathing on own \equiv 0

APGAR score delineates a quantifiable measurement for the need and effectiveness of neonatal resuscitation

Evaluates conditions during labor and delivery

1:00 MIN

Normal

7

Evaluates response to resuscitative efforts

5:00 MIN

IF ≤ 3 , can be a sign of cerebral dysfunction due to hypoxia

9

Apgar Scoring System

Indicator		0 Points	1 Point	2 Points
A	Activity (muscle tone)	Absent	Flexed arms and legs	Active
P	Pulse	Absent	Below 100 bpm	Over 100 bpm
G	Grimace (reflex irritability)	Floppy	Minimal response to stimulation	Prompt response to stimulation
A	Appearance (skin color)	Blue; pale	Pink body, Blue extremities	Pink
R	Respiration	Absent	Slow and irregular	Vigorous cry

- ▶ the Apgar score quantitates clinical signs of neonatal depression, however, it has been inappropriately used to predict individual adverse neurologic outcome.
- ▶ The Apgar score does not predict individual neonatal mortality or neurologic outcome, and should not be used for that purpose.
- ▶ Limitations of Apgar score: the Apgar score is an expression of the infant's physiologic condition at one point in time, which includes subjective components.
- ▶ There is also an expanded Apgar score which may prove to be useful in the setting of delayed cord clamping, where the time of birth, the time of cord clamping, and the time of initiation of resuscitation all can be recorded in appropriate box.

INTERPRETATION

- ▶ Apgar score in the first minute
- ▶ Apgar score in the fifth minute

▶ Who carries less risk?

- ▶ Apgar score 4/7
- ▶ Apgar score 7/7
- ▶ Apgar score 5/8
- ▶ Apgar score 3/7
- ▶ Apgar score 8/5

A score of 10 is uncommon, due to the prevalence of transient cyanosis, and does not substantially differ from a score of 9. Transient cyanosis is common, particularly in babies born at high altitude.

Apgar score

Appearance

- Skin color/Complexion
- blue all over 0
- blue at extremities, body pink (acrocyanosis) 1
- no cyanosis 2

Pulse

- Pulse rate
- <60, asystole 0
- >60 but <100 1
- >100 2

Grimace

- Reflex irritability
- no response to stimulation 0
- grimace/feeble cry when stimulated 1
- sneeze/cough/pulls away when stimulated 2

Activity

- Muscle tone
- none 0
- some flexion 1
- active movement 2

Respiration

- Breathing
- absent 0
- weak or irregular 1
- strong 2

Taken on 1st min and 5th min of life and later if necessary

determined by evaluating the newborn baby on five simple criteria on a scale from zero to two, then summing up the five values thus obtained

Scores 3 and below are generally regarded as critically low, 4 to 6 fairly low, and 7 to 10 generally normal

Heart rate, Respiratory effort, Irritability, Tone, and Color

How Ready Is This Child

ASSESSMENT OF GESTATIONAL AGE

Estimations of gestational age can be based on:

- ▶ Menstrual periods
- ▶ Date of conception
- ▶ Fetal ultrasonography
- ▶ Physical parameters after birth (eg, using scoring systems for estimation of gestational age (Ballard/Dubowitz, Lubchenko and other scores))

- ▶ Different scoring systems based on neurological and physical examination are used in the neonatal units for assessment of gestational age. Assessment of gestational age is very much helpful in labelling the newborn to be preterm, term or post-term and to assess the further outcome of the newborn infants. There are two combined clinical systems for such a purpose, Ballard and Dubowitz scoring system, and few other, rarely used, as the methods of Farr, Finnstrom, Lubchenko and Parkin which are based on external criteria, while those of Robinson and Amiel-Tison based on neurological criteria. Although separately neurological and physical criteria can estimate the gestational age but combining them makes the method more accurate.

