Introduction

Changes in motor abilities are one of the main criteria for creation of final appraisal for PE as well as a criteria for following of individual progress and improvement of every child. These parametars are highly related with the anticipation of different motor skills and habits (Matić, 1978). Explosive strength is one of the abilities that define childrens' motor space and it is highly related with the sucessful performance of many movements. In different stages of childrens development, explosive strength is manifested differently. Therfore, the aim of this paper is to determine the metric characteristics of tests used for evaluation of explosive strength at 7 years old children, as well as norms for it's objective evaluation and following of childrens development.

Method

This survey is realised as a part of larger study (Popeska, 2011) realised on a sample of 123 seven - years old children, pupils in the second grade in five primary schools in Skopje, Republic of Macedonia. Explosive strength was estimated appling following four tests:Standing broad jump (ESSDM), Throwing medicine ball 1 kg from standing position (ESFMST), Throwing medicine ball 1 kg from sitting position (ESFMG) and20m dash running (ES20VS). Tests characteristic were established using Crombah α u Spearman – Brown (SB) coefficients of reliability, Pearson coefficient of corelation and factor analysis for estimation of factor validity of the tests and Kaiser-Meyer-Olkin's measure used for estimation of reliability and representativity. The percentile distribution was used as a basis for determination of norms for evaluation of children's achievements in motor tests for estimation of explosive strength.

Results and discussion

Statistical analysis of test results, indicates that all four uesd tests are discriminative. According the asymetry of distribution of tests results, except the test Standing broad jump (ESSDM) which is easy to perform by the seven years old children, other three tests are moderately difficult for performance. According the values of significant roots, projections of isolated factor and communalities obtained using Hotelling procedure, all applied tests are valid. The high coefficients of reliability points out on significant highly reliable tests. The coefficient of representativity obtained at all four movement tasks is at the level of significance (.50). These results indicates on good methric characteristics of the tests for estimation of explosive strength. Based on this, we calculated and suggested adequate norms for evaluation of children's achievements as a manner for objective following and assesment of childrens improvement.

Conclusion

Results obtained in this survey point out that all four tests used for estimation of explosive strength at 7- years old children have good metric characteristics. According the high values of parameters for estimation of tests characteristics, especialy high values for validity and reliability obtained for the tests Standing broad jump (ESSDM) and Throwing medicine ball from sitting position (ESFMG), we recommend these two tests as most suitable for further use with 7 – years old children.

Key words: test characteristics, explosive strength, 7 - years old children
