Introduction

Involvement of the musculoskeletal system is extremely common in patients with systemic lupus erythematosus (SLE). Arthralgia, arthritis, osteonecrosis (avascular necrosis of bone), and myopathy are the principal manifestations.

Aim

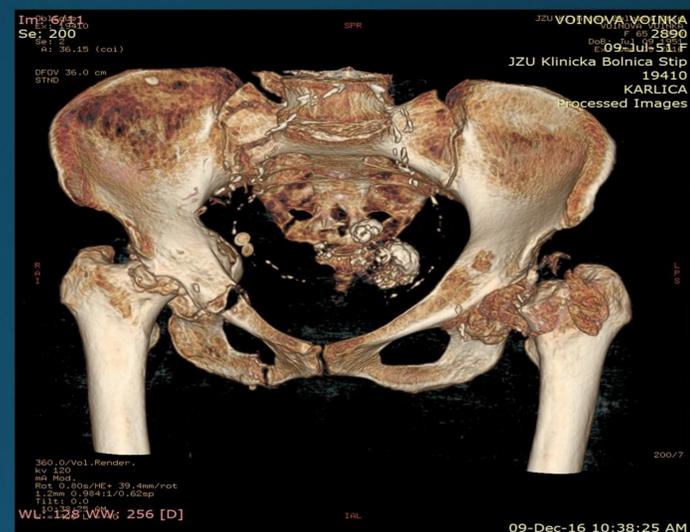

The purpose of the study is to demonstrate the complex therapeutic approach in patients with musculoskeletal manifestations of lupus.

Materials and methods

67 years old patient who complains of severe pain in the both arms, lower back pain and difficult movement with an orthopedic device. According to functional studies, movement in the hip bone (os coxae) is limited, especially in abduction and internal rotation and also limited movements in the lumbar region of the spinal column. Pseudolaseque is + on 30° bilaterally. The kyphosis and scoliosis of the thoracic spine are also expressed. Expressed muscular hypotrophy of the two lower extremities. Mediincludescament and non medicament therapy (which preformed physical factors and funds) are assigned.

X ray pelvis

3D KT of pelvis

MRI of LS spine

Results

After the applied medicament and non-medicament physical therapy an improvement in the patient's functional status is observed whit reduced pain and normalized movements.

Conclusion

The proper therapeutic approach in patients with musculoskeletal manifestations and the application of complex drug treatment and physical therapy leads to positive results to the impaired functional status.