MORBIDITY SCORING SYSTEMS

WHO DANGER SIGNS OF ILLNESS

- ▶ Health Organization (WHO) focuses on assessment of general danger signs in the examination of children presenting with illness at health care centers. WHO in 2013 strongly recommended specific danger signs that should be assessed during each postnatal care contact and the newborn should be referred for further evaluation if any of the signs are present. The family should also be encouraged to seek health care early if they identify any danger signs in-between postnatal care visits

DANGER SIGNS OF ILLNESS

The danger signs are as follows;

- ▶ stopped feeding well,
- ▶ History of convulsions,
- ▶ fast breathing (breathing rate $>60/\text{min}$)
- ▶ severe chest in-drawing,
- ▶ no spontaneous movement,
- ▶ fever (temperature $>37.5\text{ }^{\circ}\text{C}$),
- ▶ low body temperature (temperature

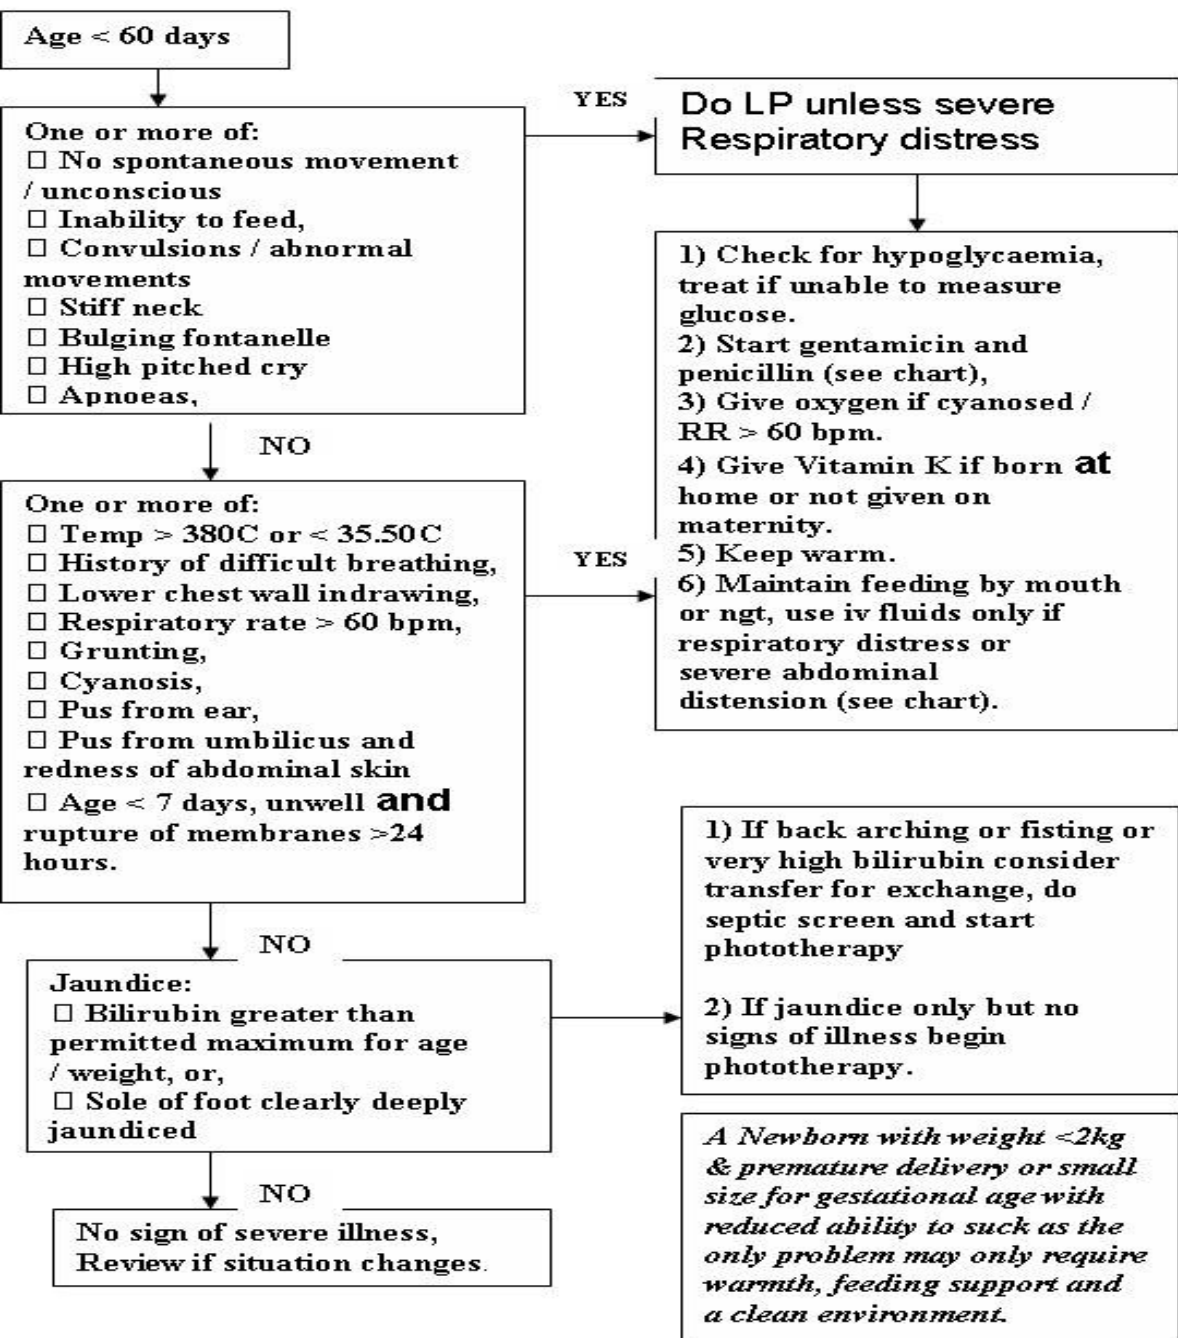

SEPSIS SCORE

- ▶ The tool below is intended for the use of clinicians trained and experienced in the care of newborn infants. Using this tool, the risk of early-onset sepsis can be calculated in an infant born ≥ 34 weeks gestation. The interactive calculator produces the probability of early onset sepsis per 1000 babies by entering values for the specified maternal risk factors along with the infant's clinical presentation.
- ▶ **World Sepsis Day 13th september**

Duration of rupture of membrane before delivery > 24 hours	1
Birth weight 2 kgs or less and / or gestation less than 37 wks	1
Total	10

SEPSIS SCREEN

At Birth

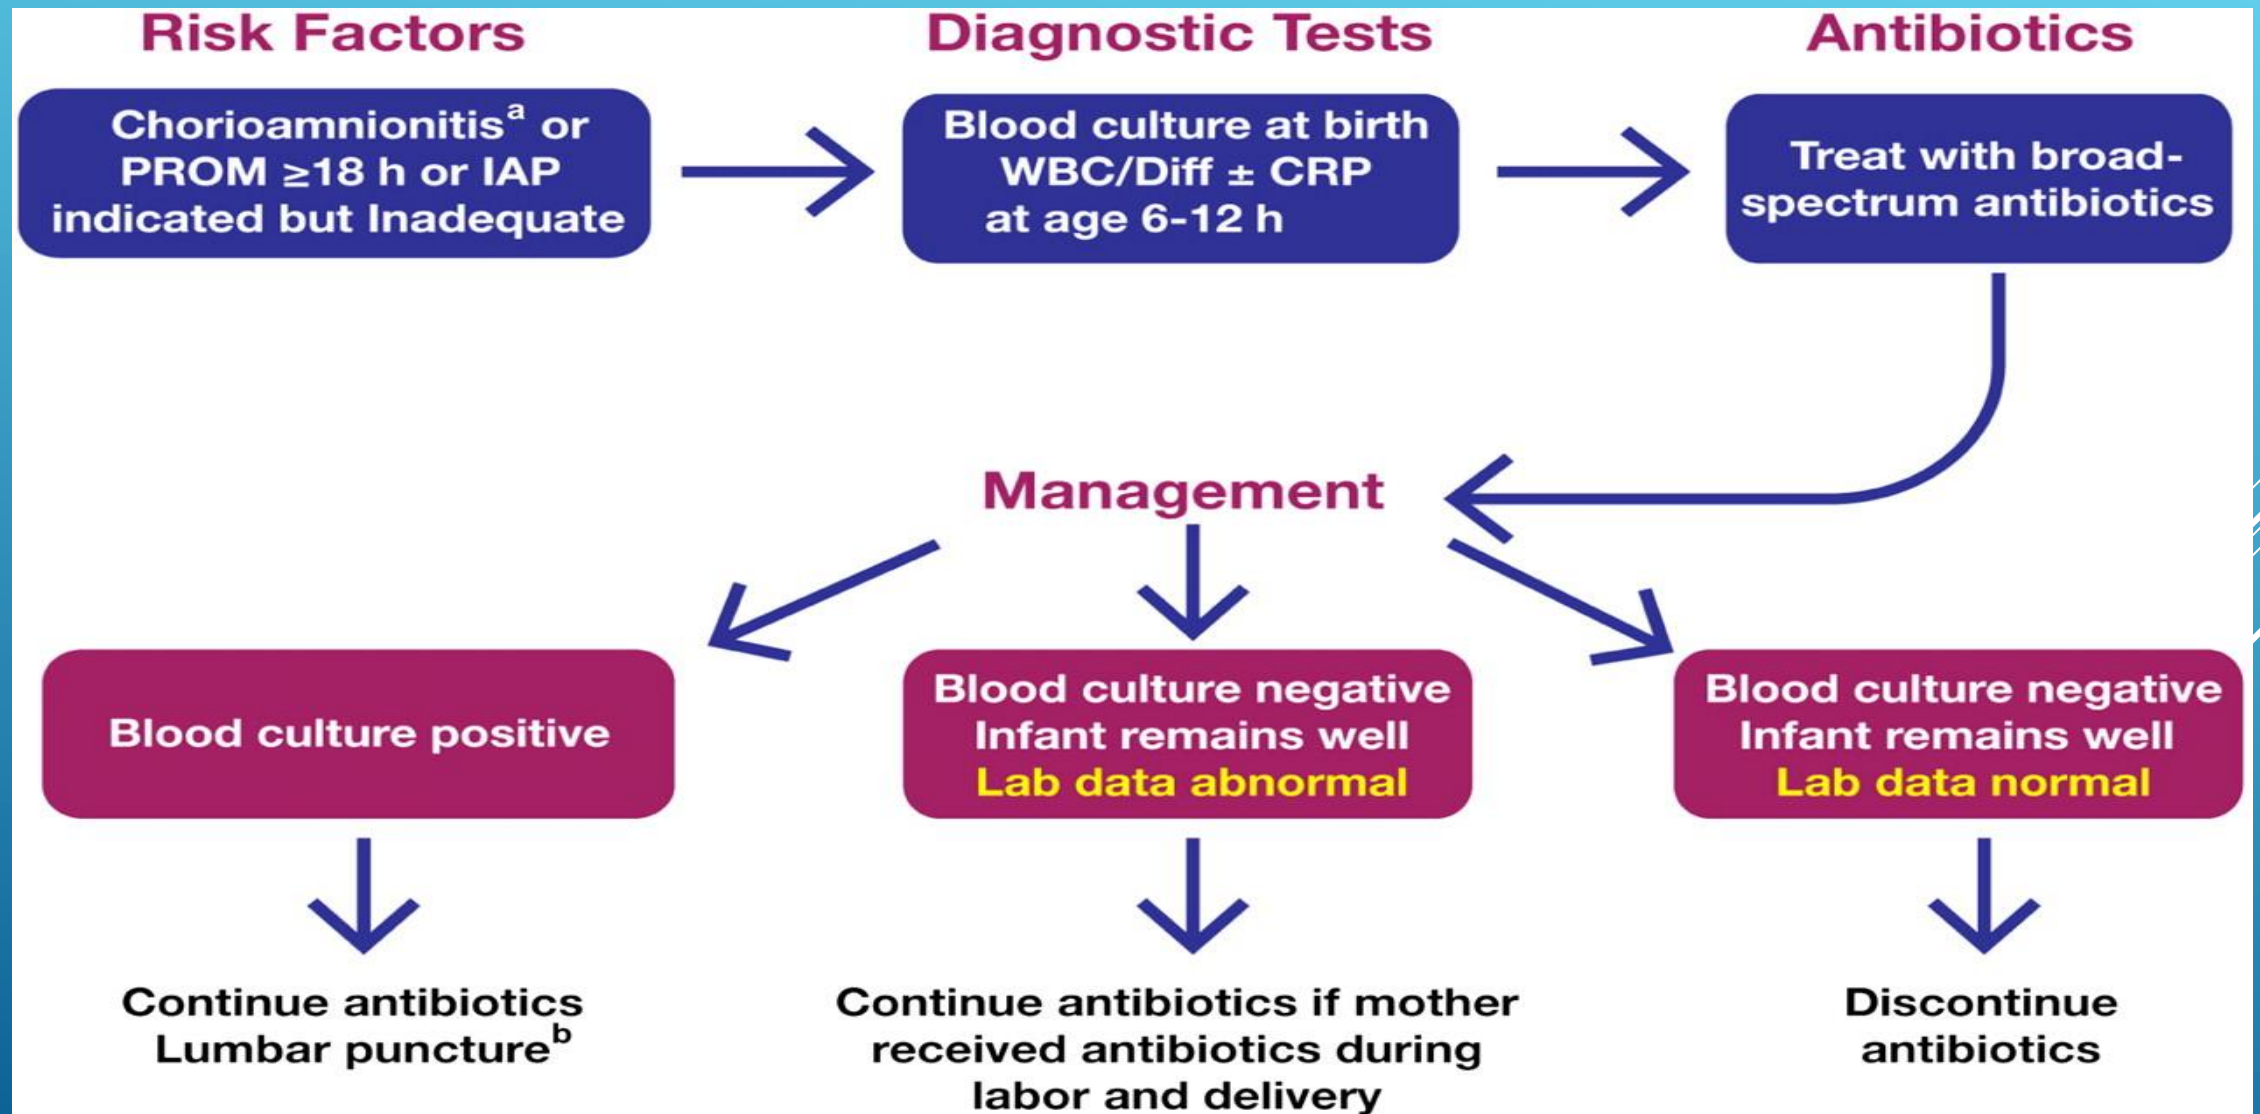

Major risk factors

1. Rupture of membranes > 24 hrs
2. Maternal intrapartum fever > 100.4^o F (>38oC)
3. Chorioamninitis
4. Sustained fetal heart rate >160/min

Minor risk factors

1. Rupture of membrane > 12 hours
2. Maternal intrapartum fever > 99.5^o F, ≥37.5oC
3. Maternal WBC > 15000 / mm³
4. Low apgar score (< 5 at 1 min, < 7 at 5min)
5. LBW (< 1500 g)
6. Preterm labour (< 37 weeks)

Evaluation of asymptomatic infants <37 weeks' gestation with risk factors for sepsis. The diagnosis of chorioamnionitis is problematic and has important implications for the management of the newborn infant.

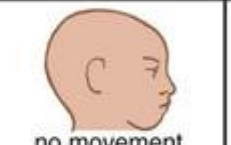

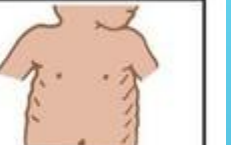

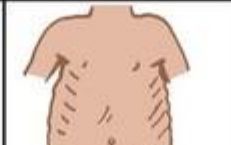

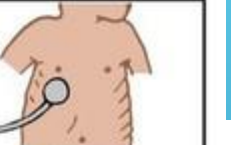

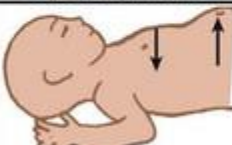

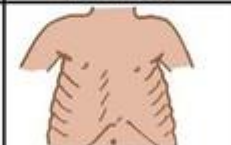

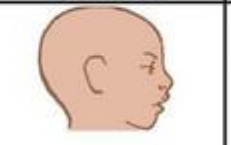

Silverman score

Assessment Criteria of RDS:

Clinical Manifestations:

- Tachypnea (80 to 120 breaths/min).
- Dyspnea.
- Substernal retraction.
- Fine inspiratory crackles.
- Audible expiratory grunt.
- Flaring of the nares.
- Cyanosis or pallor.

	Upper chest	Lower chest	Xiphoid retraction	Chin movement	Expiratory grunt
Grade 0	 synchronized	 no retraction	 none	 no movement of chin	 none
Grade 1	 lag on inspiration	 just visible	 just visible	 chin descends lips closed	 stethos. only

Retractions	None	Mild	Severe
Grunting	None	Audible with stetho.	Audible without stetho.
Air entry	C;ear	Decreased	Barely audible
RR	Under 60	60-80	Over 80 or apnea

Score : > 4 = Clinical respiratory distress; monitor ABG

> 8 = Impending respiratory failure

ESTIMATION OF THE SEVERITY OF THE HYPOXIC-ISCHEMIC ENCEPHALOPATHY (HIE)

- ▶ Still, the original Sarnat&Sarnat classification is the scoring system with high specificity- 100% for severe HIE, in detecting neonates who may not have convulsions by 6 months.
- ▶ The positive predictive value to predict convulsions were found to be 63.6% for moderate HIE and 100% for severe HIE. Modifications are made by Portman and Finner.
- ▶ The newest modification is that of Thompson, with very high specificity and sensitivity.

SCORING SYSTEM FOR HIE (SARNAT&SARNAT)

Severity	Stage 1 (Mild)	Stage 2 (Moderate)	Stage 3 (Severe)
Level of consciousness	Hyperalert	Lethargic or Obtunded	Stupor or coma
Activity	Normal	Decreased	Absent

Thompson CM, Puterman AS, Linley LL, Hann FM, van der Elst CW, Molteno CD, Malan AF. The value of a scoring system for hypoxic ischaemic encephalopathy in predicting neurodevelopmental outcome. *Acta Paediatr* 1997; 86: 757-61

SCORING SYSTEMS FOR PROGNOSIS

Mainly, statistical scores

- CRIB score (clinical risk factor score)
- SNAPPE (Score of Neonatal Acute Physiology Perinatal Extension)
- MAIN score (morbidity assessment index for newborns)
- Survival index in low birth weight infants
 - Perinatal risk score
 - Neonatal scale of morbidity

CRIB SCORE

CRIB (Clinical Risk Index for Babies)

CRIB score is a validated measure of initial mortality risk and illness severity within one hour of admission that contains only few variables. It is simple to calculate and non subjective. It is useful in identifying high-risk neonates, auditing of neonatal units and also provides a standardized mortality rate for performance comparison among neonatal units.

CRIB score takes into account the birth weight, gestational age, body temperature, base excess and sex of the baby to determine initial mortality risk.

The total CRIB score ranges from 0 to 27. The scores have further been classified into four levels as follows:

- Level 1 0 to 5
- Level 2 6 to 10
- Level 3 11 to 15
- Level 4 above 15

The higher the score, the poorer the prognosis, with worst prognosis in level 3 and 4

Variable	Values	Points
1. Gestation (weeks)	>24	0
	<24	1
2. Birth weight (g)	>1350g	0
	851-1350 g	1
	701-850 g	4
	< 700g	7
3. Congenital Malformation	No imminent life threatening	1
	With imminent life threatening	3
4. Maximum Base Excess (BE)	> -7.0 mmol/l	0
	- 7.0 to - 9.9 mmol/l	1
	- 10.0 to - 14.9 mmol/l	2
	< -15.0 mmol/l	3
5. Minimum appropriate Fio2 in first 24hrs	<0.4	0
	0.41 - 0.80	2
	0.81 - 0.90	3
	0.91 - 1.00	4
6. Maximum appropriate Fio2 in first 24hrs	<0.4	0
	0.41 - 0.80	1
	0.81 - 0.90	3
	0.91 - 1.00	5

Score of Neonatal Acute Physiology Perinatal Extension (SNAP-PE)

- An organ system, physiologic-based severity of illness index developed specifically for evaluating neonatal intensive care
- Based on objective physiologic measurements obtained from routine clinical tests and vital signs
- Contains 34 items that are scored from zero to five representing the worst physiologic derangement in the first 24 hours
- A major predictor of mortality, which is independent of birth weight

MAIN (MORBIDITY ASSESSMENT INDEX FOR NEWBORNS)

Morbidity Assessment Index for Newborns (MAIN), a validated outcome scale designed for ranking neonatal morbidity beyond 28 weeks' gestation.

- Focus is to detect clinically important effects of obstetric intervention
- Items included are clinical and laboratory data that are easily collected from the usual clinical records
- The final inventory includes 47 clinically relevant pathophysiologic items describing morbidity at birth, based on 24 attributes, and collapsed into four categories (severe, moderate, mild and no morbidity) for statistical analysis, losing much of the score's detailed information.

NBAS - BRAZELTON NEONATAL BEHAVIORAL ASSESSMENT SCALE

- ▶ The NBAS attempts to capture the behaviors of the neonate fighting with the negative stimuli, and controls interfering motor and autonomic responses in order to attend to important social and nonsocial stimuli.
- ▶ This assessment has been shown to improve developmental outcomes by enhancing the infant-caregiver relationship, and provides health visitors with the opportunity to consolidate their relationship of trust with families.[26]
- ▶ The NBAS is a multidimensional, multi-item scale and the basic score sheet includes 27 behavioral items, 18 reflex items, and 6 supplementary items. The supplementary items were constructed to measure the quality of the baby's responsiveness, the help the examiner has to invest to get the infant's optimal performance, and also the response of the examiner to the infants.

The Neonate's Health

Measuring Neonatal Health

- Brazelton Neonatal Behavioral Assessment Scale (NBAS)
 - Rates neonates on 27 items
 - Receives rating of worrisome, normal or superior
 - Most effective if given at one day and a week later
 - Can help parents interact with infants
 - Useful in research on cultural differences in parenting practices

Brazelton Scale

- Includes tests of infant reflexes, motor capacities, muscle tone, capacity for responding to objects and people, capacity to control own behavior, attention
 - Orientation to animate objects (visual/auditory)
 - Pull-to-sit (e.g., try to right his head)
 - Cuddliness (e.g., resist, passive, tries to cuddle)
 - Defensive movements (e.g., try to remove cloth from face)
 - Self-quieting activity (e.g., suck thumb, look around)

PAIN SCORE

COMPARATIVE PAIN SCALE CHART (Pain Assessment Tool)

										
0 Pain Free	1 Very Mild	2 Discomforting	3 Tolerable	4 Distressing	5 Very Distressing	6 Intense	7 Very Intense	8 Utterly Horrible	9 Excruciating Unbearable	10 Unimaginable Unspeakable
No Pain	Minor Pain			Moderate Pain			Severe Pain			
Feeling perfectly normal	Nagging, annoying, but doesn't interfere with most daily living activities. Patient able to adapt to pain psychologically and with medication or devices such as cushions.			Interferes significantly with daily living activities. Requires lifestyle changes but patient remains independent. Patient unable to adapt pain.			Disabling; unable to perform daily living activities. Unable to engage in normal activities. Patient is disabled and unable to function independently.			

NEONATAL THERAPEUTIC INTERVENTION SCORING SYSTEM (NTISS)

- Includes 70 therapies unique to neonatal intensive care, assigned a weight of one to four points by an expert panel, based on therapeutic intensity and complexity
- Score can be easily abstracted from medical records
- Provides information beyond traditional measures such as birth weight

Directly and strongly related to in-hospital mortality, length of hospital stay, clinicians' estimates of mortality risk, and total hospital charges

- But the measure is independent of birth weight and gestational age
- Appears to be problematic for infants who die within the first few hours of life

What scoring system
are we going to use?

The B & C system!

What is B & C?
